Contents

Chapter 1: Overview.....1

1.1 Command-Line Interface (CLI).....1
- 1.1.1 Accessing the EOS CLI.....2
- 1.1.2 Processing Commands.....2
- 1.1.3 Kernel-based Virtual Machine Commands and Configuration.....11
- 1.1.4 Switch Platforms.....17
- 1.1.5 Command Modes.....26
- 1.1.6 Managing Switch Configuration Settings.....29
- 1.1.7 Other Command-Line Interfaces.....32
- 1.1.8 Directory Structure.....32
- 1.1.9 Command-Line Interface Commands.....33

Chapter 2: Booting the Switch..... 92

2.1 Boot Loader Aboot..... 92
2.2 Configuration Files.....93
- 2.2.1 boot-config.....93
- 2.2.2 running-config.....98
- 2.2.3 startup-config.....98

2.3 Supervisor Redundancy..... 98
- 2.3.1 Redundancy Supervisor Protocols..... 99
- 2.3.2 Configuring Supervisor Redundancy.....100

2.4 System Reset..... 100
- 2.4.1 Typical Reset Sequence.....101
- 2.4.2 Switch Recovery..... 102
- 2.4.3 Display Reload Cause..... 102
- 2.4.4 Configuring Zero Touch Provisioning..... 103
- 2.4.5 Configuring the Networks..... 105

2.5 Aboot Shell..... 105
- 2.5.1 Aboot Shell Operation..... 106
- 2.5.2 Accessing the Aboot Shell.....107
- 2.5.3 Aboot File Structure.....108
- 2.5.4 Booting From the Aboot Shell..... 108
- 2.5.5 Secure Booting from Aboot..... 109
- 2.5.6 Aboot Commands..... 113

2.6 Aboot Configuration Commands..... 113
- 2.6.1 CONSOLESPEED.....115
- 2.6.2 NET Commands..... 116
- 2.6.3 install bios source.....118
- 2.6.4 PASSWORD (ABOOT).....119
- 2.6.5 SWI..... 120

2.7 Switch Booting Commands..... 120
- 2.7.1 boot console.....122
- 2.7.2 boot secret..... 123
- 2.7.3 boot system.....125
- 2.7.4 delete startup-config..... 126
- 2.7.5 protocol..... 127
- 2.7.6 redundancy.....129
- 2.7.7 redundancy manual switchover..... 130

2.7.8 reload 131
2.7.9 reload (scheduled) 133
2.7.10 securebootctl 135
2.7.11 show platform bios 137
2.7.12 show redundancy file-replication 139
2.7.13 show redundancy status 140
2.7.14 show redundancy switchover sso 141
2.7.15 show reload 142
2.7.16 show reload cause 143
2.7.17 show reload fast-boot 144

Chapter 3: Initial Configuration and Recovery 145

3.1 Initial Switch Access 145
3.1.1 Zero Touch Provisioning 145
3.1.2 Manual Provisioning 146
3.2 Connection Management 151
3.3 Securely Erasing a Switch Storage Device 152
3.4 Configuration Sessions Overview 154
3.4.1 Configuration Session 154
3.4.2 Replacing the Configuration 155
3.4.3 Configuration CLI 155
3.4.4 Using Service Commands in EOS 156
3.5 Using Service Commands in EOS 157
3.6 Recovery Procedures 158
3.6.1 Removing the Enable Password from the Startup Configuration 158
3.6.2 Reverting the Switch to the Factory Default Startup Configuration 159
3.6.3 Restoring the Factory Default EOS Image and Startup Configuration 160
3.6.4 USB Support for ZeroTouch Provisioning 161
3.6.5 Restoring the Configuration and Image from a USB Flash Drive 162
3.7 Session Management Commands 163
3.7.1 authentication x509 167
3.7.2 authentication 168
3.7.3 authorized-principals 169
3.7.4 cipher 170
3.7.5 client-alive 172
3.7.6 commit timer 172
3.7.7 compression 174
3.7.8 configure replace 175
3.7.9 configure session 177
3.7.10 connection 179
3.7.11 fips 180
3.7.12 hostkey 181
3.7.13 idle-timeout (Console Management) 183
3.7.14 idle-timeout (SSH Management) 184
3.7.15 idle-timeout (Telnet Management) 185
3.7.16 ip 186
3.7.17 ipv6 187
3.7.18 key-exchange 188
3.7.19 log-level 190
3.7.20 logging 192
3.7.21 login 192
3.7.22 mac 193
3.7.23 management accounts 196
3.7.24 management api eos-sdk-rpc 197
3.7.25 management api external-services 198

3.7.26 management api gnmi....199
3.7.27 management api gnsi....200
3.7.28 management api gribi....201
3.7.29 management api http-commands....202
3.7.30 management api models....204
3.7.31 management api netconf....205
3.7.32 management api restconf....206
3.7.33 management archive....207
3.7.34 management cli....208
3.7.35 management client....209
3.7.36 management console....210
3.7.37 management data source....211
3.7.38 management defaults....213
3.7.39 management dmf....215
3.7.40 management file-systems....216
3.7.41 management http-server....217
3.7.42 management ldap group....219
3.7.43 management ldap server....220
3.7.44 management nic profiles....222
3.7.45 management package....224
3.7.46 management security auto-certificate....225
3.7.47 management security entropy....227
3.7.48 management security network....228
3.7.49 management security ocsp....229
3.7.50 management security password....231
3.7.51 management security session....233
3.7.52 management security signature-verification....235
3.7.53 management security ssl....236
3.7.54 management ssh....240
3.7.55 management telnet....242
3.7.56 management timeout....243
3.7.57 protocol http (API Management)....244
3.7.58 protocol https (API Management)....245
3.7.59 protocol https certificate (API Management)....247
3.7.60 qos....248
3.7.61 rekey....249
3.7.62 reset system storage secure....251
3.7.63 show inventory....252
3.7.64 server-port....253
3.7.65 service configuration access-list....254
3.7.66 service configuration checkpoint....256
3.7.67 service configuration session commit....258
3.7.68 service configuration session logging....259
3.7.69 service configuration session max....260
3.7.70 service configuration terminal....262
3.7.71 service configuration verification....263
3.7.72 service interface inactive....264
3.7.73 service interface shutdown....266
3.7.74 service interface unconnected....267
3.7.75 service routing configuration....268
3.7.76 service routing protocols....269
3.7.77 service running-config....270
3.7.78 session-limit....272
3.7.79 show configuration checkpoints....273
3.7.80 show configuration sessions....274
3.7.81 shutdown (API Management)....276

3.7.82 shutdown (Telnet Management)..... 277
3.7.83 shutdown..... 278
3.7.84 shutdown..... 278
3.7.85 timeout..... 280
3.7.86 trusted-ca..... 281
3.7.87 user-keys..... 282
3.7.88 username ssh-key..... 283
3.7.89 username ssh-principal..... 285
3.7.90 username tcp..... 287
3.7.91 verify..... 288
3.7.92 vrf..... 289
3.7.93 vrf known-hosts..... 290
3.7.94 vrf..... 291
3.7.95 vrf (API Management)..... 292

Chapter 4: Administering the Switch..... 293

4.1 Managing the Switch Name..... 293
4.1.1 Assigning a Name to the Switch..... 293
4.1.2 Specifying DNS Addresses..... 294
4.2 System Clock and Time Protocols..... 295
4.2.1 Configuring the Time Zone..... 296
4.2.2 Setting the System Clock Manually..... 297
4.2.3 Displaying the Time..... 297
4.2.4 Network Time Protocol (NTP) Overview..... 298
4.3 Managing Display Attributes..... 303
4.3.1 Banners..... 303
4.3.2 Configuring the CLI Prompt..... 304
4.4 System Event Logging..... 305
4.4.1 Managing TCAM Capacity Warnings..... 310
4.4.2 Layer 2 MAC Learn Failure Detection..... 311
4.5 Event Monitor..... 312
4.5.1 Description..... 312
4.5.2 Configuring the Event Monitor..... 312
4.5.3 Querying the Event Monitor..... 315
4.5.4 Accessing Event Monitor Database Records..... 315
4.6 Managing EOS Extensions..... 316
4.6.1 Installing EOS Extensions..... 316
4.6.2 Installing EOS Extensions on a Dual-Supervisor Switch..... 316
4.6.3 Verifying EOS Extensions Installation..... 318
4.6.4 Uninstalling an EOS Extension..... 318
4.6.5 EOS Extensions Log Messages..... 319
4.7 Monitoring Latency..... 321
4.8 Switch Administration Commands..... 324
4.8.1 banner login..... 327
4.8.2 banner motd..... 328
4.8.3 binning..... 329
4.8.4 clear ptp interface counters..... 331
4.8.5 clock set..... 332
4.8.6 clock timezone..... 333
4.8.7 dns domain..... 335
4.8.8 email..... 336
4.8.9 event-monitor backup max-size..... 337
4.8.10 event-monitor backup path..... 339
4.8.11 event-monitor buffer max-size..... 341
4.8.12 event-monitor clear..... 342

4.8.13 event-monitor sync....343
4.8.14 event-monitor....344
4.8.15 hostname....346
4.8.16 ip domain lookup....347
4.8.17 ip domain-list....349
4.8.18 ip host....350
4.8.19 ip name-server....352
4.8.20 ipv6 host....354
4.8.21 logging buffered....355
4.8.22 logging console....357
4.8.23 logging event....359
4.8.24 logging facility....361
4.8.25 logging format....363
4.8.26 logging group....365
4.8.27 logging group host....366
4.8.28 logging group probe....367
4.8.29 logging host....368
4.8.30 logging level....370
4.8.31 logging local-interface....372
4.8.32 logging message....373
4.8.33 logging monitor....375
4.8.34 logging persistent....377
4.8.35 logging policy....378
4.8.36 logging qos....379
4.8.37 logging relogging-interval....380
4.8.38 logging repeat-messages....381
4.8.39 logging source-interface....381
4.8.40 logging synchronous....383
4.8.41 logging trap....385
4.8.42 logging vrf host....388
4.8.43 logging vrf local-interface....390
4.8.44 logging vrf source-interface....392
4.8.45 measurement end-to-end....394
4.8.46 monitor latency....395
4.8.47 no event-monitor....396
4.8.48 ntp authenticate....397
4.8.49 ntp authentication-key....398
4.8.50 ntp local....400
4.8.51 ntp local-interface....401
4.8.52 ntp serve all....403
4.8.53 ntp serve....404
4.8.54 ntp server....406
4.8.55 ntp trusted-key....409
4.8.56 power enable module....410
4.8.57 prompt....411
4.8.58 show banner....414
4.8.59 show clock....415
4.8.60 show event-monitor arp....416
4.8.61 show event-monitor igmpsnooping....418
4.8.62 show event-monitor mac....420
4.8.63 show event-monitor mroute....422
4.8.64 show event-monitor neighbor....424
4.8.65 show event-monitor nexthop-group backup-activation....425
4.8.66 show event-monitor route6....427
4.8.67 show event-monitor route....429
4.8.68 show event-monitor sqlite....431

4.8.69 show event-monitor stpunstable....432
4.8.70 show hostname....433
4.8.71 show hosts....434
4.8.72 show ip domain-name....435
4.8.73 show ip name-server....436
4.8.74 show local-clock time-properties....437
4.8.75 show logging....438
4.8.76 show logging group....440
4.8.77 show ntp associations....441
4.8.78 show ntp [ip | ipv6]....441
4.8.79 show ntp status....444

Chapter 5: 7130 Platform Layer 1 Configuration....445
5.1 Configuring Layer 1 on the 7130 Platform....445
5.1.1 Addressing 7130 Platform Speed Mismatch....448
5.1.2 Configuring the 7130 Platform and Multilane Sourcing....449
5.1.3 Using Show Commands to Confirm Source Configurations....449
5.2 7130 Layer 1 Commands....451
5.2.1 l1 source....452
5.2.2 show l1 destination....454
5.2.3 show l1 matrix....456
5.2.4 show l1 path....459
5.2.5 show l1 source....461
5.2.6 show l1 source capabilities....463

Chapter 6: Timing Protocols....464
6.1 Setting the PTP Mode....465
6.2 Enabling PTP on an Interface....465
6.3 Configuring the PTP Domain....466
6.4 Configuring the Offset Hold Time....466
6.5 Setting the PTP Priority....466
6.6 Configuring the Source IP....467
6.7 Configuring the TTL for PTP Packets....467
6.8 Configuring PTP Monitoring....467
6.9 Setting the PTP Announce Interval....469
6.10 Setting the PTP Timeout Interval....469
6.11 Configuring the PTP Delay Mechanism....470
6.12 Setting the Delay Request Interval....470
6.13 Setting the Peer Delay Request Interval....470
6.14 Setting the Peer Link Propagation Threshold....471
6.15 Setting the Interval for Sending Synchronization Messages....471
6.16 Setting the PTP Transport Type....471
6.17 Configuring a PTP Grandmaster Clocks List....475
6.18 Viewing PTP Settings and Status....476
6.18.1 Displaying General PTP Information....476
6.18.2 Displaying PTP Clock Properties....477
6.18.3 Displaying PTP Foreign Master....477
6.18.4 Displaying PTP Information for all Interfaces....477
6.18.5 Displaying PTP Interface Counters....478
6.18.6 Displaying PTP Local Clock and Offset....478
6.18.7 Displaying PTP Masters Information....478
6.18.8 Displaying PTP Monitoring Information....479
6.18.9 Displaying PTP Source IP....479
6.19 Precision Time Protocol (PTP) Commands....479

6.19.1 ptp announce interval....482
6.19.2 ptp announce timeout....483
6.19.3 ptp clock-accuracy....484
6.19.4 ptp clock-identity....485
6.19.5 ptp delay-mechanism....486
6.19.6 ptp delay-req interval....487
6.19.7 ptp domain....488
6.19.8 ptp enable....489
6.19.9 ptp forward-unicast....490
6.19.10 ptp forward-v1....491
6.19.11 ptp free-running....492
6.19.12 ptp grandmasters....493
6.19.13 ptp hold-ptp-time....495
6.19.14 ptp ip....496
6.19.15 ptp local-priority....497
6.19.16 ptp management....498
6.19.17 ptp message-type....499
6.19.18 ptp mode....500
6.19.19 ptp mpass....502
6.19.20 ptp monitor threshold mean-path-delay....503
6.19.21 ptp monitor threshold missing-message....504
6.19.22 ptp monitor threshold offset-from-master....505
6.19.23 ptp monitor threshold skew....506
6.19.24 ptp monitor....507
6.19.25 ptp netsync-monitor....508
6.19.26 ptp pdelay-neighbor-threshold....509
6.19.27 ptp pdelay-req interval....510
6.19.28 ptp priority1....511
6.19.29 ptp priority2....512
6.19.30 ptp profile....513
6.19.31 ptp role....514
6.19.32 ptp source....515
6.19.33 ptp sync timeout....516
6.19.34 ptp sync-message interval....517
6.19.35 ptp transport....519
6.19.36 ptp ttl....520
6.19.37 ptp unicast-negotiation....521
6.19.38 show ptp....522
6.19.39 show ptp foreign-master-record....523
6.19.40 show ptp interface counters....524
6.19.41 show ptp interface....526
6.19.42 show ptp local-clock....528
6.19.43 show ptp masters....529
6.19.44 show ptp monitor....530
6.19.45 show ptp source ip....531
6.19.46 show ptp unicast-negotiation....532
6.19.47 show ptp unicast-negotiation profile....534

Chapter 7: Switch Environment Control....535
7.1 Environment Control Introduction....535
7.2 Environment Control Overview....535
7.2.1 Temperature....535
7.2.2 Fans....536
7.2.3 Power....536
7.3 Configuring and Viewing Environment Settings....536

7.3.1 Overriding Automatic Shutdown..... 536
7.3.2 Viewing Environment Status..... 538
7.3.3 Locating Components on the Switch..... 540
7.4 Environment Commands..... 541
7.4.1 environment fan-speed..... 542
7.4.2 environment insufficient-fans action..... 544
7.4.3 environment overheat action..... 546
7.4.4 locator-led..... 548
7.4.5 show environment power..... 550
7.4.6 show environment temperature..... 551
7.4.7 show locator-led..... 553
7.4.8 show system environment all..... 554
7.4.9 show system environment cooling..... 555
7.4.10 show system environment power budget..... 557

Chapter 8: Upgrades and Downgrades..... 558
8.1 Upgrade/Downgrade Overview..... 558
8.2 Smart System Upgrade..... 558
8.2.1 Upgrading the EOS image with Smart System Upgrade..... 561
8.2.2 Scheduling an SSU..... 568
8.3 Standard Upgrades and Downgrades..... 569
8.3.1 Upgrading or Downgrading the EOS on a Single-Supervisor Switch..... 570
8.3.2 Upgrading or Downgrading the EOS on a Dual-Supervisor Switch..... 575
8.4 Upgrade/Downgrade Commands..... 579
8.4.1 install..... 581
8.4.2 reload fast-boot..... 582
8.4.3 reload hitless..... 584

Chapter 9: Security..... 585
9.1 User Security..... 585
9.1.1 AAA Configuration..... 585
9.2 Control Plane Security..... 748
9.2.1 Transport Layer Security..... 748
9.2.2 802.1X Port Security..... 787
9.3 Data Plane Security..... 848
9.3.1 IP NAT..... 848
9.3.2 Media Access Control Security..... 887
9.3.3 Internet Protocol Security (IPsec)..... 954
9.3.4 Macro-Segmentation Service (CVX)..... 978

Chapter 10: Quality of Service and Traffic Management..... 1017
10.1 Quality of Service..... 1017
10.1.1 Quality of Service Conceptual Overview..... 1018
10.1.2 QoS Configuration: Platform-Independent Features..... 1028
10.1.3 QoS Configuration: Arad Platform Switches..... 1030
10.1.4 QoS Configuration: Jericho Platform Switches..... 1040
10.1.5 QoS Configuration: FM6000 Platform Switches..... 1050
10.1.6 QoS Configuration: Petra Platform Switches..... 1058
10.1.7 QoS Configuration: Trident and Tomahawk Platform Switches..... 1065
10.1.8 QoS Configuration: Trident II and Helix Platform Switches..... 1076
10.1.9 Support for Configuring Color Extended Communities..... 1085
10.1.10 ACL-based QoS Configuration..... 1087
10.1.11 Configuring IPv6 Flow Label Matches for QoS..... 1091

10.1.12 Differentiated MMU Discard Counters....1093
10.1.13 txQueue Percentage-based Shaping....1094
10.1.14 Tx Queue Precision Shaping....1095
10.1.15 Configuring Round Robin Scheduling on Shaped Subinterfaces....1096
10.1.16 Explicit Congestion Notification (ECN)....1097
10.1.17 Latency-based Explicit Congestion Notification....1098
10.1.18 Configuring a Low Latency Transmit Queue Scheduler Profile....1098
10.1.19 Quality of Service Commands....1099
10.1.20 Chipset Mapping for QoS....1232
10.2 Traffic Management....1237
10.2.1 Traffic Management Conceptual Overview....1237
10.2.2 Traffic Management Configuration Arad Platform Switches....1254
10.2.3 Traffic Management Configuration FM6000 Platform Switches....1263
10.2.4 Traffic Management Configuration Petra Platform Switches....1271
10.2.5 Traffic Management Configuration Trident Platform Switches....1274
10.2.6 Traffic Management Configuration Trident II Platform Switches....1285
10.2.7 Traffic Management Configuration Commands....1287

Chapter 11: Interface Configuration....1407

11.1 Ethernet Ports....1407
11.1.1 Ethernet Ports Introduction....1407
11.1.2 Ethernet Standards....1407
11.1.3 Ethernet Physical Layer....1410
11.1.4 Interfaces....1424
11.1.5 MRU Enforcement....1429
11.1.6 Displaying Interface Interactions....1431
11.1.7 Automatic Transceiver Recovery after Power Fault....1434
11.1.8 Support for Extended ICMP Errors....1435
11.1.9 Dynamic Link Flap Damping....1437
11.1.10 Ethernet Configuration Procedures....1438
11.1.11 Ethernet Configuration Commands....1510
11.2 Port Channels and LACP....1655
11.2.1 Port Channel Introduction....1655
11.2.2 Port Channel Conceptual Overview....1655
11.2.3 Port Channel Configuration Procedures....1658
11.2.4 Load Balancing Hash Algorithms....1669
11.2.5 Port Channel and LACP Configuration Commands....1676
11.3 Multi-Chassis Link Aggregation....1748
11.3.1 MLAG Introduction....1748
11.3.2 MLAG Conceptual Overview....1749
11.3.3 MLAG Maintenance....1751
11.3.4 Configuring MLAG....1756
11.3.5 EVPN - MLAG Single-homed Hosts....1764
11.3.6 Configuring MLAG Layer 2 Subinterfaces....1765
11.3.7 Configuring Forced Periodic ARP and NDP Refresh....1767
11.3.8 MLAG Implementation Example....1768
11.3.9 MLAG Commands....1776
11.4 Data Transfer....1803
11.4.1 Data Transfer Introduction....1804
11.4.2 Data Transfer Methods....1804
11.4.3 MAC Address Table....1808
11.4.4 Configuring Ports....1813
11.4.5 Monitoring Links....1833
11.4.6 PHY test pattern CLI....1848
11.4.7 Data Transfer Commands....1853

11.5 Octal Port Renumber to Four Interfaces....1971
11.5.1 Configuring Octal Port Renumber to 4 Interfaces....1972
11.5.2 Show Commands....1973
11.5.3 Limitations....1973
11.5.4 Commands....1973

Chapter 12: Layer 1 Configuration....1975
12.1 Layer 1 Profiles....1975
12.2 Platform Support for Module Profiles....1982
12.2.1 Configuring L1 Module Profiles....1984
12.3 Layer 1 CLI Guard Relaxation....1986
12.4 Layer 1 Commands....1987
12.4.1 system l1 module....1988
12.4.2 system l1 module profile....1988
12.4.3 system l1 unsupported....1989
12.4.4 show l1 modules profile status....1990

Chapter 13: Layer 2 Configuration....1992
13.1 Spanning Tree Protocol....1992
13.1.1 Introduction to Spanning Tree Protocols....1992
13.1.2 Spanning Tree Overview....1992
13.1.3 Configuring a Spanning Tree....2001
13.1.4 STP Commands....2019
13.2 Link Layer Discovery Protocol....2104
13.2.1 LLDP Introduction....2104
13.2.2 LLDP Overview....2104
13.2.3 LLDP Configuration Procedures....2105
13.2.4 LLDP Configuration Commands....2112
13.3 Virtual LANs (VLANs)....2135
13.3.1 VLAN Introduction....2135
13.3.2 VLAN Conceptual Overview....2135
13.3.3 VLAN Configuration Procedures....2139
13.3.4 VLAN Configuration Commands....2153
13.4 DCBX and Flow Control....2201
13.4.1 Introduction....2201
13.4.2 Overview....2201
13.4.3 DCBX Configuration and Verification....2202
13.4.4 Configuring Priority-Flow-Control (PFC)....2204
13.4.5 Configuring PFC Watchdog....2205
13.4.6 DCBX and Flow Control Commands....2209
13.5 IP Address Locking....2238
13.5.1 IP Address Locking Configuration....2240
13.5.2 IP Address Locking Commands....2250
13.6 Layer 2 Protocol Forwarding....2267
13.6.1 Configuring L2 Protocol Forwarding....2267
13.6.2 L2 Protocol Forwarding Considerations....2272
13.6.3 Displaying L2 Protocol Forwarding....2272
13.7 Overview of Layer 2 Subinterfaces....2273
13.7.1 Configuring Layer 2 Subinterfaces....2274
13.7.2 QoS Show Commands....2279

Chapter 14: Layer 3 Configuration....2281
14.1 IPv4....2281

14.1.1 IPv4 Addressing....2282
14.1.2 IPv4 Routing....2292
14.1.3 IPv4 Multicast Counters....2297
14.1.4 Route Management....2300
14.1.5 IPv4 Route Scale....2318
14.1.6 IP Source Guard....2325
14.1.7 DHCP Server....2330
14.1.8 DHCP Relay Global Configuration Mode....2338
14.1.9 DHCP Snooping with Bridging....2346
14.1.10 TCP MSS Clamping....2348
14.1.11 IPv4 GRE Tunneling....2354
14.1.12 GRE Tunneling Support....2357
14.1.13 BfRuntime to Use Non-default VRFs....2363
14.1.14 IPv4 Commands....2364
14.2 IPv6....2541
14.2.1 Introduction....2542
14.2.2 IPv6 Description....2542
14.2.3 Configuring IPv6....2545
14.2.4 IPv6 Commands....2561
14.3 Ingress and Egress Per-Port for IPv4 and IPv6 Counters....2638
14.3.1 Configuration....2638
14.3.2 Show Commands....2639
14.3.3 Dedicated ARP Entry for TX IPv4 and IPv6 Counters....2640
14.3.4 Considerations....2640
14.4 Configuring DHCP....2640
14.4.1 DHCP Server....2642
14.4.2 DHCP Relay Global Configuration Mode....2654
14.4.3 DHCP Relay Agent for IPv6....2662
14.4.4 DHCP Snooping with Bridging....2665
14.4.5 DHCP Commands....2668
14.5 ACLs and Route Maps....2734
14.5.1 Introduction....2734
14.5.2 Access Control Lists....2735
14.5.3 Service ACLs....2759
14.5.4 Sub-interface ACLs....2764
14.5.5 RACL Sharing on SVIs....2765
14.5.6 Route Maps....2770
14.5.7 Prefix Lists....2776
14.5.8 Port ACLs with User-Defined Fields....2780
14.5.9 ACL, Route Map, and Prefix List Commands....2783
14.6 VRRP and VARP....2893
14.6.1 VRRP and VARP Conceptual Overview....2893
14.6.2 VRRP and VARP Implementation Procedures....2895
14.6.3 VRRP and VARP Implementation Examples....2904
14.6.4 VRRP and VARP Configuration Commands....2910
14.7 DirectFlow....2948
14.7.1 Introduction....2948
14.7.2 DirectFlow Configuration....2950
14.7.3 DirectFlow Feature Interactions....2952
14.7.4 DirectFlow Commands....2955
14.8 Decap Groups....2976
14.8.1 Decap Groups Overview....2976
14.8.2 Configuring Decap Groups....2977
14.8.3 Configuring Generic UDP Encapsulation (GUE) Decap Groups....2978
14.8.4 Decap Groups Commands....2979
14.9 Nexthop Groups....2989

14.9.1 Next-hop Group Description.....2989
14.9.2 Next-hop Group Configuration.....2989
14.9.3 Nexthop Group Commands.....2995
14.10 Setting the MTU for all Layer 3 Interfaces.....3009
14.10.1 Configuring MTU for all Layer 3 Interfaces.....3009
14.10.2 Considerations.....3010
14.10.3 Show Commands.....3010
14.11 Support for Layer 3 MTU on 7280R3/7500R3/7800R3.....3012
14.11.1 Layer 3 MTU Configuration.....3012
14.11.2 Layer 3 MTU Show Commands.....3012
14.11.3 L3 MTU Considerations.....3013
14.12 Segment Security.....3013
14.12.1 Overview of MSS-Group.....3013
14.12.2 Configuring MSS-Group.....3014
14.12.3 Segment Security Considerations.....3016
14.12.4 Show Commands.....3017
14.12.5 Segment Security Commands.....3019

Chapter 15: IP Services.....3043
15.1 CloudVision eXchange (CVX).....3043
15.1.1 Upgrading CVX.....3043
15.1.2 CVX Overview.....3044
15.1.3 CVX Services.....3046
15.1.4 Deploying CVX.....3047
15.1.5 CVX Configuration.....3056
15.1.6 CVX Secure out-of-band Connection.....3064
15.1.7 CVX High Availability.....3068
15.1.8 CVX VIP.....3075
15.1.9 CVX Commands.....3076

Chapter 16: Routing Protocols.....3104
16.1 Routing Information Protocol (RIP).....3104
16.1.1 RIP Conceptual Overview.....3104
16.1.2 Running RIP on the Switch.....3105
16.1.3 Configuring RIP on Multiple VRFs.....3108
16.1.4 RIP Commands.....3110
16.2 Open Shortest Path First – Version 2.....3126
16.2.1 OSPFv2 Introduction.....3126
16.2.2 OSPFv2 Conceptual Overview.....3127
16.2.3 Configuring OSPFv2.....3130
16.2.4 OSPFv2 Configuration Examples.....3163
16.2.5 OSPFv2 Commands.....3174
16.3 Open Shortest Path First – Version 3.....3278
16.3.1 OSPFv3 Introduction.....3278
16.3.2 OSPFv3 Conceptual Overview.....3279
16.3.3 Configuring OSPFv3.....3283
16.3.4 OSPFv3 Configuration Examples.....3299
16.3.5 OSPFv3 Commands.....3308
16.4 IS-IS.....3389
16.4.1 IS-IS Introduction.....3389
16.4.2 IS-IS Segment Routing.....3389
16.4.3 IS-IS Graceful Restart.....3392
16.4.4 IS-IS Dynamic Flooding.....3393
16.4.5 Dynamic Link Delay using TWAMP Light.....3394

16.4.6 IS-IS Configuration....3395
16.4.7 IS-IS Commands....3451
16.5 Border Gateway Protocol (BGP)....3564
16.5.1 BGP Conceptual Overview....3564
16.5.2 Configuring BGP....3584
16.5.3 BGP IPv6 Link Local Peers Discovery....3661
16.5.4 Debug Show Commands....3661
16.5.5 BGP Examples....3662
16.5.6 BGP Commands....3666
16.6 Maintenance Mode....3910
16.6.1 Overview....3910
16.6.2 Maintenance Mode Elements....3910
16.6.3 Maintenance Mode Features....3916
16.6.4 Maintenance Mode Configuration....3918
16.6.5 Maintenance Mode Commands....3927
16.7 Bidirectional Forwarding Detection....3992
16.7.1 Introduction....3992
16.7.2 BFD Configuration....3993
16.7.3 Hardware Accelerated BFD Transmit....4001
16.7.4 BFD Commands....4006
16.8 Segment Routing Over IPv6 (SRv6)....4035
16.8.1 Configuring SRv6....4038
16.8.2 SRv6 Ping....4040
16.8.3 SRv6 Traceroute....4041
16.8.4 Displaying SRv6 Configurations....4042
16.8.5 SRv6 Commands....4044
16.9 Routing Control Functions....4055
16.9.1 Understanding RCF Language and Syntax....4059
16.9.2 Configuring RCF Functions....4072
16.9.3 Configuring RCF Points of Application....4075
16.9.4 Using RCF Code with Configuration Sessions....4076
16.9.5 RCF Compilation Errors....4077
16.9.6 RCF Function Show Commands....4080
16.9.7 Router Control Functions Commands....4085
16.9.8 RCF - BGP Agent Support....4105
16.9.9 RCF - IpRIB Agent Support....4191
16.9.10 RCF - IS-IS Agent Support....4193
16.9.11 RCF - KernelFib Agent Support....4196
16.9.12 RCF - LDP Agent Support....4198
16.9.13 RCF - VrfLeak Agent Support....4199

Chapter 17: Multicast....4201
17.1 Multicast Architecture....4201
17.1.1 Overview....4201
17.1.2 Multicast Architecture Description....4202
17.1.3 Multicast Listener Discovery (MLD)....4204
17.1.4 Multicast Route Counters....4210
17.1.5 Multicast (S,G) Counters....4212
17.1.6 Static IP Mroute....4214
17.1.7 Static Multicast....4218
17.1.8 Configuring Multicast....4219
17.1.9 Multicast Commands....4229
17.2 IGMP and IGMP Snooping....4283
17.2.1 IGMP Snooping....4283
17.2.2 IGMP Host Proxy Description....4284

17.2.3 Supported Features..... 4284
17.2.4 IGMP Protocols.....4285
17.2.5 Configuring IGMP..... 4285
17.2.6 Configuring IGMP Snooping..... 4289
17.2.7 IGMP Host Proxy.....4300
17.2.8 Accelerated Software Upgrade Support for IGMP Snooping.....4303
17.2.9 IGMP and IGMP Snooping Commands.....4308
17.3 Protocol Independent Multicast..... 4413
17.3.1 Introduction.....4413
17.3.2 Overview..... 4413
17.3.3 Configuring PIM..... 4416
17.3.4 Multicast Example.....4424
17.3.5 PIM Commands..... 4428
17.4 Multicast Source Discovery Protocol (MSDP).....4490
17.4.1 MSDP Introduction.....4490
17.4.2 MSDP Description.....4490
17.4.3 MSDP Configuration..... 4493
17.4.4 MSDP Commands..... 4504
17.5 Audio Video Bridging (AVB).....4539
17.5.1 AVB Overview.....4539
17.5.2 AVB Protocols.....4540
17.5.3 AVB Configuration..... 4542
17.5.4 AVB Commands..... 4547

Chapter 18: Virtual Extensible LANs (VXLANs).....4559
18.1 VXLAN Introduction..... 4559
18.2 VXLAN Description.....4559
18.2.1 VXLAN Architecture.....4560
18.2.2 VXLAN Gateway.....4561
18.2.3 VXLAN Processes..... 4561
18.2.4 Multicast and Broadcast over VXLAN..... 4562
18.2.5 VXLAN and MLAG.....4563
18.2.6 VXLAN Bridging and Routing Support..... 4566
18.2.7 Data Structures.....4566
18.3 VXLAN Configuration.....4567
18.3.1 Configuring the VTI.....4567
18.3.2 Head End Replication Configuration.....4570
18.3.3 VXLAN Routing Configuration..... 4570
18.3.4 Configuring VXLAN Routing with Overlay VRFs..... 4577
18.3.5 Configuring VXLAN over MLAG..... 4577
18.3.6 Configuring VXLAN Control Service.....4578
18.3.7 Configuring VXLAN Multicast Decapsulation.....4579
18.3.8 VXLAN Decapsulation for interface with multiple VRFs..... 4579
18.3.9 VXLAN Rules Support for Mirror ACLs Configuration..... 4579
18.3.10 Configuring EVPN VXLAN.....4580
18.3.11 Displaying VXLAN Configuration..... 4586
18.3.12 Displaying VXLAN Bridging and Routing Support..... 4589
18.4 VXLAN Commands.....4592
18.4.1 clear vxlan counters.....4593
18.4.2 designated-forwarder election hold-time.....4594
18.4.3 igmp snooping.....4595
18.4.4 interface vxlan.....4597
18.4.5 ip address virtual..... 4599
18.4.6 redistribute attached-host..... 4601
18.4.7 show arp..... 4602

18.4.8 show interfaces VXLAN....4605
18.4.9 show service vxlan....4606
18.4.10 show vxlan address-table....4607
18.4.11 show vxlan counters....4609
18.4.12 show vxlan flood vtep....4611
18.4.13 show vxlan vtep....4613
18.4.14 vxlan flood vtep....4615
18.4.15 vxlan multicast-group decap....4617
18.4.16 vxlan source-interface....4618
18.4.17 vxlan udp-port....4620
18.4.18 vxlan vlan vni....4622
18.4.19 vxlan vni notation dotted....4624

Chapter 19: Ethernet VPN (EVPN)....4625
19.1 EVPN Overview....4625
19.1.1 EVPN Terminology....4627
19.1.2 EVPN Service Models....4630
19.1.3 VCS and EVPN in DCI....4633
19.1.4 EVPN MPLS LAYER 3 VPN (Type-5 Route)....4634
19.1.5 EVPN VXLAN IPv6 Overlay....4635
19.1.6 iBGP as PE-CE Protocol for BGP and EVPN L3 VPNs....4636
19.2 EVPN Layer 3 Core Operations....4636
19.2.1 MAC Address Learning....4636
19.2.2 ARP Suppression....4638
19.2.3 MAC Mobility....4638
19.2.4 MAC Address Damping....4639
19.2.5 Broadcast and Multicast Traffic....4639
19.3 Integrated Routing and Bridging....4641
19.3.1 IP VPN....4647
19.4 VPN MPLS Transport Options....4650
19.4.1 LDP....4654
19.4.2 ISIS-SR....4655
19.4.3 BGP-LU (BGP-SR)....4657
19.5 EVPN Type-5 Routes: IP Prefix Advertisement....4660
19.6 BGP PIC Edge for EVPN VXLAN Routes for Remote VTEP Failures....4662
19.6.1 Configuring BGP PIC Edge for EVPN VXLAN Routes for Remote VTEP Failures....4663
19.6.2 Show Commands....4664
19.6.3 Troubleshooting....4666
19.6.4 Limitations....4666
19.7 VXLAN DSCP Mapping....4666
19.8 EVPN E-Tree for MPLS and VXLAN....4668
19.9 EVPN IGP Cost for VTEP Reachability....4669
19.9.1 Configuring EVPN IGP Cost for VTEP Reachability....4669
19.9.2 Show Commands....4671
19.10 EVPN VXLAN Single-Gateway Centralized Routing....4672
19.11 Inter-VRF Local Route Leaking....4673
19.11.1 Inter-VRF Local Route Leaking using BGP VPN....4673
19.11.2 Inter-VRF Local Route Leaking using VRF-leak Agent....4679
19.12 EVPN Multicast VRF Leaking....4679
19.13 Static Inter-VRF Route....4683
19.13.1 Configuration....4683
19.13.2 Show Commands....4683
19.13.3 Limitations....4684
19.14 VCS to EVPN Hitless Migration....4684
19.14.1 Configuring EVPN VXLAN Single-Gateway Centralized Routing....4684

19.14.2 Displaying ECPN VXLAN Information..... 4688
19.14.3 Configuration Considerations.....4691
19.15 Configuring EVPN.....4691
19.15.1 Configuring BGP-EVPN and VCS on CVX.....4691
19.15.2 EVPN MPLS Virtual Private Wire Service (VPWS)..... 4693
19.15.3 Configuring Multi-Homing on a Multi-Domain EVPN VXLAN-MPLS Gateway..... 4698
19.15.4 Configuring iBGP PE-CE Protocol for BGP/EVPN L3 VLANs..... 4701
19.15.5 DCI Gateway with a Layer 3 EVPN Overlay and Multi-Domain VRF.....4701
19.15.6 Configuring EVPN VXLAN Single-Gateway Centralized Routing..... 4703
19.16 Sharing an Equivalence Class Entry Across Multiple VRFs..... 4711
19.17 Sample Configurations..... 4712
19.17.1 EVPN VXLAN IRB Sample Configuration..... 4712
19.17.2 Multi-Tenant EVPN VXLAN IRB Sample Configuration.....4716
19.17.3 EVPN MPLS Sample Configuration.....4738
19.17.4 EVPN VXLAN IPv6 Overlay..... 4752
19.17.5 IP VPNs Sample Configuration..... 4753
19.18 EVPN and VCS Commands.....4773
19.18.1 bfd vtep evpn.....4775
19.18.2 encapsulation VXLAN layer-3 set next-hop igp-cost..... 4776
19.18.3 e-tree.....4777
19.18.4 ip hardware fib vxlan..... 4777
19.18.5 leak routes..... 4778
19.18.6 next-hop resolution disabled.....4779
19.18.7 redistribute bgp evpn VXLAN..... 4780
19.18.8 redistribute router-mac next-hop vtep primary.....4781
19.18.9 redistribute service VXLAN.....4782
19.18.10 remote leaf host drop..... 4783
19.18.11 route-target.....4784
19.18.12 route-target export..... 4785
19.18.13 route-target import..... 4786
19.18.14 route-target route-map.....4788
19.18.15 router general.....4790
19.18.16 router multicast vrf leak..... 4791
19.18.17 show bgp evpn..... 4792
19.18.18 show bgp evpn sanity.....4794
19.18.19 show e-tree vlan..... 4797
19.18.20 show ip bgp vrf.....4798
19.18.21 show ip route vrf.....4799
19.18.22 show ipv6 bgp vrf..... 4800
19.18.23 show ipv6 route vrf..... 4801
19.18.24 show l2rib input all.....4802
19.18.25 show l2Rib input VXLAN-control-service.....4803
19.18.26 show l2rib output..... 4804
19.18.27 show service VXLAN address-table..... 4805
19.18.28 show vrf leak flapping.....4807
19.18.29 show VXLAN control-plane.....4808
19.18.30 vlan (VLAN-AWARE-Bundle configuration mode)..... 4809
19.18.31 vni-aware-bundle.....4810

Chapter 20: Multiprotocol Label Switching (MPLS).....4811

20.1 MPLS..... 4811
20.1.1 MPLS Overview..... 4811
20.1.2 MPLS Implementation.....4811
20.1.3 MPLSoGRE Filtered Mirroring..... 4812
20.1.4 Mixed TTL/DSCP in MPLS Tunnel Termination.....4812

20.1.5 Support for MPLS Packets in IP ACLs....4813
20.1.6 DSCP-to-TC Maps for MPLS Traffic to Layer 3 VRFs....4814
20.1.7 Configuring MPLS....4814
20.2 BGP/MPLS L3 VPN....4824
20.2.1 Overview....4825
20.2.2 Configuring BGP/MPLS Layer 3 VPN....4826
20.2.3 LDP Pseudowire Show Commands....4833
20.2.4 Limitations....4834
20.3 EVPN MPLS Shared ESI Label....4835
20.3.1 Configuring EVPN MPLS Shared ESI Label....4835
20.3.2 EVPN MPLS Shared ESI Label Show Commands....4836
20.3.3 Limitations....4837
20.4 LDP Graceful Restart....4837
20.5 LDP Pseudowire....4839
20.5.1 Configuring LDP Pseudowire....4840
20.5.2 LDP Pseudowire Limitations....4842
20.5.3 LDP Pseudowire Show Commands....4843
20.6 LDP Entropy Label....4844
20.6.1 Configuring LDP Entropy Label....4844
20.6.2 Show Commands....4844
20.6.3 Limitations....4845
20.7 MPLS Commands....4847
20.7.1 authentication....4849
20.7.2 cspf delay....4851
20.7.3 entropy-label....4852
20.7.4 fast-reroute....4853
20.7.5 fast-reroute reversion....4855
20.7.6 graceful-restart....4856
20.7.7 hello interval....4857
20.7.8 mpls ldp graceful-restart....4857
20.7.9 mpls icmp source-interface....4860
20.7.10 mpls ip....4862
20.7.11 mpls parsing speculative....4864

Chapter 22: Visibility and Monitoring Services....5014

22.1 Test Access Point Aggregation....5014
22.1.1 TAP Aggregation Introduction....5015
22.1.2 TAP Aggregation Description....5015
22.1.3 TAP Aggregation Extra MPLS Pop (4 to 6 Labels)....5018
22.1.4 TAP Aggregation Configuration....5020
22.1.5 TAP Aggregation Traffic Steering....5034
22.1.6 TAP Aggregation GUI....5044
22.1.7 TAP Aggregation Keyframe and Timestamp Configuration....5047
22.1.8 TapAgg GRE Tunnel Termination....5049
22.1.9 Tap Aggregation Hardware Forwarding Profile....5055
22.1.10 TAP Aggregation MPLS Pop....5057
22.1.11 TAP Aggregation 802.1br EVN Tag Stripping....5058
22.1.12 TAP Aggregation Commands....5061
22.2 Latency Analyzer (LANZ)....5122
22.2.1 Introduction to LANZ....5122
22.2.2 LANZ Overview....5123
22.2.3 Configuring LANZ....5124
22.2.4 LANZ Commands....5136
22.3 Sampled Flow Tracking....5181
22.3.1 Sampled Flow Tracking Overview....5181
22.3.2 Configuring Sampled Flow Tracking....5182
22.3.3 Hardware Flow Tracking with IPFIX Export....5185
22.3.4 Postcard Telemetry....5189
22.3.5 Inband Network Telemetry (INT) Support....5191
22.3.6 Sampled Flow Tracking Configuration Examples....5194
22.3.7 Sampled Flow Tracking Commands....5195

22.4 sFlow....5217
22.4.1 sFlow Conceptual Overview....5217
22.4.2 Configuring sFlow....5224
22.4.3 Egress Sampling for sFlow Interfaces....5230
22.4.4 sFlow Subinterfaces....5231
22.4.5 sFlow Commands....5232
22.5 SNMP....5258
22.5.1 SNMP Introduction....5258
22.5.2 SNMP Conceptual Overview....5259
22.5.3 Configuring SNMP....5260
22.5.4 SNMP Commands....5272
22.6 VM Tracer....5314
22.6.1 Introducing VM Tracer....5314
22.6.2 VM Tracer Description....5314
22.6.3 VM Tracer Configuration Procedures....5316
22.6.4 VM Tracer Commands....5322
22.7 MapReduce Tracer....5348
22.7.1 MapReduce Tracer Introduction....5348
22.7.2 MapReduce Tracer Configuration....5350
22.7.3 Displaying MapReduce Tracer Results....5355
22.7.4 MapReduce Tracer Commands....5364
22.8 Transceiver Performance Monitoring....5411
22.8.1 Transceiver Performance Monitoring Overview....5411
22.8.2 Configuring Transceiver Performance Monitoring....5411
22.8.3 Transceiver Performance Monitoring....5413
22.8.4 Displaying Transceiver Performance Monitoring....5413
22.8.5 Transceiver Performance Monitoring Commands....5423
22.9 NDR Sensor....5434
22.9.1 NDR Sensor Extension Installation....5436
22.9.2 Configuration....5436
22.9.3 Upgrading EOS and/or NDRSensor.swix Extension....5440
22.9.4 Show Commands....5441
22.9.5 Limitations....5443
22.9.6 AVA Sensor Commands....5443
22.10 Connectivity Monitor....5446
22.10.1 Connectivity Monitor Command Reference....5446

Chapter 1

Overview

This section contains the following topic:

Command-Line Interface (CLI)

Arista Networks features switches with high-density, non-blocking Ethernet ports controlled through an extensible, Linux-based, modular network operating system. The intended audience for this manual is network administrators who configure Arista switches. A working knowledge of network administration is assumed.

New Features

This guide may not describe the features added in the most recent EOS version. For information on undocumented features, consult the TOI documents here: https://www.arista.com/en/support/toi.

Switch Platforms

A list of Arista switches and detailed information about each is available here: https://www.arista.com/en/products.

Recently released switches may not appear in the list but can be found in the most recent Release Notes (found under Active Releases here: https://www.arista.com/en/support/software-download).

Open-Source Licenses

Portions of Arista Networks software are covered by open-source licenses, including the GNU General Public License (GNU GPL).

See https://www.arista.com/en/support/product-documentation/gpl.

CloudVision

The configuration tasks required to deploy CloudVision, CVX, and CVP are in the CloudVision Configuration Guide. The latest version is available here: https://www.arista.com/en/cg-cv/.

Supported Features

For the complete supported features list in the latest EOS release, see https://www.arista.com/en/support/product-documentation/supported-features.

For details on a specific release, see the Release Notes (found under Active Releases here: https://www.arista.com/en/support/software-download).

1.1 Command-Line Interface (CLI)

The command-line interface (CLI) provides a tool for controlling the switch and displaying information about status and configuration. This chapter describes the use of the CLI.

This chapter includes these sections:

- Accessing the EOS CLI
- Processing Commands
- Kernel-based Virtual Machine Commands and Configuration
- Switch Platforms
- Command Modes
- Managing Switch Configuration Settings
- Other Command-Line Interfaces
- Directory Structure
- Command-Line Interface Commands

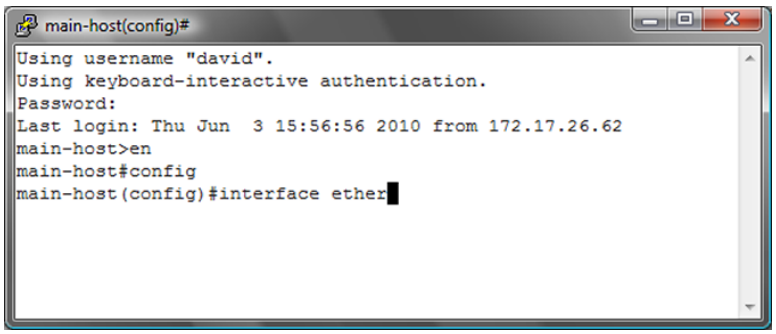
1.1.1 Accessing the EOS CLI

Open an EOS CLI session through these connections:

- Ethernet management ports
- Console port
- Telnet connections
- Secure Shell (SSH)

The following figure displays the EOS CLI in a Secure Shell connection.

Figure 1-1: EOS Command-Line Interface



1.1.2 Processing Commands

1.1.2.1 Command Execution

Command keywords are not case-sensitive. The CLI also accepts truncated keywords that uniquely correspond to one command.

- The command abbreviation **con** does not execute a command in Privileged EXEC mode because the names of two commands begin with these letters: **configure** and **connect**.

```
switch# con
% Ambiguous command
```

- The command abbreviation **conf** executes **configure** in Privileged EXEC mode because no other command name begins with **conf**.

```
switch# conf
switch(config)#
```

1.1.2.2 Creating an Alias

The alias command creates an alias for a CLI command. Entering the alias in the CLI executes the corresponding command.

Example

This command creates an alias, **srie**, for the command **show running-config interface ethernet 1-5**.

```
switch(config)# alias srie show running-config interface ethernet 1-5
switch(config)# srie
interface Ethernet1
   switchport access vlan 33
   storm-control broadcast level 1
   spanning-tree portfast
   spanning-tree bpduguard enable
interface Ethernet2
   switchport access vlan 33
   spanning-tree portfast
interface Ethernet3
   switchport access vlan 33
   spanning-tree portfast
   spanning-tree bpduguard enable
interface Ethernet4
interface Ethernet5
   shutdown
```

1.1.2.3 Cursor Movement Keystrokes

EOS supports these cursor movement keystrokes:

- **Ctrl-B** or the **Left Arrow** key moves cursor to the left.

- **Ctrl-F** or the **Right Arrow** key moves cursor to the right.
- **Ctrl-A** moves cursor to beginning of line.
- **Ctrl-E** moves cursor to end of line.
- **Esc-B** moves cursor left one word.
- **Esc-F** moves cursor right one word.

1.1.2.4 History Substitution Keystrokes

The history buffer retains the last 20 commands entered. History substitution keystrokes that access previously entered commands include:

- **Ctrl-P** or the **Up Arrow** key - Recalls the most recent buffered commands. Repeat to recall older commands.
- **Ctrl-N** or the **Down Arrow** key - Recalls more recent commands after using the **Ctrl-P** or the **Up Arrow**. Repeat to recall newer commands.

The **`show history`** command in Privileged EXEC mode displays the history buffer contents.

```
switch# show history
  en
  config
  exit
  show history
```

1.1.2.5 Command Lists and Syntax Assistance

EOS CLI uses widely followed conventions for providing command lists and syntax assistance. All command modes use these conventions.

- To display all commands available at this level, type a question mark (**?**):

```
switch# ?
  clear       Reset functions
  connect     Open a terminal connection
  default     Set a command to its defaults
  disable     Turn off privileged commands
  enable      Turn on privileged commands
  exit        Exit from the EXEC
  logout      Exit from the EXEC
  no          Negate a command or set its defaults
  ping        Send echo messages
  show        Show running system information
  ssh         Open ssh connection
  tcpdump     Monitor packets with tcpdump
  telnet      Open a telnet connection
  terminal    Configure the terminal
  traceroute  Trace route to destination
  watch       Execute a command repeatedly
  who         Display information about terminal lines
  zerotouch   ZeroTouch configuration
```

Note: Traditional EOS or Linux `ping`/`traceroute` fails to check uSID reachability in SRv6 due to an ICMPv6 checksum mismatch. This occurs because the destination address (DA) changes

as the packet traverses the Segment List, but calculates the initial checksum on the original DA. To correctly verify reachability, you must use the `srv6 ping` command.

- To display a list of commands beginning with a specific character sequence, type the sequence followed by a question mark.

```
switch# di?
diff  dir  disable
```

- To display the command keywords or arguments, type a question mark as an argument.

```
switch# ping ?
WORD  Ping destination address or hostname
ip    IPv4 echo
ipv6  IPv6 echo
mpls  Send echo messages for LSP
vrf   Ping in a VRF
```

- The switch accepts an address-mask or CIDR notation (address-prefix) in commands that require an IP address and mask. For example, EOS processes these commands identically:

```
switch(config)# ip route 0.0.0.0 255.255.255.255 10.1.1.254
switch(config)# ip route 0.0.0.0/32 10.1.1.254
```

- The switch accepts an address-wildcard or CIDR notation in commands requiring an IP address and wildcard. Wildcards use zeros to mask portions of the IP address and are found in some protocol configuration statements, including OSPF. The switch processes these commands identically:

```
switch(config-router-ospf)# network 10.255.255.1 0.0.0.255 area 15
switch(config-router-ospf)# network 10.255.255.1/24 area 15
```

1.1.2.6 Regular Expressions

A regular expression uses a search pattern composed of symbols, letters and numbers. Some CLI parameters are defined as regular expressions for specifying more expressive search criteria. The switch uses regular expression pattern matching in several BGP commands.

The functionality of a regular expression for an AS-Path varies based on BGP `regex asn` and string mode configurations in the **`ip as-path regex-mode`** command.

The following tables describe the behavior of special characters in `asn` and `string` modes respectively.

Table 1: Functionality of Special Characters in ASN Mode

Special Characters	Characters Names	Description	Examples
.	Period	Matches any AS number.	'.' matches '200'. '10.20' matches '10 30 20', but does not match '10 20'.
^	Caret	Matches the specified expression at the beginning of an input string. Also used to exclude expressions in brackets while matching.	'^123' matches '123', '123 456', '123 456 789', and so on; but does not match '1234'. '[^12]' matches '1', '2', '3', and so on; but does not match '12'.
*	Asterisk	Matches an entire AS number that appears either zero or more times.	'200_100*_300' matches '200 300', '200 100 300', '200 100 100 300', and so on. '^100*$' matches empty AS path, '100', '100 100', '100 100 100', and so on.
+	Plus sign	Matches an entire AS number appearing either one or more times.	'10_20+_30' matches '10 20 30', '10 20 20 30' and so on; but does not match '10 200 30'.
$	Dollar sign	Matches the specified expression at the end of an input string.	'1_2_3$' matches '1 2 3', but does not match '1 2 3 4'.
[]	Brackets	Matches either an AS number, or a range of AS numbers separated by a hyphen.	'[10_20_30-39]' matches '10', '20', '30', '31',...'39'.
?	Question mark	Matches either zero or one occurrence of the pattern but the previous operand or entire AS number may appear zero or one time.	'100_200?' matches '100' and '100 200'. '100_200?$' does not match with '100 20'.
|	Pipe	Matches the specified AS number on either side of the vertical bar.	'6400|6500' matches either '6400' or '6500'.
( )	Parenthesis	Nests specified AS numbers for matching.	'^(100(200|300))$' matches either '100 200' or '100 300'. '^100_200\|300_400$' matches AS path either "100 200" or "300 400".
_	Underscore	Matches specified AS numbers that are converted into AS number delimiters.	'_123_456_' matches '123 456'. '_333_444_' matches '111 222 {333 444}'.

Note: Precede the question mark (**?**) with **Ctrl+V** sequence to prevent it from interpretation as a help command.

Table 2: Functionality of Special Characters in String Mode

Special Characters	Characters Names	Description	Examples
.	Period	Matches any single character.	‘1.2’ matches ‘102’.
^	Caret	Matches the specified expression at the beginning of an input string.	‘^123’ matches ‘123’, ‘1234’, ‘12345’, and so on. It also matches ‘123 456’, ‘123 456 789’, and so on.
*	Asterisk	Matches either zero or more sequences of the expression preceding the asterisk.	'^5*$' matches an empty AS path, '5', '55', '555', and so on.
+	Plus sign	Matches either one or more sequences of the expression preceding the plus sign.	‘5+’ matches to ‘5’, ‘55’, ‘555’, and so on.
$	Dollar sign	Matches the expression at the end of an input string.	‘123$’ matches ‘123’, but does not match ‘1234’.
[]	Brackets	Matches either characters or a range of characters separated by a hyphen, within left and right brackets.	‘[025-7]’ matches ‘0’, ‘2’, and digits from ‘5’ to ‘7’; but does not match digits from ‘1’, ‘3’, ‘4’, ‘8’, and ‘9’.
?	Question mark	Matches either zero or one occurrence of the pattern.	'12?3' matches '13' and '123'.
|	Pipe	Matches either one of the expressions or expression patterns on either side of the vertical bar.	‘14(36|75)12’ matches either ‘143612’ or ‘147512’; but does not match ‘1412’, ‘14367512’, ‘14363612’ or ‘14757512’.
( )	Parenthesis	Nests specified expressions for matching.	‘(17)*’ matches any number of the two-character string ‘17’.
_	Underscore	For AS-Path regex, '_' matches curly brackets '{}', the beginning of input string, the end of input string, or space.	‘_1300_’ matches ‘100 {1300 1400}’, ‘100 1300 200’, and so on.
{}	Braces	Matches repetitions of the previous expression with the number of repetitions provided in braces.	'10{2,3}' matches '100' and '1000'.
\	Backslash	Matches the character following the backslash and special characters.	‘\(42’ matches ‘(42’.

Precede the question mark (**?**) with **Ctrl+V** sequence to prevent it from interpretation as a help command.

1.1.2.7 Scheduling CLI Commands

The schedule command facilitates the periodic execution of the specified CLI command. Command parameters configure the time to start script execution, the interval between consecutive execution instances, the maximum time to execute the script, and the maximum number of file logs to create.

The schedule config command sets configuration parameters with the CLI scheduler.

The show schedule command lists the commands currently scheduled for periodic execution and displays the summary of the specified scheduled command.

Examples

- This command schedules the execution of a script once every ***720*** minutes (12 hours) and terminates the script execution if it exceeds ***40*** minutes. If max-log-files set to zero, the script output does not log any information..

```
switch# schedule ms_1 interval 720 timeout 40 max-log-files 0 command bash /mnt/flash/my
script.sh
```

- To verify the configuration, use the **`show schedule ms_1`** command:

```
switch(config)# show schedule ms_1
 CLI command "bash /mnt/flash/myscript.sh" is scheduled next at "03:54:54 07/15/2025", interval
 is 720 minutes
 Timeout is 40 minutes
 Maximum of 0 log files will be stored
 Verbose logging is off
 No log files are stored in flash:/schedule/ms_1/
```

- This command saves the running configuration contents to a log file every ***60*** minutes (1 hour) and terminates the script execution if it exceeds 30 minutes and creates up to ***24*** log files.

```
switch(config)# schedule backup-test interval 60 max-log-files 24 command show running-config
```

- This command allows the switch to concurrently execute up to ***2*** scheduled commands.

```
switch(config)# schedule config max-concurrent-jobs 2
```

- This command lists the commands scheduled for periodic execution.

```
switch(config)# schedule config max-concurrent-jobs 3
switch(config)# show schedule summary
Maximum concurrent jobs  3
Prepend host name to logfile: No
Name            At time      Last    Interval   Timeout   Max     Logfile Location
  Status
                             time     (mins)    (mins)    log
                                                         files
------------- ------------- ------- ---------- -------- -------- --------------------------
----- ------
tech-support      now        00:29      60        30      100     flash:schedule/tech-support/
  Success
thelp           12:02:00     00:02      60        40      100     flash:schedule/thelp/
  Fail
                06/05/2018
```

1.1.2.8 Running Bash Shell Commands Automatically with Event Handlers

Event handlers execute a Linux Bash shell command in response to a specific system event. An event handler consists of a Bash command, a trigger and a delay; when the trigger event occurs, the action is scheduled to run after ***delay*** seconds.

To create an event handler, use the event-handler command. This creates a new event handler and places the CLI in event handler configuration mode for that handler. Use the action bash command to configure a Bash command to run when the handler triggers, and the trigger command to specify the trigger. Event handlers can be triggered by various events, including the following:

- System booting
- Change in a specified interface's operational status or IP address
- Change in the ***startup-config*** file
- State change in a virtual machine monitored by VM Tracer

To change the delay period between the trigger and the action, use the delay command.

When an action runs, certain information passes to it through environment variables. For the boot trigger, no variables are set. For the **interface** triggers, the following variables are set and passed to the action:

- ***$INTF*** interface name.
- ***$OPERSTATE*** current operational status of the specified interface.
- ***$IP-PRIMARY*** current primary IP address of the specified interface.

To execute more than one Bash command in response to a trigger, create a script containing the desired commands and enter the file path to the script as the argument of the action bash command.

To display information about all event handlers or about a specific event handler, use the show event-handler command.

The **`no event-handler`** command deletes an event handler.

Examples

- These commands create an event handler named ***eth_4*** which sends an email to a specified address when a change occurs in the operational status of ***Ethernet interface 4***:

```
switch(config)# event-handler eth_4
switch(config-event-eth_4)# action bash email x@yz.com -s "Et4 $OPERSTATE"
switch(config-event-eth_4)# trigger on-intf ethernet 4 operstatus
switch(config-event-eth_4)# delay 60
switch(config-event-eth_4)# exit
switch(config)#
```

  The above handler uses the ***$OPERSTATE*** variable to include the current operational state, linkup or linkdown, in the subject of the email. Note that the action only function if you configured email on the switch.

- These commands create an event handler named ***onStartup*** which executes a user-defined script 60 seconds after the system boots.

```
switch(config)# event-handler onStartup
switch(config-event-onStartup)# action bash /mnt/flash/startupScript1
switch(config-event-onStartup)# trigger onboot
switch(config-event-onStartup)# delay 60
```

```
switch(config-event-onStartup)# exit
switch(config)#
```

The above handler also executes on exiting from Event-handler Configuration Mode.

- This command displays information about all event handlers configured on the system.

```
switch# show event-handler
Event-handler onStartup
Trigger: onBoot delay 60 seconds
Action: /mnt/flash/startupScript1
Last Trigger Activation Time: 1 minutes 51 seconds ago
Total Trigger Activations: 1
Last Action Time: 51 seconds ago
Total Actions: 1 switch#
```

- This command deletes the event handler named ***onStartup***.

```
switch(config)# no event-handler onStartup
switch(config)#
```

1.1.2.9 Running Adverse Drop Counters Monitor with Event Handlers

A monitoring capability for adverse drop counters can be used as a warning that the system has encountered an abnormal condition. The adverse drop counter monitor runs periodically (with a default of 60 seconds) and performs the following actions:

- Reads the values of adverse drop counters.
- Compares each value to the value read in the previous run.
- If counter values increase more than a certain threshold (with a default of 100), it is considered as a threshold violation.
- If any counter has more than a certain number of threshold violations within a specific time window (with a default of 3 violations within 15 minutes) a syslog message is logged.

No configuration is required to enable adverse drop counters monitor with event handlers. It is enabled by default and can be disabled, and can be customized for duration of time window and threshold levels. To customize the delay, polling interval, and condition for width, violation count, and threshold of this event handler, use the `event-handler DropCountersHandler` command. To display details of this event handler, use the `show event-handler DropCountersHandler` command.

Examples

- These commands customize the delay, polling interval, and condition for width, violation count, and threshold of this event handler. Each parameter may be customized separately, with all other parameters remaining unchanged.

```
switch(config)# event-handler DropCountersHandler
switch(config-DropCountersHandler)# action bash DropCounterLog.py -l
switch(config-DropCountersHandler)# delay 0
switch(config-DropCountersHandler)# trigger on-counters
switch(config-DropCountersHandler-counters)# poll interval 60
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -w 800" > 0
```

```
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -c 5" > 0
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -t 200" > 0
switch(config-DropCountersHandler-counters)#
```

- This command disables this event handler.

```
switch(config)# no event-handler DropCountersHandler
switch(config)#
```

- This command displays details of this event-handler.

```
switch(config)# show event-handler DropCountersHandler
Event-handler DropCountersHandler (BUILT-IN)
Trigger: on-counters delay 0 seconds
  Polling Interval: 60 seconds
  Condition: bashCmd."DropCounterMonitor.py" > 0
Threshold Time Window: 0 Seconds, Event Count: 1 times
Action: DropCounterLog.py -l
Action expected to finish in less than 20 seconds
Total Polls: 39
Last Trigger Detection Time: 38 minutes 22 seconds ago
Total Trigger Detections: 1
Last Trigger Activation Time: 38 minutes 22 seconds ago
Total Trigger Activations: 1
Last Action Time: Never
Total Actions: 1

switch(config)#
```

1.1.3 Kernel-based Virtual Machine Commands and Configuration

Arista EOS has leveraged its unmodified Linux kernel, and embraced open source standards-based technology that has brought operating system virtualization to Ethernet switching, utilizing the kernel-based virtual machine (KVM) as follows:

- The hypervisor uses the Linux kernel.
- The kernel module provides the core virtualization infrastructure.
- The CPU-specific implementation provides the processor-specific module (Intel or AMD).
- The Modified Quick Emulator (QEMU) which transforms the Linux kernel into the hypervisor and provides the generic machine emulator and virtualizer KVM.

The standard Linux kernel uses the hypervisor, resulting in changes to the standard kernel, such as memory support and scheduler. Optimizations to these Linux components, such as a new scheduler in the 2.6 kernel, benefit both the hypervisor (host operating system) and Linux guest operating systems. With the kernel acting as the hypervisor, the switch can run other operating systems, such as Windows or Linux.

All components required are pre-installed with the Arista EOS software image, requiring only the download of the image. A few additional configuration steps get the KVM fully operational.

This chapter contains the following sections:

- KVM Commands

- KVM Configuration

1.1.3.1 KVM Commands

The following table covers KVM commands used throughout the configuration.

Table 3: KVM Commands

Command	Description
comment	Up to 240 character comment for this mode.
default	Set a command to its defaults.
disk-image	Add Virtual Machine disk image.
enable	Enable VM.
exit	Exit from Virtual Machine configuration mode.
memory-size	Set memory size.
no	Negate a command or set its defaults.
show	Show running system information.
virtual-nic	Add virtual NIC.
vnc-port	Set VNC server port.
! !	Append to comment.

1.1.3.1.1 CLI Commands

The following KVM CLI commands are used throughout the configuration.

vm

In **config** mode, the vm CLI command creates or deletes a KVM configuration, or enters **config-vm** mode. A newly created KVM as an empty config file path and initially disabled.

The CLI command syntax is as follows:

```
[no] vm NAME
```

config-file

In **config-vm** mode, the **config-file** CLI command sets the path of the **libvirt** config file, using standard file syntax (e.g. **flash:vm/NetscalerVPX.xml** or **sata1:vm/NetscalerVPX.xml** or **/mnt/sata1/vm/NetscalerVPX.xml**). Changing this value does not affect the state of a currently enabled KVM. To use the new file, the user must disable and then re-enable the KVM.

The CLI command syntax is as follows:

```
config-file [PATH]
```

enabled

In **config-vm** mode, the **enabled** CLI command allows enabling a currently disabled VM, causing it to start up immediately. If a VM is enabled in the **startup-config**, it starts up automatically when EOS boots or when **VirtAgent** starts.

The CLI command syntax is as follows:

```
[no] enabled
```

Disabling a currently enabled VM initiates a shutdown process in the following sequence:

- Attempt to shut down the VM politely if the guest OS supports ACPI.
- If the VM is still running after 30 seconds, terminate it.

show vm

In **enable** mode, the **show vm** CLI command prints information about the configuration and status of a KVM, or of all KVMs if **NAME** is omitted, as follows:

- Configuration: Name, config file path, and enabled.
- Status: PID, log file path, and serial console pty path.
- Current resource usage: RES, CPU%.
- (Detailed only) contents of the log file.

(Detailed only) contents of the config file.

The CLI command syntax is as follows:

```
show vm [detailed] [NAME]
```

attach vm

In **enable** mode, the **attach vm** CLI command connects to a KVM serial console pty using virsh console.

Note: Press **Ctrl-]** to exit to the CLI.

The CLI command syntax is as follows:

attach vm [NAME]

show tech-support

The CLI command syntax is as follows:

show tech-support [detailed] [NAME]

reload

In **enable** mode, the **reload** CLI command executes before restarting the system, and shuts down currently enabled KVMs using the same process as the **no enabled** command in **config-vm** mode.

The CLI command syntax is as follows:

reload

1.1.3.2 KVM Configuration

Arista EOS enables kernel-based virtual machine (KVM) instances by running KVM on the control-plane CPU of the switch. KVM instances can be defined from the CLI.

To configure a KVM, you must download the virtual machine image and configure the EOS.

This section contains the following topics:

- Configuring a KVM
- Configuring a Guest KVM

1.1.3.2.1 Configuring a KVM

To configure a KVM, perform the following steps:

1. Download the Virtual Machine Image to **/mnt/flash**
2. Name the virtual machine - **switch(config)# virtual-machine [kvm_name]**

```
switch(config)# virtual-machine foo
```

3. Provide a pointer to the image - **switch(config-vm-foo)# disk-image [file:[path] image-format [format]**

```
switch(config-vm-foo)# disk-image file:/mnt/flash/fedora.img image-format qcow2
```

4. Define the amount of memory allocated: **switch(config-vm-foo)#memory-size [size in bytes]**

5. Bind the virtual NIC to an SVI or management interface - **switch(config-vm-foo)#virtual-nic 1 vlan [1-4] switch(config-vm-foo)# virtual-nic 1 management [1-4]**

6. Create the VNC server's tcp port (display): **switch(config-vm-foo)# vnc-port [vnc-port number]**

7. Enable the virtual machine - **switch(config-vm-foo)# enable**

   Optionally attach to the virtual machine through a VNC client pointed to the switch IP address. However, if Kernel **hair-pinning** is currently not enabled, preventing communication directly with the local switch, all traffic must have a destination on another networked device such as a router, switch, or server.

For specifics about KVM visit http://www.linux-kvm.org/.

Note: In the Real VNC Viewer for **Options**, **Expert**, and **ColorLevel**, if the default value is ***pal8***, establishing a session may fail. If this occurs, set this value to **full** and **reconnect**.

Example

```
switch# copy http://berrange.fedorapeople.org/images/2012-02-
29/f16-x86_64-openstack-sda.qcow2
(http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-
openstack-sda.qcow2) flash:
...
switch(config)# virtual-machine foo
switch(config-vm-foo)# disk-image file:/mnt/flash/fedora.img image-format qcow2
switch(config-vm-foo)# memory-size 512
switch(config-vm-foo)# virtual-nic 1 vlan 1
switch(config-vm-foo)# virtual-nic 2 management 1
switch(config-vm-foo)# vnc-port 5900
switch(config-vm-foo)# enable
```

1.1.3.2.2 Configuring a Guest KVM

To configure a guest KVM, perform the following steps:

1. Download the Virtual Machine Image to **/mnt/flash**

2. Name the virtual machine: **switch(config)# virtual-machine [guest_name]**

```
switch(config)# virtual-machine guest123
```

3. Provide a pointer to the image: **switch(config-vm-guest123)# disk-image [file:[path] image-format [format]**

```
switch(config-vm-guest123)# disk-image flash:f16-x86_64-openstack-sda.qcow2 image-format ?
iso iso image format   qcow qcow image format   qcow2 qcow2 image format   raw raw image format

vmdk vmdk image format
switch(config-vm-guest123)# disk-image
flash:f16-x86_64-openstack-sda.qcow2 image-format qcow2
```

4. Define the amount of memory allocated: **switch(config-vm-guest123)#memory-size [size in bytes]**

5. Bind the virtual NIC to an SVI (or management interface): **switch(config-vm-guest123)# virtual-nic 1 vlan [1-4] switch(config-vm-guest123)# virtual-nic 2 management [1-4]**

6. Create the VNC server TCP port (display): **switch(config-vm-guest123)# vnc-port [vnc-port number]**

7. Enable the virtual machine: **switch(config-vm-guest123)# enable**

Example

```
switch# copy http://berrange.fedorapeople.org/images/2012-02-
29/f16-x86_64-openstack-sda.qcow2
(http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-
openstack-sda.qcow2) flash:
...
switch# config terminal
switch(config)# virtual-machine ?
    WORD Virtual Machine name
switch(config)# virtual-machine foo
switch(config-vm-foo)# disk-image flash:f16-x86_64-openstack-sda.qcow2 image-format ?
    iso           iso image format
    qcow          qcow image format
    qcow2         qcow2 image format
    raw             raw image format
    vmdk          vmdk image format
switch(config-vm-foo)# disk-image flash:f16-x86_64-openstack-sda.qcow2 image-format qcow2
switch(config-vm-foo)# memory-size 1024
switch(config-vm-foo)# virtual-nic ?
    <1-4>         Virtual NIC Id
switch(config-vm-foo)# virtual-nic 1 ?
    Management    Management interface
    Vlan          Vlan interface
switch(config-vm-foo)# virtual-nic 1 vlan 1
switch(config-vm-foo)# virtual-nic 2 management 1
switch(config-vm-foo)# enable
switch(config-vm-foo)#
switch(config-vm-foo)# ^Z
switch# write mem
switch#
switch# show virtual-machine detail
Virtual Machine: foo
    Enabled:           Yes
    State:             Running
    Disk Image:        /mnt/flash/f16-x86_64-openstack-sda.qcow2
    Disk Image Format: qcow2
    Memory Size: 1024MB
    VNC port: 5900
    Virtual Nic: vnic1
        Mac Address:   52:54:00:ee:11:c9
        Device:        Vlan1
        Model Type:    e1000
    Virtual Nic:       vnic2
        Mac Address:   52:54:00:df:2a:e1
```

```
        Device:        Management1
        Model Type:    e1000 switch#
```

1.1.4 Switch Platforms

Features and CLI commands vary by switch platform. CLI options may also vary by switch platform for commands that are available on all platforms. Command descriptions in this manual describe feature availability and command parameters on the basis of switch platform, noting exceptions that exist among models that use a common platform.

- Arista Switches lists the Arista switches and platforms upon which they operate.
- Features lists Arista switch feature availability by switch platform. For the latest features, also consult the Release Notes.

These sections describe the following topics:

- Viewing the Model Number
- Modular System Platforms – 7500 and 7500E Series Switches
- Viewing Modules on 7300 Series Modular Switches
- Multi-Chip Devices

1.1.4.1 Viewing the Model Number

To view the switch's model number through the CLI, enter the `show version` command.

Example

This command displays the model number, serial number, system MAC address, and manufacturing information of a DCS-7150S-64 switch.

```
switch> show version
Arista DCS-7150S-64-CL-F
Hardware version:    01.01
Serial number:       JPE13120819
System MAC address:  001c.7326.fd0c

Software image version: 4.13.2F
Architecture:           i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                 16 hours and 39 minutes
Total memory:           4017088 kB
Free memory:            1348228 kB switch>
```

1.1.4.2 Modular System Platforms – 7500 and 7500E Series Switches

Modular switch platforms depend on their installed modules along with the fabric and forwarding software modes. The `show module` command displays the fabric modules in the switch. System performance on

switches containing both module types is based on first-generation fabric capabilities. As a best practice, avoid switch configurations with mixed fabric modules.

These sections describe modular switch components and software modes that program their capacities.

1.1.4.2.1 Fabric Modules and Fabric Mode – 7500 and 7500E Series Switches

Each modular switch fabric module falls into one of two categories as first-generation or E-Series:

- First-generation fabric modules support all basic switch functions.
- E-Series fabric modules support faster fabric link speeds, greater internal table capacities, and advanced encoding formatting.

Fabric mode determines the switch fabric performance capabilities. This mode must match the fabric modules in the switch. Fabric mode settings include the following:

- **fe600**: Supports first-generation fabric modules.
- **fe1600**: Supports E-Series fabric modules.

E-series fabric modules can operate in **fe600** mode, but limited to first-generation fabric performance. First-generation modules cannot operate in **fe1600** mode. Switches containing both types of modules must be set to **fe600** mode. As a best practice, avoid switch configurations with mixed fabric modules.

When a switch reloads, the switch determines the fabric mode by the following, in order of precedence:

1. Switches reloading in **petraA** forwarding compatibility mode described in Linecard Modules and Forwarding Compatibility Mode – 7500 and 7500E Series) and also reloading in **fe600** fabric mode.
2. As specified by the platform sand fabric mode (7500 and 7500E Series) statement in ***running-config***.
3. The first fabric module that becomes operational as the switch reloads.

In switches with a homogeneous module set, the fabric mode matches the fabric modules. Switches with a mixed set of modules typically reload in **fe600** mode because first generation modules become operational before E-Series modules. However, the fabric mode in mixed module switches that are reloading cannot be guaranteed in the absence of the first two conditions.

Example

This command configures the switch to reload in **fe1600** fabric mode to support E-series fabric modules. After issuing this command, the switch should be reset only after exchanging all switch fabric modules to E-series modules.

```
switch(config)# platform sand fabric mode fe1600
switch(config)# exit
switch# show platform sand compatibility
                    Configuration        Status
Forwarding mode     None                 Arad
Fabric mode         Fe1600               Fe600 switch#
```

1.1.4.2.2 Determining the Operating Platform of a Switch

FM6000 Platforms

To determine the operating platform on switch, display **platform** command options from Global Configuration command mode.

This command displays the operating platform of a switch operating on the FM6000 platform (7150 Series switches).

```
switch(config)# platform ?
  fm6000  FM6000 chip
switch(config)#platform
```

Arad and Petra Platforms

The **platform ?** command displays the same options on Arad and Petra platform switches. Refer to Viewing the Model Number to determine the switch model number.

- Fixed system switches (DCS-7048 Series) operate on the Petra platform.
- Modular switches (DCS-7500 Series) operate on Arad and Petra platforms. Modular System Platforms – 7500 and 7500E Series Switches describe platform usage on these switches.

Arad and Petra platform switch typically utilize multiple chips. Multi-Chip Devices describe methods of determining the port distribution on multi-chip platforms.

Example

These commands display platform options of a switch operating on either Petra or Arad platforms.

```
switch(config)# platform ?
  arad    Arad switch chip
  fe1600  Fe1600 chip
  fe600   Fe600 fabric chip
  petraA  PetraA switch chip
  ptp     Precision Time Protocol
  sand    Sand platform

switch(config)#platform
```

Trident and Trident II Platforms

The **platform ?** command returns **trident** on switches that operate on Trident or Trident II platforms. Trident II platform switches include options that configure the forwarding and routing tables. To determine the Trident platform that a switch uses, display **platform trident** options.

These commands indicate that the switch is operating on the Trident II platform:

```
switch(config)# platform ?
  ptp      Precision Time Protocol
  trident  Trident chip

switch(config)# platform trident ?
  fabric            Fabric configuration
```

```
  forwarding-table  Forwarding table configuration
  mmu               Trident MMU configuration
  routing-table     Routing table configuration

switch(config)#platform trident
```

Fixed and Modular switches are available that operate on the Trident II platform. Refer to Viewing the Model Number to determine the switch model number. Viewing Modules on 7300 Series Modular Switches displays the modules on a Trident II platform modular switch.

Trident II platform switches typically utilize multiple chips. Multi-Chip Devices describes methods of determining port distribution on multi-chip platforms.

1.1.4.2.3 Linecard Modules and Forwarding Compatibility Mode – 7500 and 7500E Series

Each modular switch linecard module has a category of first-generation or E-Series:

- First-generation linecard modules support all basic switch functions.
- E-Series linecard modules support provide faster data processing, greater internal table capacities, and advanced encoding formatting.

The forwarding compatibility mode determines the switch performance capabilities when forwarding data between linecard interfaces. Forwarding compatibility mode settings include the following:

- **PetraA**: Supports first-generation linecard modules.
- **Arad**: Supports E-Series linecard modules.

Forwarding compatibility mode determines the operational capacity of installed linecards. The following table lists the affect of the forwarding compatibility mode on linecard module types.

Table 4: Linecard Module and Forwarding Mode Performance

Linecard Module Type	Forwarding Compatibility Mode	Linecard Operating Capacity
First-generation	petraA	First-generation performance capacity.
First-generation	arad	Linecard is powered-down.
E-Series	petraA	First-generation performance capacity.
E-Series	arad	E-series performance capacity.

Note: Switches must contain E-Series fabric modules to operate at E-Series performance capacities.

Configure the forwarding compatibility mode using the `platform sand forwarding mode (7500 and 7500E Series)` command. This command may be required after exchanging a linecard for a different module type or in switches containing first-generation and E-series linecards.

Without a `platform sand forwarding mode (7500 and 7500E Series)` command, the first operational linecard after reloading the switch determines the forwarding compatibility mode. In a switch reloading with a homogeneous module set, the forwarding compatibility mode matches the linecards. Switches with a mixed set of modules typically reload in **petraA** mode because first generation modules become operational before E-Series modules. However, forwarding compatibility mode for reloading mixed module switches is not guaranteed without a **`platform sand forwarding mode`** command.

Example

This command changes the forwarding software mode to support E-series linecard modules. This command should be run only after exchanging all linecards to E-series modules.

```
switch(config)# platform sand forwarding mode arad
switch(config)#
```

1.1.4.2.4 Viewing Modules – 7500 and 7500E Series

The `show module` command displays the model number of all installed modules.

- This command displays the modules of a 7504 switch that contains first-generation modules.

```
switch> show module
Module    Ports Card Type                            Model           Serial No.
--------- ----- ------------------------------------ --------------- -----------
1         2     DCS-7500 Series Supervisor Module    7500-SUP        JSH11440327
2         1     Standby supervisor                   Unknown         Unknown
3         48    48-port SFP+ 10GigE Linecard         7548S-LC        JSH10449938
4         48    48-port SFP+ 10GigE Linecard         7548S-LC        JSH11091247
5         48    48-port SFP+ 10GigE Linecard         7548S-LC        JSH11211614
6         48    48-port SFP+ 10GigE Linecard         7548S-LC        JSH11520288
Fabric1   0     DCS-7504 Fabric Module               7504-FM         JSH11451230
Fabric2   0     DCS-7504 Fabric Module               7504-FM         JSH11451210
Fabric3   0     DCS-7504 Fabric Module               7504-FM         JSH11410115
Fabric4   0     DCS-7504 Fabric Module               7504-FM         JSH11380318
Fabric5   0     DCS-7504 Fabric Module               7504-FM         JSH11340955
Fabric6   0     DCS-7504 Fabric Module               7504-FM         JSH11410128

Module    MAC addresses                          Hw      Sw      Status
--------- -------------------------------------- ------- ------- -------
1         00:1c:73:03:06:ac - 00:1c:73:03:06:ac  07.06   4.12.1  Active
2                                                        4.12.1  Standby
3         00:1c:73:03:80:44 - 00:1c:73:03:80:73  06.00           Ok
4         00:1c:73:03:e4:34 - 00:1c:73:03:e4:63  07.10           Ok
5         00:1c:73:12:0b:3f - 00:1c:73:12:0b:6e  07.30           Ok
6         00:1c:73:12:b6:3f - 00:1c:73:12:b6:6e  08.00           Ok
Fabric1                                          05.03           Ok

```

1.1.4.4 Multi-Chip Devices

Trident II, Petra, and Arad platform switches and linecards utilize multiple chips, with Ethernet ports evenly distributed among the chips. Creating multi-port data structures (including port channels) that include ports from multiple chips protects against the failure of an individual chip on a device.

The following sections describe methods of determining port distribution on various switch platforms

Petra Fixed Switches

7048-Series switches are Petra platform devices that distribute ports among two PetraA chips. The **`show platform petraA port-info routing`** command displays the ports that are controlled by each chip.

Example

This command displays the following Ethernet port distribution on a DCS-7048-T switch:

- ***Petra0*** chip controls ***Ethernet 1*** through ***Ethernet 32***.
- ***Petra1*** chip controls ***Ethernet 33*** through ***Ethernt 52***.

```
switch# show platform petraA port-info routing

Petra Modular Switches

Linecards on 7500-Series modular switches distribute Ethernet ports among multiple petraA chips. The **`show platform petraA port-info routing`** command displays the ports that are controlled by each chip on all PetraA linecards or on a single linecard.

Example

This command displays the following Ethernet port distribution on ***linecard 4*** of a DCS-7504 switch:

- ***Petra4/0*** chip controls ***Ethernet 4/1*** through ***Ethernet 4/8***.
- ***Petra4/1*** chip controls ***Ethernet 4/9*** through ***Ethernet 4/16***.
- ***Petra4/2*** chip controls ***Ethernet 4/17*** through ***Ethernet 4/24***.
- ***Petra4/3*** chip controls ***Ethernet 4/25*** through ***Ethernet 4/32***.
- ***Petra4/4*** chip controls ***Ethernet 4/33*** through ***Ethernet 4/40***.
- ***Petra4/5*** chip controls ***Ethernet 4/41*** through ***Ethernet 4/48***.

Arad Modular Switches

7500-E Series linecards distribute Ethernet ports among multiple Arad chips. The **`show platform arad port-info routing`** command displays the ports that are controlled by each chip on all Arad linecards.

Example

This command displays the following Ethernet port distribution on the 7500E-72S-LC linecard that is inserted as ***module 3*** in a DCS-7508E switch:

- ***Arad3/0*** chip: ***Ethernet 3/1***– ***Ethernet 3/20***.
- ***Arad3/1 chip***: ***Ethernet 3/21*** – ***Ethernet 3/34*** and ***Ethernet 3/49/1*** – ***Ethernet 3/49/12***.
- ***Arad3/2*** chip: ***Ethernet 3/35*** – ***Ethernet 3/48*** and ***Ethernet 3/50/1*** – ***Ethernet 3/50/12***.

```
switch# show platform arad mapping

switch#
```

Trident II Fixed Switches

Trident II platform devices distribute their ports among multiple Trident II chips. The **`show platform trident system port`** command displays the ports that are controlled by each chip.

Example

This command displays the following Ethernet port distribution on a DCS-7250QX-64-F switch:

- ***Trident 0*** chip controls ***Ethernet 1/1*** through ***Ethernet 16/4***.
- ***Trident 1*** chip controls ***Ethernet 17/1*** through ***Ethernet 32/4***.
- ***Trident 2*** chip controls ***Ethernet 33/1*** through ***Ethernet 48/4***.
- ***Trident 3*** chip controls ***Ethernet 49/1*** through ***Ethernet 64/4***.

```
switch# show platform trident system port

                                                                  Port
      Intf              Chip            ModId       Logical       Physical   MMU
--------------------- ----------------- ----------- ------------- ---------- ---
      Ethernet1/1       Linecard0/0      1           1             17         9
      Ethernet1/2       Linecard0/0      1           2             18         10

      Ethernet16/3      Linecard0/0      1           60            107        98
      Ethernet16/4      Linecard0/0      1           61            108        99
```

```
      Ethernet64/2      Linecard0/3      4           62            106        97
      Ethernet64/3      Linecard0/3      4           63            107        98
      Ethernet64/4      Linecard0/3      4           64            108        99

-------------------------------------------------------------------------------
switch#
```

Trident II Modular Switches

Linecards on 7300-Series modular switches distribute Ethernet ports among multiple Trident II chips. The **`show platform trident system port`** command can display the ports that are controlled by each chip on all linecards or on a single chip.

This command displays the following Ethernet port distribution on DCS-7304-F switch that contains a 7300X-32Q-LC linecard as ***module 3***:

- ***Trident 0*** chip controls ***Ethernet 1/1*** through ***Ethernet 16/4*** (on ***module 3***).
- ***Trident 1*** chip controls ***Ethernet 17/1*** through ***Ethernet 32/4*** (on ***module 3***).

```
switch# show platform trident system port

-------------------------------------------------------------------------------------
                                                                  Port
     Intf              Chip             ModId       Logical       Physical       MMU
--------------------- ----------------- ----------- ------------- -------------  ---
    Ethernet3/1/1      Linecard3/0       5           1             17            4
    Ethernet3/2/1      Linecard3/0       5           2             21            5

    Ethernet3/16/3     Linecard3/0       5           51            111           102
    Ethernet3/16/4     Linecard3/0       5           52            112           103

    Ethernet3/32/3     Linecard3/1       6           63            111           102
    Ethernet3/32/4     Linecard3/1       6           64            112           103

-------------------------------------------------------------------------------------
switch#
```

1.1.5 Command Modes

Command modes define the user interface state. Each mode is associated with commands that perform a specific set of network configuration and monitoring tasks.

- Mode Types lists the available modes.
- Navigating Through Command Modes lists mode entry and exit commands.
- Command Mode Hierarchy describes the mode structure.
- Group-Change Configuration Modes describes editing aspects of these modes.

1.1.5.1 Mode Types

The switch includes these command modes:

- **EXEC** - EXEC mode commands display system information, perform basic tests, connect to remote devices, and change terminal settings. When logging into EOS, you enter EXEC mode.

EXEC mode prompt - `switch>`

- **Privileged EXEC** - Privileged EXEC mode commands configure operating and global parameters. The list of Privileged EXEC commands consists of a superset of the EXEC command set. You can configure EOS to require password access to enter Privileged EXEC from EXEC mode.

  Privileged EXEC mode prompt: `switch#`

- **Global Configuration** - Global Configuration mode commands configure features that affect the entire system, such as system time or the switch name.

  Global Configuration mode prompt - `switch(config)#`

- **Interface Configuration** - Interface configuration mode commands configure or enable Ethernet, VLAN, and Port-Channel interface features.

  Interface Configuration mode prompt - `switch(config-if-Et24)#`

- **Protocol specific mode** - Protocol specific mode commands modify global protocol settings. Protocol specific mode examples include **ACL Configuration** and **Router BGP Configuration**.

  The prompt indicates the active command mode. For example, the Router BGP command prompt is `switch(config-router-bgp)# .`

1.1.5.2 Navigating Through Command Modes

To change the active command mode, perform one of these actions:

- To enter EXEC mode, log into the switch.
- To enter Privileged EXEC mode from EXEC, type **`enable`** (or **`en`**) followed, if prompted, by the **enable** password:

```
switch# en
Password:
switch#
```

- To enter Global Configuration mode from Privileged EXEC, type **`configure`** (or **`config`**):

```
switch# config
switch(config)#
```

- To enter Interface Configuration mode from Global Configuration, type **`interface`** and the name of the interface to be modified:

```
switch(config)# interface Et24
switch(config-if-Et24)#
```

- To enter a protocol specific configuration mode from Global Configuration, type the required command for the desired mode.

```
switch(config)# router bgp 100
switch(config-router-bgp)#
```

- To return one level from any configuration mode, type **exit**.

```
switch(config)# exit
switch#
```

- To return to Privileged EXEC mode from any configuration mode, type **end** or **Ctrl-Z**.

```
switch(config-if-Et24)# <Ctrl-z>
switch#
```

- To return to EXEC mode from Privileged EXEC mode, type **disable** (or **dis**).

```
switch# dis
switch>
```

- To exit EOS and log out of the CLI, type **exit** from EXEC mode or Privileged EXEC mode.

```
switch# exit
login:
```

1.1.5.3 Command Mode Hierarchy

Command modes are hierarchical. The parent mode of a specified command mode is the mode that contains the command that enters the specified mode.

Example

EXEC mode contains the **enable** command, which enters Privileged EXEC mode. Therefore, EXEC is the parent mode of Privileged EXEC.

Commands that are executable in a specified command mode include all commands available in the specified mode plus all commands executable from its parent mode.

Example

EXEC mode includes the **ping** command. EXEC mode is the parent mode of Privileged EXEC mode. Therefore, Privileged EXEC mode includes **ping**.

Additionally, Privileged EXEC is the parent mode of Global Configuration mode. Therefore, Global Configuration mode also includes **ping**.

Executing a configuration mode command from a child mode may change the active command mode.

Example

Global Configuration mode contains **interface ethernet** and **ip access-list** commands, which enter Interface Configuration and Access Control List (ACL) Configuration modes, respectively. When the switch is in Interface Configuration mode, the **ip access-list** command is available and changes the active mode to ACL Configuration.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# ip access-list master-list
switch(config-acl-master-list)#
```

The **exit** command changes the active command mode to its parent mode. When executed from Privileged EXEC or EXEC modes, the exit command terminates the session.

Example

- This command exits Global Configuration mode to Privileged EXEC mode.

```
switch(config)#exit
switch#
```

- This command terminates the user session.

```
switch# exit
```

1.1.5.4 Group-Change Configuration Modes

Group-change modes apply all changes made during an edit session only after exiting the mode. Changes are stored when the user exits the mode, either through an **exit** or **end** command or through a command that enters a different configuration mode.

The **abort** command discards all changes not previously applied.

Access Control List (ACL) and Multiple Spanning Tree (MST) configuration modes are examples of group-change modes.

1.1.6 Managing Switch Configuration Settings

1.1.6.1 Verifying Settings for the Current Mode

To display only the lines of ***running-config*** that affect the current mode, use the **active** option of the show (various configuration modes) command. This command option is available in all configuration modes except global configuration.

Example

Type **`show active`** to display the content of ***running-config*** that affects the current mode. To include default settings in the display, type **`show active all`**.

```
switch(config-router-ospf3)# show active all
ipv6 router ospf 9
   router-id 0.0.0.0
   default-metric 10
   distance ospf intra-area 10
   area 0.0.0.200 default-cost 10
   area 0.0.0.200
   no log-adjacency-changes
   timers spf 5
switch(config-router-ospf3)#
```

To display any comments associated with the current mode, use the **comment** option of the `show (various configuration modes)` command.

Example

Type **`show comment`** to display any comments attached to the current mode.

```
switch(config-router-ospf3)# show comment
Comment for router-ospf3:
    Consult Thomas Morton before making changes to the OSPF configuration.
switch(config-router-ospf3)#
```

1.1.6.2 Verifying the Running Configuration Settings

The **`running-config`** command is the virtual file that stores the operating configuration. The **`show running-config`** command displays the **`running-config`**. The command is supported in Privileged EXEC mode.

Example

Type **`show running-config`** in Privileged EXEC mode. The response in the example is truncated to display only the ip route configured.

```
switch# show running-config
! Command: show running-config

!
ip route 0.0.0.0/0 192.0.2.1
!

end switch#
```

1.1.6.3 Adding a Comment to a Configuration Mode

To add a comment to most switch configuration modes, use the `comment (various configuration modes)` command. Comments cannot be modified, but can be replaced by entering the **comment** command again and entering new text. Comments cannot be added to global configuration mode.

To append to an existing comment, enter !! followed by additional comment text. To display comments for the active mode, use the **show comment** command. The **no comment** and **default comment** commands remove the comment from **running-config**.

Examples

- These commands enter a comment in Router OSPF3 Mode.

```
switch(config-router-ospf3)# comment
Enter TEXT message. Type 'EOF' on its own line to end.
Consult Thomas Morton before making changes to the OSPF configuration.
EOF
switch(config-router-ospf3)#
```

- These commands append additional information to the comment entered above.

```
switch(config-router-ospf3)# !! x2735
switch(config-router-ospf3)# show comment
Comment for router-ospf3:
    Consult Thomas Morton before making changes to the OSPF configuration.
    x2735
switch(config-router-ospf3)#
```

1.1.6.4 Saving the Running Configuration Settings

startup-config is the file, stored in internal flash memory, that the switch loads when it boots. Configuration changes that are not saved to **startup-config** are lost the next time the switch is booted.

The **write** and **copy running-config startup-config** commands store the operating configuration to **startup-config**. Both commands are supported in Privileged EXEC mode.

Example

These equivalent commands save the current operating configure to the startup-config file.

```
switch# write

switch# copy running-config startup-config
```

The **show startup-config** command displays the startup configuration file. The command is supported in Privileged EXEC mode.

Example

Type **show startup-config** to display the startup configuration file. The response in the example is truncated to display only the ip route configured in Admin Username.

```
switch# show startup-config
! Command: show startup-config
! Startup-config last modified at  Wed Feb 19 08:34:31 2014 by admin
!
```

```
!
ip route 0.0.0.0/0 192.0.2.1
!

end switch#
```

1.1.7 Other Command-Line Interfaces

EOS can access other CLIs that provide switch commands, files, and services.

- Aboot Command-Line Interface describes the boot-loader CLI.
- Bash Shell describes the Bash shell CLI.

1.1.7.1 Aboot Command-Line Interface

Aboot is the switch boot loader. It reads a configuration file from the internal flash or a USB flash drive and attempts to boot a software image.

The switch opens an Aboot shell if the switch does not find a software image, the configuration is corrupted, or the user terminates the boot process. The Aboot shell provides a CLI for manually booting a software image, recovering the internal flash to its default factory state, running hardware diagnostics, and managing files.

1.1.7.2 Bash Shell

The switch provides a Linux Bash shell for accessing the underlying Linux operating system and extensions. The Bash shell is accessible in all command modes except EXEC. Mode Types describes EOC command modes.

- To enter the Bash, type **`bash`** at the prompt.

```
switch# bash

Arista Networks EOS shell

[admin@Switch ~]$
```

- To exit the Bash, type **`logout`**, **`exit`**, or **Ctrl-D** at the Bash prompt.

```
[admin@Switch ~]$ logout
switch#
```

1.1.8 Directory Structure

EOS operates from a flash drive root mounted as the **/mnt/flash** directory on the switch. The EOS CLI supports these file and directory commands:

- **`delete`**: Delete a file or directory tree.
- **`copy`**: Copy a file.

- **more**: Display the file contents.
- **diff**: Compares the contents of files located at specified URLs.
- **rename**: Rename a file.
- **cd**: Change the current working directory.
- **dir**: Lists directory contents, including files and subdirectories.
- **mkdir**: Create a directory.
- **rmdir**: Remove a directory.
- **pwd**: Display the current working directory.

Verify flash memory space before copying a file. When a file is copied to flash, it is first written to a temporary file and then renamed to the destination rather than directly overwriting the destination file. This protects the integrity of the existing file if the **copy** command is interrupted, but requires more free space to complete the process.

Switch directory files are accessible through the Bash shell and Aboot. When entering the Bash shell from the switch, the working directory is located in **/home** and has the name of the user name from which Bash was entered.

Example

These commands were entered from the user name john:

```
switch# bash
[john@switch ~]$ pwd
/home/john
[john@switch ~]$
```

In this instance, the working directory is **/home/john**.

When a flash drive is inserted in the USB flash port, flash drive contents are accessible through **/mnt/usb1**.

When entering Aboot, the working directory is the root directory of the boot.

1.1.9 Command-Line Interface Commands

Mode Navigation Commands

- alias
- bash
- configure (configure terminal)
- copy running-config

- daemon
- disable
- enable
- end
- exit

File Transfer Commands

- ip ftp client source-interface
- ip http client local-interface
- ip ssh client source-interface
- ip tftp client source-interface

File Management Commands

- configure checkpoint
- configure network
- copy running-config
- dir
- pwd

Modular Switch Platform Commands

- platform arad lag mode
- platform sand fabric mode (7500 and 7500E Series)
- platform sand forwarding mode (7500 and 7500E Series)
- platform sand lag hardware-only
- platform sand lag mode
- show platform sand compatibility
- show platform sand lag hardware-only

CLI Scheduling Commands

- schedule
- schedule config
- show schedule

Event Handler Commands

- action bash
- delay
- event-handler
- event-handler DropCountersHandler
- show event-handler
- show event-handler DropCountersHandler
- trigger

Terminal Parameter Commands

- terminal length
- terminal monitor

Display and Comment Commands

- comment (various configuration modes)
- show (various configuration modes)
- show module
- show version

1.1.9.1 action bash

The **action bash** command specifies a Bash shell command to run when an event handler triggers. When an event handler triggers,the execution of the associated shell command delays by a configurable period set by the delay command. Only a single Bash command may be configured for an event handler, but the command may have multiple arguments. If more than one Bash command must be executed in response to a trigger, create a script containing the desired commands and enter the file path to the script as the argument of the **action bash** command.

To specify the event that triggers the action, use the trigger command.

If the event handler uses an **on-intf** trigger, the following environment variables pass to the action and can be used as arguments to the Bash command:

- ***$INTF*** interface name.
- ***$OPERSTATE*** current operational status of the specified interface.
- ***$IP-PRIMARY*** current primary IP address of the specified interface.

Command Mode

Event-Handler Configuration

Command Syntax

action bash ***command***

Parameters

command Bash shell command to be executed when the event handler triggers.

Examples

- This command configures the event handler **onStartup** to run a script on the flash drive.

```
switch(config-handler-onStartup)# action bash /mnt/flash/myScript1
switch(config-handler-onStartup)#
```

- This command configures the event handler **eth_4** to send email to the specified address when a change occurs for the operational status of ***Ethernet interface 4***.

```
switch(config-event-eth_4)# action bash email x@yz.com -s "Et4 $OPERSTATE"
switch(config-event-eth_4)#
```

  The above action uses the ***$OPERSTATE*** variable to include the current operational state, `linkup` or `linkdown`, in the subject of the email. Note that the action only functions if you configure email on the switch.

1.1.9.2 alias

The **alias** command creates an alias for a CLI command. Entering the alias in the CLI executes the corresponding command. Once created, an alias becomes accessible in all modes and all user sessions, but subject to all the restrictions of the original command.

When using a command alias, no tokens may precede the alias except the **no** and **default** keywords. However, an alias can incorporate positional parameters.

In online help, precede aliases with an asterisk (*****) in this format:

*alias_name=command_name

The **no alias** and **default alias** commands remove the specified alias.

Command Mode

Global Configuration

Command Syntax

alias ***alias_name command_name***

no alias ***alias_name***

default alias ***alias_name***

Parameters

- ***alias_name*** - The string substituted for the original command. The string can include letters, numbers, and punctuation, but no spaces. If the alias name string has an identical existing command, the alias supercedes the original command.
- ***command_name*** - The command executed when entering the alias in the CLI. If the original command requires additional parameters, they must be included in the *command_name* string in the following manner:

  Positional parameters have the form `%n` and must be whitespace-delimited. Represent the first parameter using `%1` and any additional parameters must be numbered sequentially. When executing the alias, a value must be entered for each parameter or the CLI display the error `%` incomplete command".

Examples

- This command creates **e** an alias for the command **enable.**

```
switch(config)#alias e enable
```

- This command makes **srie** an alias for the command **show running-config interface ethernet 1-6.**

```
switch(config)#alias srie show running-config interface ethernet 1-6
```

- These commands uses **ss** an alias for the command **show interfaces ethernet <range> status** with a positional parameter for the port range, then use the alias to display the status of ports 4/1-4/5.

```
switch(config)#alias ss show interfaces ethernet %1 status
switch(config)#ss 4/1-4/5
Port      Name            Status       Vlan       Duplex  Speed Type
Et4/1                     connected    in Po1       full  10000 10GBASE-SRL
Et4/2                     notconnect   in Po1       full  10000 10GBASE-SRL
Et4/3                     notconnect   1            full  10000 10GBASE-SRL
Et4/4                     notconnect   1            full  10000 10GBASE-SRL
Et4/5                     notconnect   1            full  10000 10GBASE-SRL
```

1.1.9.3 bash

The **bash** command starts the Linux Bash shell. The Bash shell allows access to the underlying Linux operating system and system extensions.

To exit the Bash, type **logout**, **exit**, or **Ctrl-D** at the Bash prompt.

Command Mode

Privileged EXEC

Command Syntax

```
bash
```

Examples

- This command starts the Bash shell.

```
switch#bash
Arista Networks EOS shell
[admin@switch ~]$
```

- This command, executed within Bash, exits the Bash shell.

```
[admin@switch ~]$ logout
switch#
```

1.1.9.4 comment (various configuration modes)

The **comment** command adds a comment for the active configuration mode to ***running-config***. Comments cannot be modified, but can be replaced by entering the **comment** command again and entering new text. To append to an existing comment, enter **!!** followed by additional comment text. To display comments, use the **comment** option of the show (various configuration modes) command.

The **no comment** and **default comment** commands remove the comment from ***running-config***.

You cannot add comments to the global configuration mode through the EOS.

Command Mode

All configuration modes except Global Configuration

Command Syntax

`comment` *comment_text* `EOF`

`no comment`

`default comment !!` *comment_text*

Parameters

- ***comment_text*** To create a comment, enter a message when prompted. The message may span multiple lines.
- **EOF** - To end a comment, type EOF on its own line (case sensitive) and press **enter**.

Examples

- This command adds a comment to the active configuration mode.

```
switch(config-sg-radius-RAD-SV1)# comment
Enter TEXT message. Type 'EOF' on its own line to end.
Consult Thomas Morton before making changes to the RADIUS configuration.
EOF
switch(config-sg-radius-RAD-SV1)#
```

- This command appends a line to the comment for the active configuration mode.

```
switch(config-sg-radius-RAD-SV1)# !! x3452
switch(config-sg-radius-RAD-SV1)#
```

1.1.9.5 configure (configure terminal)

The **`configure`** command places the switch in the Global Configuration mode to configure features at the system level. You can move to Interface Configuration mode and protocol-specific mode from the ***Global Configuration*** mode. The command may also be entered as configure terminal.

Command Mode

Privileged EXEC

Command Syntax

`configure` **[*terminal*]**

Example

This command places the switch in the Global Configuration mode.

```
switch> enable
switch# configure
switch(config)#
```

1.1.9.6 configure checkpoint

The **`configure checkpoint`** command saves the running configuration to a checkpoint file. This checkpoint file can be used for restoring the current running configuration in future, if required.

Command Mode

Privileged EXEC

Command Syntax

`configure checkpoint` **{restore *checkpoint_name* | save [*checkpoint_name*]}**

Parameters

- **restore *checkpoint_name*** - Restores the running configuration from the specified checkpoint file.
- **save *checkpoint_name*** - Saves the running configuration to the specified checkpoint file.

Guidelines

If the filename already exists, EOS overwrites the filename. If you enter the command without a checkpoint name, the switch automatically saves the checkpoint with the format of `date-time-hash_value` where the date has the format `MMDD`. The time has the format `HH:MM`, and the hash value generates randomly for each automatically named checkpoint file.

Examples

- This command saves ***running-config*** to the ***ca_test*** checkpoint file.

```
switch# configure checkpoint save ca_test
```

- This command restores the ***running-config*** from the ***ca_test*** checkpoint file.

```
switch# configure checkpoint restore ca_test
! Preserving static routes. Use 'no ip routing delete-static-routes' to clear them.
```

- This command saves ***running-config*** to the ***13Aug2018*** checkpoint file. The **`dir`** command shows the contents of the checkpoint directory.

```
switch# configure checkpoint save
switch# dir checkpoint:
Directory of checkpoint:/

```

1.1.9.7 configure convert

The **`configure convert`** command converts the current configuration syntax to the specified syntax.

Command Mode

Privileged EXEC

Command Syntax

`configure convert` ***new-syntax***

Parameter

new-syntax converts ***running-config*** to the current version of EOS.

Example

This command converts running-config to the current version of EOS.

```
switch# configure convert new-syntax

WARNING!
Converting existing configuration to new syntax will lose backward compatibility.
Make sure you won't downgrade to releases that only support the old syntaxes.

Proceed [ y/n ]
```

1.1.9.8 configure network

The **`configure network`** command is deprecated. Use the **`copy`** <*url*> ***running-config*** command to configure the switch from a local file or network location.

1.1.9.9 copy running-config

The current operating configuration of the switch is stored in a virtual file called running-config. The copy running-config command saves the contents of the running-config virtual file to a new location.

Command Mode

Privileged EXEC

Command Syntax

`copy running-config` ***destination***

Parameters

- ***destination*** - The destination for the contents of the running-config file. Values include:
  - **startup-config** - The configuration file that the switch loads when it boots.

- The **`copy running-config`**, **`startup-config`**, and **`write`** commands are equivalent.
  - **`file`**: a file in the switch file directory.
  - **`flash`**: a file in flash memory.
  - **`url`** any valid URL.

The **`copy running-config url`** and **`write network url`** commands are equivalent.

Examples

- This command copies running-config to the startup-config file.

```
switch# copy running-config startup-config
switch#
```

- This command copies running-config to a file called ***rc20110617*** in the dev subdirectory of the switch directory.

```
switch# copy running-config file:dev/rc20110617
switch#
```

1.1.9.10 daemon

The **daemon** command accesses Daemon Configuration Mode for adding or removing external daemons and scripts, and managed by ProcMgr.

The **no daemon** and **default daemon** commands delete the daemon by removing the corresponding **daemon** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

daemon ***daemon_name***

no daemon ***daemon_name***

default daemon ***daemon_name***

Parameters

daemon_name - A label that references the Daemon Configuration Mode.

Example

These commands enters daemon configuration mode and initiates the daemon script.

```
switch(config)# daemon process1
switch(config-daemon-process1)# command process-script -i -m
switch(config-daemon-process1)#
```

1.1.9.11 delay

The **`delay`** command specifies the time in seconds the system delays between a triggering event and executing an event handler action. The default delay is ***20*** seconds.

Command Mode

Event-Handler Configuration

Command Syntax

`delay` ***seconds***

Parameters

seconds - Specify the number of seconds to delay before executing the action. The default is 20.

Example

This command configures the event handler Eth5 to delay 10 seconds before executing.

```
switch(config-handler-Eth5)# delay 10
switch(config-handler-Eth5)#
```

1.1.9.12 dir

The **dir** command displays a list of files on a file system.

Command Mode

Privileged EXEC

Command Syntax

dir [**SCOPE**][**FILE TYPE**]

Parameters

- ***scope*** - Select the files to display. Options include the following:
  - ***no parameter*** - Lists normal files in current directory.
  - **/all** - List all files, including hidden files.
  - ***/recursive*** -list files recursively.
- ***file_type*** - The options include the following:
  - ***no parameter*** - Lists undeleted files.
  - **all_filesystems** - List files on all filesystems including deleted files, undeleted files, and files with errors.
  - ***extensions*** - Specify the directory or file name.
  - ***file*** - Specify the directory or file name.
  - ***flash*** - Specify the directory or file name.
  - ***supervisor-peer*** - Specify the directory or file name.
  - ***usb1*** - Specify the directory or file name.
  - ***system*** - Specify the directory or file name.

Example

This command displays the flash directory.

```
switch# dir flash:
Directory of flash:/

       -rwx   293409892           Oct 23 08:55  EOS-4.11.0.swi
       -rwx   221274543            Sep 6 13:37  EOS-4.7.5.swi
       -rwx   271453650            Sep 4 19:13  EOS_4.10.1-SSO.swi
       -rwx      135168           Dec 31  1979  FSCK0000.REC
       -rwx          26           Oct 23 13:51  boot-config
       -rwx        8570           Sep 10 12:22  cfg_sso_mst
```

```
        -rwx        5642           Sep 20 10:35  config.reset
        drwx        4096           Oct 23 13:59  debug
        -rwx          12           Oct 23 13:56  kernel-params
        drwx        4096           Oct 23 14:59  persist
        drwx        4096            Sep 6 14:50  schedule
        -rwx        5970           Oct 23 13:53  startup-config switch#
```

1.1.9.13 disable

The **disable** command exchanges the session's current command mode with the specified privilege level.

Command Mode

Privileged EXEC

Command Syntax

disable [*privilege_level*]

Parameters

privilege_level - Specify the new privilege for the session from ***0*** to ***15***. Levels ***2*** through ***15*** place the switch in Privileged EXEC mode. Values of ***0*** or ***1*** leave the switch in EXEC mode.

- ***no parameter*** - Specify the session the assigned default level of ***1***.
- <**0** to **15**> - Specifies session level.

Restrictions

New privilege level must be less than the session current level.

Example

This command exits Privileged EXEC mode level of 15 to enter EXEC mode level 1.

```
switch# disable
switch>
```

1.1.9.14 enable

The **enable** command places the switch in Privileged EXEC mode. If an **enable** password is set, the CLI displays a password prompt when a user enters the **enable** command. If the user enters an incorrect password three times, the CLI displays the EXEC mode prompt.

To set a local **enable** password, use the **enable** password command.

Command Mode

EXEC

Command Syntax

enable [***privilege_level***]

Parameters

- *privilege_level* - Specify the session privilege level. Values range from ***0*** to ***15***. Values of ***0*** or ***1*** places the switch in EXEC mode. Any level above ***1*** leaves the switch in Privileged EXEC mode.
  - ***no parameter*** - Assign the session a default level of ***15***.
  - <**0** to **15**> - Specifies session level.

Example

This command places the switch in Privileged EXEC mode with the default privilege level of ***15***.

```
switch> enable
switch#
```

1.1.9.15 end

The **end** command exits to Privileged Exec mode from any Configuration mode. If the switch is in a group-change mode (such as ACL-Configuration mode or MST-Configuration mode), the **end** command also saves all pending changes made in that mode to ***running-config***.

Command Mode

All configuration modes

Command Syntax

```
end
```

Example

This command exits to Privileged Exec mode.

```
switch(config-if-Et25)# end
switch#
```

1.1.9.16 event-handler DropCountersHandler

The **event-handler DropCountersHandler** command enables the adverse drop counters monitor with event handlers. EOS enables the DropCountersHandler event handler by default, and can be customized for duration of time window and threshold levels.

The **no event-handler DropCountersHandler** command disables the adverse drop counters monitor with event handlers. The **default event-handler DropCountersHandler** command resets the DropCountersHandler event handler to the system default.

Command Mode

Global Configuration

Command Syntax

event-handler DropCountersHandler

no event-handler DropCountersHandler

default event-handler DropCountersHandler

Examples

- These commands customize the delay, polling interval, and condition for width (-w), violation count (-c), and threshold (-t) of this event handler. Each parameter may be customized separately, with all other parameters remaining unchanged.

```
switch(config)# event-handler DropCountersHandler
switch(config-DropCountersHandler)# action bash DropCounterLog.py -l
switch(config-DropCountersHandler)# delay 0
switch(config-DropCountersHandler)# trigger on-counters
switch(config-DropCountersHandler-counters)# poll interval 60
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -w 800" > 0
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -c 5" > 0
switch(config-DropCountersHandler-counters)# condition
bashCmd."DropCounterMonitor.py" -t 200" > 0
switch(config-DropCountersHandler-counters)#
```

- This command disables this event handler.

-
```
switch(config)# no event-handler DropCountersHandler
switch(config)#
```

1.1.9.17 event-handler

An event handler executes a Linux Bash shell command in response to a specific system event. An event handler consists of a Bash command, a trigger and a delay; when the trigger event occurs, the action is scheduled to run after ***delay*** seconds.

The **`event-handler`** command places the switch in Event-handler Configuration Mode for the specified event handler. If the named event handler does not already exist, this command creates it. Event-handler configuration mode uses a group change mode that configures event handlers.

Save the changes made in a group change mode by leaving the mode through the **`exit`** command or by entering another configuration mode.

These commands are available in event-handler configuration mode:

- action bash
- delay
- trigger

The **`no event-handler`** and **`default event-handler`** commands delete the specified event handler by removing it from ***running config***.

Command Mode

Global Configuration

Command Syntax

`event-handler` ***name*** **`exec mode control`** - Enables event handler and must be configured before using other event-handler commands.

`no event-handler` ***name***

`default event-handler` ***name***

Parameters

name - Specify the event-handler name to configure. If the named event handler does not already exist, this command creates it.

Example

This command places the switch in the Event-handler Configuration Mode for an event handler called ***Eth_5***.

```
switch(config)# event-handler Eth_5
switch(config-handler-Eth_5)#
```

1.1.9.18 exit

The exit command places the switch in the parent of the command mode from which the exit command was entered.

- When used in Global configuration, the switch enters ***Privileged EXEC mode***.
- When used in ***EXEC*** or ***Privileged EXEC mode***, the **`exit`** command terminates the user session.
- When the command is used in a group-change mode (such as ***ACL-Configuration mode*** or ***MST-Configuration mode***), the **`exit`** command also applies all pending changes made in that mode.

Command Mode

All modes

Command Syntax

`exit`

Examples

- This command exits Global Configuration mode to ***Privileged EXEC*** mode.

```
switch(config)# exit
switch#
```

- This command terminates the user session.

```
switch# exit
```

1.1.9.19 ip ftp client source-interface

By default, the FTP (File Transfer Protocol) source IP address is selected by the switch (the IP address of the source interface if one is assigned). The **`ip ftp client source-interface`** command allows the user to override the default FTP source address.

The **`ip ftp client source-interface`** and **`ip ftp source-interface`** commands have equivalent functionally. In each case, **`ip ftp client source-interface`** is stored in ***running-config***.

The **`no ip ftp client source-interface`** and **`default ip ftp client source-interface`** commands restore default behavior by removing the **`ip ftp client source-interface`** statement from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ip ftp` [*client*] **source-interface** *interface* [**vrf** *vrf_name*]

`no ip ftp` [*client*] *source-interface*

`default ip ftp` [*client*] *source-interface*

Parameters

- ***client*** Parameter has no functional effect.
- **INTERFACE** - Specify the interface providing the IP address. Options include:
  - **`ethernet`** ***e_num*** - Ethernet interface specified by ***e_num***.
  - **`loopback`** ***l_num*** - Loopback interface specified by ***l_num***.
  - **`management`** ***m_num*** - Management interface specified by ***m_num***.
  - **`port-channel`** ***p_num*** - Port-channel interface specified by ***p_num***.
  - **`tunnel`** ***t_num*** - Tunnel interface specified by ***t_num***.
  - **`vlan`** ***v_num*** - VLAN interface specified by ***v_num***.
  - **`vrf`** ***vrf_name*** - Uses the specified user-defined VRF.

Examples

- These commands configure the ***10.10.121.15*** as the source IP address the switch uses when communicating with FTP servers.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# ip address 10.10.121.15/24
switch(config-if-Et17)# ip ftp client source-interface ethernet 17
switch(config)#
```

- This command configures the switch to use ***interface tunnel 45*** and ***vrf vrf01*** when communicating with FTP servers.

```
switch(config)#ip ftp client source-interface tunnel 45 vrf vrf01
switch(config)#
```

1.1.9.20 ip http client local-interface

The **`ip http client local-interface`** command specifies the source IP address for hypertext transfer protocol (HTTP) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The **`no ip http client local-interface`** and **`default ip http client local-interface`** commands restore default behavior by removing the **`ip http client local-interface`** statement from ***running-config*** .

Command Mode

Global Configuration

Command Syntax

`ip http client local-interface` *interface* [`vrf` *vrf_name*]

`no ip http client local-interface`

`default ip http client local-interface`

Parameters

- ***interface*** - Specify the interface providing the IP address. Options include:
  - **`ethernet`** ***e_num*** - Ethernet interface specified by ***e_num***.
  - **`loopback`** ***l_num*** - Loopback interface specified by ***l_num***.
  - **`management`** ***m_num*** - Management interface specified by ***m_num***.
  - **`port-channel`** ***p_num*** - Port-channel interface specified by ***p_num***.
  - **`vlan`** ***v_num*** - VLAN interface specified by ***v_num***.
- **`vrf`** ***vrf_name*** - Uses the specified user-defined VRF.

Examples

- These commands configure the ***10.15.17.9*** as the source IP address the switch uses when communicating with HTTP servers.

```
switch(config)# interface vlan 10
switch(config-if-Vl10)# ip address 10.15.17.9/24
switch(config-if-Vl10)# ip http client local-interface vlan 10
switch(config)#
```

- This command configures the switch to use ***interface tunnel 45*** and ***vrf vrf01*** when communicating with HTTP servers.

```
switch(config)# ip http client local-interface tunnel 45 vrf vrf01
switch(config)#
```

1.1.9.21 ip ssh client source-interface

The **`ip ssh client source-interface`** command specifies the source IP address for secure shell (SSH) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The **`ip ssh client source-interface`** and **`ip ssh source-interface`** commands are functionally equivalent. In each case, **ip ssh client source-interface** is stored in ***running-config***.

The **`no ip ssh client source-interface`** and **`default ip ssh client source-interface`** commands restore default behavior by removing the **ip ssh client source-interface** statement from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ip ssh` **[client]** **`source-interface`** ***interface*** **[`vrf`** ***vrf_name*****]**

`no ip ssh` **[client]** **`source-interface`**

`default ip ssh` **[client]** **`source-interface`**

Parameters

- **`client`** - The parameter has no functional effect.
- ***interface*** - The interface providing the IP address. Options include:
  - **ethernet *e_num*** - The Ethernet interface specified by ***e_num***.
  - **loopback *l_num*** - The Loopback interface specified by ***l_num***.
  - **management *m_num*** - The Management interface specified by ***m_num***.
  - **port-channel *p_num*** - The Port-channel interface specified by ***p_num***.
  - **vlan *v_num*** - The VLAN interface specified by ***v_num***.
- **`vrf`** ***vrf_name*** Uses the specified user-defined VRF.

Examples

- These commands configure the ***10.17.17.9*** as the source IP address the switch uses when communicating with SSH servers.

```
switch(config)# interface vlan 10
switch(config-if-Vl10)# ip address 10.17.17.9/24
```

```
switch(config-if-Vl10)# ip ssh client source-interface vlan 10
switch(config)#
```

- This command configures the switch to use ***interface tunnel 45*** and ***vrf vrf01*** when communicating with SSH servers.

```
switch(config)#ip ssh client source-interface tunnel 45 vrf vrf01
switch(config)#
```

1.1.9.22 ip tftp client source-interface

The **ip tftp client source-interface** command specifies the source IP address for Trivial File Transfer Protocol (TFTP) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The **ip tftp client source-interface** and **ip tftp source-interface** commands are functionally equivalent. In each case, **ip tftp client source-interface** is stored in ***running-config***.

The **no ip tftp client source-interface** and **default ip tftp client source-interface** commands restore default behavior by removing the **ip tftp client source-interface** statement from ***running-config***.

Command Mode

Global Configuration

Command Syntax

ip tftp **[client]** **source-interface** ***interface*** **[vrf** ***vrf_name***]

no ip tftp **[client]** **source-interface**

default ip tftp **[client]** **source-interface**

Parameters

- **client** - The parameter has no functional effect.
- ***interface*** - The interface providing the IP address. Options include:
  - **ethernet** ***e_num*** - The Ethernet interface specified by ***e_num***.
  - **loopback** ***l_num*** - The Loopback interface specified by ***l_num***.
  - **management** ***m_num*** - The Management interface specified by ***m_num***.
  - **port-channel** ***p_num*** - The Port-channel interface specified by ***p_num***.
  - **vlan** ***v_num*** - The VLAN interface specified by ***v_num***.
- **vrf** ***vrf_name*** Uses the specified user-defined VRF.

Examples

- These commands configure the ***10.15.17.9*** as the source IP address the switch uses when communicating with TFTP servers.

```
switch(config)# interface vlan 10
```

```
switch(config-if-Vl10)# ip address 10.15.17.9/24
switch(config-if-Vl10)# ip tftp client source-interface vlan 10
switch(config)#
```

- This command configures the switch to use ***interface tunnel 45*** and ***vrf vrf01*** when communicating with TFTP servers.

```
switch(config)# ip tftp client source-interface tunnel 45 vrf vrf01
switch(config)#
```

1.1.9.23 platform arad lag mode

The **`platform arad lag mode`** command allows configuration of LAGs with more than 16 members.

Command Mode

Global Configuration

Command Syntax

`platform arad lag mode` [**1024x16** | **256x64** | **512x32**]

Examples

- This command configures 1024 LAGs with 16 members each.

```
switch(config)# platform arad lag mode 1024x16
! Change will take effect only after switch reboot.
switch(config)#
```

- This command configures 256 LAGs with 64 members each.

```
switch(config)# platform arad lag mode 256x64
! Change will take effect only after switch reboot.
switch(config)#
```

- This command configures 512 LAGs with 32 members each.

```
switch(config)# platform arad lag mode 512x32
! Change will take effect only after switch reboot.
switch(config)#
```

1.1.9.24 platform sand fabric mode (7500 and 7500E Series)

The **`platform sand fabric mode`** command specifies the fabric mode for the switch to operate after the next system reload. The command has no operational effect until the switch reloads.

The fabric mode determines the modular switch fabric performance capabilities and must be compatibile with the installed fabric modules. Fabric mode settings include the following:

- **fe600**: Supports first-generation fabric modules.
- **fe1600**: Supports E-Series fabric modules.

Note: Switches that reload in **petraA** forwarding compatibility mode (platform sand forwarding mode (7500 and 7500E Series)) also reload in fe600 fabric mode regardless of the presence of a **`platform sand fabric mode`** statement in ***running-config***.

The switch's fabric mode setting must match the capabilities of its installed fabric modules. Reloading the switch in a different mode may be required after exchanging fabric modules for a different module type. The show module command displays the fabric modules in the switch.

Each fabric module is categorized as first-generation or E-Series:

- First-generation fabric modules support all basic switch functions.
- E-Series fabric modules support faster fabric link speeds, greater internal table capacities, and advanced encoding formatting.

E-series fabric modules can operate in **fe600** mode, but are limited to first-generation fabric performance. First-generation modules cannot operate in **fe600** mode. Switches containing both types of modules must be set to **fe600** mode. Best practice is to avoid switch configurations with mixed fabric modules.

When a switch reloads, EOS determines the fabric mode by the following (in order of precedence):

1. Switches reloading in **petraA** forwarding compability mode also reload in **fe600** fabric mode .
2. As specified by the **platform sand fabric mode** statement in ***running-config***.
3. The first fabric module that becomes operational as the switch reloads.

In switches with a homogeneous module set, the fabric mode matches its fabric modules. Switches with a mixed set of modules are typically reloaded in **fe600** mode because first generation modules are usually operational before E-Series modules. However, the fabric mode in mixed module switches that are reloading cannot be guaranteed in the absence of the first two conditions.

The **`no platform sand fabric mode`** and **`default platform sand fabric mode`** commands remove the **`platform sand fabric mode`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`platform sand fabric mode` [*mode_setting*]

`no platform sand fabric mode`

`default platform sand fabric mode`

Parameters

- ***mode_setting*** - Specifies the switch fabric mode. Options include the following:
  - **fe16000 -** E-Series fabric mode.
  - **fe600 -** First-generation fabric mode.

Example

This command configures the switch to reload in **fe1600** fabric mode to support E-series fabric modules. After issuing this command, the switch should be reset only after exchanging all switch fabric modules to E-series modules.

```
switch(config)# platform sand fabric mode fe1600
switch(config)# exit
switch# show platform sand compatibility
                    Configuration        Status
Forwarding mode     None                 Arad
Fabric mode         Fe1600               Fe600 switch#
```

1.1.9.25 platform sand forwarding mode (7500 and 7500E Series)

The **`platform sand forwarding mode`** command specifies the forwarding compatibility mode under which the switch operates after the next system reload. The command has no operational effect until the switch reloads.

Forwarding compatibility mode specifies switch forwarding capabilities and configures performance capacity of installed linecards. Forwarding compatibility modes settings include:

- **petraA**: Supports first-generation fabric modules.
- **arad**: Supports E-Series fabric modules.

Note: Switches that reload in **petraA** forwarding compatibility mode also reload in **fe600** fabric mode regardless of the presence of a platform sand fabric mode (7500 and 7500E Series) statement in ***running-config***.

This command may be required after exchanging a linecard for a different module type or in switches containing first-generation and E-series linecards. The show module command displays the linecard modules in the switch.

Each modular switch linecard module is categorized as first-generation or E-Series:

- First-generation linecards support all basic switch functions.
- E-Series linecards support provide faster data processing, greater internal table capacities, and advanced encoding formatting.

The forwarding compatibility mode determines the operational capacity of installed linecards. The following table lists the affect of the forwarding compatibility mode on all linecard module types.

Table 5: Linecard Module and Forwarding Mode Performance

Linecard Module Type	Forwarding Software Mode	Linecard Operating Capacity
First-generation	petraA	Linecard performs at first-generation performance capacity.
First-generation	arad	Linecard is powered-down.
E-Series	petraA	Linecard performs at first-generation performance capacity.
E-Series	arad	Linecard performs at E-series performance capacity.

Note: Linecards operate at E-Series performance capacities only on switches that contain E-Series fabric modules and have a fabric mode setting of **fe1600** fabric mode (platform sand fabric mode (7500 and 7500E Series)).

Without a platform sand fabric mode (7500 and 7500E Series) command, forward compatibility mode is determined by the first linecard that becomes operational after reloading the switch. In a switch that is reloaded with a homogeneous module set, forwarding compatibility mode matches its linecards. Switches with a mixed set of modules are typically reloaded in **petraA** mode because first generation modules are usually operational before E-Series modules. However, forwarding compatibility mode in mixed module switches that are reloading is not guaranteed without a **`platform sand forwarding mode`** command.

The **`no platform sand forwarding mode`** and **`default platform sand forwarding mode`** commands restore the **platform sand forwarding mode** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
platform sand forwarding mode  [mode_setting]

no platform sand forwarding mode

default platform sand forwarding mode
```

Parameters

- **MODE_SETTING** - Specifies the switch's software forwarding mode. Options include:
  - **`arad`** - The switch supports E-Series linecard capabilities.
  - **`petraA`** - The switch supports first-generation linecard capabilities.

Example

This command changes the forwarding software mode to support E-series linecard modules. This command should be run only after exchanging all linecards to E-series modules.

```
switch(config)# platform sand forwarding mode arad
switch(config)#
```

1.1.9.26 platform sand lag hardware-only

The **platform sand lag hardware-only** command specifies that all LAGs use hardware resources including single member LAGs. Hardware resource allocation and deallocation traffic disruption occurs on the first member addition or deletion, rather than the second member addition or deletion.

The **no platform sand lag hardware-only** and **default platform sand lag hardware-only** commands specify that LAGs are not required to be implemented in hardware, and therefore some LAGs may be implemented in software. Permitting both hardware and software LAGs may increase the total number of port-channels because EOS has no resource limit on the number of software LAGs.

Command Mode

Global Configuration

Command Syntax

platform sand lag hardware-only

no platform sand lag hardware-only

default platform sand lag hardware-only

Examples

- This command configures all LAGs to use hardware resources. All existing one member LAGs will be allocated hardware resources, when available.

```
switch(config)# platform sand lag hardware-only
switch(config)#
```

- This command allows certain LAGs (single member LAGs) to not consume hardware resources. All existing one member LAGs will release their hardware resources.

```
switch(config)# no platform sand lag hardware-only
switch(config)#
```

1.1.9.27 platform sand lag mode

The **platform sand lag mode** configures two Link Aggregation Groups (LAG) partitions, Partition A and Partition B, to support twice as many available Port Channels. Use this command if the current LAG mode does not allow creating a large number of Port Channels on a single partition. Disable the usage of Partion B using the **platform sand lag mode 1024x16** command.

Note: Changing the configuration of the LAG mode requires the switch to restart and apply the configuration.

Command Mode

Global Configuration

Command Syntax

platform sand lag mode [2048x8 | 1024x16 | 512x32 | 256x64 | 128x128 | 64x256]

Parameters

- **2048x8** - Specify 2048 LAGs with 8 members each.
- **1024x16** - Specify 1024 LAGs with 16 members each.
- **512x32** - Specify 512 LAGs with 32 members each.
- **256x64** - Specify 256 LAGs with 64 members each.
- **128x128** - Specify 128 LAGs with 128 members each.
- **64x256** - Specify 64 LAGs with 256 members each.

Example

To configure a switch with 512 LAGS and 32 members each, use the following command:

```
switch(config)# platform sand lag mode 512x32
```

Use the **show platform sand lag mode** to display the LAG mode for Partition A and B:

```
switch(config)# show platform sand lag mode
Partition     Configuration        Status
A             1024x16              1024x16
B             1024x16              1024x16
```

1.1.9.28 pwd

The **pwd** command displays the working directory.

Command Mode

Privileged EXEC

Command Syntax

pwd

Example

This command shows that the working is Flash.

```
switch# pwd
flash:/
switch#
```

1.1.9.29 schedule config

The schedule config command sets configuration parameters to the CLI scheduler.

The **no schedule config max-concurrent-jobs** and **default schedule config max-concurrent-jobs** commands reset the limit of maximum concurrent jobs to the default value of 1 by removing the corresponding schedule config max-concurrent-jobs statement from running-config.

The **no schedule config prepend-hostname-logfile** and **default schedule config prepend-hostname-logfile** commands reset the log filenames to the default state.

Command Mode

Global Configuration

Command Syntax

`schedule config`{*max-concurrent-jobs limit* | *prepend-hostname-logfile*}

`no schedule config` {*max-concurrent-jobs limit* | *prepend-hostname-logfile*}

`default schedule config` {*max-concurrent-jobs limit* | `prepend-hostname-logfile`}

Parameters

- **max-concurrent-jobs *limit*** - Specifies the maximum number of concurrent commands that can run on the switch. The maximum concurrent jobs ranges from ***1*** to ***4***. The default value is ***1***.
- ***prepend-hostname-logfile*** - Enables prepending hostnames to log filenames. By default, this option is enabled.

Examples

- This command configures to concurrently run a maximum of three commands on the switch.

```
switch(config)# schedule config max-concurrent-jobs 3
switch(config)# show schedule summary
Maximum concurrent jobs  3
Prepend host name to logfile: No
Name            At time      Last    Interval   Timeout   Max     Logfile Location
Status
                             time     (mins)    (mins)    log
                                                         files
------------- ------------- ------- ---------- -------- -------- ------------------------------ ------
tech-support      now        00:29      60        30      100     flash:schedule/tech-support/   Success
thelp           12:02:00     00:02      60        40      100     flash:schedule/thelp/
Fail
                06/05/2018
switch(config)#
```

- This command enables prepending the hostname to log filenames.

```
switch(config)# schedule config prepend-hostname-logfile
switch(config)# show schedule summary
```

```
Maximum concurrent jobs  3
Prepend host name to logfile: Yes
Name            At time      Last    Interval   Timeout   Max     Logfile Location
Status
                             time     (mins)    (mins)    log
                                                         files
------------- ------------- ------- ---------- --------- -------- ------------------------------- ------
tech-support      now        00:29      60         30      100     flash:schedule/tech-support/   Success
thelp           12:02:00     00:02      60         40      100     flash:schedule/thelp/
Fail
                06/05/2018
switch(config)#
```

1.1.9.30 schedule

The schedule command facilitates the periodic execution of a specified CLI command. Command parameters configure the start time of periodic execution, the interval between consecutive execution instances, the maximum time allotted for command execution, and the maximum number of log files that can be created.

The **`no schedule`** and **`default schedule`** commands disable execution of the specified command.

Command Mode

Global Configuration

Command Syntax

`schedule` *schedule_name* **PERIOD** {max-log-files *count* | timeout *timeout_interval*}{command *cmd* | logging verbose | loglocation *flash:*}

`no schedule` *schedule_name*

`default schedule` *schedule_name*

Parameters

- ***schedule_name*** Label associated with the scheduled command.
- **PERIOD** Start time for execution and interval between consecutive execution instances. The interval ranges from ***2*** to ***1440*** minutes. The default interval while scheduling the **`show tech-support`** command is ***60*** minutes. Options include:
  - **at** Start time for execution. Options include:
    - ***hh:mm:ss*** **interval** ***interval*** The command execution starts at the specified time and repeats at the specified interval.
    - ***hh:mm:ss mm/dd/yyyy*** **interval** ***interval*** The command execution starts at the specified time on the specified day and repeats at the specified interval.
    - ***hh:mm:ss*** **once** The command execution starts at the specified time and does not repeat.
    - ***hh:mm:ss mm/dd/yyyy*** **once** The command execution starts at the specified time on the specified day and does not repeat.
    - ***hh:mm:ss yyyy-mm-dd*** **interval** ***interval*** The command execution starts at the specified time on the specified day and repeats at the specified interval.
    - ***hh:mm:ss yyyy-mm-dd*** **once** The command execution starts at the specified time on the specified day and does not repeat.
  - **interval** ***interval*** The command execution starts immediately and repeats at the specified interval.
  - **now interval** ***hh:mm:ss*****interval** ***interval******hh:mm:ss mm/dd/yyyy*****interval** ***interval*****once*****hh:mm:ss******hh:mm:ss mm/dd/yyyy*****once*****hh:mm:ss yyyy-mm-dd*****interval** ***interval*****once*****hh:mm:ss yyyy-mm-dd*****interval** ***interval*****now interval** ***interval*** The command execution starts immediately and repeats at the specified interval.

- **max-log-files** ***count*** Maximum number of log files command generates for command output. The count of maximum log files ranges from ***1*** to ***10000***. The default count of maximum log files while scheduling the **`show tech-support`** command is ***100***.
- **timeout** ***timeout_interval*** Maximum time allotted for the script execution. The timeout interval ranges from ***1*** to ***480*** minutes. The default timeout is ***30*** minutes.

  Note: The command execution is terminated if it exceeds the specified timeout interval. The timeout allotted for the scheduled command must not be greater than the corresponding interval.

- **command** ***cmd*** The command that needs to be executed.
- **logging verbose** Sets the logging level to “verbose.” A syslog entry is added after the execution of the scheduled command, regardless of whether the scheduled command has succeeded or failed. In the absence of **logging verbose**, the syslog entry is added only if the execution of the scheduled command fails with an error.
- **loglocation** ***destination*** The flash destination for scheduled command output files.

Guidelines

Log files created by the command are stored in the **flash:/schedule/** ***scheduled_name*** **/** directory. Empty log files are created for commands that do not generate any output.

Examples

- This command saves the running configuration contents to the log file every hour with immediate effect and creates a maximum of 24 log files.

```
switch(config)# schedule backup-test interval 60 max-log-files 24 command show running-config
```

- This command starts the script execution at 12:00:00 and repeats every 720 minutes. The script execution is terminated if it exceeds 20 minutes. It generates a maximum of one log file because the specified bash command does not have an output.

```
switch(config)# schedule ms1 at 12:00:00 interval 720 timeout 20 max-log-files 1 command bash /
mnt/flash/myscript.sh
```

- The show schedule command lists the commands currently scheduled for periodic execution and displays the summary of the specified scheduled command.

```
switch# show schedule summary
Maximum concurrent jobs  1
Prepend host name to logfile: Yes

Name At time Last  Interval Timeout  Max    Logfile Location    Status
             time  (mins)   (mins)   log
                                     files
---- ------- ----- -------- -------- ------ -------------------  -------
ms1   now    23:03   720       20      1    flash:/schedule/ms1 Success switch#
```

1.1.9.31 show (various configuration modes)

The **show** command, when executed within a configuration mode, can display data in ***running-config*** for the active configuration mode.

Command Mode

All configuration modes except Global Configuration

Command Syntax

`show` [**data_type**]

Parameters

- **data_type** - Specifies display contents. Values include:
  - **active** - Displays ***running-config*** settings for the configuration mode.
  - **active all** - Displays ***running-config*** plus defaults for the configuration mode.
  - **active all detail** - Displays ***running-config*** plus defaults for the configuration mode.
  - **comment** - Displays comment entered for the configuration mode.

Related Commands

The **show** commands in ACL Configuration Mode and MST Configuration Mode include the **active** and **comment** options along with additional mode-specific options.

Example

This command shows the server-group-TACACS+ configuration commands in ***running-config***.

```
switch(config-sg-tacacs+-TAC-GR)# show active
   server TAC-1
   server 10.1.4.14
switch(config-sg-tacacs+-TAC-GR)#
```

1.1.9.32 show event-handler DropCountersHandler

The show event-handler command displays details of the DropCountersHandler event handler.

Command Mode

Privileged EXEC

Command Syntax

show event-handler DropCountersHandler

Example

This command displays details of this event handler.

```
switch(config)# show event-handler DropCountersHandler
Event-handler DropCountersHandler (BUILT-IN)
Trigger: on-counters delay 0 seconds
  Polling Interval: 60 seconds
  Condition: bashCmd."DropCounterMonitor.py" > 0
Threshold Time Window: 0 Seconds, Event Count: 1 times
Action: DropCounterLog.py -l
Action expected to finish in less than 20 seconds
Total Polls: 39
Last Trigger Detection Time: 38 minutes 22 seconds ago
Total Trigger Detections: 1
Last Trigger Activation Time: 38 minutes 22 seconds ago
Total Trigger Activations: 1
Last Action Time: Never
Total Actions: 1

switch(config)#
```

1.1.9.33 show event-handler

The show event-handler command displays the contents and activation history of a specified event handler or all event handlers.

Command Mode

Privileged EXEC

Command Syntax

`show event-handler` **[*handler_name*]**

Parameters

handler_name - The optional name of an event handler to display. If no parameter specified, the command displays information for all event handlers configured on the system.

Example

This command displays information about an event handler called ***eth_5***.

```
switch# show event-handler Eth_5
Event-handler Eth_5
Trigger: on-intf Ethernet5 on ip delay 20 seconds
Threshold Time Window: 0 Seconds, Event Count: 1 times
Action: :
Device-health Action: None
Action expected to finish in less than 10 seconds
Last Trigger Detection Time: 15 days 2 hours 19 minutes ago
Total Trigger Detections: 1
Last Trigger Activation Time: 15 days 2 hours 19 minutes ago
Total Trigger Activations: 1
Last Action Time: 15 days 2 hours 19 minutes ago
Total Actions: 1 switch#
```

1.1.9.34 show module

The **show module** command displays information that identifies the supervisor, fabric, and linecard modules in a modular switch, including model number, serial number, hardware version number, software version (supervisors only), MAC address (supervisors and linecards), and operational status.

Command Mode

EXEC

Command Syntax

`show module` [*module_name*]

Parameters

- ***module_name*** - Specifies modules for which data is displayed. Options include:
  - ***no parameter*** - All modules (identical to **all** option).
  - **fabric *fab_num*** - Specified fabric module. Number range varies with switch model.
  - **linecard *line_num*** - Linecard module. Number range varies with switch model.
  - **supervisor *super_num*** - Supervisor module. Number range varies with switch model.
  - ***mod_num*** - Supervisor (1 to 2) or linecard (3 to 18) module.
  - **all** - All modules.

Related Command

show version displays model and serial numbers of modular system components.

Examples

- This command displays information about all installed modules on a DCS-7504 switch.

```
switch# show module
Module    Ports Card Type                            Model           Serial No.
--------- ----- ------------------------------------ --------------- -----------

Fabric4                                          00.00           Ok switch#
```

1.1.9.35 show platform sand compatibility

The **show sand platform compatibility** command displays the fabric and forwarding modes. These modes determine switch forwarding capabilities and programs performance capacity of installed linecards

Information that identifies the supervisor, fabric, and linecard modules in the modular switch, including model number, serial number, hardware version number, software version (supervisors only), MAC address (supervisors and linecards), and operational status.

Command Mode

Privileged EXEC

Command Syntax

show platform sand compatibility

Related Commands

- platform sand fabric mode (7500 and 7500E Series) specifies the fabric software mode.
- platform sand forwarding mode (7500 and 7500E Series) specifies the forwarding software mode.

Example

This command indicates that the switch is in Fe600 fabric mode and PetraA forwarding mode.

```
switch# show platform sand compatibility
                     Configuration        Status
Forwarding mode      None                 PetraA
Fabric mode          None                 Fe600 switch#
```

1.1.9.36 show platform sand lag hardware-only

The **show platform sand lag hardware-only** command displays whether or not LAGs are hardware-only.

Command Mode

Privileged EXEC

Command Syntax

show platform sand lag hardware-only

Examples

- This command indicates that LAGs are hardware-only.

```
switch(config)# platform sand lag hardware-only
switch(config)# exit
switch# show platform sand lag hardware-only
Hardware resources are used for all LAGs: True switch#
```

- This command indicates that LAGs are not hardware-only.

```
switch(config)# no platform sand lag hardware-only
switch(config)# exit
switch# show platform sand lag hardware-only
Hardware resources are used for all LAGs: False switch#
```

1.1.9.37 show schedule

The **show schedule** command displays logging output on the terminal during the current terminal session. This command affects only the local monitor. The no terminal monitor command disables direct monitor display of logging output for the current terminal session.

The **show schedule** command displays the list of active scheduled commands and the summary of specified scheduled command.

Command Mode

Global Configuration

Command Syntax

show schedule {***schedule_name*** | **summary**}

Parameters

- ***schedule_name*** - Displays the summary of the specified scheduled command.
- **summary** - Displays the list of active scheduled commands.

Examples

- This command displays the summary of the ***thelp*** schedule.

```
switch(config)# show schedule thelp
The last CLI command failed with exit status 1
CLI command "show THelp" is scheduled next at "02:02:35 06/19/2018", interval is
60 minutes
Timeout is 40 minutes
Maximum of 100 log files will be stored
Verbose logging is off
100 log files currently stored in flash:/schedule/thelp

Start time                Size          Filename
------------------------ ---------------- ----------------------------------
Jun 19 2018 01:02       60.0 bytes       ro301_thelp_2018-06-19.0102.log.gz
Jun 19 2018 00:02       60.0 bytes       ro301_thelp_2018-06-19.0002.log.gz
Jun 18 2018 23:02       60.0 bytes       ro301_thelp_2018-06-18.2302.log.gz
Jun 18 2018 22:02       60.0 bytes       ro301_thelp_2018-06-18.2202.log.gz
Jun 18 2018 21:02       60.0 bytes       ro301_thelp_2018-06-18.2102.log.gz

switch(config)#
```

- This command displays the summary of scheduled commands.

```
switch(config)# show schedule summary
Maximum concurrent jobs  1
Prepend host name to logfile: Yes
Name            At time      Last    Interval   Timeout   Max     Logfile Location
Status
                             time     (mins)    (mins)    log
                                                         files
------------- ------------- ------- ---------- -------- -------- ------------------------------- ------
```

```
tech-support       now         00:29      60         30       100      flash:schedule/tech-support/   Success
thelp            12:02:00      00:02      60         40       100      flash:schedule/thelp/
Fail
                 06/05/2018
switch(config)#
```

1.1.9.38 show version

The **`show version`** command displays information that identifies the switch, including its model number, serial number, and system MAC address. The command also provides hardware and software manufacturing information, along with the available memory and elapsed time from the most recent reload procedure.

Command Mode

EXEC

Command Syntax

`show version` [*info_levelL*]

Parameters

info_level - Specifies information the command displays. Options include:

- ***no parameter*** - Lsts model and serial numbers, manufacturing data, uptime, and memory.
- **detail** - Data listed ***no parameter*** option plus version numbers of internal components.

Related Command

show module displays model and serial numbers of modular system components.

Example

This command displays the switch model number, serial number, hardware and software manufacturing information, uptime, and memory capacity.

```
switch> show version
Arista DCS-7150S-64-CL-F
Hardware version:    01.01
Serial number:       JPE13120819
System MAC address:  001c.7326.fd0c

Software image version: 4.13.2F
Architecture:           i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                 1 hour and 36 minutes
Total memory:           4017088 kB
Free memory:            1473280 kB switch>
```

1.1.9.39 terminal length

The terminal length command overrides automatic pagination and sets pagination length for all show commands on a terminal. If the output of a show command is longer than the configured terminal length, the output pauses after each screen of output, prompting the user to continue.

To disable pagination for an SSH session, set terminal length to 0. By default, all console sessions have pagination disabled.

The **no** terminal length and **default terminal length** commands restore automatic pagination by removing the terminal length command from ***running-config***.

The pagination setting is persistent if configured from Global Configuration mode. If configured from EXEC mode, the setting applies only to the current CLI session. Pagination settings may also be overridden when you adjust the size of the SSH terminal window, but can be reconfigured by running the terminal length command again.

Command Mode

EXEC

Command Syntax

```
terminal length lines

no terminal length

default terminal length
```

Parameters

lines - The number of lines to be displayed at a time. Values range from ***0*** through ***32767***. A value of ***0*** disables pagination.

Examples

- This command sets the pagination length for the current terminal session to 10 lines.

```
switch# terminal length 10
Pagination set to 10 lines.
```

- This command configures the switch to paginate terminal output automatically based on screen size for the current terminal session.

```
switch# no terminal length
```

- These commands disable pagination globally.

```
switch# configure
switch(config)# terminal length 0
Pagination disabled.
```

1.1.9.40 terminal monitor

The terminal monitor command enables the display of logging output on the terminal during the current terminal session. This command affects only the local monitor. The no terminal monitor command disables direct monitor display of logging output for the current terminal session.

Command Mode

Privileged EXEC

Command Syntax

terminal monitor

no terminal monitor

default terminal monitor

Example

This command enables the display of logging to the local monitor during the current terminal session.

```
switch# terminal monitor
switch#
```

1.1.9.41 trigger

The **`trigger`** command specifies what event will trigger the event handler. Handlers can be triggered either by the system booting or by a change in a specified interface's IP address or operational status.

To specify the action to be taken when the handler is triggered, use the action bash command.

Command Mode

Event-Handler Configuration

Command Syntax

`trigger` **EVENT**

Parameters

- ***event*** - The event that triggers the configuration mode event handler. Values include:
  - **`onboot`** - Triggers when the system reboots, or when you exit event-handler configuration mode. This option takes no further arguments, and passes no environment variables to the action triggered.
    - `on-intf` **INTERFACE CHANGE** - Triggers when a change is made to the specified interface.
    - `on-startup-config` - Triggers when a change is made to the ***startup-config*** file.
    - `vm-tracer vm` triggers when a virtual machine monitored by VM Tracer changes state.
- ***interface*** the triggering interface. Values include:
  - **`ethernet`** ***number*** Ethernet interface specified by ***number***.
  - **`loopback`** ***number*** loopback interface specified by ***number***.
  - **`management`** ***number*** management interface specified by ***number***.
  - **`port-channel`** ***number*** channel group interface specified by ***number***.
  - **`vlan`** ***numver*** VLAN interface specified by ***number***.
- ***change*** the change being watched for in the triggering interface. Values include:
  - **`ip`** triggers when the IPv4 address of the specified interface is changed.
  - **`ip6`** triggers when the IPv6 address of the specified interface is changed.
  - **`operstatus`** triggers when the operational status of the specified interface changes.

Examples

- This command configures the event handler ***Eth5*** to be triggered when there is a change in the operational status or IP address of ***Ethernet interface 5***.

```
switch(config-handler-Eth5)# trigger on-intf Ethernet 5 operstatus ip
switch(config-handler-Eth5)#
```

- This command configures the event handler “onStartup” to be triggered when the system boots, or on exiting ***event-handler configuration mode***.

```
switch(config-handler-onStartup)# trigger onboot
switch(config-handler-onStartup)#
```

Chapter 2

Booting the Switch

This chapter describes the switch boot process, describes configuration options, and lists the components it requires, including the boot loader, the boot loader shell, and other configuration files.

This chapter includes the following sections:

- Boot Loader Aboot
- Configuration Files
- Supervisor Redundancy
- System Reset
- Aboot Shell
- Aboot Configuration Commands
- Switch Booting Commands

2.1 Boot Loader Aboot

Aboot is the boot loader for Arista switches. In addition to booting the switch EOS, Aboot provides a shell for changing boot parameters, restoring default switch settings, diagnosing hardware problems, and managing switch files. Aboot Shell describes the Aboot shell.

The boot process loads an EOS image file, initiates switch processes, performs self-tests, restores interface settings, and configures other network parameters. The replacement image file can be in the switch's flash or on a device in the flash drive port. Configuration files stored in flash memory specify boot parameters.

Aboot supports most available USB flash drive models. The flash drive must be formatted using the FAT or VFAT file system. Windows NT File System (NTFS) is not supported.

Aboot initiates a system reboot upon a **`reload`** command or by restoring power to the switch. Before loading the EOS image file, Aboot provides an option to enter the Aboot shell. The user can either enter the shell to modify boot parameters or allow the switch to boot.

You can monitor the boot process through a terminal connected to the console port. Configuration file settings configure the console port to interact with the terminal.

2.2 Configuration Files

Three files define the switch boot behaviour and configuration state:

- **boot-config** - specifies the location and name of the EOS image to be loaded at boot time.
- **startup-config** - contains the configuration that is loaded when the switch boots.
- **running-config** - contains the current, active configuration of the switch.

Note: If you modify the configuration but do not save it, the **running-config** and **startup-config** become out of sync. These unsaved changes are present only in the running configuration and lost upon reboot unless saved to the startup configuration.

2.2.1 boot-config

The ***boot-config*** file is an ASCII file that Aboot uses to configure console communication settings, locate the EOS flash image, and specify initial network configuration settings.

Aboot boots the EOS flash software image (extension .swi) referenced by ***boot-config*** if the user does not interrupt the boot process. See Aboot Shell, which describes how Aboot uses ***boot-config***.

You can view and edit the ***boot-config*** file contents. Viewing and editing options include:

- View ***boot-config*** file contents with the **`more boot-config`** command:

```
switch(config)# more boot-config
SWI=flash:/EOS.swi
CONSOLESPEED=2400
Aboot password (encrypted): $1$A8dZ3GLZ$knKrBpTyg5dhmtGdCdwNM.
switch(config)#
```

- View ***boot-config*** settings with the **`show boot-config`** command:

```
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: 2400
Aboot password (encrypted): $1$A8dZ3GLZ$knKrBpTyg5dhmtGdCdwNM.
Memory test iterations: (not set)
switch(config)#
```

- Modify file settings from the command line with EOS `boot` commands.

  See Programming boot-config from the Programming boot-config from the CLI for a list of **`boot`** commands.

- Edit the file directly by using vi from the Bash shell.

See boot-config Command Line Content for a list of ***boot-config*** parameters.

2.2.1.1 boot-config File Structure

Each line in the ***boot-config*** file specifies a configuration setting and has this format:

NAME=VALUE

- NAME is the parameter label.
- VALUE indicates the parameter's bootup setting.

The NAME and VALUE fields cannot contain spaces.

Aboot ignores blank lines and lines that begin with a # character.

2.2.1.2 boot-config Command Line Content

Aboot configuration commands that ***boot-config*** files can contain include:

- SWI specifies the location and file name of the EOS image file that Aboot loads when booting, using the same format as the boot command to designate a local or network path.

  Example

```
SWI=flash:EOS.swi             <---flash drive location
SWI=usb1:/EOS1.swi            <---USB drive location
SWI=file:/tmp/EOSexp.swi      <---switch directory location
SWI=/mnt/flash/EOS.swi
SWI=http://foo.com/images/EOS.swi
SWI=ftp://foo.com/images/EOS.swi
SWI=tftp://foo.com/EOS.swi
SWI=nfs://foo.com/images/EOS.swi
```

- CONSOLESPEED specifies the console baud rate. The connected terminal must match the specified rate to communicate with the switch. Baud rates options include ***1200***, ***2400***, ***4800***, ***9600***, ***19200***, ***38400***, ***57600***, and ***115200***. The default baud rate is ***9600***.

  Example

```
CONSOLESPEED=19200
```

- PASSWORD (ABOOT) specifies the Aboot password, as described in Accessing the Aboot Shell. The Aboot shell does not require a password when ***boot-config*** does not contain a **PASSWORD** command.

  Example

```
PASSWORD=$1$CdWp5wfe$pzNtE3ujBoFEL8vjcq7jo/
```

- Aboot uses NET commands during switch booting to configure the network interface for the switch. You can enter this manually in Aboot.

NETDEV indicates the configured network interface. If ***boot-config*** does not contain a **NETDEV** command, the booting process does not attempt to configure a network interface. Other **NET** commands specify settings that Aboot uses to configure the interface.

Examples

- This **NETDEV** command specifies ***management port 1*** as the network interface to be configured by ***boot-config***:

```
NETDEV=ma1
```

- This **NETAUTO** command instructs the switch to configure the network interface through a DHCP server, ignoring other NET settings:

```
NETAUTO=dhcp
```

- These **NET** commands configure the network interface:

```
NETIP=10.12.15.10
NETMASK=255.255.255.0
NETGW=10.12.15.24
NETDOMAIN=mycompany.com
NETDNS=10.12.15.13
```

2.2.1.3 Programming boot-config from the CLI

The switch CLI provides **boot** commands for editing ***boot-config*** content. The **boot** commands are not accessible from a console port CLI. You can modify parameters by directly editing the ***boot-config*** file, which is not configurable from a **boot** command.

Commands that configure boot parameters include **boot system**, **boot secret**, and **boot console**.

boot system

The `boot system` command provides the EOS image file location to Aboot.

Examples

- This command specifies EOS1.swi as the software image load file on USB flash memory.

```
switch(config)# boot system usb1:EOS1.swi
```

- The **boot system** command adds this line to ***boot-config***.

```
SWI=usb1:/EOS1.swi
```

- This command designates EOS.swi as the EOS software image load file on the switch flash.

```
switch(config)# boot system flash:EOS.swi
```

- The **`boot system`** command adds this line to ***boot-config*** respectively:

```
SWI=flash:/EOS.swi
```

boot secret

The `boot secret` command sets the Aboot password. It supports both encrypted (MD5 and SHA512) and unencrypted (clear text) password formats. The SHA512 is the default format when entering **clear text** or **unencrypted** passwords.

Examples

- The commands `boot secret xr19v` and `boot secret 0 xr19v` are equivalent and use SHA512 as the default password encryption format.

```
switch#(config)# boot secret 0 xr19v
switch#(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): $6$/DxU6.VPVxuBxzxK$2x4TKrZgNXvQaFnltaILliDAx3m7a7I2tLar4UtIOrBAv
Rmn/R9xpGjnV3qUczG1yjsBEfGnsdzeM3PTGpLpz1
Memory test iterations: (not set)
Checksum: 08e06211bc4a2d9d1b516aca390a302a2e7fc871
Checksum algorithm: sha1

Secure boot: disabled
SPI flash protection: disabled
SPI flash update: disabled
Password storage: boot-config
Measured boot: disabled
Arista certificate: enabled
Upgrade cert:
-----BEGIN CERTIFICATE-----
MIIFfDCCA2SgAwIBAgITKAAAABA/utRCnITtCQAAAAAAEDANBgkqhkiG9w0BAQsF

**<output omitted>**

WkoS40M0c5KUTF83wiaUmA==
-----END CERTIFICATE-----
```

- The `boot secret` commands earlier add this line to boot-config:

```
PASSWORD=$6$/DxU6.VPVxuBxzxK$2x4TKrZgNXvQaFnltaILliDAx3m7a7I2tLar4UtIOrBAvRmn/R9xpGjnV3qUcz
G1yjsBEfGnsdzeM3PTGpLpz1
```

At this point, the user must enter **xr19v** at the login prompt to access the Aboot shell.

- This command sets the Aboot password to xr123. The encrypted string generated previously is xr123 as the clear-text seed.

```
switch(config)# boot secret 5 $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
```

- This command removes the Aboot password; it does not authenticate subsequent Aboot access.

```
switch(config)# no boot secret
```

- This command shows that there is now no Aboot password.

```
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): (not set)
```

boot console

The `boot console` command sets console settings for attaching devices.

Examples

- This command sets the console speed to ***4800*** baud:

```
switch(config)# boot console speed 4800
```

- This command shows the console speed.

```
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: 4800
Aboot password (encrypted): (not set)
```

- The **`boot console`** command earlier adds this line to ***boot-config***:

```
CONSOLESPEED=4800
```

install bios source

The `install bios source` command loads an Aboot Update File (AUF) to provide a signed method of upgrading Aboot.

Examples

- This command installs the file *update.auf* stored in **`/mnt/flash`**:

```
switch# install bios source flash:/update.auf
```

- This command performs a reboot directly after the installation:

```
switch# install bios source flash:/update.auf reload
```

- This command skips the prompts and performs the installation automatically:

```
switch# install bios source flash:/update.auf now
```

- This command performs the installation only on the standby supervisor:

```
switch# install bios source flash:/update.auf standby
```

Note: On a modular system with two supervisors, Aboot gets upgraded on both by default.

2.2.2 running-config

The ***running-config*** is a virtual file that contains the system's operating configuration, formatted as a command sequence. Commands entered from the CLI modify the ***running-config***, and copying a file to ***running-config*** updates the operating configuration by executing the commands in the copied file.

Commands for viewing and copying ***running-config*** include:

- **`show running-config`** displays the contents of ***running-config***.
- **`copy running-config startup-config`** copies ***running-config*** contents to ***startup-config***.
- **`write`** copies ***running-config*** contents to ***startup-config***.

2.2.3 startup-config

The ***startup-config*** file is stored in flash memory and contains the configuration the switch loads when booting. During a switch boot, ***startup-config*** replaces the ***running-config***. When the system reboots, changes to ***running-config*** that are not in ***startup-config*** are lost.

Commands affecting ***startup-config*** include the following:

- **`show startup-config`** displays the contents of ***startup-config***.
- **`copy`** ***file_name*** **`startup-config`** copies contents of the specified file to ***startup-config***.
- **`delete startup-config`** deletes the ***startup-config*** file.

2.3 Supervisor Redundancy

On modular switches with redundant supervisor modules, the standby supervisor switch can take control to minimize downtime and data loss in the case of a reset, reload, or failure of an active supervisor. The redundancy protocol configured on the active supervisor determines the switchover.

Use the `show redundancy status` command to display both the supervisors' state and the current redundancy protocol. Use the `show redundancy file-replication` command to display the state of configuration file synchronization between the supervisors,

2.3.1 Redundancy Supervisor Protocols

There are three available supervisor redundancy protocols.

Route Processor Redundancy (RPR)

EOS uses the default redundancy protocol, Route Processor Redundancy (RPR), which synchronizes ***startup-config*** files between the supervisor modules and partially boots the standby supervisor to a standby warm state but does not synchronize ***running-config***. If the active supervisor fails or a manual switchover initiates with the `redundancy manual switchover` command, the standby supervisor will become active. The running state, including the spanning tree, is lost, bringing down all links temporarily.

Under RPR, you can access the CLI of the standby supervisor by SSH or through the console port, but the available command set is limited. Any configuration changes made to the standby supervisor will be lost when the supervisor reboots.

Stateful Switchover (SSO)

Note: The active and standby supervisors must run the same version of EOS software. If the software versions do not match, the operation redundancy state uses RPR.

In the Stateful Switchover (SSO) protocol, the switch synchronizes ***startup-config*** and ***running-config*** files between the supervisor modules. It fully boots the standby module to a standby hot state to speed up the switchover process and minimize packet loss. If the active supervisor fails or initiates a manual switchover, the standby supervisor immediately becomes active, and maintains the L2 running state. An SSO switchover is largely transparent from the outside. Still, because the L3 state has not synchronized, the switchover can result in traffic loss for traffic forwarded on routes learned by a dynamic routing protocol. Enabling nonstop forwarding can eliminate most packet loss for BGP and OSPF.

Under SSO, the console port can access the CLI of the standby supervisor, and has a limited command set. The switch loses any configuration changes on the standby supervisor when the supervisor reboots.

Note: When upgrading the EOS on a dual-supervisor switch to an SSO-capable version (*4.11.0* or higher) from a version that does not support SSO, both supervisors reset simultaneously, causing several seconds of system downtime.

Simplex

A switch with a simplex protocol disables the standby supervisor, and switchover does not occur even if the active supervisor fails. To reload the active supervisor results in system downtime while the supervisor

reboots and the standby supervisor remains disabled. The redundancy protocol must change to RPR or SSO to transfer control of the switch to the standby supervisor.

Under the simplex protocol, the console port can access the CLI of the disabled supervisor, and has a limited command set.

The switch loses any configuration changes on the standby supervisor when the supervisor reboots.

2.3.2 Configuring Supervisor Redundancy

To configure the Supervisor Redundancy protocol, use the `protocol` command in redundancy configuration mode accessed with the `redundancy` command.

Changing the redundancy protocol on the active supervisor resets the standby supervisor regardless of the redundancy protocol, and executing the **`write`** command on the active supervisor synchronizes the ***startup-config*** files between supervisors in RPR and SSO modes.

Examples

- These commands display the current redundancy state of the switch and the most recent file synchronization information.

```
switch# show redundancy status
  my state = ACTIVE
peer state = STANDBY WARM
      Unit = Primary
   Unit ID = 1

Redundancy Protocol (Operational) = Route Processor Redundancy
Redundancy Protocol (Configured) = Route Processor Redundancy
Communications = Up
Ready for switchover

  Last switchover time = 7:23:56 ago
Last switchover reason = Supervisor has control of the active supervisor lock
switch# show redundancy file-replication
0 files unsynchronized, 2 files synchronized, 0 files failed, 2 files total.

File                   Status         Last Synchronized
---------------------- -------------- -------------------
file:persist/sys       Synchronized   0:10:04 ago
flash:startup-config   Synchronized   0:10:04 ago switch#
```

- These commands set the redundancy protocol for the active supervisor to stateful switchover (SSO).

```
switch# config
switch(config)# redundancy
switch(config-redundancy)# protocol sso
Peer supervisor will be restarted.
switch(config-redundancy)#
```

2.4 System Reset

When a reset condition exists, Aboot can either reset the switch without user intervention or facilitate a manual reset through the Aboot shell. A reset operation clears the switch, including memory states and other hardware logic.

- **Fixed systems**: The power supply remains powered up during the reset. All other switch components lose power for two to five seconds.
- **Modular systems**: The power supply on the active supervisor remains powered up during the reset. All other supervisor components lose power for at least one second. In Stateful Switchover (SSO) and Route Processor Redundancy (RPR) modes, resetting the standby supervisor does not affect the active supervisor. However, resetting the active supervisor causes the standby supervisor to become active immediately. After the supervisor becomes functional, it manages the power cycling of all line cards.

The `reload` command initiates an immediate reset, terminating all CLI instances not running through the console port. The console port CLI displays messages that the switch generates during a reset. The standby supervisor does not terminate CLI sessions on modular switches with redundant supervisors.

The `reload (scheduled)` command schedules a reset operation to initiate at a specific time or after a specified period.

2.4.1 Typical Reset Sequence

The `reload` command power cycles the switch and resets it under Aboot control. The hard reset clears the switch, including memory states and other hardware logic.

By default, the **`reload`** command triggers a request to store unsaved ***running-config*** commands and an option to open the Aboot shell before starting the reboot when accessing the CLI through the console port. The switch then begins the reboot process, which Aboot controls.

The following procedure provides an example of a typical restart.

1. Begin the reboot process by typing the **`reload`** command:

   ```
   switch# reload
   ```

   The switch sends a message to confirm the reload request:

   ```
   Proceed with reload? [confirm]
   ```

2. Select **enter** or type **y** to confirm the requested reload. Pressing any other key terminates the reload operation.

   The switch sends a series of messages, including a notification that a message was broadcast to all open CLI instances, informing them that the system rebooted. The reload pauses when the CLI displays the Aboot shell notification line.

   ```
   Broadcast message from root@mainStopping sshd: [ OK ]
   SysRq : Remount R/O
   Restarting system

   Aboot 1.9.0-52504.EOS2.0
   ```

```
Press Control-C now to enter Aboot shell
```

3. To continue the reload process, do nothing. Typing **Ctrl-C** opens the Aboot shell; see Aboot Commands for Aboot editing instructions.
4. The switch continues the reset process, displaying messages indicating the completion of individual tasks. The reboot is complete when the CLI displays a login prompt.

```
Booting flash:/EOS.swi
Unpacking new kernel
Starting new kernel

[ OK ] crond: [ OK ]

switch login:
```

5. Log in to the switch to resume configuration tasks.

2.4.2 Switch Recovery

Aboot can automatically erase the internal flash and copy the contents of a USB drive inserted before powering up or rebooting the switch. This recovery method does not require access to the switch console or Aboot password entry, even if the ***boot-config*** file lists one.

Aboot invokes the recovery mechanism only in each of these two conditions:

- It ignores the file contents. Providing an empty text file is sufficient.
- If the USB drive contains a ***boot-config*** file, the timestamp must differ from the timestamp of the ***boot-config*** file on the internal flash.

  This prevents Aboot from invoking the recovery mechanism again on every boot if you leave the flash key inserted.

To use this recovery mechanism, set up and install the USB drive with the current EOS software image, a customized or empty ***boot-config***, and an empty file named “fullrecover.”

Check that the ***boot-config*** has a current timestamp to meet the earlier conditions.

2.4.3 Display Reload Cause

The `show reload cause` command displays the cause of the most recent system reset and lists recommended actions, if any exist, to avoid future spontaneous resets or resolve other issues that may have caused the reset.

Example

To display the 'reset cause', type **`show reload cause`** at the prompt.

```
switch# show reload cause
Reload Cause 1:
------------------
Reload requested by the user.

Recommended Action:
------------------
No action necessary.

Debugging Information:
----------------------
None available.
switch#
```

2.4.4 Configuring Zero Touch Provisioning

Zero Touch Provisioning (ZTP) is a switch configuration method that uses files referenced by a DCHP server to initially provision the switch without user intervention. A switch enters ZTP mode if flash memory does not reload a ***startup-config*** or ***zerotouch-config*** file.

ZTP cancelation boots the switch without using a ***startup-config*** file. Flash memory does not store a ***startup-config*** file for a canceled ZTP mode. The switch returns to ZTP mode on subsequent reboots until the ***startup-config*** file stores to flash. This section describes the steps to implement, monitor, and cancel ZTP.

2.4.4.1 Configuring the Network for ZTP

A switch performs the following after booting in ZTP mode:

- It configures each physical interface to **no switchport** mode.
- It sends a DHCP query packet on all Ethernet and management interfaces.

After the switch receives a DHCP offer, it responds with a DHCP request for ***Option 66*** (TFTP server name), ***Option 67*** (bootfile name), and dynamic network configuration settings. When the switch receives a valid DHCP response, it configures the network settings and fetches the file from the location listed in ***Option 67***. If ***Option 67*** returns a network URL (**`http:// or ftp://`**), the switch obtains the file from the network. If ***Option 67*** returns a file name, the switch retrieves the file from the TFTP server listed in ***Option 66***.

The ***Option 67*** file can be a ***startup-config*** file or a boot script. The switch distinguishes between a ***startup-config*** file and a boot script by examining the first line in the file:

- The first line of a boot file must consist of the #! characters followed by the interpreter path. The switch executes the code in the script and then reboots. The boot script may fetch an EOS software image or perform customization tasks.

The following boot file fetches an EOS software image and stores a startup configuration file to flash.

```
#!/usr/bin/Cli -p2
copy http://company.com/startup-config flash:startup-config
copy http://company.com/EOS-2.swi flash:EOS-2.swi
config
boot system flash:EOS-2.swi
```

- The switch identifies any other file as a ***startup-config*** file. The switch copies the ***startup-config*** file into flash as **`mnt/flash/startup-config`**, then reboots.

  The switch uses its system MAC address as the DHCP client identifier and **Arista** as the Vendor Class Identifier (***Option 60***). When the switch receives an HTTP URL through ***Option 67***, it sends the following HTTP headers in the GET request:

```
X-Arista-SystemMAC:
X-Arista-HardwareVersion:
X-Arista-SKU:
X-Arista-Serial:
X-Arista-Architecture:
```

2.4.4.2 Monitoring ZTP Progress

A switch displays the following message after rebooting when it does not contain a ***startup-config*** file:

```
No startup-config was found.

The device is in Zero Touch Provisioning mode and is attempting to
download the startup-config from a remote system. The device will not
be fully functional until a valid startup-config is downloaded
from a remote system or Zero Touch Provisioning is canceled. To cancel
Zero Touch Provisioning, login as admin and type 'zerotouch cancel'
at the CLI.

switch login:
```

After successfully downloading a ***startup-config*** file, the switch displays a CONFIG_DOWNLOAD_SUCCESS message and continues the reload process described in the Typical Reset Sequence.

```
===============================================================================

Successful download
--------------------

Apr 15 21:36:46 switch ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on  [
Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21,
Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9,
Management1, Management2 ]
Apr 15 21:36:56 switch ZeroTouch: %ZTP-5-DHCP_SUCCESS: DHCP response received on
Ethernet24  [ Mtu: 1500; Ip Address: 10.10.0.4/16; Nameserver: 10.10.0.1; Domain:

SysRq : Remount R/O
Restarting system

Aboot 1.9.0-52504.EOS2.0

Press Control-C now to enter Aboot shell
```

2.4.4.3 ZTP Failure Notification

The switch displays a **DHCP_QUERY_FAIL** message when it does not receive a valid DHCP response within 30 seconds of sending the query. The switch then sends a new DHCP query and waits for a response. The switch sends queries until it receives a valid response or cancels ZTP mode.

```
switch login: admin
admin
switch>Apr 15 21:28:21 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP
request on  [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18,

Ethernet9, Management1, Management2 ]
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-DHCP_QUERY_FAIL: Failed to get a
valid DHCP response
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-RETRY: Retrying Zero Touch
Provisioning from the beginning (attempt 1)
Apr 15 21:29:22 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on
[ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21,
Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9,
Management1, Management2 ]
```

2.4.4.4 Canceling ZTP Mode

Log into the console to boot the switch without a ***startup-config*** file, then cancel ZTP mode. After the switch boots, it uses all factory default settings. Flash memory prevents the switch from entering ZTP mode on subsequent boots when a ***startup-config*** file exits.

2.4.5 Configuring the Networks

If the ***boot-config*** file contains a NETDEV statement, Aboot attempts to configure the network interface as specified by Network configuration commands. See boot-config Command Line Content for a list of commands that define the network configuration.

2.5 Aboot Shell

The Aboot shell is an interactive command-line interface used to manually boot a switch, restore the internal flash to its factory-default state, run hardware diagnostics, and manage files. The Aboot shell resembles the Linux Bourne Again Shell (Bash).

The Aboot shell provides commands for restoring the state of the internal flash to factory defaults or a customized default state. You can select these recovery methods to:

- Restore the factory-default flash contents before transferring the switch to another owner.
- Restore Aboot shell access if the Aboot password is lost or forgotten.
- Restore console access if the baud rate or other settings are incompatible with the terminal.
- Replace the internal flash contents with configuration or image files stored on a USB flash drive.

2.5.1 Aboot Shell Operation

When the switch powers on or reboots, Aboot reads the configuration from ***boot-config*** on the internal flash and attempts to boot a configured EOS software image with the extension **`.swi`**.

You can monitor the automatic boot process or enter the Aboot shell only from the console port. You can connect a PC or terminal directly to the port and run a terminal emulator to interact with the serial port or access it through a serial concentrator device.

The ***boot-config*** stores the console settings, and uses the factory-default settings of ***9600*** baud, no parity, ***8*** character bits, and ***1*** stop bit. If you do not know the current settings, perform a full flash recovery to restore the factory default settings. When the console port connects and the configured terminal settings are proper, the terminal displays a message similar to the following a few seconds after powering up the switch:

```
Aboot 1.0.0

Press Control-C now to enter the Aboot shell
```

To abort the automatic boot process and enter the Aboot shell, select **Ctrl-C** (ASCII 3 in the terminal emulator) after the *Press Control-C now to enter Aboot shell* message appears. Pressing **Ctrl-C** can interrupt the boot process up through the starting of the new kernel.

If the ***boot-config*** file does not contain a password command, the Aboot shell starts immediately. Otherwise, you must enter the password using the password prompt to start the shell. If you enter the wrong password three times, Aboot displays this message:

```
Type "fullrecover" and press Enter to revert /mnt/flash to factory default

state, or just press Enter to reboot:
```

- Selecting **Enter** continues a normal soft reset without entering the Aboot shell.
- Typing **`fullrecover`** and pressing **Enter** performs a full flash recovery to restore the factory-default settings, removing all previous flash drive contents.

The Aboot shell starts by printing:

```
Welcome to Aboot.
```

Aboot then displays the **Aboot#** prompt.

Aboot reads the configuration from ***boot-config*** on the internal flash.

2.5.2 Accessing the Aboot Shell

This procedure accesses the Aboot Shell.

1. Reload the switch and select **enter** or type **y** when prompted, as described in the Typical Reset Sequence.
   The command line displays this Aboot entry prompt.

```
Press Control-C now to enter Aboot shell
```

2. Type **Ctrl-C**.
   If the ***boot-config*** file does not contain a PASSWORD command, the CLI displays an Aboot welcome banner and prompt.

```
^C Welcome to Aboot.
Aboot#
```

   The CLI displays a password prompt if the ***boot-config*** file contains a PASSWORD command. In this case, proceed to **Step 3**. Otherwise, the CLI displays the Aboot prompt.
3. If prompted, enter the Aboot password.

```
Press Control-C now to enter Aboot shell
 ^CAboot password:
Welcome to Aboot.
Aboot#
```

   Aboot allows three attempts to enter the correct password. After the third attempt, the CLI prompts the user to continue the reboot process without entering the Aboot shell or restoring the flash drive to the factory default state.

```
Press Control-C now to enter Aboot shell
^CAboot password:
incorrect password
Aboot password:
incorrect password
Aboot password:
incorrect password
Type "fullrecover" and press Enter to revert /mnt/flash to factory default
state, or just press Enter to reboot: fullrecover
All data on /mnt/flash will be erased; type "yes" and press Enter to proceed,
or just press Enter to cancel:
```

   The **fullrecover** operation replaces the flash contents with a factory default configuration. The CLI displays text similar to the following when performing a **fullrecover**, finishing with another entry option in the Aboot shell.

Note: For hardware purchased after June 2017, the factory default partition does not have the backup EOS software image. It increases the flash size on smaller flash size disks, and other options are available in the **`fullrecover`** command functionality to restore the factory default EOS image applicable to both fixed system and modular system hardware.

```
Erasing /mnt/flash
Writing recovery data to /mnt/flash
boot-config
startup-config
EOS.swi
210770 blocks
Restarting system.

Aboot 1.9.0-52504.EOS2.0

Press Control-C now to enter Aboot shell
```

2.5.3 Aboot File Structure

When you enter the Aboot CLI, the current working directory is the root directory on the switch. Switch image and configuration files are at **/mnt/flash.** When exiting the Aboot shell, only **/mnt/flash** preserves the contents. The **/mnt** directory contains the file systems of storage devices. Aboot mounts the internal flash device at **/mnt/flash**.

When you insert a USB flash drive in one of the flash ports, Aboot mounts its file system on **/mnt/usb1**. The file system is unmounted when you remove the USB flash drive from the port. Most USB drives contain an LED that flashes when the system is accessing it; wait to remove the drive from the flash port until the LED stops flashing.

2.5.4 Booting From the Aboot Shell

Aboot boots the EOS software image (with the extension .swi), which is available in ***boot-config*** automatically if you take no action during the boot process. Suppose the boot process fails for any reason, such as an incorrectly configured software image. In that case, Aboot enters the shell, allowing you to manually correct the configuration or boot a software image. The **`boot`** command loads and boots an EOS software image file.

The **`boot`** command syntax is

`boot` ***SWI***

where ***SWI*** lists the location of the EOS image that the command loads. ***SWI*** options include:

- ***device:path*** loads the image file from the specified storage device. The default ***device*** value is **flash**; other values include **file** and **usb1**.
- */PATH* loads the image file from the specified path in the switch directory.
- **http://*server/path*** loads the image file from the HTTP server on the host server.

- **ftp://*server/path*** loads the image file from the FTP server on the host server.
- **tftp://*server/path*** loads the image file from the TFTP server on the host server.
- **nfs://*server/path*** mounts the path's parent directory from the host server and loads the image file from the loaded directory.

It accepts the same commands as the SWI variable in the boot-config file. See boot-config Command Line Content for a list of boot command formats.

If the ***boot-config*** does not have a specified image or booting the image results in an error condition, for example, an incorrect path or unavailable HTTP server, Aboot halts the boot process and drops into the shell.

Example

To boot EOS.swi from internal flash, enter one of these commands on the Aboot command line:

```
boot flash:EOS.swi
```

```
boot /mnt/flash/EOS.swi
```

2.5.5 Secure Booting from Aboot

Secure boot provides a security feature in Aboot, Arista bootloader, that verifies the cryptographic signature of the EOS software image before booting up the switch. Aboot embeds certificates that allow it to recognize and validate official EOS releases from Arista. If a successful signature verification occurs, the secure boot check passes and Aboot proceeds to boot the software image. If the signature verification fails, the switch aborts booting the software.

In addition to the verification of Arista signed images, secure boot can also validate images using a user-configured root certificate. This mechanism allows you to sign your SWI images and have them recognized by secure boot. It is also possible to configure secure boot to only accept SWI images signed by the user certificate.

Secure boot prevents and detects unauthorized modifications to the software image by anyone with access to EOS. To provide this guarantee, it must not be possible for anyone, including a system administrator, to disable any of the secure boot configuration or firmware components from EOS. That includes disabling secure boot, changing the certificates used to validate the software image signature, or unauthorized modifications to the BIOS or Aboot firmware.

Two main components store the firmware and secure boot configuration:

- The BIOS SPI flash
- The Trusted Platform Module (TPM) Nonvolatile Random Access Memory (NVRAM)

When properly configured with secure boot enabled, EOS locks both hardware components before running the software image. This ensures that no component of secure boot can be tampered with from EOS.

The switch embeds the bootloader Aboot in the BIOS firmware and stores the complete firmware image, BIOS plus Aboot, in the BIOS SPI flash. The flash also stores certificates used by secure boot to validate the image signature. Configure the BIOS SPI flash as write-protected by Aboot to prevent unauthorized modifications to the BIOS, Aboot, or secure boot certificates from EOS.

The TPM NVRAM stores critical configuration parameters for secure boot. The NVRAM indexes that store secure boot data in the TPM can only be overwritten by using the highest level of privilege on the TPM. Aboot unconditionally locks the highest level of privilege on the TPM prior to transferring execution to EOS, and ensures that NVRAM sections storing the secure boot level configuration cannot undergo modification.

Use the following commands to enable, disable, or display secure boot:

```
Aboot# securebootctl secureboot -enable
Aboot# securebootctl secureboot -display
Secure Boot enabled
```

```
Aboot# securebootctl secureboot -disable
Aboot# securebootctl secureboot -display
Secure Boot disabled
```

Use the following command to add a certificate path, /mnt/flash/user-test.crt, for secure boot:

```
Aboot# secureboot cert -add /mnt/flash/user-test.crt
Added the following user certificate:
DC=com, DC=test, CN=User Test Cert
```

Use the following command to display certificate information:

```
Aboot# securebootctl cert -display
Arista: DC=com, DC=mycompany, CN=MyCompany Issuing Cert Authority
```

Use the following commands to configure Arista Certificates to verify software images:

```
Aboot# securebootctl aristacert -enable
Aboot# securebootctl aristacert -display
Arista certificate used
Aboot# securebootctl cert -display
Arista: DC=com, DC=aristanetworks, CN=AristaIT-ICA ECDSA Issuing Cert Authority
```

Use the following command to disable Arista certificates for secure boot:

```
Aboot# securebootctl aristacert -disable
Aboot# securebootctl aristacert -display
Arista certificate ignored
Aboot# securebootctl cert -display
Arista: ignored
User: No certificate is configured
```

If you enable secure boot, disable Arista certificates, and no user certificate configured, the switch does not boot because it cannot find a valid certificate to verify the software image. The following message displays on the switch:

```
=== WARNING ===
```

```
Invalid configuration detected:
- Arista certificate ignored
- no user certificate inserted
- Secure Boot is enabled

Boot is not going to be allowed until one of those is addressed.

Please insert a user certificate, enable the Arista certificate or disable Secure Boot to proceed
 to EOS.
```

Using an Aboot Password

Secure boot compatible Aboot images support storing an Aboot password in the TPM as a more secure option than storing the password in /mnt/flash. You can only configure the password in the Aboot mode. Once you set the password, EOS can no longer set the Aboot password.

Use the following command to display the Aboot password status:

```
Aboot# securebootctl abootpassword -display
Password status: disabled
```

EOS disables the password by default.

Use the following commands to enable the password, and then display password information:

```
Aboot# securebootctl abootpassword -enable
Enter password:
Confirm password:
Aboot# securebootctl abootpassword -display
Password status: enabled
Password value: $6$poC4fj2Bk4aAPKga$hOl92bbCeyU9UM3sv3hfesRamMaQwLH5Yi01LhW/hw2BtNyQ8UmvhreMFS
rDoQ6ji9WB1l5e/.KDWhtP4zMLW0
```

Displaying Boot Information

The **show boot** command displays the following information on platforms that support secure boot:

```
switch# show boot
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): (not set)
Memory test iterations: (not set)

Secure boot: enabled
SPI flash protection: enabled
Password storage: tpm
Arista certificate: enabled
Extra certificate:
-----BEGIN CERTIFICATE-----

-----END CERTIFICATE-----
```

2.5.5.1 Measured Boot

Measured boot provides a tamper-detection mechanism that records the system boot process. It calculates the cryptographic hashes of system components and configurations, and then securely stores them in the

Platform Configuration Registers PCRs) of a Trusted Platform Module (TPM) chip. This process creates a hash chain of the boot sequence. After the system starts, the TPM Quote operation, along with the extension records, verify the PCR values and confirms that the system components haven't changed and has trusted software.

Measured boot differs based on the version of TPM installed on the system. Use the following commands to determine the TPM version:

```
switch# show management security
[...]
Security Chip: IFX SLB9670 TPM 1.2 (6.43.243.0)
[...]
```

The output displays TPM Version 1.2.

```
switch# show management security
[...]
STM ST33TPHF2X TPM 2.0 (1.512))
[...]
```

Enabling or Disabling Measured Boot

EOS stores the Secure Boot configuration, including the measured boot configuration, in the TPM NVRAM. The NVRAM indexes storing the secure boot data can only be configured as writable with the highest privilege level on the TPM, `platform authorization` for TPM 2.0 or `physical presence` for TPM 1.2.

Aboot unconditionally locks the highest level of privilege on the TPM before transferring execution to EOS. You can only configure measured boot in Aboot mode.

Use the following command to enable measured boot:

```
Aboot# securebootctl measuredboot -enable
Aboot# securebootctl measuredboot - display
Measure Boot enabled
```

Use the following commands to disable measured boot and display the measured boot status:

```
Aboot# securebootctl measuredboot -disable
Aboot# securebootctl measuredboot - display
Measure Boot disabled
```

Note: You cannot disable measured boot from EOS. It must be disabled in Aboot mode.

Displaying Measured Boot Status

Use the following command to display measured boot status:

```
switch#  show boot
[...]
Measured boot: enabled
[...]
```

2.5.6 Aboot Commands

To list the contents of the internal flash, enter **`ls /mnt/flash`** at the Aboot# prompt.

Example

```
Aboot# ls /mnt/flash
EOS.swi boot-config startup-config
```

Commonly used commands include the following:

- **`ls`** prints a list of the files in the current working directory.
- **`cd`** changes the current working directory.
- **`cp`** copies a file.
- **`more`** prints the contents of a file one page at a time.
- **`vi`** edits a text file.
- **`boot`** boots a software image file.
- **`swiinfo`** prints information about a software image.
- **`recover`** recovers the factory-default configuration.
- **`reboot`** reboots the switch.
- **`udhcpc`** configures a network interface automatically via DHCP.
- **`ifconfig`** prints or alters network interface settings.
- **`wget`** downloads a file from an HTTP or FTP server.
- **`showtech`** prints device hardware information.

Aboot can access networks through the Ethernet management ports. Aboot provides unconfigured network interfaces mgmt1 and mgmt2 by default. You can configure management port settings using Aboot shell commands such as **`ifconfig`** and **`udhcpc`**. After configuring a management interface, use **`wget`** to transfer files from an HTTP or FTP server, **`tftp`** to transfer files from a TFTP server, or **`mount`** to mount an NFS filesystem.

2.6 Aboot Configuration Commands

This section describes the Aboot configuration commands that a ***boot-config*** file can contain.

- CONSOLESPEED
- NET commands

Installation Commands (Aboot)

- install bios source
- PASSWORD (ABOOT)
- SWI

2.6.1 CONSOLESPEED

The **CONSOLESPEED** command in the ***boot-config*** file specifies the console baud rate when the switch is booted. The connected terminal must match the specified rate to communicate with the switch. Baud rate options include ***1200***, ***2400***, ***4800***, ***9600***, ***19200***, ***38400***, ***57600***, and ***115200***.

The default baud rate is ***9600***.

Command Syntax

CONSOLESPEED= *baud_rate*

Parameters

baud_rate specifies the console speed. Values include **1200**, **2400**, **4800**, **9600**, **19200**, **38400**, **57600**, and **115200**.

Example

This command in a ***boot-config*** file sets the baud rate to 2400 when the switch boots.

```
CONSOLESPEED=2400
```

2.6.2 NET Commands

Aboot uses **NET** commands in the ***boot-config*** file during switch booting to configure the network interface used for switch configuration. You can enter these commands manually in Aboot.

NETDEV indicates the configured network interface. If ***boot-config*** does not contain a **NETDEV** command, the booting process does not attempt to configure a network interface. Other **NET** commands specify settings that Aboot uses to configure the interface.

Command Syntax

NETDEV=*device_interface*

NETAUTO=*auto_setting*

NETIP=*interface_address*

NETMASK=*interface_mask*

NETGW=*gateway_address*

NETDOMAIN=*domain_name*

NETDNS=*dns_address*

Parameters

- ***device_interface*** the network interface. Options include:
  - **ma1** management ***port 1***.
  - **ma2** management ***port 2***.
- ***auto_setting*** the configuration method. Options include:
  - **dhcp** interface is configured through a DHCP server; other NET commands are not.
  - If the **NETAUTO** command is omitted, the interface configures with other NET commands.
- ***interface_address*** interface IP address, in dotted-decimal notation.
- ***interface_mask*** interface subnet mask, in dotted-decimal notation.
- ***gateway_address*** default gateway IP address, in dotted decimal notation.
- ***domain_name*** interface domain name.
- ***dns_address*** IP address of the Domain Name Server, in dotted decimal notation.

Examples

- This command specifies management ***port 1*** as the network interface configured for management traffic.

```
NETDEV=ma1
```

- This command instructs the switch to configure the network interface through a DHCP server, ignoring other **NET** commands.

```
NETAUTO=dhcp
```

- These **NET** commands configure the network interface.

```
NETIP=10.12.15.10
NETMASK=255.255.255.0
NETGW=10.12.15.24
NETDOMAIN=mycompany.com
NETDNS=10.12.15.13
```

2.6.3 install bios source

`install bios source` command is used to install an Aboot Update File (AUF) to upgrade Aboot firmware.

`install bios source` indicates the location of the source file and the actions taken.

Command Syntax

`install bios source` *SOURCE* [active | standby] [reload | now]

Parameters

SOURCE the file location.

Examples

- This command installs an AUF file *update.auf* stored in */mnt/flash*.

```
switch# install bios source flash:/update.auf
```

Note: Follow the prompts after executing the command during the installation process.

- This command performs a reboot directly after installation.

```
switch# install bios source flash:/update.auf reload
```

- This command skips the prompts and performs the reboot automatically after installation.

```
switch# install bios source flash:/update.auf now
```

- This command performs the installation only on the standby supervisor.

```
switch# install bios source flash:/update.auf standby
```

Note: By default, the active supervisor gets upgraded, followed by the standby where applicable.

2.6.4 PASSWORD (ABOOT)

PASSWORD specifies the Aboot password, as described in Accessing the Aboot Shell. The Aboot shell does not require a password when ***boot-config*** does not contain a **PASSWORD** command.

The ***boot-config*** file stores the password as an MD5-encrypted string generated from a clear-text seed by the UNIX password program or the crypt library function. When entering the Aboot password, the user types the clear-text seed.

There is no method of recovering the password from the encrypted string. If the clear-text password is lost, delete the corresponding **PASSWORD** command line from the ***boot-config*** file.

> **Note:**
> The EOS boot secret command adds or modifies the **PASSWORD** configuration line.

Command Syntax

`PASSWORD` = *encrypted_string*

Parameters

encrypted_string, the encrypted string that corresponds to the clear-text Aboot password.

Example

This line is a **PASSWORD** command example in which the encrypted string corresponds to the clear-text password ***abcde***.

```
PASSWORD=$1$CdWp5wfe$pzNtE3ujBoFEL8vjcq7jo/
```

2.6.5 SWI

SWI specifies the location and file name of the EOS image file that Aboot loads when booting, using the same format as ***boot-config*** to designate a local or network path.

Command Syntax

`SWI` = **SWI_PATH**

Parameters

SWI_PATH specifies the location of the EOS image file. Options include:

- ***file_path*** specifies a file location on the internal flash drive.
- **file**:***file_path*** specifies a file location in the switch directory.
- **usb1**:***file_path*** specifies a file location on the USB drive.
- **http**:***file_path*** specifies an HTTP path to the image file.
- **ftp**:***file_path*** specifies an FTP path to the image file.
- **tftp**:***file_path*** specifies a TFTP path to the image file.
- **nfs**:***file_path*** specifies an NFS path to the image file.

Examples

- This SWI command in ***boot-config*** causes Aboot to boot the switch from the file **`EOS.swi`** on the switch's internal flash drive.

```
SWI=flash:EOS.swi
```

- This SWI command in ***boot-config*** causes Aboot to boot the switch from the file **`EOS.swi`** at the specified location on foo.com.

```
SWI=http://foo.com/images/EOS.swi
```

2.7 Switch Booting Commands

- boot console
- boot secret
- boot system
- delete startup-config

- protocol
- redundancy
- redundancy manual switchover
- reload
- reload (scheduled)
- show platform bios
- show redundancy file-replication
- show redundancy status
- show redundancy switchover sso
- show reload
- show reload cause
- show reload fast-boot

2.7.1 boot console

The **boot console** command configures terminal settings for serial devices connecting to the console port. The only console setting specified from ***boot-config*** is **speed**.

The factory-default console settings are ***9600*** baud, no parity, ***8*** character bits, and ***1*** stop bit. If you do not know the current settings, restore the factory default settings described in Restoring the Factory Default EOS Image and Startup Configuration.

The **no boot console** and **default boot console** commands restore the factory default settings on the switch and remove the corresponding **CONSOLESPEED** command from the ***boot-config*** file.

Command Mode

Global Configuration

Command Syntax

boot console speed ***baud_rate***

Parameters

baud_rate console baud rate. Options include ***1200***, ***2400***, ***4800***, ***9600***, ***19200***, ***38400***, ***57600***, and ***115200***.

Examples

- This command sets the console speed to ***57600*** baud.

```
switch(config)# boot console speed 57600
switch(config)#
```

- This command displays the result of the console speed change.

```
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: 57600
Aboot password (encrypted): (not set)
switch(config)#
```

- The above **boot console** command adds the following line to ***boot-config***.

```
CONSOLESPEED=57600
```

2.7.2 boot secret

The **boot secret** command creates or edits the Aboot shell password and stores the encrypted string in the **PASSWORD** command line of the ***boot-config*** file.

The **no boot secret** and **default boot secret** commands remove the Aboot password from the ***boot-config*** file. When the Aboot password does not exist, no password is required to enter the Aboot shell.

Command Mode

Global Configuration

Command Syntax

boot secret [***encrypt_type***] ***password***

no boot secret

default boot secret

Parameters

- ***encrypt_type*** indicates the encryption level of the password parameter. Settings include the following:
  - **no parameter** and the password contains clear text.
  - **0** specifies the password as clear text. Equivalent to the ***no parameter*** case.
  - **5** the password is an MD5-encrypted string.
  - **sha512**, the password is entered as a **sha512** encrypted string.
- ***password*** specifies the boot password.
  - ***password*** must be in clear text if ***encrypt_type*** specifies clear text.
  - ***password*** must be an appropriately encrypted string if ***encrypt_type*** specifies encryption.

Restrictions

Trident platform switches do not support the **sha512** encryption option.

Examples

- Use the following commands to set the Aboot password to `xr19v`.

```
switch(config)# boot secret xr19v
switch(config)#
```

```
switch(config)# boot secret 0 xr19v
switch(config)#
```

This command displays the result:

```
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): $1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
switch(config)#
```

The **`boot secret`** commands earlier add this line to ***boot-config***:

```
PASSWORD=$1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
```

The user must enter **`xr19v`** at the login prompt to access the Aboot shell.

- These commands set the Aboot password to ***xr123*** and display the resulting ***boot-config*** code. In the past, the encrypted string uses ***xr123*** as the clear-text seed.

```
switch(config)# boot secret 5 $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
switch(config)# show boot-config
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
switch(config)#
```

The **`boot secret`** command above adds this line to ***boot-config***:

```
PASSWORD=$1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
```

The user must enter ***xr123*** at the login prompt to access the Aboot shell.

- This command removes the Aboot password, allowing access to the Aboot shell without a password.

```
switch(config)# no boot secret
switch(config)#
```

2.7.3 boot system

The **boot system** command specifies the location of the EOS software image that Aboot loads when the switch boots. The command can refer to files on Flash or a module in the USB flash port.

Command Mode

Global Configuration

Command Syntax

boot system ***device file_path***

Parameters

- ***device*** - Location of the image file. Options include:
  - **file:** - File is located in the switch file directory.
  - **flash:** - File is located in flash memory.
  - **usb1:** - File is located on a drive inserted in the USB flash port. Available if you have a USB flash drive in the port.
  - **file_path** path and name of the file.

Examples

- This command designates ***EOS1.swi***, on USB flash memory, as the EOS software image load file.

```
switch(config)# boot system usb1:EOS1.swi
switch(config)#
```

The **boot system** command earlier adds this line to ***boot-config***.

```
SWI=usb1:/EOS1.swi
```

- This command designates ***EOS1.swi***, on the switch flash, as the EOS software image load file.

```
switch(config)# boot system flash:EOS.swi
switch(config)#
```

The **boot system** command earlier adds this line to ***boot-config***:

```
s
```

2.7.4 delete startup-config

The **`delete startup-config`** command erases or deletes the ***startup-config*** file.

Command Mode

Privileged EXEC

Command Syntax

`delete startup-config` [***confirmation***]

Parameters

confirmation confirmation for immediate erasure. Options include:

- **`no parameter`** the switch requires a confirmation before starting the erasure.
- **`now`** the erasure begins immediately without prompting the user to confirm the request.

Examples

- This command deletes the startup configuration from the switch. After entering the **`delete startup-config`** command, the switch sends a message prompting the user to confirm the request.

```
switch# delete startup-config
Proceed with erasing startup configuration? [confirm] y
switch#
```

- This command deletes the startup configuration from the switch immediately without prompting.

```
switch# delete startup-config now
switch#
```

2.7.5 protocol

The **protocol** command configures how the supervisors on a modular switch handles switchover events. By default, EOS sets the switch to **route processor redundancy (RPR)**, which synchronizes ***startup-config*** files between the supervisor modules and partially boots the standby supervisor. You can set the mode to **simplex** (manual switchover only) or to **stateful switchover (SSO)**, which synchronizes both ***startup-config*** and ***running-config*** files between the supervisor modules, fully boots the standby module to speed the switchover process, and minimizes packet loss. SSO synchronizes the L2 state between the supervisors, but the L3 state is not synchronized. This can result in traffic loss for traffic forwarded on routes learned by a dynamic routing protocol. Enabling nonstop forwarding can eliminate most packet loss for BGP and OSPF.

The **no protocol** and **default protocol** commands set the redundancy protocol to the default value (**rpr**) by removing the **protocol** command from ***running-config***.

Command Mode

Redundancy Configuration

Command Syntax

protocol {rpr | simplex | sso}

no protocol

default protocol

Parameters

- **rpr** route processor redundancy protocol (RPR, the default).
- **simplex** no redundancy. Switchover must be initiated manually.
- **sso** stateful switchover (SSO).

Related Commands

redundancy places switch in redundancy configuration mode.

Example

These commands enter Redundancy Configuration Mode and set the redundancy protocol to SSO.

```
switch(config)# redundancy
switch(config-redundancy)# protocol sso
switch(config-redundancy)#
```

2.7.6 redundancy

The **redundancy** command places the switch in Redundancy Configuration Mode.

Command Mode

Global Configuration

Command Syntax

redundancy

Commands Available in Redundancy Configuration Mode

protocol

Related Commands

redundancy manual switchover manually initiates a switchover.

Example

These commands enter Redundancy Configuration Mode and set the redundancy protocol to stateful switchover.

```
switch(config)# redundancy
switch(config-redundancy)# protocol sso
switch(config-redundancy)#
```

2.7.7 redundancy manual switchover

The **`redundancy manual switchover`** command immediately switches control of the switch to the standby supervisor. If the redundancy mode is set to simplex or the standby supervisor is unavailable for any other reason, this command will not function.

Command Mode

Privileged EXEC

Command Syntax

```
redundancy manual switchover
```

Related Command

`redundancy` places the switch in Redundancy Configuration Mode..

Example

This command forces a switchover to the standby supervisor. The switchover is executed immediately without further confirmation from the user.

```
switch# redundancy manual switchover
This supervisor will be restarted.
switch#
```

2.7.8 reload

The **reload** command power cycles the switch and resets it under Aboot control. The hard reset clears the switch, including memory states and other hardware logic.

Note: The `reload fast-boot` and `reload hitless` commands initiate Smart System Upgrade (SSU). For a description of this feature and the appropriate command syntax, refer to the Smart System Upgrade (Leaf SSU) section.

The command behaves differently in fixed and modular systems.

- **Fixed 1-RU systems** - The power supply remains powered up through the reset. All other switch components lose power for two to five seconds.
- **Modular systems** - The power supply on the active supervisor remains powered up through the reset. All other supervisor components lose power for at least one second. After the supervisor becomes functional, it manages the power-cycling of all line cards.

Command Mode

Privileged EXEC

Command Syntax

`reload` [*target*] [*confirmation*]

Parameters

- ***target*** - Specifies the supervisor(s) to reset. Some options are available only on dual-supervisor switches. Options include:
  - **no parameter** - Resets the active supervisor.
  - **all** - Resets supervisors.
  - **peer** - Resets the peer supervisor.
  - **power** - Resets the active supervisor.
- ***confirmation*** confirmation for immediate reset. Options include:
  - **no parameter** the switch requires a confirmation before starting the reset.
  - **now** the reset begins immediately without prompting the user to confirm the request.

Related Commands

- `reload (scheduled)` schedules a pending reload operation.

- `show reload cause` displays cause of most recent reload.

Examples

- Begin the reboot process by typing the **`reload`** command:

```
switch# reload
switch#
```

- After entering the **`reload`** command, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, and then asks the user to confirm the reload request. In this example, the user does not save modifications to the system before reloading.

```
System configuration has been modified. Save? [yes/no/cancel/diff]:n
Proceed with reload? [confirm]y
```

- The switch responds by broadcasting messages, including a notification about the system rebooted to all open CLI instances. The reload pauses to provide an option for the user to enter Aboot shell. The Aboot shell supports commands that restore the state of the internal flash to factory defaults or create a customized default state.

```
Broadcast message from root@mainStopping sshd: [  OK  ]
SysRq : Remount R/O
Restarting system

Aboot 1.9.0-52504.EOS2.0

Press Control-C now to enter Aboot shell
```

- No action required to continue the reset process. The switch displays messages to indicate the completion of individual tasks. The reboot completes when the CLI displays a login prompt.

```
Booting flash:/EOS.swi
Unpacking new kernel

2.7.9 reload (scheduled)

The **reload (scheduled)** command configures the switch to reset at a specified time or after a specified interval. Refer to reload for the functional details of the reset operation.

The switch prompts to save the configuration and confirm the reload request. Once confirmed, the switch resumes normal operation until the reload initiates.

The **reload cancel**, **no reload**, and **default reload** commands cancel the pending reload operation.

Command Mode

Privileged EXEC

Command Syntax

reload [**all** | **power** | peer] {**at** *hh:mm* [*month* | *day*] | **in** *hh:mm*} [**force** | **reason**]

reload cancel

no reload

default reload

Parameters

- **All** - Reloads all supervisors.
- **Power** - Resets the active supervisor.
- **Peer** - Resets the peer supervisor.
- **At** - Performs reload at specified times.
  - ***hh:mm*** - Specifies reload time in hours (0 to 23) and minutes (0 to 59). If no month and day specified, reload occurs at the specified time on the day the command is issued.
    - ***Month*** optionally specifies the month of the year (Jan, Feb, etc.)
      - ***Day*** day of the month. Values range from ***1*** to ***31***.
- **In** performs the reload after a specified delay.
  - ***hh:mm*** specifies delay before reload in hours (***0*** to ***23***) and minutes (***0*** to ***59***).
- **Force** performs action immediately without prompting.
- **Reason** enter text to display explaining the purpose of the reload.

- **`Cancel`** cancels any existing reload request.

Related Commands

- reload initiates an immediate reload operation.
- show reload displays time and reason of any pending reload operation.

Examples

- This command schedules a switch reset to begin in 12 hours.

```
switch# reload in 12:00
System configuration has been modified. Save? [yes/no/cancel/diff]:y
Proceed with reload? [confirm]
Reload scheduled for Tue Mar 27 05:57:25 2012 (in 11 hours 59 minutes)
switch#
```

- This command cancels a scheduled reset.

```
switch# no reload
Scheduled reload has been cancelled switch#
```

- This command schedules a reload of the active supervisor to begin in 12 hours.

```
switch# reload power in 12:00
Reload scheduled for Thu Feb 13 18:56:01 2020 (in 11 hours 59 minutes)
switch#
```

2.7.10 securebootctl

The **securebootctl** command in the Privileged EXEC Mode manages and displays the status of **Secure Boot** on Arista switches. Secure Boot ensures the integrity of the boot process by validating the cryptographic signature of the EOS software image before execution.

Command Mode

EXEC

Command Syntax

securebootctl secureboot [-enable | -disable | -display]

securebootctl cert [[-add *path*] -delete | -display]

securebootctl aristacert [-disable | -enable | -display]

securebootctl abootpassword [-disable | -enable | -display]

Parameters

- **securebootctl secureboot** - Enable, disable, or display information about secure boot.
- **securebootctl cert** - Add a path to a certificate on the switch and display information about the certificate. Or delete the certificate.
- **securebootctl aristacert** - Configure secure boot to use Arista certificates for validating software images before installing them on the switch.
- **securebootctl abootpassword** - Enable, disable, or display passwords for secure boot.
- **securebootctl measuredboot** - Enable, disable, or display measured boot.

Examples

Use the following command to enable secure boot:

```
Aboot# securebootctl secureboot -enable
Aboot#
```

Use the following command to add the path, /mnt/flash, to a certificate on the switch:

```
Aboot# securebootctl cert -add /mnt/flash
Aboot#
```

Use the following command to enable an Arista certificate on the switch:

```
Aboot# securebootctl aristacert -enable
Aboot#
```

Use the following command to enable a password for secure boot on the switch:

```
Aboot# securebootctl abootpassword -enable
Enter password:
Confirm password:
```

2.7.11 show platform bios

The **`show platform bios [history | detail]`** command displays the BIOS versions on the switch.

Command Mode

EXEC

Command Syntax

`show platform bios`

Examples

- This command displays the Running, Programmed, and Fallback versions of Aboot.

```
switch# show platform bios
FixedSystem BIOS versions
  Location   Version
  ---------- ----------------------------------
  Running   Aboot-norcal9-9.0.5-13882759
  Programmed Aboot-norcal9-9.0.3-4core-13882759
  Fallback   Aboot-norcal9-9.0.3-4core-13882759 switch#
```

- This command displays the BIOS installation history.

```
switch# show platform bios history
Supervisor-1 BIOS version history

Timestamp           Version
------------------- ----------------------------------
2020-04-07 04:20:22 Aboot-norcal9-9.0.5-13882759
2020-04-05 08:32:03 Aboot-norcal9-9.0.3-4core-13882759

Supervisor-2 BIOS version history

Last update failed on 2020-04-15: Compatibility check failed.

Timestamp           Version
------------------- ----------------------------------
2020-04-05 08:32:09 Aboot-norcal9-9.0.5-13882759 switch#
```

- This command displays the BIOS installation history details.

```
switch# show platform bios history detail
Supervisor-1 BIOS version history

Timestamp           Version                           Checksum
------------------- --------------------------------- ---------
2020-04-07 04:20:22 Aboot-norcal9-9.0.5-13882759      3fa8...
2020-04-05 08:32:03 Aboot-norcal9-9.0.3-4core-13882759 bb39...

Supervisor-2 BIOS version history

Last update failed on 2020-04-15: Compatibility check failed.

Timestamp           Version                           Checksum
------------------- --------------------------------- ---------
```

```

switch#
```

2.7.12 show redundancy file-replication

The **show redundancy file-replication** command displays the status and last synchronization date of file replication between the supervisors on the switch.

Command Mode

EXEC

Command Syntax

show redundancy file-replication

Related Commands

- show redundancy status displays the status and redundancy protocol of supervisors.
- show redundancy switchover sso displays the stateful switchover information since last reload.

Example

This command displays the supervisors current file replication status.

```
switch# show redundancy file-replication
0 files unsynchronized, 2 files synchronized, 0 files failed, 2 files total.

File                   Status         Last Synchronized
---------------------- -------------- -----------------------
file:persist/sys       Synchronized   25 days, 19:48:26 ago
flash:startup-config   Synchronized   25 days, 19:48:26 ago switch#
```

2.7.13 show redundancy status

The **`show redundancy status`** command displays the current status (active or standby) and the configured redundancy protocol of both supervisors, and summary information about the latest switchover event.

Command Mode

EXEC

Command Syntax

`show redundancy status`

Related Commands

- `show redundancy file-replication` displays status of file replication between supervisors.
- `show redundancy switchover sso` displays stateful switchover information since last reload.

Example

This command displays redundancy information for both supervisors and a summary of the latest switchover.

```
switch# show redundancy status
  my state = ACTIVE
peer state = STANDBY WARM
      Unit = Primary
   Unit ID = 1

Redundancy Protocol (Operational) = Route Processor Redundancy
Redundancy Protocol (Configured) = Route Processor Redundancy
Communications = Up
Ready for switchover

Last operational redundancy mode change time = 2:17:51 ago
Last operational redundancy mode change reason = Supervisor has control of the active supervisor
 lock
Last peer switchover time = never
Last peer switchover cause = None
```

2.7.14 show redundancy switchover sso

The **show redundancy switchover sso** command displays the number of stateful switchovers since the last reload and a log of the events in the latest stateful switchover.

Command Mode

EXEC

Command Syntax

show redundancy switchover sso

Related Commands

- show redundancy file-replication displays the status of file replication between supervisors.
- show redundancy status displays the status and redundancy protocol of supervisors.

Example

This command displays the stateful switchover information.

```
switch# show redundancy switchover sso
Total number of Stateful Switchover completed since reload: 4

Latest Stateful Switchover occured 29 days, 12:48:22 ago @ 2012-06-09 19:47:50
(completed)
  0.000000: switchover started
  0.000235: stage PCIEAcquired started
  0.000349:   event PCIEAcquired:__dummyInternal1__ completed
  0.000394:   event PCIEAcquired:PlxPcie-system started
  0.027738:   event PCIEAcquired:PlxPcie-system completed
  0.027829: stage PCIEAcquired is complete
  0.027935: stage DmaReady started
  0.028042:   event DmaReady:ForwardingAgent started
  0.079620:   event DmaReady:ForwardingAgent completed
  0.079699: stage DmaReady is complete
  0.079781: stage TimeCriticalServices started
  0.079887:   event TimeCriticalServices:__dummyInternal1__ completed
  0.079928:   event TimeCriticalServices:Stp started
  0.208035:   event TimeCriticalServices:Stp completed
  0.208120: stage TimeCriticalServices is complete
              <-------OUTPUT OMITTED FROM EXAMPLE------->
 39.675076: stage NonCriticalServices started
 39.675145:   event NonCriticalServices:__dummyInternal1__ completed
 39.675183: stage NonCriticalServices is complete
 39.675399: switchover is complete switch#
```

2.7.15 show reload

The **show reload** command displays the time and reason for any pending reload operation. The reload (scheduled) command schedules a reload operation and can be used to cancel a pending reload.

Command Mode

EXEC

Command Syntax

show reload

Related Commands

- reload (scheduled) schedules a pending reload operation.
- show reload cause displays cause of most recent reload.

Example

These commands schedule a reload for 2:45 pm, display the time of the pending reload, and then cancel the scheduled reload.

```
switch# reload at 14:45
Proceed with reload? [confirm]
Reload scheduled for Tue Mar 27 14:45:00 2012 ( in 4 hours 11 minutes )
switch# show reload
Reload scheduled for Tue Mar 27 14:45:00 2012 ( in 4 hours 11 minutes )
switch# reload cancel
Scheduled reload has been cancelled switch#
```

2.7.16 show reload cause

The **show reload cause** command displays the reason for the most recent reload operation. The command displays recommended actions and debug information related to the executed reload.

Command Mode

EXEC

Command Syntax

show reload cause

Related Commands

- reload initiates an immediate reload operation.
- show reload displays time and reason of all pending reload operations.

Example

This command displays the cause of the most recent reload operation.

```
switch# show reload cause
Reload Cause 1:
-------------------
Reload requested by the user.

Recommended Action:
-------------------
No action necessary.

Debugging Information:
----------------------
None available.
switch#
```

2.7.17 show reload fast-boot

The **`show reload fast-boot`** command verifies that the switch configuration is valid for Smart System Upgrade (SSU).

Command Mode

EXEC

Command Syntax

`show reload fast-boot`

Related Commands

- `reload` initiates an immediate reload operation.
- `show reload` displays time and reason of all pending reload operations.

Example

This command displays why SSU cannot be initiated and which features must be reconfigured to allow SSU to proceed.

```
switch# show reload fast-boot
'reload fast-boot' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports switch#
```

Chapter 3

Initial Configuration and Recovery

This chapter describes initial configuration and recovery tasks. Subsequent chapters provide details about features introduced in this chapter.

This chapter contains these sections:

- Initial Switch Access
- Connection Management
- Securely Erasing a Switch Storage Device
- Configuration Sessions Overview
- Using Service Commands in EOS
- Recovery Procedures
- Session Management Commands

3.1 Initial Switch Access

Arista network switches provide two initial configuration methods:

- Zero Touch Provisioning (ZTP) configures the switch without user interaction.
- Manual provisioning configures the switch with commands entered by a user through the CLI.

3.1.1 Zero Touch Provisioning

Zero Touch Provisioning (ZTP) configures a switch without user intervention by downloading a startup configuration file, ***startup-config***, or a boot script from a location specified by a DHCP server. Configuring the Network for ZTP describes network tasks required to set up ZTP.

If the flash memory does not contain a **`startup-config`** or **`zerotouch-config`** file, the switch enters ZTP mode when it boots . It remains in ZTP mode until you cancel ZTP mode or until the switch retrieves a ***startup-config*** or a boot script. After downloading a file through ZTP, the switch reboots again, using the retrieved file.

Security Considerations

The ZTP process cannot distinguish an approved DHCP server from a rogue DHCP server. For secure provisioning, you must ensure that only approved DHCP servers can communicate with the switch until

after completing the ZTP process. Arista also recommends validating the EOS image on your ZTP server by confirming that the MD5 checksum matches the MD5 checksum found on the EOS download page of the Arista website.

On a UNIX server, the **md5sum** command calculates this checksum:

```
% md5sum EOS.swi
3bac45b96bc820eb1d10c9ee33108a25  EOS.swi
```

Use this command from the CLI or within the Bash shell of a switch.

```
switch# bash md5sum /mnt/flash/EOS-4.18.0F.swi
73435f0db3af785011f88743f4c01abd  /mnt/flash/EOS-4.18.0F.swi

switch#[admin@switch ~]$ md5sum /mnt/flash/EOS-4.18.0F.swi
73435f0db3af785011f88743f4c01abd /mnt/flash/EOS-4.18.0F.swi
[admin@switch ~]$
```

To provision the switch through ZTP, use the following steps:

1. Mount the switch in a permanent location.
2. Connect at least one management or Ethernet port to a network that can access the DHCP server and the configuration file.
3. Provide power to the switch.

Note: ZTP does not initiate if flash memory contains either a ***startup-config*** or ***zerotouch-config*** file.

You can monitor the ZTP progress on the console port. The Console Port section provides information for setting up the console port. Canceling Zero Touch Provisioning provides information for monitoring ZTP progress and canceling ZTP mode.

3.1.2 Manual Provisioning

Initial manual switch provisioning requires the cancellation of ZTP mode, the assignment of an IP address to a network port, and the establishment of an IP route to a gateway. The serial console and Ethernet management ports perform the initial provisioning.

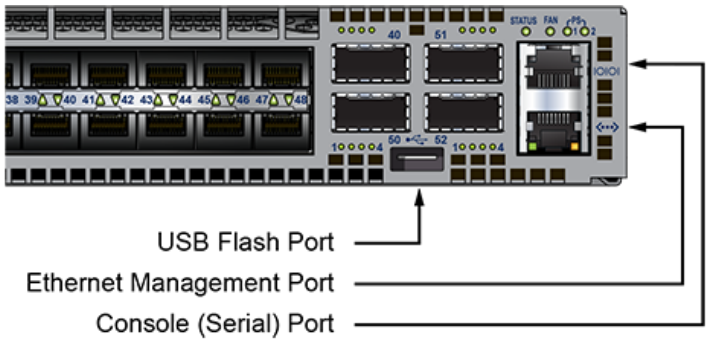
- Use the console port for serial access to the switch. These conditions may require serial access:
  - Management ports do not have assigned IP addresses.
  - The network is inoperable.
  - Unavailable password for the user's login.
  - The password to access the *enable* mode is not available.

- It uses the Ethernet management ports for out-of-band network management tasks. That port must have IP address before using a management port for the first time.

3.1.2.1 Console Port

The console port is a serial port located on the front of the switch. The Figure 3-1: Switch Ports section displays the console port on the DCS-7050T-64 switch. Use a serial or RS-232 cable to connect to the console port. The accessory kit also includes an RJ-45 to DB-9 adapter cable connecting to the switch.

Figure 3-1: Switch Ports



Port Settings

Use these settings when connecting the console port:

- 9600 baud
- no flow control
- 1 stop bit
- no parity bits
- 8 data bits

Admin Username

The initial configuration provides one username, **admin**, without an assigned password. You can only log into the switch through the console port using the admin username without a password. After assigning a password to the **admin** username, log into the switch through any port.

The username command modifies a specified username and can be used to create or delete usernames, including **admin**.

Example

This command assigns the password **pxq123** to the **admin** username:

```
switch(config)# username admin secret pxq123
switch(config)#
```

When the switch reboots, EOS loses the passwords unless the startup configuration saves the new or altered passwords.

Note: Access the Aboot shell through the console port to log into the switch after deleting usernames from the configuration.

3.1.2.2 Canceling Zero Touch Provisioning

Zero Touch Provisioning (ZTP) installs a ***startup-config*** file from a network location if flash memory does not contain a ***startup-config*** or ***zerotouch-config*** file when the switch reboots. Canceling ZTP is required if the switch cannot download a ***startup-config*** or boot script file.

When the switch boots without a ***startup-config*** or ***zerotouch-config*** file, EOS displays the following message through the console port:

```
No startup-config was found.

The device is in Zero Touch Provisioning mode and is attempting to
download the startup-config from a remote system. The device will not
be fully functional until a valid startup-config is downloaded
from a remote system or Zero Touch Provisioning is cancelled. To cancel
Zero Touch Provisioning, login as admin and type 'zerotouch cancel'
at the CLI.

localhost login:
```

To cancel ZTP mode, log into the switch with the **admin** password, then enter the **zerotouch cancel** command. The switch immediately boots without installing a ***startup-config*** file.

```
localhost login: admin
admin
localhost>Apr 15 21:28:21 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP
request on  [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18,

Restarting system

Aboot 1.9.0-52504.EOS2.0
Press Control-C now to enter the Aboot shell
```

To avoid entering ZTP mode on subsequent reboots, create a ***startup-config*** file described in **Step 8** of the Ethernet Management Port.

3.1.2.3 Ethernet Management Port

Arista switches provide one or more Ethernet management ports for configuring the switch and managing the network out of the band. The Figure 3-1: Switch Ports section displays the location of the Ethernet management ports on a DCS-7050T-64 switch. Managing the switch requires only one port.

Access the Ethernet management port(s) remotely over a common network or locally through a connected PC. Before you can access the switch through a remote connection, the switch must have an IP address and a static route to the default gateway. Configure a virtual IP address on a modular switch with dual supervisors to access the management port on an active supervisor.

Assigning a Virtual IP Address to Access the Active Ethernet Management Port

This procedure assigns a virtual IP address on modular switches with dual supervisors, which connects to the Ethernet management port of the active supervisor. See the following section to assign a physical IP address to an Ethernet management port.

1. Connect a PC or terminal server to the console port. Use the settings listed in Console Port under Port Settings.

2. Use the command **admin** at the login prompt to log into the switch. Initial login through the console port does not require a password.

```
Arista EOS
switch login: admin
Last login: Fri Apr 9 14:22:18 on Console switch>
```

3. Use the command **enable** at the command prompt to enter Privileged EXEC mode.

```
switch> enable
switch#
```

4. Use the command **configure terminal** or **config** to enter global configuration mode.

```
switch# configure terminal
switch(config)#
```

5. Use the command **interface management 0** to enter interface configuration mode for the virtual interface that accesses management port 1 on the currently active supervisor.

```
switch(config)# interface management 0
switch(config-if-Ma0)#
```

6. Use the command **ip address**, followed by the desired address, to assign a virtual IP address to access to the active management port. This command assigns IP address 10.0.2.5 to management port 0.

```
switch(config-if-Ma0)# ip address 10.0.2.5/24
```

7. Use the command **exit** at both the interface and global configuration prompts to return to ***Privileged EXEC*** mode.

```
switch(config-if-Ma0)# exit
switch(config)# exit
switch#
```

8. Use the command **`write`** (or **`copy running-config startup-config)`** to save the new configuration to the ***startup-config*** file.

```
switch# write
switch#
```

Assigning an IP Address to a Specific Ethernet Management Port

Use the following steps to assign an IP address to a specific Ethernet management port:

1. Connect a PC or terminal server to the console port. Use the settings listed in Console Port under Port Settings.

2. Use the command **`admin`** at the login prompt to log into the switch. The initial login does not require a password.

```
Arista EOS
switch login: admin
Last login: Fri Apr 9 14:22:18 on Console switch>
```

3. Use the command **`enable`** at the command prompt to enter Privileged EXEC mode.

```
switch> enable
switch#
```

4. Use the command **`configure terminal`** (or **config**) to enter Global Configuration Mode.

```
switch# configure terminal
```

5. Use the command **`interface management 1`** to enter Interface Configuration Mode. Use the available management port for management port 1.

```
switch(config)# interface management 1
switch(config-if-Ma1)#
```

6. Use the command **`ip address`**, followed by the desired address, to assign an IP address to the port. This command assigns the IP address 10.0.2.8 to management port 1.

```
switch(config-if-Ma1)# ip address 10.0.2.8/24
```

7. Use the command **exit** at the Interface and Global Configuration Mode prompts to return to Privileged EXEC mode.

```
switch(config-if-Ma1)# exit
switch(config)# exit
switch#
```

8. Use the command **write** (or **copy running-config startup-config)** to save the new configuration to the ***startup-config*** file.

```
switch# write
switch#
```

Configuring a Default Route to the Gateway

Use the following steps to configure a default route to a gateway located at 10.0.2.1.

1. Enter global configuration mode.

```
switch> enable
switch# configure terminal
```

2. Create a static route to the gateway with the IP route command.

```
switch(config)# ip route 0.0.0.0/0 10.0.2.1
```

3. Save the new configuration.

```
switch# write
switch#
```

3.2 Connection Management

The switch supports three connection methods:

- Console
- SSH
- Telnet

The switch always enables the console and SSH. By default, EOS disables Telnet.

Management commands place the switch in a configuration mode to change session connection parameters.

Examples

- The management console command places the switch in Console Management Mode:

```
switch(config)#management console
```

```
switch(config-mgmt-console)#
```

- The management ssh command places the switch in SSH Management Mode:

```
switch(config)#management ssh
switch(config-mgmt-ssh)#
```

- The management telnet command places the switch in Telnet Management Mode:

```
switch(config)#management telnet
switch(config-mgmt-telnet)#
```

- The **exit** command returns the switch to global configuration mode:

```
switch(config-mgmt-ssh)#exit
switch(config)#
```

The `idle-timeout` commands shown in the following examples configure the idle timeout period for the configured connection type. The idle timeout defines the wait for a connection after a recent command before shutting down the connection. Setting the idle timeout to zero automatically disables the connection timeout, the default setting.

Examples

- The idle-timeout (SSH Management) command configures an SSH idle-timeout period of three hours.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# idle-timeout 180
```

- The idle-timeout (Telnet Management) command automatically disable the connection timeout for Telnet connections.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# idle-timeout 0
```

The shutdown (Telnet Management) command turns the Telnet on and off on the switch.

- These commands enable Telnet.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# no shutdown
```

- These commands disable Telnet.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# shutdown
```

3.3 Securely Erasing a Switch Storage Device

The Secure Erase feature completely wipes all data from the flash and optional SSD storage devices. It targets partitions mounted at /mnt/crash, /mnt/flash, and /mnt/drive (if present), securely erasing them. After erasing the data, it restores the original partition structure, destroys the Master Boot Record (MBR), and recreates the file systems, labels, and mount points with the same options. The **EOS.swi** and the **boot-config** files must be manually reinstalled afterwards, followed by a reboot using Aboot or the full recovery process.

All secure erasing is best effort. Use firmware-based secure erase when available and a software-based mechanism when the firmware mechanism might fail or be insufficient such as writing random data after sending an ATA Secure Erase command or does not exist. Unfortunately, no non-physically destructive mechanism can guarantee the destruction of all data on a storage device.

Note: Certain Arista switches have a dedicated storage device for serial console logging. The console output contains sensitive data, and the switch does not secure erasing this storage device. Locate platform support and usage information regarding serial console here.

Preparing for Secure Erase

Always connect to the switch or supervisor through the serial console before executing the **`reset system storage secure`** command. This command leaves the switch in Aboot mode, which is only accessible via the serial console. If the system has dual supervisors, Secure Erase can only be run on the standby supervisor or when redundancy is disabled (Simplex redundancy) or the command will fail. After execution, access the switch through the serial console to complete the recovery process.

Performing Secure Erase

To securely erase the flash and optional SSD storage device(s) on supported platforms, use the `reset system storage secure` command.

Examples

- The following commands check the redundancy status of the supervisor to be erased, then perform a switchover to change its status to **`standby`** preparatory to initiating the secure erase:

```
switch# show redundancy status
  my state = ACTIVE
peer state = STANDBY WARM
      Unit = Primary
   Unit ID = 1

Redundancy Protocol (Operational) = Route Processor Redundancy
Redundancy Protocol (Configured) = Route Processor Redundancy
Communications = Up
Ready for switchover

Last operational redundancy mode change time = 2:17:51 ago
Last operational redundancy mode change reason = Supervisor has control of the active
 supervisor lock
Last peer switchover time = never
Last peer switchover cause = None
switch#
switch# redundancy manual switchover
This supervisor will be restarted.
```

- Example of error output when attempting to use **Secure Erase** in the active supervisor with redundancy enabled.

```
switch# reset system storage secure
! ERROR! Cannot reset system storage
on the active supervisor while another
supervisor is on standby.
```

- The following command securely erases data stored on the switch, excluding dedicated console logging storage. The **Secure Erase** process does not restore or reinstall the EOS, that is, it doesn't copy the `EOS.swi` and boot-config files.

```
switch#reset system storage secure
WARNING! This will destroy all
data and will NOT be recoverable.
Device will reboot into Aboot, and
execution may take up to one hour.
```

```
Would you like to proceed? [y/N] y

Aboot# pwd
/mnt/flash
Aboot# ls -l
drwxrwxr-x    3 root     eosadmin      4096 Jul 21 10:23 aboot
drwxrwx---    2 root     eosadmin     16384 Jul 21 10:21 lost+found

drwxr-xr-x    2 root     eosadmin      4096 Jul 21 10:23 tpm-data
```

3.4 Configuration Sessions Overview

The **configure session** command creates a configuration session for CLI commands and ends it after issuing the **commit** command. Each **configure session** has a unique name. You can enter, modify, and exit the session anytime without impacting the currently running system configuration.

While in the commit stage of a session, the ***running-config*** command creates copies of the modified configuration of the session, overwriting any other configuration changes made since creating the session. A session can be aborted or removed, which removes the session completely and frees up memory used by the session. You must explicitly request the changes in a deferred session to the switch configuration by entering a **commit** command and exiting the mode. Alternatively, abandon the changes by entering an **abort** command. The switch discards an uncommitted configuration session if the switch reboots and the session times out after 24 hours.

Configuration sessions implement the changes after verifying that no configuration errors occur. Configuration sessions allow the administrator to pre-provision a group of CLI commands in a named session and execute each configuration session at specified times.

Note: Committing a configuration session replaces the ***running-config*** with the session configuration which includes the running configuration at the initial session and the commands entered as part of the session. Any changes made to ***running-config*** since the initiation of the session overwrite the session during the commit stage.

3.4.1 Configuration Session

The **configure session** command allows you to execute a series of configuration changes in a temporary location and commit them to ***running-config*** by issuing the **commit** command.

- **configure session <name of session>** and ***running-config***: The user enters a session (versus **configure terminal** where configuration sessions are not used). It creates a system-named session if a session name is not specified, and it copies a snapshot of the current ***running-config*** into the session's data structure as the basis of further configuration changes.
- CLI configuration commands - The user can run any commands inside the session.
- **rollback clean-config** - The user can run the **rollback** command to revert the session configuration to the factory-default configuration (or clean configuration).

- **`show session-config`** - The user can run **`show session-config`** to show the session configuration, which will be the future ***running-config*** after committing.
- **`commit`** - Issues the **`commit`** command to commit the changes and replace the current ***running-config***.
- **`abort`** - Abort the session and discard all changes.
- **`exit`** - **exit** from the session and return to the same session by running the **`configure session`** again.
- For a named session, more than one CLI instance can enter the same session and change the session configuration. After the session commits in any of the CLIs, no other CLI can commit or make any other changes in that session.

Note: Committing a configuration session replaces ***running-config*** with the session configuration, which consists of the running configuration at the initial session and the commands entered as part of the session. Any changes made to ***running-config*** since the initiation of the session overwrite when the session is in the commit stage.

3.4.2 Replacing the Configuration

The command **`configure replace URL`** replaces the current ***running-config*** with the configuration saved in a **URL**. By default, the configuration in the **`configure replace URL`** replaces ***running-config*** only if the configuration in the URL loads without errors. The command **`configure replace URL ignore-errors`** force the operation even if there are errors.

Note: The command **`copy`** ***URL*** **`running-config`** applies a saved configuration file to the system and appends that configuration to the current ***running-config*** instead of replacing it. However, Arista recommends using the command **`configure replace`** ***URL*** to streamline the process of restoring the system to a known good configuration.

The normal workflow uses a configuration session to perform the **`configure replace`**.

3.4.3 Configuration CLI

In the CLI, execute the following configuration steps to create a configuration session.

1. **`configure session`** [*name of session*]

   Create or enter a session. If a name is not specified, it automatically generates. The user is in the session configuration mode, and the prompt will change to show the first six characters of the session name. Designating the name of a session is optional. When the *name of session* is not specified, a unique name is assigned.

   ```
   no configure session  name of session
   ```

   Delete the specified configuration session. Designating the name of a session is required.

2. **`commit`**

   Commit the changes made in the session. Configuration mode issues this command within the session.

   ```
   abort
   ```

Abort the session, which is the same as deleting it. Configuration mode issues this command within the session.

3. **`rollback clean-config`**

   Revert the configuration in the session to the clean, factory-default configuration. Configuration mode issues this command within the session.

4. **`service configuration session max completed`** *number*

   Sets a limit on the maximum number of saved committed sessions.

5. **`service configuration session max pending`** *number*

   Sets a limit on the maximum number of uncommitted sessions that can be outstanding.

3.4.4 Using Service Commands in EOS

In Arista EOS, **`service`** commands act as global master switches. Unlike standard interface or routing commands that define *what* the network should do, **`service`** commands interact directly with the underlying Linux kernel and system manager (Sysdb) to dictate *how* the switch operates under the hood. They control daemon architecture, hardware resource allocation, and how the command-line parser interprets syntax. The commands control the following areas in EOS:

- **Routing and Control Plane Architecture** - The **`service routing`** commands dictate how the switch processes complex routing and handles control-plane memory.

Command	Function
`service routing protocols model multi-agent`	Shifts the switch from a legacy monolithic routing process (`ribd`) to Arista's decoupled, high-scale "ArBGP" architecture.
`service routing configuration bgp no-equals-default`	Scrubs default configuration commands from the running configuration to keep the CLI output clean.
`service routing configuration route-map no-set-community explicit members`	Allows you to surgically remove a single BGP community from a list in a route-map, rather than forcing the rewrite of the entire line.

- **Configuration Management and Change Control** - The **`service configuration`** commands manage the interactions between an administrator and the switch as well as manage rolling back configurations.

Command	Function
`service configuration terminal disabled`	Disables standard live configuration. Forces all users and scripts to use `configure session` to stage and review changes before committing them.
`service configuration session max pending` ***number***	Limits how many uncommitted staging workspaces can be open concurrently.
`service configuration session max completed` ***number***	Defines how deep the historical archive goes for saving successfully committed sessions and their exact CLI diffs.
`service configuration checkpoint max` ***number***	Adjusts the retention limit for full-system configuration snapshots.

- **Hardware and Interface Management** - The **`service interface`** commands interact directly with the physical ASICs, port allocation, and optical transceivers on the switch.

Command	Function
service interface inactive port-id allocation disabled	Reclaims hardware resources on high-density modular chassis by preventing the switch from assigning internal Port IDs to physically down or unprovisioned interfaces.
service interface shutdown default	Changes the factory default behavior so that all unconfigured ports are placed in an administratively down state.
service interface shutdown delay ***seconds***	Introduces a physical hardware buffer between typing `shutdown` and the port actually dropping, allowing routing protocols to gracefully reroute traffic.

3.5 Using Service Commands in EOS

In Arista EOS, **`service`** commands act as global master switches. Unlike standard interface or routing commands that define *what* the network should do, **`service`** commands interact directly with the underlying Linux kernel and system manager (Sysdb) to dictate *how* the switch operates under the hood. They control daemon architecture, hardware resource allocation, and how the command-line parser interprets syntax. The commands control the following areas in EOS:

- **Routing and Control Plane Architecture** - The **`service routing`** commands dictate how the switch processes complex routing and handles control-plane memory.

Command	Function
service routing protocols model multi-agent	Shifts the switch from a legacy monolithic routing process (`ribd`) to Arista's decoupled, high-scale "ArBGP" architecture.
service routing configuration bgp no-equals-default	Scrubs default configuration commands from the running configuration to keep the CLI output clean.
service routing configuration route-map no-set-community explicit members	Allows you to surgically remove a single BGP community from a list in a route-map, rather than forcing the rewrite of the entire line.

- **Configuration Management and Change Control** - The **`service configuration`** commands manage the interactions between an administrator and the switch as well as manage rolling back configurations.

Command	Function
service configuration terminal disabled	Disables standard live configuration. Forces all users and scripts to use `configure session` to stage and review changes before committing them.
service configuration session max pending ***number***	Limits how many uncommitted staging workspaces can be open concurrently.
service configuration session max completed ***number***	Defines how deep the historical archive goes for saving successfully committed sessions and their exact CLI diffs.
service configuration checkpoint max ***number***	Adjusts the retention limit for full-system configuration snapshots.

- **Hardware and Interface Management** - The **`service interface`** commands interact directly with the physical ASICs, port allocation, and optical transceivers on the switch.

Command	Function
`service interface inactive port-id allocation disabled`	Reclaims hardware resources on high-density modular chassis by preventing the switch from assigning internal Port IDs to physically down or unprovisioned interfaces.
`service interface shutdown default`	Changes the factory default behavior so that all unconfigured ports are placed in an administratively down state.
`service interface shutdown delay` ***`seconds`***	Introduces a physical hardware buffer between typing `shutdown` and the port actually dropping, allowing routing protocols to gracefully reroute traffic.

3.6 Recovery Procedures

These sections describe the following switch recovery procedures:

- Removing the Enable Password from the Startup Configuration
- Reverting the Switch to the Factory Default Startup Configuration
- Restoring the Factory Default EOS Image and Startup Configuration
- USB Support for ZeroTouch Provisioning
- Restoring the Configuration and Image from a USB Flash Drive

The first three procedures require Aboot Shell access through the console port. If the console port becomes inaccessible, use the last procedure in the list to replace the configuration file through the USB Flash Drive.

The Removing the Enable Password from the Startup Configuration section describes the switch booting process and includes descriptions of the Aboot shell, Aboot boot loader, and required configuration files.

3.6.1 Removing the Enable Password from the Startup Configuration

The **`enable password`** controls access to Privileged EXEC mode. The switch stores the **enable password** as an encrypted string generated from the clear-text password to prevent unauthorized disclosure. When using local switch authentication mode and a configured **`enable password`**, the CLI prompts to enter the clear-text password after entering the **`enable`** command at the EXEC prompt.

The ***startup-config*** file stores the encrypted **`enable password`** to ensure the switch loads it when rebooting. If the text version of the **`enable password`** is lost or forgotten, restore access to enable mode by removing the encrypted **`enable password`** from the startup configuration file.

Note: During the recovery process, the secondary supervisor must be physically removed from the system containing more than one supervisor. It ensures that the switch does not recover the previous configuration from the secondary supervisor upon reboot during the recovery process.

This procedure restores access to enable mode without changing any other configuration settings.

1. Access the Aboot shell:
   a. Power cycle the switch by successively removing and restoring access to its power source.
   b. Enter **Ctrl-C** when prompted early in the boot process.
   c. Enter the Aboot password if prompted. If you do not know the Aboot password, refer to Restoring the Factory Default EOS Image and Startup Configuration for instructions on reverting all flash directory contents to the factory default, including the startup configuration and EOS image.
2. Change the active directory to the **/mnt/flash** directory.

```
Aboot# cd /mnt/flash
```

3. Open the startup-config file using VI or emacs.

```
Aboot# vi startup-config
```

4. Remove the enable password line.

```
enable password 5 $1$dBXo2KpF$Pd4XYLpI0ap1ZaU7glG1w/
```

5. Save the changes and exit vi.
6. Exit Aboot. The switch reboots.

```
Aboot# exit
```

3.6.2 Reverting the Switch to the Factory Default Startup Configuration

The ***startup-config*** file contains configuration parameters that the switch uses during a boot. Parameters that do not appear in the ***startup-config*** set to factory defaults when the switch reloads. The process requires the Aboot password if Aboot is password protected.

This procedure reverts EOS configuration settings to default by bypassing the ***startup-config*** file during a switch boot.

1. Access the Aboot shell through the console port:
   a. Enter reload at the Privileged EXEC prompt.
   b. Enter **Ctrl-C** when prompted early in the boot process.
   c. Enter the Aboot password if prompted. If you do not know the Aboot password, refer to Restoring the Factory Default EOS Image and Startup Configuration for instructions on reverting all flash directory contents to the factory default, including ***startup-config*** and EOS image.
2. Change the active directory to the **/mnt/flash** directory.

```
Aboot# cd /mnt/flash
```

3. Rename the startup configuration file.

```
Aboot# mv startup-config startup-config.old
```

4. Exit Aboot. This boots the switch.

```
Aboot# exit
```

5. Cancel Zero Touch Provisioning (ZTP). Refer to Canceling Zero Touch Provisioning for instructions.
   For non-canceled ZTP, the switch performs one of the following actions:
   - Boots using the ***startup-config*** file or boot script that it obtains from the network, or
   - Remains in ZTP mode if the switch cannot download a ***startup-config*** file or boot script.
6. Configure the **admin** and **enable** passwords.

```
switch> enable
switch# configure terminal
switch(config)# enable password xyz1
switch(config)# username admin secret abc41
```

7. Save the new ***running-config*** to the startup configuration file.

```
switch# write
```

8. (Optional) Delete the old startup configuration file.

```
switch# delete startup-config.old
```

After canceling ZTP, the switch reboots using the factory default settings and to avoid entering ZTP mode on subsequent reboots, create a ***startup-config*** file before the next switch reboot.

3.6.3 Restoring the Factory Default EOS Image and Startup Configuration

A **`fullrecover`** command removes all internal flash contents including configuration files, EOS image files, and user files, and then restores the factory default EOS image and ***startup-config***. When the default image becomes outdated, the switch requires a subsequent installation of the current EOS image. This process requires Aboot shell access through the console port.

Note: For hardware available after June 2017, the factory default partition does not contain the backup EOS software image. It increases the flash size on smaller flash disks. Other options are available in the **`fullrecover`** command functionality to restore the factory default EOS image. It applies to both fixed system and modular system hardware.

This procedure restores the factory default EOS image and startup configuration.

1. Access the Aboot shell through the console port:
   a. Enter reload at the Privileged EXEC prompt.
   b. Enter **Ctrl-C** when prompted early in the boot process.
   c. Enter the Aboot password if prompted. If you do not know the Aboot password, enter an empty password three times, after which the CLI displays:

```
Type "fullrecover" and press Enter to revert /mnt/flash to factory default state, or just
 press Enter to reboot:
```

   d. Type **fullrecover** and go to 4.
2. Enter **fullrecover** at the Aboot prompt.

```
Aboot#fullrecover
```

Aboot displays this warning:

```
All data on /mnt/flash will be erased; type "yes" and press Enter to proceed, or just press
 Enter to cancel:
```

3. Enter **yes** and press the **Enter** key.
   The switch performs one of the following actions:
   - Erases the contents of **/mnt/flash**.
   - Writes new boot-config, startup-config, and EOS.swi files to **/mnt/flash**.
   - Returns to the Aboot prompt.
4. Exit Aboot.The switch reboots.

```
Aboot#exit
```

   The serial console settings restore to their default values (9600/N/8/1/N).
5. Reconfigure the console port if you require non-default settings.
6. Cancel Zero Touch Provisioning (ZTP). Refer to Canceling Zero Touch Provisioning for instructions.
   If you do not cancel ZTP, the switch does one of the following:
   - Boots, using the ***startup-config*** file or boot script that it obtains from the network or
   - Remains in ZTP mode if the switch cannot download a ***startup-config*** file or boot script.

   When you cancel ZTP, the switch reboots using the factory default settings. To avoid entering ZTP mode on subsequent reboots, create a ***startup-config*** file before the next switch reboot.

3.6.4 USB Support for ZeroTouch Provisioning

Use Arista's Zero Touch Provisioning to configure a switch without user intervention. The USB adds another way to provide the bootstrap name and verify the authenticity of the file server.

3.6.4.1 USB Deployment

When using a USB drive during ZTP, configure the following features:

1. Specify the location of the bootstrap file instead of using DHCP Option 67.
2. Provide the ***x509*** root of trust for verifying the bootstrap download location.
3. Provide the enrollment token for CloudVision Service customers.

3.6.4.2 Configuration

Plug in a USB flash drive containing a *yaml configuration* file into the Arista EOS switch before powering it on.

The configuration (**<USB-ROOT>/ztp/ztpConfig.yaml**) should look like this:

```
"bootstrapUrl"
"serverCaCertificate"
"enrollmentToken"
```

```
"version": "1.0"
```

bootstrapUrl - The URL for bootstrap file, such as **`https://cvp/config.py`**.

```
"bootstrapUrl"
```

serverCaCertificate - The path for the ***x509*** root of trust on the remote file server on the USB, such as **`"ca.crt"`**.

```
"serverCaCertificate"
```

enrollmentToken - The path for the enrollment token on the USB, such as **`"token.tok"`**

```
"enrollmentToken"
```

All ZTP related files, **`serverCaCertificate`** and **`enrollmentToken`**, should be present in (**`<USB-ROOT>/ztp/* ),`** and the location specified in the ztpConfiguration **`yaml w.r.t`** to this folder.

```
"version": "1.0"
```

All the fields are optional. The following example displays a valid configuration. It performs as if no USB in place.

```
"bootstrapUrl"
"serverCaCertificate"
"enrollmentToken"
"version": "1.0"
```

- The following is a sample of the configuration. Use the following structure for the USB drive:
- USB Drive Roo
  - **`ca.crt`**
  - **`token.tok`**

```
"bootstrapUrl"
"serverCaCertificate"
"enrollmentToken"
"version": "1.0"
```

3.6.4.3 Advantages of USB ZTP

- DHCP Server no longer need to configure Option 67.
- The boot script location can now undergo additional checks, such as validating the endpoint before downloading and running the boot script.
- If you want to enroll your devices with the CloudVision Service can do so easily.

3.6.5 Restoring the Configuration and Image from a USB Flash Drive

The USB flash drive port restores an original configuration when you cannot establish a connection to the console port. This process removes the contents of the internal flash drive, restores the factory default configuration, and installs a new EOS image from the USB flash drive.

This procedure restores the factory default configuration and installs an EOS image stored on a USB flash drive.

1. Prepare the USB flash drive:
   a. Verify the drive has a MS-DOS or FAT file system format. Most USB drives ship with a pre-formatted with a compatible file system.
   b. Create a text file named **fullrecover** on the USB flash drive. The filename does not have an extension. The file may be empty.
   c. Create a text file named **boot-config**. The last modified timestamp of the **boot-config** file on the USB flash must differ from the timestamp of the **boot-config** file on the switch.
   d. Enter this line in the new **boot-config** file on the USB flash:

      ```
      SWI=flash:EOS.swi
      ```

   e. Copy an EOS image file to the flash drive. Rename it **EOS.swi** if it has a different file name. For best results, the flash drive should contain only these three files because the procedure copies all files and directories on the USB flash drive to the switch.
      - fullrecover
      - boot-config
      - EOS.swi
2. Insert the USB flash drive into the USB flash port on the switch, as shown in Figure 3-1: Switch Ports.
3. Connect a terminal to the console port and configure it with the default terminal settings (9600/N/8/1) to monitor progress messages on the console.
4. Power up or reload the switch.

   The switch erases internal flash contents and copies the files from the USB flash drive to internal flash. The switch then boots automatically.
5. Cancel Zero Touch Provisioning (ZTP). Refer to Canceling Zero Touch Provisioning for instructions.

   If ZTP is not canceled, the switch either:
   - Boots, using the startup-config file or boot script that it obtains from the network or
   - Remains in ZTP mode if the switch cannot download a ***startup-config*** file or boot script.

   After canceling ZTP, the switch reboots using the factory default settings to avoid entering ZTP mode on subsequent reboots and creates a ***startup-config*** file before the next switch reboot.

3.7 Session Management Commands

Global Configuration Commands

- commit timer
- configure replace
- configure session
- management accounts
- management api eos-sdk-rpc
- management api external-services
- management api gnmi
- management api gnsi
- management api gribi
- management api http-commands
- management api models
- management api netconf
- management api restconf
- management archive
- management cli
- management client
- management console
- management data source
- management defaults
- management dmf
- management file-systems
- management http-server
- management ldap group
- management ldap server
- management package
- management security auto-certificate
- management security entropy
- management security network

- management security password
- management security session
- management security signature-verification
- management security ssl
- management nic profiles
- management ssh
- management telnet
- reset system storage secure

Service Configuration Commands

- service configuration access-list
- service configuration checkpoint
- service configuration session commit
- service configuration session logging
- service configuration session max
- service configuration terminal
- service configuration verification
- service interface inactive
- service interface shutdown
- service interface unconnected
- service routing configuration
- service running-config

Management Configuration Commands

- authentication x509
- authentication
- authorized-principals
- cipher
- compression
- connection
- fips
- hostkey
- idle-timeout (Console Management)

- idle-timeout (SSH Management)
- idle-timeout (Telnet Management)
- ip
- ipv6
- key-exchange
- log-level
- logging
- login
- mac
- protocol http (API Management)
- protocol https (API Management)
- protocol https certificate (API Management)
- qos
- rekey
- server-port
- session-limit
- shutdown (API Management)
- shutdown (Telnet Management)
- timeout
- trusted-ca
- user-keys
- username ssh-key
- username ssh-principal
- username tcp
- verify
- vrf known-hosts
- vrf
- vrf (API Management)

Display Commands

- show inventory

3.7.1 authentication x509

The **authentication x509** command in the SSH Management Authentication x509 Configuration Mode configures x509 certificates for the SSH connection.

The **no** version of the command disables the configuration and removes it from the ***running-config***.

Command Mode

SSH Management Configuration

Authentication x509 Configuration

Command Syntax

authentication x509 [server ssl profile ***profile_name*****] [username [domain | omit]]**

no authentication x509

Parameters

- **authentication x509** - Configure x509 certificate authentication settings.
- **server ssl profile** ***profile_name*** - Specify an SSL profile to use with the SSH connection.
- **username** - Configure matching the SSH username to a presented X509 certificate Common Name and SAN.
  - **domain** - Configure the treatment of the domain name in a presented X509 certificate Common Name and SAN.
  - **omit** - Ignore the domain name in a presented X509 certificate Common Name and SAN when matching them against the logging in SSH username

Example

Use the following commands to allow SSH authentication match the SSH user name to a presented x509 certificate and ignore the domain presented in the certificate:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authentication x509
switch(config-mgmt-ssh-auth-x509)# username domain omit
switch(config-mgmt-ssh-auth-x509)#
```

3.7.2 authentication

The **authentication** command in the SSH Management Configuration Mode configures authentication parameters for the SSH connection.

The **no** version of the command disables the configuration and removes it from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

authentication [empty-passwords [auto | deny | permit]] [protocol [keyboard-interactive | multi-factor | password | public-key]]

no authentication

Parameters

- **authentication** - Configure authentication settings.
- **empty-passwords [auto | deny | permit]** - Specify to permit or deny empty passwords. The configuration uses **auto** by default to auto-determine if allowing empty passwords or not.
- **protocol [keyboard-interactive | multi-factor | password | public-key]**
  - **keyboard-interactive** - Enable keyboard interactive authentication.
  - **multi-factor** - Enable multifactor authentication methods.
  - **password** - Enable password authentication.
  - **public-key** - Enable public key authentication.

Example

Use the following commands to allow SSH authentication to use empty passwords:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authentication empty-passwords permit
switch(config-mgmt-ssh)#
```

3.7.3 authorized-principals

The **authorized-principals** command in the SSH Management Configuration Mode allows the configuration of authorized principals for SSH. The authorized-principals mechanism defines which identities or principals within a signed certificate have permission to log in as a specific local user.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

authorized-principals command ***WORD ARGUMENTS***

no authorized-principals command

Parameters

- **authorized-principals** - Configure authorized-principals settings.
- **command** - Configure the authorized principals command.
- ***WORD*** - Specify the authorized principals script filename.
- **ARGUMENTS** - Specify the input data to pass to the authorized principals command.

Example

Use the following commands to run the script, `/mnt/flash/scripts/get-principals.py`:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authorized-principals command /mnt/flash/scripts/get-principals.py
switch(config-mgmt-ssh)#
```

3.7.4 cipher

The **cipher** command in the SSH Management Configuration Mode defines the specific symmetric encryption algorithms used for SSH sessions. During the SSH handshake, the switch and client compare lists of supported ciphers and must find a common match to establish an encrypted tunnel. If no match found, the switch rejects the connection.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

cipher ***algorithm***

no cipher

Parameters

- **cipher** - Add symmetric encryption algorithms.
- ***algorithm*** - Add any of the following algorithms to the configuration:
  - **3des-cbc** - Triple DES (112 bit)
  - **aes128-cbc** - Advanced Encryption Standard (128 bit, CBC mode)
  - **aes128-ctr** - Advanced Encryption Standard (128 bit, counter mode)
  - **aes128-gcm@openssh.com** - Advanced Encryption Standard (128 bit, Galois/Counter mode)
  - **aes192-cbc** - Advanced Encryption Standard (192 bit, CBC mode)
  - **aes192-ctr** - Advanced Encryption Standard (192 bit, counter mode)
  - **aes256-cbc** - Advanced Encryption Standard (256 bit, CBC mode)
  - **aes256-ctr** - Advanced Encryption Standard (2562 bit, counter mode)
  - **aes256-gcm@openssh.com** - Advanced Encryption Standard (256 bit, Galois/Counter mode)
  - **arcfour** - Arcfour stream cipher (RC4 like)
  - **arcfour128** - Arcfour stream cipher (RFC 4345, 128 bit)
  - **arcfour256** - Arcfour stream cipher (RFC 4345, 256 bit)
  - **blowfish-cbc** - Blowfish block cipher (128 bit, CBC mode)

- **`cast128-cbc`** - CAST-128 (RFC 2144, 128 bit, CBC mode
- **`chacha20-poly1305@openssh.com`** - ChaCha20 stream cipher and Poly1305 authenticator

Example

Use the following commands to add the algorithms, `aes192-cbc` and `blowfish-cbc`, to the configuration:

```
switch(config)# managment ssh
switch(config-mgmt-ssh)# cipher aes192-cbc blowfish-cbc
switch(config-mgmt-ssh)#
```

3.7.5 client-alive

The **client-alive** command in the SSH Management Configuration Mode manages the SSH session persistence and timeouts. The switch proactively checks if a connected client has an active session.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

client-alive [count-max ***number*****] interval** ***time*****]**

no client-alive

Parameters

- **client-alive** - Configure SSH Client Alive parameters.
- **count-max** ***number*** - Specify the number of times the switch sends a keepalive request without receiving a response before considering the session dead and terminates it. The default number is 3.
- **interval** ***time*** - Specify the time in seconds that the switch waits before sending a keepalive requests to the client through the encrypted channel. Use a value between 1 and 60 seconds with a default of 0. If configured as 60, the switch pings the client every minute of inactivity.

Example

Use the following commands to configure a maximum count of 5 and an interval of 10 seconds:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# client-alive count-max 5 interval 10
switch(config-mgmt-ssh)#
```

3.7.6 commit timer

The **commit timer** command can automatically roll back changes performed during a configuration session if you haven't confirmed them within a preset time interval. This feature can prevent a user from committing configuration changes that could cause a network disruption. The **no commit timer** command deletes the session.

Command Mode

Configure Session Configuration Mode

Command Syntax

`commit timer` *hh:mm:ss*

Parameters

hh:mm:ss - Specify the time interval for the commit session.

Example

Use the following command to create a commit timer for *01.00.00* hour:

```
switch(config-s-MySession)# commit timer 01:00:00
switch#
```

3.7.7 compression

The **compression** in the SSH Management Configuration Mode controls compressing the data stream from the SSH server before encrypting it. This optimizes bandwidth on slow or congested management links such as out-of-band serials consoles over LTE or saturated WAN links.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

compression disable

Parameters

- **compression** - Configure SSH compression algorithms.
- **disabled** - Disable SSH compression algorithms.

Example

Use the following commands to disable SSH compression algorithms:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# compression disable
switch(config-mgmt-ssh)#
```

3.7.8 configure replace

The **`configure replace`** command replaces the current configuration with a new configuration from the specified source.

Command Mode

Privileged EXEC

Command Syntax

`configure replace` *source_file_path:source_file_name* [ignore-errors] [md5 *md5sum*] [skip-checkpoint] [vrf *instance_name*]

Parameters

- ***source_file_path:source_file_name*** replaces the current configuration with the configuration from the specified source file.
- **`boot-extensions:`** - Replace the current configuration with the boot extensions configuration.
- **`certificate:`** - Replace the current configuration with the certificate configuration.
- **`checkpoint:`** - Replace the current configuration with the checkpoint configuration.
- **`clean-config:`** - Replace the current configuration with a clean, default configuration.
- **`extension:`** - Replace the current extensions configuration with an extensions configuration.
- **`file:`** - Replace the current configuration with a configuration from a file location.
- **`flash:`** - Replace the current configuration with a configuration from a flash location.
- **`ftp:`** - Replace the current configuration with a configuration from a FTP location.
- **`http:`** - Replace the current configuration with a configuration from an HTTP location.
- **`https:`** - Replace the current configuration with a configuration from an HTTPS location.
- **`installed-extensions:`** - Replace the current configuration with the installed extensions status.
- **`running-config:`** - Replaces the current configuration with the running configuration.
- **`scp:`** - Replace the current configuration with a configuration from an SCP location.
- **`sftp:`** - Replace the current configuration with a configuration from an SFTP location.
- **`snapshot:`** - Replace the current configuration with a configuration from a snapshot.
- **`ssh-auth-principals-cmd:`** - Retrieve a configuration from an SSH location and replace the current configuration.

- **`ssh-ca-key:`** - Retrieve a configuration from an SSH location and replace the current configuration.
- **`ssh-key:`** - Retrieve a configuration from an SSH location and replace the current configuration.
- **`ssh-revoke-list:`** - Retrieve a configuration from an SSH location and replace the current configuration.
- **`startup-config:`** - Replace the current configuration with the startup configuration.
- **`system:`** - Retrieve a configuration from a system location and replace the current configuration.
- **`terminal:`** - Retrieve a configuration from a terminal location and replace the current configuration.
- **`tftpt:`** - Retrieve a configuration from a TFTP location and replace the current configuration.
- **`ignore-errors`** - Replace the configuration and ignore errors while loading the new configuration.
- **`md5`** *md5sum* - Performs a checksum to validate data integrity with the specified MD5 hashing algorithm.
- **`skip-checkpoint`** - Skips creating the checkpoint file of ***running-config***.

Example

This command replaces the current configuration state with the startup configuration.

```
switch(config)# configure replace start-config
! Preserving static routes. Use 'no ip routing delete-static-routes' to clear them.
switch#
```

3.7.9 configure session

The **`configure session`** command allows a series of temporary configuration changes and commits to ***running-config*** later by issuing the **`commit`** command. EOS discards an uncommitted configuration session if the switch reboots and times out after 24 hours.

Note: Committing a configuration session replaces ***running-config*** with the session configuration, which consists of the running configuration at the initial session and the commands entered as part of the session. When the session commits, it overwrites any changes to ***running-config*** since the initiation.

The **`no configure session`** *session_name* and **`default configure session`** ***session_name*** commands delete the specified configuration session.

Command Mode

Privileged EXEC

Command Syntax

`configure session` [*session_name*] [abort | commit | [description *description*]]

`no configure session` *session_name*

`default configure session`

Parameter

- ***session_name*** - Create a name for the configuration session.
- **abort** - Ends the configuration sessions and deletes it.
- **commit** - Commits the changes executed during the session.
- **description *description*** - Create a description for the configuration session.

Guidelines

- Creates a session with a name generated by the switch if you do not specify a session name.
- The switch permits up to five uncommitted sessions.
- When the switch reboots, it discards the uncommitted sessions.
- Uncommitted sessions time out after 24 hours.

Example

This command creates a session named ***MySession***) and adds commands. Issuing the **`commit`** command executes all commands and overwrites any configuration performed since the creation of the session.

```
switch(config)#configure session
switch(config-s-sess-1)#aaa authentication dot1x default group radius
switch(config-s-sess-1)#dot1x system-auth-control
switch(config-s-sess-1)#commit
switch(config-s-sess-1)#
```

3.7.10 connection

The **connection** command in the SSH Management Configuration Mode configures session-handling and security for SSH connections.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

connection [limit ***number_sessions*****] per-host [** ***number_sessions*****]**

no connection

default connection

Parameters

- **connection** - Configure settings for SSH connections.
- **limit** ***number_sessions*** - Configure the maximum number of concurrent SSH sessions.
- **per-host** ***number_sessions*** - Configure the maximum number of concurrent SSH sessions from a single host.

Example

Use the following commands to configure a limit of 50 concurrent SSH sessions:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# connection limit 50
switch(config-mgmt-ssh)#
```

3.7.11 fips

The **fips** command in the SSH Management Configuration Mode configures the switch to strictly enforce FIPS 140-2/140-3 compliance for all incoming connections. When enabled, the switch disables all cryptographic algorithms not officially validated by Federal Information Processing Standards (FIPS).

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

fips restrictions

no fips restrictions

default fips restrictions

Parameters

- **fips** - Configure FIPS settings.
- **restrictions** - Enable FIPS algorithms for SSH connections.

Example

Use the following commands to enable FIPS algorithms for SSH connections on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# fips restrictions
switch(config-mgmt-ssh)#
```

3.7.12 hostkey

The **hostkey** command in the SSH Management Configuration Mode configures the client connections and server connections host keys on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

hostkey [client strict-checking] [server [cert *hostkey_filename*] [dsa | ecdsa-nistp256 | ecdsa-nistp521 | ed25519 | rsa] [ssh-key *filename*]

no hostkey

default hostkey

Parameters

- **hostkey** - Configure host key settings.
- **restrictions** - Enable FIPS algorithms for SSH connections.
- **client strict-checking** - Enforce strict host key checking for SSH clients.
- **server** - Configure the switch SSH host key settings:
  - **cert *hostkey_filename*** - Specify the certificate filename for SSH on the host.
  - **dsa** - Specify a Digital Signature Algorithm.
  - **ecdsa-nistp256** - Specify the Elliptic Curve Digital Signature Algorithm NIST-P256.
  - **ecdsa-nistp521** - Specify the Elliptic Curve Digital Signature Algorithm NIST-P521.
  - **ed25519** - Specify the Edwards-curve Digital Signature Algorithm 2551.
  - **rsa** - Specify the RSA Encryption Algorithm.
  - **ssh-key: *filename*** - Specify the SSH private key file name.

Example

Use the following commands to enable the client strict host key checking for SSH connections on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# hostkey client strict-checking
switch(config-mgmt-ssh)#
```

3.7.13 idle-timeout (Console Management)

The **idle-timeout (Console Management)** command configures the idle-timeout period for console connection sessions. The idle timeout refers to the length of time that a connection waits after a user's most recent command before shutting down the connection. By default, setting the idle timeout to zero disables the connection timeout automatically.

The **no idle-timeout** and **default idle-timeout** commands disable the automatic connection timeout by removing the **idle-timeout** statement from ***running-config***.

Command Mode

Management Console Configuration

Command Syntax

`idle-timeout` *idle_period*

`no idle-timeout`

`default idle-timeout`

Parameters

idle_period session idle-timeout length. Options include:

- ***0*** - Disables the automatic connection timeout.
- ***1 to 86400*** - Configures the automatic timeout period in minutes.

Examples

- These commands configure a console idle-timeout period of three hours, then return the switch to global configuration mode.

```
switch(config)# management console
switch(config-mgmt-console)# idle-timeout 180
switch(config-mgmt-console)# exit
switch(config)#
```

- These commands disable automatic connection timeout.

```
switch(config)# management console
switch(config-mgmt-console)# idle-timeout 0
switch(config-mgmt-console)#
```

3.7.14 idle-timeout (SSH Management)

The **idle-timeout (SSH Management)** command configures the idle-timeout period for SSH connection sessions. The idle timeout refers to the length of time that a connection waits after a user's most recent command before shutting down the connection. Setting the idle timeout to zero disables the connection timeout automatically.

The **no idle-timeout** and **default idle-timeout** commands disable the automatic connection timeout by removing the **idle-timeout** statement from ***running-config***.

Command Mode

Management SSH Configuration

Command Syntax

idle-timeout ***idle_period***

no idle-timeout

default idle-timeout

Parameters

idle_period session idle-timeout length. Options include the following:

- ***0*** - Disables the automatic connection timeout.
- ***1 to 86400*** - Configures the automatic timeout period in minutes.

Examples

- These commands configure an SSH idle-timeout period of three hours, then return the switch to global configuration mode.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# idle-timeout 180
switch(config-mgmt-ssh)# exit
switch(config)#
```

- These commands disable automatic connection timeout.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# idle-timeout 0
switch(config-mgmt-ssh)#
```

3.7.15 idle-timeout (Telnet Management)

The **`idle-timeout (Telnet Management)`** command configures the idle-timeout period for Telnet connection sessions. The idle timeout refers to the length of time that a connection waits after a user's most recent command before shutting down the connection. Setting the idle timeout to zero disables the connection timeout automatically.

The **`no idle-timeout`** and **`default idle-timeout`** commands disable the automatic connection timeout by removing the **`idle-timeout`** statement from ***running-config***.

Command Mode

Management Telnet

Command Syntax

`idle-timeout` *idle_period*

`no idle-timeout`

`default idle-timeout`

Parameters

idle_period session idle-timeout length. Options include:

- ***0*** - Disables the automatic connection timeout.
- ***1 to 86400*** - Configures the automatic timeout period in minutes.

Examples

- These commands configure a Telnet idle-timeout period of three hours, then return the switch to ***global configuration mode***.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# idle-timeout 180
switch(config-mgmt-telnet)# exit
switch(config)#
```

- These commands disable automatic connection timeout.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# idle-timeout 0
switch(config-mgmt-telnet)#
```

3.7.16 ip

The **ip** command in the SSH or Telnet Management Configuration Mode configures the IPv4 access group parameters for an SSH or Telnet session.

The **[no | default]** versions of the command disables the configuration and removes it from the ***running-config***.

Command Mode

SSH Management Configuration

Telnet Management Configuration

Command Syntax

ip access-group ***list_name*** **in [vrf** ***vrf_name*****]**

no access-group ***list_name***

default access-group ***list_name***

Parameters

- **access-group** ***list_name*** - Specify a name for the IPv4 access control list.
- **in** - Apply the access control list to inbound packets.
- **vrf** ***vrf_name*** - Specify the VRF to apply the IP access group list. If not specified, the configuration applies to the default VRF.

Example

Use the following commands to apply the IPv6 access group list, *MyAGL*, to inbound packets on VRF, *bluengreen*, Telnet management sessions:

```
switch(config)# management telnet
switch(config-mgmt-telnet)# ip access-group MyAGL in vrf bluengreen
switch(config-mgmt-telnet)#
```

3.7.17 ipv6

The **ipv6** command in the SSH or Telnet Management Configuration Mode configures the IPv6 access group parameters for an SSH or Telnet session.

The **[no | default]** versions of the command disables the configuration and removes it from the ***running-config***.

Command Mode

SSH Management Configuration

Telnet Management Configuration

Command Syntax

ipv6 access-group ***list_name*** **in [vrf** ***vrf_name*****]**

no access-group ***list_name***

default access-group ***list_name***

Parameters

- **access-group** ***list_name*** - Specify a name for the IPv6 access control list.
- **in** - Apply the access control list to inbound packets.
- **vrf** ***vrf_name*** - Specify the VRF to apply the IP access group list. If not specified, the configuration applies to the default VRF.

Example

Use the following commands to apply the IPv6 access group list, *MyAGL*, to inbound packets on VRF, *bluengreen*, Telnet management sessions:

```
switch(config)# management telnet
            switch(config-mgmt-telnet)# ipv6 access-group MyAGL in vrf bluengreen
            switch(config-mgmt-telnet)#
```

3.7.18 key-exchange

The **key-exchange** command in the SSH Management Configuration Mode specifies the mathematical algorithms used by the switch to securely negotiate a shared session key with an SSH peer. The command applies to client and server connections.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

key-exchange [curve25519-sha256@libssh.org | diffie-hellman-group-exchange-sha1 | diffie-hellman-group-exchange-sha256 | diffie-hellman-group1-sha1 | diffie-hellman-group14-sha | diffie-hellman-group14-sha256 | diffie-hellman-group16-sha512 | diffie-hellman-group18-sha512 | ecdh-sha2-nistp256 | ecdh-sha2-nistp384 | ecdh-sha2-nistp521 | gss-curve25519-sha256- | gss-gex-sha1- | gss-group1-sha1- | gss-group14-sha1- | gss-group14-sha256- | gss-group16-sha512- | gss-nistp256-sha256- | mlkem768x25519-sha25 | sntrup761x25519-sha512 | sntrup761x25519-sha512@openssh.com]

no key-exchange

default key-exchange

Parameters

- **key-exchange** - Select algorithms from the following list:
  - **curve25519-sha256@libssh.org** - Specify the Elliptic Curve 255519 with SHA-256 algorithm.
  - **diffie-hellman-group-exchange-sha1** - Specify the Negotiated Group Exchange with SHA-1 algorithm.
  - **diffie-hellman-group-exchange-sha256** - Specify the Negotiated Group Exchange with SHA-256 algorithm.
  - **diffie-hellman-group1-sha1** - Specify the Oakley Group 2 with SHA-1 algorithm.
  - **diffie-hellman-group14-sha** - Specify the Oakley Group 14 with SHA-1 algorithm.
  - **diffie-hellman-group14-sha256** - Specify the Oakley Group 14 with SHA-256 algorithm.
  - **diffie-hellman-group16-sha512** - Specify the Oakley Group 16 with SHA-512 algorithm.
  - **diffie-hellman-group18-sha512** - Specify the Oakley Group 18 with SHA-512 algorithm.

- **ecdh-sha2-nistp256** - Specify the Elliptic Curve NIST P256 algorithm.
- **ecdh-sha2-nistp384** - Specify the Elliptic Curve NIST P384 algorithm.
- **ecdh-sha2-nistp521** - Specify the Elliptic Curve NIST P521 algorithm.
- **gss-curve25519-sha256-**Generic Security Service ECDH over Curve25519 with SHA-256 algorithm
- **gss-gex-sha1-** - Specify the Generic Security Service DH with SHA-1 algorithm.
- **gss-group1-sha1-** - Specify the Generic Security Service DH using Oakley Group 2 with SHA-1 algorithm.
- **gss-group14-sha1-** - Specify the Generic Security Service DH using Oakley Group 14 with SHA-1 algorithm.
- **gss-group14-sha256-** - Specify the Generic Security Service DH using Oakley Group 14 with SHA-256 algorithm.
- **gss-group16-sha512-** - Specify the Generic Security Service DH using Oakley Group 16 with SHA-256 algorithm.
- **gss-nistp256-sha256-** - Specify the Generic Security Service ECDH over NIST P256 with SHA-256 algorithm.
- **mlkem768x25519-sha25** - Specify the Hybrid Module Lattice mlkem768 and X25519 with SHA-256 algorithm.
- **sntrup761x25519-sha512** - Specify the Hybrid Streamlined NTRU Prime sntrup761 and X25519 with SHA-512 algorithm.
- **sntrup761x25519-sha512@openssh.com** - Specify the Hybrid Streamlined NTRU Prime sntrup761 and X25519 with SHA-512 algorithm.

Example

Use the following commands to select the algorithm, `ecdh-sha2-nistp256`, for key exchange for SSH connections on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# key-exchange ecdh-sha2-nistp256
switch(config-mgmt-ssh)#
```

3.7.19 log-level

The **log-level** command in the SSH Management Configuration Mode defines the verbosity of the SSH service messages sent to the system logs.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

log-level [debug | debug1 | debug2 | debug3 | error | fatal | info | quiet | verbose]

no log-level

default default

Parameters

- **log-level** - Select from the following list to add a log-level to the SSH service messages:
  - **[debug | debug1 | debug2 | debug3]** - Progressively detailed troubleshooting logs. **debug3** logs sensitive information and should only be used during active troubleshooting sessions.
  - **error** - Log significant errors that prevent a command or session from proceeding normally.
  - **fatal** - Log only fatal errors that cause the SSH session or process to crash.
  - **info** - Log standard events such as logins, logouts, and standard operational events. (Default)
  - **quiet** - No logging for the SSH service.
  - **verbose** - Logs detailed information about authentication and connection progress.

Example

Use the following commands to set the log level for SSH connections on the switch to `error`:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# log-level error
switch(config-mgmt-ssh)#
```

3.7.20 logging

The **logging** command in the SSH Management Configuration Mode directs SSH service log events to the EOS system logging facility (syslog).

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

logging target system

no logging

default logging

Parameters

- **logging** - Configure logging for the SSH service.
- **target** - Specify the target for the SSH/SSHD service logs.
- **system** - Set the target destination for the SSH log messages to the system log buffer.

Example

Use the following commands to set the log messages destination to the syslogs on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# logging target system
switch(config-mgmt-ssh)#
```

3.7.21 login

The **login** command in the Console, SSH, or Telnet Management Configuration Mode allows the configuration of login parameters for the sessions.

The **[no | default]** versions of the command disables the configuration and removes it from the ***running-config***.

Command Mode

Console Management Configuration

SSH Management Configuration

Telnet Management Configuration

Command Syntax

`login user match-list` ***list_name*** **`[invert-result]`**

`no login user match-list` ***list_name***

`default login user match-list` ***list_name***

Parameters

- **`login user match-list`** ***list_name*** - Specify a list of users to match.
- **`[invert-result]`** - Invert the match list results.

Example

Use the following commands to match the user list, *`MyUsers`*, for a console management session:

```
switch(config)# managment console
switch(config-mgmt-console)# login user match-list MyUsers
switch(config-mgmt-console)#
```

3.7.22 mac

The **mac** command in the SSH Management Configuration Mode specifies the algorithms the switch uses to verify the data integrity of SSH packets, ensuring that traffic has not been tampered with in transit.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

```
mac [hmac-md5-96 | hmac-md5-96-etm@openssh.com | hmac-md5-etm@openssh.com |
hmac-ripemd160 | hmac-sha1 | hmac-sha1-96 | hmac-sha1-96-etm@openssh.com |
hmac-sha1-etm@openssh.com | hmac-sha2-256 | hmac-sha2-256-etm@openssh.com |
hmac-sha2-512 | hmac-sha2-512-etm@openssh.com | umac-128-etm@openssh.com |
umac-128@openssh.com | umac-64-etm@openssh.com | umac-64@openssh.com]

no mac

default mac
```

Parameters

- **mac** - Specify algorithms from the following list.
  - **hmac-md5-96** - Specify the Hash Message Authentication Code MD5 algorithm.
  - **hmac-md5-96-etm@openssh.com** - Specify the Hash Message Authentication Code MD5 for use in ESP and AH algorithm.
  - **hmac-md5-etm@openssh.com** - Specify the Encrypt-Then-Mac HMAC MD5-96 algorithm.
  - **hmac-ripemd160** - Specify the Hash Message Authentication Code RIPEMD-160 algorithm.
  - **hmac-sha1** - Specify the Hash Message Authentication Code SHA-1 algorithm.
  - **hmac-sha1-96** - Specify the Hash Message Authentication Code SHA-1 for use in ESP and AH algorithm.
  - **hmac-sha1-96-etm@openssh.com** - Specify the Encrypt-Then-Mac HMAC SHA1-96 algorithm.
  - **hmac-sha1-etm@openssh.com** - Specify the Encrypt-Then-Mac HMAC SHA1 algorithm.
  - **hmac-sha2-256** - Specify the Encrypt-Then-Mac HMAC SHA1 algorithm.
  - **hmac-sha2-256-etm@openssh.com** - Specify the Elliptic Curve NIST P384 algorithm.
  - **hmac-sha2-512** - Specify the Hash Message Authentication Code SHA2-512 algorithm.
  - **hmac-sha2-512-etm@openssh.com** - Specify the Encrypt-Then-Mac HMAC SHA2-512 algorithm.

- **umac-128-etm@openssh.com** - Specify the Encrypt-Then-Mac HMAC UMAC-128 algorithm.
- **umac-128@openssh.com** - Specify the Hash Message Authentication Code UMAC-128 algorithm.
- **umac-64-@openssh.com** - Specify the Encrypt-Then-Mac HMAC UMAC-64 algorithm.
- **umac-64@openssh.com** - Specify the Encrypt-Then-Mac HMAC UMAC-646 algorithm.

Example

Use the following commands to add the MAC algorithm, **hmac-sha2-256**, on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# mac hmac-sha2-256
switch(config-mgmt-ssh)#
```

3.7.23 management accounts

The **management accounts** command enters the Accounts Management Configuration Mode and allows the creation of user accounts on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Accounts Management Configuration

Command Syntax

management accounts

[no | default] management accounts

Parameters

- **management accounts** - Enters Accounts Management Configuration Mode.
  - **account** - Enters the Account Configuration Mode after adding a user name.
    - **session limit** ***value*** - Add the number of allowed sessions from 1 to 100 per user.
  - **password policy** ***policy_name*** - Configure password policies.
  - **session default-limit** ***value*** - Configure the maximum number of remote sessions per user.

Example

Use the following commands to enter Accounts Management Configuration Mode and add a user *tech_support1* with a session limit of *10*:

```
switch(config)# management accounts
switch(config-mgmt-accounts)# account tech_support1
switch(config-mgmt-acct-tech_support1)# session limit 10
```

3.7.24 management api eos-sdk-rpc

The **management api eos-sdk-rpc** command places the switch in EOS SDK RPC API Management Configuration Mode.

The **no management api eos-sdk-rpc** and **default management api eos-sdk-rpc** commands delete the EOS SDK RPC API Management Configuration statements from ***running-config***.

EOS SDK RPC API management configuration mode does not invoke a group change mode. The ***running-config*** changes immediately upon entering commands. Exiting the EOS SDK RPC API Management Configuration Mode does not affect the ***running-config***. The **exit** command returns the switch to Global Configuration Mode.

Command Mode

Global Configuration

Command Syntax

```
management api eos-sdk-rpc

no management api eos-sdk-rpc

default management api eos-sdk-rpc
```

Commands Available in EOS SDK RPC API Configuration Mode

- **transport (EOS SDK RPC API Management)**

Examples

- This command places the switch in EOS SDK RPC API management configuration mode.

```
switch(config)# management api eos-sdk-rpc
switch(config-mgmt-api-eos-sdk-rpc)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-eos-sdk-rpc)# exit
switch(config)#
```

3.7.25 management api external-services

The **management api external-services** command places the switch in External Services API configuration mode.

The **no management api external-services** and **default management api external-services** commands delete the mgmt-api-external-services configuration mode statements from ***running-config***.

External Services API configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting the External Services API configuration mode does not affect the ***running-config***. The **exit** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api external-services

no management api external-services

default management api external-services
```

Commands Available in Mgmt-API Configuration Mode

- **shutdown (External Services API Management)**
- **vrf (External Services API Management)**

Examples

- This command places the switch in External Services API Management configuration mode.

```
switch(config)# management api external-services
switch(config-mgmt-api-external-services)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-external-services)# exit
switch(config)#
```

3.7.26 management api gnmi

The **management api gnmi** command places the switch in GNMI API Management configuration mode.

The **no management api gnmi** and **default management api gnmi** commands delete the mgmt-api-gnmi configuration mode statements from ***running-config***.

GNMI API Management configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting the GNMI API Management configuration mode does not affect ***running-config***. The **exit** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api gnmi

no management api gnmi

default management api gnmi
```

Commands Available in Mgmt-API Configuration Mode

- **operation (GNMI API Management)**
- **provider (GNMI API Management)**
- **transport (GNMI API Management)**

Examples

- This command places the switch in GNMI API Management configuration mode.

```
switch(config)# management api gnmi
switch(config-mgmt-api-gnmi)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-gnmi)# exit
switch(config)#
```

3.7.27 management api gnsi

The **`management api gnsi`** command places the switch in GNSI API management configuration mode.

The **`no management api gnsi`** and **`default management api gnsi`** commands delete the mgmt-api-gnsi configuration mode statements from ***running-config***.

GNSI API Management configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting the GNSI API Management configuration mode does not affect ***running-config***. The **`exit`** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api gnsi

no management api gnsi

default management api gnsi
```

Commands Available in GNSI API Management Configuration Mode

- `service (GNSI API Management)`
- `transport (GNSI API Management)`

Examples

- This command places the switch in GNSI API Management configuration mode.

```
switch(config)# management api gnsi
switch(config-mgmt-api-gnsi)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-gnsi)# exit
switch(config)#
```

3.7.28 management api gribi

The **management api gribi** command places the switch in gRIBI API Management configuration mode.

The **no management api gribi** and **default management api gribi** commands delete the mgmt-api-gribi configuration mode statements from ***running-config***.

gRIBI API Management configuration mode is not a group change mode; ***running-config*** changes immediately upon entering commands. Exiting the gRIBI API Management configuration mode does not affect ***running-config***. The **exit** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api gribi

no management api gribi

default management api gribi
```

Commands Available in gRIBI API Management Configuration Mode

- `transport (gRIBI API Management)`

Examples

- This command places the switch in gRIBI API Management configuration mode.

```
switch(config)# management api gribi
switch(config-mgmt-api-gribi)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-gribi)# exit
switch(config)#
```

3.7.29 management api http-commands

The **`management api http-commands`** command places the switch in HTTP Commands API Management Configuration Mode.

The **`no management api http-commands`** and **`default management api http-commands`** commands delete the HTTP Commands API Management Configuration Mode statements from ***running-config***.

HTTP Commands API Management Configuration Mode is not a group change mode. The ***running-config*** changes immediately upon entering commands. Exiting HTTP Commands API Management configuration mode does not affect ***running-config***. The **`exit`** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api http-commands

no management api http-commands

default management api http-commands
```

Commands Available in HTTP Commands API Management Configuration Mode

- `protocol http`
- `protocol https`
- `protocol https certificate`
- `protocol shutdown`
- `protocol vrf`

Examples

- This command places the switch in HTTP Commands API Management Configuration Mode.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)#
```

- This command returns the switch to Global Configuration Mode.

```
switch(config-mgmt-api-http-cmds)# exit
switch(config)#
```

3.7.30 management api models

The **`management api models`** command places the switch in Models API Management configuration mode.

The **`no management api models`** and **`default management api models`** commands delete the mgmt-api-models configuration mode statements from ***running-config***.

Models API Management configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting Models API Management configuration mode does not affect ***running-config***. The **`exit`** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api models

no management api models

default management api models
```

Commands Available in Models API Management Configuration Mode

- `models (Models API Management)`
- `modules (Models API Management)`
- `provider (Models API Management)`

Examples

- This command places the switch in Models API Management configuration mode.

```
switch(config)# management api models
switch(config-mgmt-api-models)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-models)# exit
switch(config)#
```

3.7.31 management api netconf

The **`management api netconf`** command places the switch in Netconf API Management configuration mode.

The **`no management api netconf`** and **`default management api netconf`** commands delete the mgmt-api-netconf configuration mode statements from ***running-config***.

Netconf API Management configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting Netconf API Management configuration mode does not affect ***running-config***. The **`exit`** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api netconf

no management api netconf

default management api netconf
```

Commands Available in Netconf API Management Configuration Mode

- `transport (Netconf API Management)`

Examples

- This command places the switch in Netconf API Management configuration mode.

```
switch(config)# management api netconf
switch(config-mgmt-api-netconf)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-netconf)# exit
switch(config)#
```

3.7.32 management api restconf

The **management api restconf** command places the switch in Restconf API Management configuration mode.

The **no management api restconf** and **default management api restconf** commands delete the mgmt-api-restconf configuration mode statements from ***running-config***.

Restconf API Management configuration mode is not a group change mode; ***running-config*** is changed immediately upon entering commands. Exiting Restconf API Management configuration mode does not affect ***running-config***. The **exit** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
management api restconf

no management api restconf

default management api restconf
```

Commands Available in Restconf API Management Configuration Mode

- `transport (Restconf API Management)`

Examples

- This command places the switch in Restconf API Management configuration mode.

```
switch(config)# management api restconf
switch(config-mgmt-api-restconf)#
```

- This command returns the switch to global management mode.

```
switch(config-mgmt-api-restconf)# exit
switch(config)#
```

3.7.33 management archive

The **management archive** command enters the Archive Management Configuration Mode and allows you to manage log archives and archive space.

Command Mode

Global Configuration

Archive Management Configuration

Command Syntax

management archive [destination flash:] [quotapct ***percentage*****] shutdown**

Parameters

- **management archive** - Enters the Archive Management Configuration Mode.
- **destination flash:** - Configure a destination for the archive files.
- **quotapct** ***percentage*** - Set the quota percentage value from 0 to 100.
- **shutdown** - Disables log archiving on the switch.

Example

Use the following commands to configure the quota percentage as *50*:

```
switch(config)# management archive
switch(config-mgmt-archive)# quotapct 50
switch(config-mgmt-archive)#
```

3.7.34 management cli

The **management cli** command places the switch in CLI Management Configuration Mode and allows you to configure command line options.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

CLI Management Configuration

Command Syntax

management cli command deprecated log

[no | default] management cli command deprecated log

Parameters

- **management cli** - Enters the CLI Management Configuration Mode.
- **command** - Configure command options.
- **deprecated - Configure the CLI behavior for deprecated commands.**
- **log** - Create a syslog message when executing a deprecated command.

Example

Use the following commands to create a syslog message when executing a deprecated command:

```
switch(config)# management cli
switch(config-mgmt-cli)# command deprecated log
switch(config-mgmt-cli)#
```

3.7.35 management client

The **management client** command enters the Client Management Configuration Mode and configures remote applications or scripts that utilize the switch powerful eAPI (EOS API) to programmatically send configuration and show commands.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Client Management Configuration

Command Syntax

management client api gnmi [group ***group_name*** **member** ***server_name*****] [server** ***server_name*****]**

[no | default] management client api gnmi

Parameters

- **management client api gnmi** - Configures the switch as a gNMI client.
- **group** ***group_name*** - Configure gNMI server group definitions.
- **member** ***server_name*** - Add a gNMI server to the group.
- **server** ***server_name*** - Add a gNMI server to the configuration.

Example

Use the following commands to add the group, *gnmi_group*, and the member, *gnmi_server1* to the client configuration:

```
switch(config)# management client api gnmi
switch(config-mgmt-client-api-gnmi)# group gnmi_group member gnmi_server1
switch(config-mgmt-client-api-gnmi)#
```

3.7.36 management console

The **management console** command places the switch in Console Management Configuration Mode to adjust the idle-timeout period for console connection sessions. The idle-timeout period determines the inactivity interval that terminates a connection session.

The **no management console** and **default management console** commands delete the Console Management Configuration Mode statements from ***running-config***.

The Console Management Configuration Mode is not a group change mode. The ***running-config*** changes immediately upon entering commands. Exiting the Console Management Configuration Mode does not affect ***running-config***. The **exit** command returns the switch to Global Configuration Mode.

Command Mode

Global Configuration

Command Syntax

management console [idle-timeout ***minutes*****] [login prompt hostname fqdn] timeout** ***minutes*** **warning*****minutes*****]**

no management console

default management console

Parameters

- **idle-timeout** ***minutes*** - Configure the time a login can be idle before timing out on the switch.
- **login** - Configure options related to logging into the switch.
  - **prompt hostname fqdn** - Configure the login prompt to use the hostname.
- **timeout** ***minutes*** **warning*****minutes*** - Configure the session timeout from 0 to 86400 minutes and generate a warning message about the impending timeout. The warning value must be less than the configured timeout value.

Examples

- The following command places the switch into Console Management Configuration Mode:

```
switch(config)# management console
switch(config-mgmt-console)#
```

- This command returns the switch to Global Management Mode:

```
switch(config-mgmt-console)# exit
switch(config)#
```

3.7.37 management data source

The **management data source** command enters the Data Source Management Configuration Mode and allows defining the rules and actions taken on specific data streams.

Command Mode

Global Configuration

Data Source Management Configuration

Command Syntax

management data source [disable] [sensor ***sensor_name*** **[disabled | ip address** ***ip_address*** **port** ***port*****] [traffic-policies [disabled] [field-set [ipv4 prefix** ***source_name*****] [[ipv6 prefix** ***source_name*****] [service** ***source_name*****]]**

Parameters

- **management data source** - Enters the Data Source Configuration Mode.
- **disable** - Disable the management data source.
- **sensor** ***sensor_name*** - Specify the name of a sensor.
  - **disabled** - Disable the sensor.
  - **ip address** ***ip_address*** - Specify the IPv4 or IPv6 address of the sensor.
  - **port** ***port*** - Specify the port.
- **traffic-policies** - Configure traffic policies to apply to the data source.
- **disabled** - Disable traffic policies on the switch.
- **field-set** - Configure field sets to use with the traffic policies.
  - **ipv4 prefix** ***source_name*** - Specify the IPv4 prefix and source name.
  - **ipv6 prefix** ***source_name*** - Specify the IPv6 prefix and source name.
  - **service** ***source_name*** - Specify the service and source name.

Example

Use the following commands to configure a sensor, *sensor_db*, with the IPv4 address, *192.168.92.157*, and port *443*:

```
switch(config)# managment data source
switch(config-mgmt-ds)# sensor sensor_db
switch(config-mgmt-ds-sensor-sensor_db)# ip 192.168.96.157 port 443
switch(config-mgmt-ds-sensor-sensor_db)#
```

3.7.38 management defaults

The **management defaults** command enters the Defaults Management Configuration Mode and configures storing secrets on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Defaults Management Configuration

Command Syntax

```
management defaults secret hash [md5 | scrypt | sha-512 | yescrypt]

[no | default] management defaults
```

Parameters

- **management defaults** - Enters the Defaults Management Configuration Mode.
- **secret** - Configure storing secrets.
- **hash** - Specify a hash algorithm to use for secrets.
  - **md5** - Specify Message-Digest Algorithm 5.
  - **scrypt** - Specify scrypt, a password-based key derivation function (KDF) designed specifically to make brute-force attacks against hashed passwords significantly harder, even when attackers use specialized hardware like GPUs or FPGAs.
  - **sha-512** - Specify SHA-512 a cryptographic hash function that is part of the SHA-2 family, standardized by NIST (National Institute of Standards and Technology). It is a highly secure and widely used algorithm for ensuring data integrity and securing digital operations.
  - **yescrypt** - Specify yescrypt, a modern, highly secure password-based key derivation function (KDF) designed as a successor and alternative to functions like PBKDF2, scrypt, and bcrypt. It was developed by Alexander Peslyak (Solar Designer) and is specifically engineered to achieve the best possible resistance against hardware-accelerated cracking attacks using GPUs, FPGAs, and ASICs.

Example

Use the following commands to add MD5 as the secret hash:

```
switch(config)# managment defaults
        switch(config-mgmt-defaults)# secret hash md5
```

3.7.39 management dmf

The **management dmf** command in the DANZ Monitoring Fabric (DMF) Configuration Mode allows the configuration of up to two DMF controllers on the network.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

DANZ Monitoring Fabric (DMF) Configuration

Command Syntax

managment dmf [disabled] [controller address ***ip_address1*** **controller address** ***ip_address2***

[no | default]> managment dmf

Parameters

- **disabled** - Disables DMF on the switch.
- **controller address** ***ip_address1*** - Configure the first DMF controller with an IPv4 or IPv6 address.
- **controller address** ***ip_address2*** - Configure the second DMF controller with an IPv4 or IPv6 address.

Example

Use the following commands to add a DMF controller, *172.16.23.47*, to the switch:

```
switch(config)# manangement dmf
switch(config-mgmt-dmf)# controller 172.16.21.47
switch(config-mgmt-dmf)#
```

3.7.40 management file-systems

The **management file-systems** command in the File Systems Management Configuration Mode allows the configuration and management of the file system on the switch.

Command Mode

Global Configuration

File Systems Management Configuration

Command Syntax

management file-systems nfs [crash: ***directory_name*****] [file:** ***directory_name*****] [flash:** ***directory_name*****]**

Parameters

- **nfs** - Specifies the network file system.
- **crash:** ***directory_name*** - Specify the location of the crash files.
- **file:** ***directory_name*** - Specify the location of the files.
- **flash:** ***directory_name*** - Specify the location of the flash files.

Example

Use the following commands to manage the crash files:

```
switch(config)# management file-systems
            switch(config-mgmt-file-systems)# nfs crash:
```

3.7.41 management http-server

The **management http-server** command enters the HTTP Management Configuration Mode of the switch to allow Application Programming Interface (API) access to the switch for programmatic commands.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

HTTP Management Configuration

Command Syntax

management http-server [cors allowed-origin origin ***server_address*** **| all | *]**

management http-server default-services

management http-server header csp frame-ancestors uri

management http-server log-level [alert | crit | debug | emerg | error | info | notice | warn]

management http-server protocol [http [localhost | port ***port_number*****]] [https [port** ***port_number*** **| ssl** ***profile_name*****]] [unix-socket]**

management http-server qos dscp ***dscp_value***

management http-server vrf [default | ***vrf_name***

Parameters

- **management http-server cors** - Specify Cross-Origin Resource Sharing for the HTTP Server.
  - **allowed-origin** ***server_address*** - Specify an allowed origin server IP address.
  - **[all | *]** - Specify all to allow all CORS.
- **management http-server default-services** - Specify to use default services, capi-doc and tapagg, for the HTTP Server.
- **management http-server header** - Configure additional headers for the HTTP Server.
  - **csp** - Specify content security policy headers.
  - **frame-ancestors** - Specify CSP directive frame-ancestors.

- **uri** - Configure the URI for the host.

- **management http-server log-level** - Specify any of the level parameters to log as a syslog message.
- **management http-server protocol** - Configure server options.
  - **http [localhost | port** ***port_number*** - Configure a local host and port for the HTTPS Server.
  - **https [port** ***port_number*** **| ssl** ***profile_name*** - Configure a port and SSL profile name.
  - **unix-socket** - Specify a Unix Domain Socket.
- **management http-server qos** - Configure Quality of Service (QoS) parameters.
  - **dscp** - ***exit***
- **management http-server vrf [default |** ***vrf_name*** - Specify using the default VRF on the switch or another configured VRF.

Example

Use the following commands to specify using the default services for the HTTP Server:

```
switch(config)# management http-server
switch(config-mgmt-http-server)# default-services
switch(config-mgmt-http-server)#
```

3.7.42 management ldap group

The **management ldap** command in the Global Configuration mode enters the switch into LDAP Management Configuration Mode and allows the configuration of an LDAP group and server. This allows the switch to authenticate and authorize users against an external Lightweight Directory Access Protocol (LDAP) server and centralizes user management.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

LDAP Management Configuration

Command Syntax

management ldap [group policy ***policy_name*** **group** ***group_name*** **role** ***role_name*** **[after | before]** ***group_name*** **[privilege** ***level*****]**

Parameters

- **management ldap** - Configure LDAP options.
  - **group policy** ***policy_name*** - Configure a group policy name.
  - **group** ***group_name*** - Configure the group name to add to the configuration.
  - **role** ***role_name*** - Specify the role name for the group.
  - **[after | before]** ***group_name*** - Specify adding the role before or after a rule.
  - **privilege** ***level*** - Configure a privilege level between 0 and 15.

Example

Use the following commands to add the policy, *policy1*, to group, *ldap_group*, with the role of *manager*, and privilege level 10:

```
switch(config)# management ldap
switch(config-mgmt-ldap)# group policy policy1
switch(config-mgmt-ldap-gp-policy1)# group ldap_group role manager privilege 10
switch(config-mgmt-ldap-gp-policy1)#
```

3.7.43 management ldap server

The **management ldap server** command enters the LDAP Management Configuration Mode and allows the configuration of an LDAP server for authentication on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

LDAP Management Configuration

Command Syntax

management ldap server [defaults [authorization group policy ***policy_name*****]** **[base-dn** ***domain_name*****]** **[rdn attribute user** ***attr_name*****]** **[search username** ***username*** **password** ***password*****]** **[ssl-profile** ***profile_name*****]** **[timeout** ***seconds*****]]** **[host** ***host_name*** **port** ***port_number*** **vrf** ***vrf_name*****]**

[no | default] management ldap server

Parameters

- **management ldap server** - Enters the LDAP Management Configuration Mode and allows the configuration of an LDAP server.
- **defaults** - Configure default LDAP options for all servers.
  - **authorization group policy** ***policy_name*** - Configure LDAP options for user authorization using a group policy name.
  - **base-dn** ***domain_name*** - Specify a distinguished domain name.
  - **rdn attribute user** ***attr_name*** - Add an attribute for a Relative Distinguished Name.
  - **search username** ***username*** **password** ***password*** - Configure search options for the LDAP server.
  - **ssl-profile** ***profile_name*** - Add an SSL profile to the configuration.
  - **timeout** ***seconds*** - Configure the length of time to wait before timing out the session.
- **host** ***host_name*** - Specify a hostname or IP address of the LDAP server.
  - **port** ***port_number*** - Specify a port number. The configuration uses port 389 by default.
  - **vrf** ***vrf_name*** - Specify the VRF name for the configuration.

Example

Use the following commands to use *arista.com* as the base Domain Name:

```
switch(config)# management ldap
switch(config-mgmt-ldap)# server defaults
switch(config-ldap-defaults)# base-dn arista.com
switch(config-ldap-defaults)#
```

3.7.44 management nic profiles

The **management nic profiles** command enters the Network Interface Card (NIC) Profile Configuration Mode and allow configuration of an interface for an internal service client such as ZTP or an internal monitoring process that needs to reach a provisioning server.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Network Interface Card (NIC) Profile Configuration

Command Syntax

management nic profiles profile ***profile_name*** **[connection [ssl profile** ***profile_name*****] [timeout** ***seconds*** **]] [job** ***job_name*** **metric path** ***path_name*****] [port** ***port_number*****] [system auto-discovered]] [polling interval** ***interval***

[no | default] management nic profiles profile ***profile_name***

Parameters

- **management nic profiles profile** ***profile_name*** - Configure a name for the NIC profile.
- **connection** - Configure connection parameters:
  - **ssl** - Add an SSL profile to the connection
  - **timeout - Configure the length of time, in seconds, before the connection disconnects.**
- **job** ***job_name*** - Specifies the type of job to run on the client.
  - **metric path** ***path_name*** - Specify the metric path, in the format of a URL, used for the job.
  - **port** ***port_number*** - Specify a port between 1 and 65535.
  - **system auto-discovery** - Specify if you want to auto-discover jobs on the switch.
- **polling interval** ***interval*** **seconds** - Specify a polling interval between 1 and 600 seconds.

Example

Use the following commands to add an SSL profile, *secure_1*, to the NIC profile, *nic_mgmt*:

```
switch(config)# management nic profiles profile nic_mgmt
switch(config-mgmt-nic-profile-nic_mgmt)# connection ssl profile secure_1
switch(config-mgmt-nic-profile-nic_mgmt)#
```

3.7.45 management package

The **management package** command in the Package Management Configuration Mode configures a remote source for downloading optional software extension packages.

Command Mode

Global Configuration

Package Management Configuration

Command Syntax

management package repository ***repo_name*** **[description** ***description*****] [type** ***description*****] [url** ***url*****]**

Parameters

- **management package** - Enters the Package Management Configuration Mode on the switch.
- **repository** ***repo_name*** - Specify the repository name.
- **description** ***description*** - Create a description of repository that used in `show` commands.
- **type yum** - Retrieve the files using *yum*.
- **url*****url*** - Specify the network path to the repository server. The URL defines transport protocol for the files.

Example

Use the following commands to create a repository, *prod_ext*, with the URL, *https://10.11.10.27/arista/extensions/*:

```
switch(config)# management package
            switch(config-mgmt-package)# management package repository pProd-Ext type url
 https://10.11.10.27/arista/extensions/
```

3.7.46 management security auto-certificate

The **management security auto-certificate** command enters the Auto-Certificate Security Management Configuration Mode and automates the management and renewal of the digital certificates used by the switch for various secure management services such HTTPS for APIs.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Auto-Certificate Security Management Configuration

Command Syntax

management security auto-certificate [profile ***profile_name*** **[digest [sha256 | sha384 | sha512]] [key** ***key_name*** **] [parameters [distinguished-name [common-name** ***name***] **[country** ***name*** **[email** ***email*** **] [locality** ***locality***] **[organization*****organization***] **[organization-unit** ***unit***] **[serial-number** ***number*** **] [state** ***state***]] **[subject-alternative-name [dns** ***dns_name***] **[email** ***email***] **[ip** ***ip_address***] **[uri** ***uri***] **] [protocol instance** ***instance_name***] **[renewal** ***seconds*** **seconds]]**

management security auto-certificate [protocol est ***profile_name*** **[connection retry [count** ***num_retries***] **[interval** ***seconds*** **seconds]] [credentials enroll [secret [0 | 7 | 8a]** ***secret***] **[token [0 | 7 | 8a]** ***token***] **[username** ***username*** **]] [disabled] [server [ssl profile** ***profile_name***] **[url** ***url*** **] [vrf** ***vrf_name***

Parameters

- **management security** ***profile_name*** - Enters the Security Management Configuration Mode.
- **auto-certificate profile** ***profile_name*** - Configure profile options for Automatic Certificate Management.
  - **digest [sha256 | sha384 | sha512** - Specify the digest algorithm used to sign a Certificate Signing Request (CSR).
  - **key** ***key_name*** - Configure a key name used for the certificate.
  - **parameters** - Configure the certificate parameters.
    - **distinguished-name** - Configure a distinguished name for the certficate.
      - **common-name** ***name*** - Specify the common name.
      - **country** ***name*** - Specify the country.
      - **email** ***email*** - Specify the email address used for the certificate.
      - **locality** ***locality*** - Specify the locality.
      - **organization** ***organization*** - Add the organization.

- **organization-unit** ***unit*** - Specify the organization unit.
- **serial-number** ***number*** - Specify the serial number.
- **state** ***state*** - Specify the state.

- **subject-alternative-name** - Configure the alternative subject name extension.
  - **dns** ***dns_name*** - Add the name of the DNS server.
  - **email** ***email*** - Add the email address.
  - **ip** ***ip_address*** - Specify the IP address of the DNS server.
  - **uri** ***uri*** - Specify the Universal Resource Indicator (URI).

- **auto-certificate protocol est** ***profile_name*** - Specify the profile name for Enrollment over Secure Transport (EST).
  - **connection retry** - Configure the number of times to retry the connection.
    - **count** ***num_retries*** - Specify the number of retries.
    - **interval** ***seconds*** - Specify the interval between connection retries.
    - **seconds** - Specify the unit of time.
  - **credentials** - Configure the credentials used with EST.
    - **enroll** - Enroll with the following credentials:
      - **secret [0 | 7 | 8a** ***secret*** - Configure a secret.
      - **token [0 | 7 | 8a** ***token*** - Configure a JSON token.
      - **username** ***username*** - Configure a username and secret.
        - **secret [0 | 7 | 8a*****secret***
    - **re-enroll** - Re-enroll with the following credentials:
      - **secret [0 | 7 | 8a** ***secret*** - Configure a secret.
      - **token [0 | 7 | 8a** ***token*** - Configure a JSON token.
      - **username** ***username*** - Configure a username and secret.
        - **secret [0 | 7 | 8a** ***secret***
    - **disabled** - Temporarily disable sending requests to the EST server.
    - **server** - Configure the EST server options:
      - **ssl profile** ***profile_name*** - Specify an SSL profile.
      - **url** ***url*** - Specify the URL of the EST server.
      - **vrf** ***vrf_name*** - Specify the VRF used for the EST server.

3.7.47 management security entropy

The **management security entropy** command manages the source of cryptographic entropy (randomness) and provides high quality randomness for SSH keys, SSL/TLS certificates, and random session identifiers.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security entropy source [cpu jitter] [hardware exclusive] [haveged]

[no | default] management security entropy

Parameters

- **entropy source** - Configure the source used for entropy on the switch.
- **cpu jitter** - Configure using a CPU-based source with the Jitter RNG algorithm.
- **hardware exclusive** - Configure using hardware exclusively for entropy.
- **haveged** - Use the Hardware Volatile Entropy Gathering and Extension (HAVEGED) algorithm to quickly and efficiently generate high quality cryptographic entropy.

Example

Use the following command to use *cpu jitter* for security entropy:

```
switch(config)# managment security
switch(config-mgmt-security)# entropy cpu jitter
switch(config-mgmt-security)#
```

3.7.48 management security network

The **management security network** command enters the Security Management Configuration mode and then configures security policies that govern the access and behavior of various management applications on the switch. It defines rules to protect the control plane from unauthorized or malicious network activity.

The **[no | default]** versions of the command return the feature to its default settings.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security network client protocol [ftp | http | tftp] disabled

[no | default] management security network client protocol

Parameters

- **network** - Configure network protocols.
- **client** - Specify client traffic.
- **protocol** - Select a protocol for client traffic.
- **[ftp | http | tftp] disabled** - Disables the protocol and no longer allows clients to connect over these protocols.

Example

Use the following commands to disable FTP client traffic:

```
switch(config)# management security
switch(config-mgmt-security)# network client protocol ftp disabled
switch(config-mgmt-security)#
```

3.7.49 management security ocsp

The **management security ocsp** command enters the Security Online Certificate Status Protocol (OCSP) Configuration Mode and quickly checks the revocations status of digital certificates used by management services such as HTTP or LDAP over TLS.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security ocsp profile ***profile_name*** **[chain certificate requirement responder [all | leaf | none]] [extension nonce request [disabled | response]] [response validity-time extended-by** ***seconds*****] [timeout** ***seconds*****] [url** ***url*****] [vrf** ***vrf*****]**

[no | default] management security ocsp profile ***profile_name***

Parameters

- **ocsp profile** ***profile_name*** - Configure a name for the OCSP profile.
  - **chain** - Configure a chained certificate for OCSP.
    - **certificate requirement - Add a check to the certificate for validity.**
    - **responder** - Configure the requirements for querying the OCSP responder.
      - **all** - Perform OCSP verification on the whole chain.
      - **leaf** - Specify to only perform OCSP verification on the leaf.
      - **none** - Specify to only perform OCSP verification on certificates with a specified responder.
  - **extension nonce request** - Configure sending a nonce in the OCSP requests.
    - **disabled** - Specify to not send a nonce in the OCSP request.
    - **response** - Specify to require the OCSP nonce in the OCSP response.
  - **response validity-time extended-by** ***seconds*** - Configure a leeway time when checking the validity of OCSP responses from 1 to 10800 seconds.
  - **timeout** ***seconds*** - Configure the length of time to timeout OCSP queries from 1 to 600 seconds.
  - **url** ***url*** - Configure the URL of overriding OSCP responder.

- **`vrf`** ***vrf*** - Configure the VRF as the location to perform OCSP queries.

Example

Use the following commands to add the profile, *OCSP_1*, with an *extension nonce request* of *disabled*

```
switch(config)# management security
switch(config-mgmt-security)# ocsp profile OCSP_1
switch(config-mgmt-sec-ocsp-profile-OCSP_1)# extension nonce request disabled
switch(config-mgmt-sec-ocsp-profile-OCSP_1)#
```

3.7.50 management security password

The **management security password** command enters the Security Management Configuration Mode and configures robust password policies for all local user accounts.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security password [encryption reversible aes-256-gcm] [encryption-key common custom ***key*****] [minimum length** ***num_char*****] [policy** ***policy_name*** **[deny last** ***pw_count*****] [maximum repetitive** ***num_char*** **sequential** ***num_char*****] [minimum [changed** ***num_char*****] [digits** ***num_char*****] [length** ***num_char*****] [lower** ***num_char*****] [** ***num_char*****] [upper*****num_char*****]]**

[no | default] management security password

Parameters

- **password** - Configure password policies for the management interface.
- **encryption reversible aes-256-gcm** - Configure a common encryption algorithm.
- **encryption-key common custom** ***key*** - Configure a 32-byte customized encryption key.
- **minimum length** ***num_char*** - Configure a minimum length between 1 and 32 characters.
- **policy** ***policy_name*** - Configure password complexity settings for a policy profile.
  - **deny last** ***pw_count*** -
  - **maximum [repetitive |sequential]** ***num_char***
  - **minimum** - Configure the following minimum settings:
    - **changed** ***num_char*** - Configure the number of positional characters that must change 0 to 65535.
    - **digits** ***num_char*** - Configure the number of digits required for the password 0 to 65535.
    - **length** ***num_char*** - Configure the number of characters for the password 0 to 65535.
    - **lower** ***num_char*** - Configure the number of lower case characters required for the password from 0 to 65535.

- **special** ***num_char*** - Configure the number of special characters, `!"#$%&\'()*+,-./:;<=>?@[^]_`{|}~`, required for the password from 0 to 65535
- **upper** ***num_char*** - Configure the number of lower case characters required for the password from 0 to 65535.

Example

Use the following commands to create a password policy, `ldap_access`, with the minimum length of 15 characters:

```
switch(config)# management security
switch(config-mgmt-security)# policy ldap_access
switch(config-pwd-policy-ldap_access)# minimum length 15
switch(config-pwd-policy-ldap_access)#
```

3.7.51 management security session

The **management security session** command enters the Security Management Configuration Mode and configures the session parameters that govern the behavior, timeouts, and security of interactive management sessions.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security session shared-secret profile ***profile_name*** **secret** ***secret_name*** **[0 | 7 | 8a]** ***password*** **[infinite] [** ***mm/dd/yyyy hh:mm:ss*** **[infinite |** ***date*** **local-time] [receive-lifetime** ***mm/dd/yyyy hh:mm:ss*** **[infinite |** ***date*** **local-time]] [transmit-lifetime [infinite** ***mm/dd/yyyy hh:mm:ss date*** **local-time]]**

Parameters

- **session shared-secret profile** ***profile_name*** - Configure a profile for shared secret settings.
- **secret** ***secret_name*** - Configure a name for the secret.
  - **0** - Indicates that the key is not encrypted.
  - **7** - Specifies that a hidden string follows.
  - **8a** - Specifies that an AES-256-GCM encrypted key follows.
  - ***password*** - Specify a password
    - **infinite** - Specify an infinite lifetime for the password.
      - **infinite**
      - ***mm/dd/yyyy*** - Specify a date in the month/day/year format.
      - ***yyyy-mm-dd*** - Specify a date in the year-month-day format.
    - ***mm/dd/yyyy*** - Specify a date in the month/day/year format.
    - **receive-lifetime** - Configure the lifetime for receiving the key.
      - **infinite**

        - ***mm/dd/yyyy*** - Specify a date in the month/day/year format.
        - ***yyyy-mm-dd*** - Specify a date in the year-month-day format.
    - **`transmit-lifetime`** - Configure the lifetime for transmitting the key.
        - **`infinite`**
        - ***mm/dd/yyyy*** - Specify a date in the month/day/year format.
        - ***yyyy-mm-dd*** - Specify a date in the year-month-day format.
    - ***yyyy-mm-dd*** - Specify a date in the year-month-day format.
- **`local-time`** - Configure secrets using the local timezone from the system clock. By default, the parameter sets to UTC.

Example

Use the following commands to configure a session to use the profile, `mySession`, with the secret name, `mySecret`, and the secret, `qwerty`, with an infinite `receive-lifetime` and `transmit-lifetime`, with the default local-time:

```
switch(config)# management security
switch(config-mgmt-security)# session shared-secret profile mySession
switch(config-mgmt-sec-sh-sec-profile-mySession)# secret mySecret 0 qwerty receive-lifetime
 infinite
transmit-lifetime infinite local-time
switch(config-mgmt-sec-sh-sec-profile-mySession)#
```

3.7.52 management security signature-verification

The **management security signature-verification** command enters the Security Management Configuration Mode and apply a named SSL profile that dictates the policies for verifying the integrity of the system files related to secure TLS/SSL communications.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Security Management Configuration

Command Syntax

management security signature-verification extension ssl profile ***profile_name***

[no | default] management security signature-verification

Parameters

- **signature-verification** - Configure verifying signatures of files.
- **extension** - Specifies that the policy applies specifically to SWIX signatures.
- **ssl** - Specifying using SSL to verify the signatures.
- **profile** ***profile_name*** - Specify an SSL profile name to use for verification. It must contain a trusted root or intermediate CA certificate corresponding to the private key used by the software vendor.

Example

Use the following commands to verify SWIX signatures using the SSL profile, `swix_ca`:

```
switch(config)# management security
switch(config-mgmt-security)# signature-verification extension ssl profile swix_ca
switch(config-mgmt-security)#
```

3.7.53 management security ssl

The **management security ssl** command enters the SSL Security Management Configuration mode to configure and manage the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) parameters for all secure management services on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

SSL Security Management Configuration

Command Syntax

management security ssl [monitor expiry ***time*** **[days | hours] [log interval** ***time*** **[days | hours]]**

management security ssl [profile ***profile_name*** **[certificate** ***cert_name*** **[auto-certificate** ***cert_name*****] [common-name [key** ***key_name*****] [username regexp** ***regex*****]] [local** ***cert_name*** **key** ***cert_name*****] [policy [expiry-date ignore] [key** ***key_name*****]] [requirement extended-key-usage [hostname match] [key** ***key_name*****]] [chain [certificate** ***cert_name*****] [local** ***cert_name*****] [policy [expiry-date ignore]] [requirement [basic-constraint ca true] [include root-ca]] [cipher [v1.0** ***cipher_list*****] [v1.3** ***cipher_list*****] [diffie-hellman parameters [ffdhe2048 | ffdhe3072 | ffdhe4096 | generated]] [dtls version [1.0 | 1.2 | add | remove]] [fips restrictions] [key-establishment-group** ***group_names*****] [peer certificate [format ip-address exact] [requirement [hostname match subject-alternative-name [common-name]]] [revocation [crl [name** ***crl_name*****] [policy expiry-date ignore]] [ocsp profile** ***profile_name*****]] [signature algorithm** ***alg_list*****] [tls versions [1.0 | 1.1 | 1.2 | 1.3 | add | remove]] [trust [certificate** ***cert_name*****] [policy expiry-date ignore]] [requirement [basic-constraint ca true] [hostname fqdn]] [system]**

[no | default] management security ssl monitor

[no | default] management security ssl profile

Parameters

- **ssl monitor** - Configure monitoring options for all certificates.
  - **expiry** - Log SSL monitoring warnings for certificates approaching an expiration date.
  - ***time*** **[days | hours]** - Configure the amount of time prior to certificate expiration from 1 to 999 in days or hours.

- **log interval** - Configure logging intervals for sending logs to the syslog server.
- ***time*** **[days | hours]** - Configure the length of time between send log messages from 1 to 999 in days or hours.

- **ssl profile** ***profile_name*** - Configure an SSL profile for SSL Security Management.
  - **certificate** - Configure a certificate for self-authentication.
    - ***cert_name*** - Specify the name of the certificate.
    - **auto-certificate** ***profile_name*** - Specify the name of an auto-certificate profile.
    - **common-name**
      - **key** ***key_name*** - Configure the key matching the certificate.
      - **username regex** ***regex*** - Configure the REGEX to extract the username.
    - **local** ***cert_name*** - Configure a local certificate name.
      - **key** ***key_name*** - Configure a key matching the local certificate.
    - **policy** - Configure the policy for the certificate.
      - **expiry-date ignore** - Ignore the expiration date of the certificate.
      - **key** ***key_name*** - Configure a key matching the certificate.
    - **requirement** - Add a check to validate the certificate.
      - **extended-key-usage** - Configure extended key usage for the certificate.
      - **hostname match** - Specify to verify and match the hostname for the certificate.
      - **key** ***key_name*** - Configure a key matching the certificate.
  - **chain** - Configured chained certificates.
    - **certificate** ***cert_name*** - Specify a certificate name.
    - **local** ***cert_name*** - Configure a local certificate name.
    - **policy** - Configure the policy for the certificate.
      - **expiry-date ignore** - Ignore the expiration date of the certificate.
    - **requirement** - Add a check to validate the certificate.
      - **extended-key-usage** - Configure extended key usage for the certificate.
      - **hostname match** - Specify to verify and match the hostname for the certificate.
  - **cipher** - Configure TLS ciphers.
    - **v1.0** ***cipher_list*** - Specify the cipher lists, separated by a colon, for TLS versions 1.0, 1.1, and 1.2.
    - **v1.3** ***cipher_list*** - Specify the cipher lists, separated by a colon, for TLS versions 1.3.
  - **diffie-hellman parameters** - Configure Diffie-Hellman parameters:
    - **ffdhe2048** - Specify from RFC7919.
    - **ffdhe3072** - Specify from RFC7919.

- **ffdhe4096** - Specify from RFC7919.
- **generated** - Specify 2048-bit parameters generated by the switch.

- **dtls version** - Configure Datagram Transport Layer Security (DTLS) settings:
  - **1.0** - Specify DTLS version 1.0.
  - **1.2** - Specify DTLS version 1.2.
  - **add** - Add versions to the list.
  - **remove** - Remove versions from the list.
- **fips restrictions** - Configure FIPS restrictions.
- **key-establishment-group** ***group_names*** - Configure TLS 1.3 key establishment groups using canonical names recognized by the TLS standards.
- **peer certificate** - Configure peer-related certificate options:
  - **format ip-address exact** - Specify the format rules for IP addresses to reject wildcards in the IP address.
  - **requirement hostname match subject-alternative-name [common-name]** - Specify a check for certificate validity to include hostname matching for the common name.
- **revocation** - Configure checking of the revocation status for certificates.
  - **crl name** ***crl_name*** **- Specify the name of the Certificate Revocation List (CRL).**
    - **policy expiry-date ignore** - Configure the policy to ignore certificate expiration dates.
  - **ocsp profile** ***profile_name*** - Specify the name of the Online Certificate Status Protocol (OCSP) profile.
- **signature algorithm** ***alg_list*** - Specify the TLS signature algorithm list.
- **tls** - Configure TLS settings.
  - **versions** - Specify the TLS version:
    - **1.0**
    - **1.1**
    - **1.2**
    - **1.3**
    - **add** - Add versions to the list.
    - **remove** - Remove versions from the list.
- **trust** - Configure a trusted certificate.
  - **certificate** ***cert_name*** - Specify the name of a certificate.
  - **policy expiry-date ignore** - Configure the policy to ignore expiration dates.
  - **requirement** - Add a check to validate the certificate.

- **basic-constraint ca true** - Configure the Certificate Authority attribute to true and allow the CA to sign and issue other certificates in the trust chain This certificate is the trust anchor or an intermediate authority.
- **hostname fqdn** - Specify that the hostname must be a fully qualified domain name without wildcards.

- **system** - Specify using a system-supplied trust certificate.

Example

Use the following commands to set the SSL monitoring of certificates to log warning for certificate expiration to 10 days and log the warning to syslog every 8 hours:

```
switch(config)# management security
switch(config-mgmt-security)# ssl monitor expiry 10 days log interval 8 hours
switch(config-mgmt-security)#
```

3.7.54 management ssh

The **management ssh** command places the switch in SSH Management Configuration Mode to adjust SSH session connection parameters.

The **no management ssh** and **default management ssh** commands delete the SSH Management Configuration Mode statements from ***running-config***.

The ***mgmt-ssh*** configuration mode does not provide a group change mode. The ***running-config*** changes immediately upon entering commands. Exiting the SSH Management Configuration Mode does not affect ***running-config***. The **exit** command returns the switch to Global Configuration Mode.

Command Mode

Global Configuration

Command Syntax

```
management ssh

no management ssh

default management ssh
```

Parameters

- **authentication** - Change authentication settings.
- **authorized-principals** - Configure the authorized principals settings.
- **cipher** - Configure an exclusive list of cryptographic ciphers for SSH.
- **client-alive** - Set SSH ClientAlive options.
- **compression** - Configure SSH compression algorithms.
- **connection** - Configure settings for SSH connections.
- **fips restrictions** - Configure FIPS settings.
- **hostkey** - Set SSH hostkey related options.
- **idle-timeout** - Set idle session timeout (minutes).
- **ip access group** - Set the SSH IPv4 configuration.
- **ipv6 access group** - Set the SSH IPv6 configuration.
- **key-exchange** - Configure an exclusive list of key-exchange methods for SSH.

- **log-level** - Configure SSH daemon logging level.
- **logging** - Configure SSH system logging.
- **login timeout** - Configure options related to logging into SSH.
- **mac hmac** - Exclusive list of MAC algorithms for SSH.
- **qos** - Configure QoS parameters.
- **rekey** - Configure the length of time before rekeying SSH connections.
- **server-port** - Change the server port.
- **shutdown** - Disable SSH on the switch.
- **trusted-ca** - Configure a trusted certficate.
- **user-keys** - Configure SSH user key settings.
- **username** - Configure SSH user-specific settings.
- **verify** - Configure option for SSH verification.
- **vrf** - Configure the VRF to use for SSH.

Examples

- This command places the switch in SSH Management Configuration Mode:

```
switch(config)# management ssh
switch(config-mgmt-ssh)#
```

- This command returns the switch to Global Configuration Mode:

```
switch(config-mgmt-ssh)# exit
switch(config)#
```

3.7.55 management telnet

The **management telnet** command places the switch in Telnet Management Configuration Mode to adjust Telnet session connection parameters.

The **no management telnet** and **default management telnet** commands delete the Telnet Management Configuration Mode statements from ***running-config***.

The Telnet Management Configuration Mode does not provide a group change mode. The ***running-config*** changes immediately upon entering commands. Exiting the Telnet Management Configuration Mode does not affect the ***running-config***. The **exit** command returns the switch to Global Configuration Mode.

Command Mode

Global Configuration

Command Syntax

management telnet

no management telnet

default management telnet

Examples

- This command places the switch in Telnet Management Configuration Mode:

```
switch(config)# management telnet
switch(config-mgmt-telnet)#
```

- This command returns the switch to Global Configuration Mode:

```
switch(config-mgmt-telnet)# exit
switch(config)#
```

3.7.56 management timeout

The **management timeout** command in the Console, SSH, or Telnet Configuration Mode allows the configuration of the SSH, Telnet, and Console **timeout** parameter.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Console Configuration

SSH Configuration

Telnet Configuration

Command Syntax

management [console | ssh | telnet] timeout ***minutes*** **warning** ***minutes*****]**

no management [console | ssh | telnet] timeout

default management [console | ssh | telnet]

Parameters

- **timeout** ***minutes*** **warning** ***minutes*** - Configure the session timeout from 0 to 86400 minutes and generate a warning message about the impending timeout. The warning value must be less than the configured timeout value..

Example

Specify a console timeout of 30 minutes and issue a warning 5 minutes before closing the session:

```
switch(config)# management console
switch(config-mgmt-console)# timeout 30 warning 25
```

3.7.57 protocol http (API Management)

The **`protocol http`** command enables the hypertext transfer protocol (HTTP) server.

The **`no protocol http`** and **`default protocol http`** commands disable the HTTP server by removing the **protocol http** statement from ***running-config***.

Command Mode

Mgmt-API Configuration

Command Syntax

`protocol http` [**TCP_PORT**]

`no protocol http`

`default protocol http`

Parameters

- **TCP_PORT** Port number used for the HTTP server. Options include:
  - **no parameter** Specifies default ***port number 80***.
  - **port *1 to 65535*** Specifies HTTP server port number. The value ranges from ***1*** to ***65535***.

- **localhost** The name of the server bound on the localhost.
- **port** The number of the TCP port to serve on.

Related Commands

management api http-commands places the switch in ***mgmt-api configuration mode***.

Example

These commands enables the management API for the HTTP server.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)#
```

3.7.58 protocol https (API Management)

The **`protocol https`** command enables the HTTP secure server. The HTTP secure server is active by default.

The **`default protocol https`** command restores the default setting by removing the **`no protocol https`** statement from ***running-config***. The **`no protocol https`** command disables the HTTP secure server.

Command Mode

API Management Configuration

Command Syntax

`protocol https` [**TCP_PORT**]

`no protocol https`

`default protocol https`

Parameters

- **TCP_PORT** - Port number used for the HTTPS server. Options include:
  - **no parameter** - Specifies default ***port number 443***.
  - **port *1 to 65535*** - Specifies HTTP server port number. The value ranges from ***1*** to ***65535***.
- **certificate** - The HTTPS key and certificate to use for the switch.
- **cipher** - Exclusive list of cryptographic ciphers.
- **key-exchange** - Exclusive list of key-exchange algorithms.
- **mac** - Exclusive list of MAC algorithms.
- **port** - The TCP port number to serve on.
- **ssl** - Configure SSL options.

Related Commands

management api http-commands places the switch in ***API Management Configuration Mode***.

Examples

- These commands enables service to the HTTP server. The **no shutdown** command allows access to the service.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# protocol https
switch(config-mgmt-api-http-cmds)# no shutdown
```

- These commands specify the port number used for the HTTPS server. The **no shutdown** command allows access to the service.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# protocol https port 52
switch(config-mgmt-api-http-cmds)# no shutdown
```

3.7.59 protocol https certificate (API Management)

The **`protocol https certificate`** command configures the HTTP secure server to request an X.509 certificate from the client. The client then authenticates the certificate with a public key.

The **`no protocol https certificate`** and **`default protocol https certificate`** commands restore default behavior by removing the **`protocol https certificate`** statement from ***running-config***.

Command Mode

API Management Configuration

Command Syntax

```
protocol https certificate

no protocol https certificate

default protocol https certificate
```

Related Command

management api http-commands places the switch in ***API Management Configuration Mode***.

Example

These commands configure the HTTP secure server to request an X.509 certificate from the client for authentication.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# protocol https certificate
switch(config-mgmt-api-http-cmds)#
```

3.7.60 qos

The **qos** command in the SSH Management Configuration Mode applies the Differentiated Services Code Point (DSCP) markings to SSH traffic and ensures prioritizing packets on the network.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

qos dscp ***dscp_value***

no qos dscp

default qos dscp

Parameters

- **qos dscp*dscp_value*** - Apply a QoS DSCP value between 0 and 63 to SSH traffic. Using 0 applies a Best Effort tag to the traffic.

Example

Use the following commands to set the QoS DSCP value to 16 (Network Management) on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# qos dscp 16
switch(config-mgmt-ssh)#
```

3.7.61 rekey

The **rekey** command in the SSH Management Configuration Mode forces the SSH session to renegotiate new symmetric encryption keys after meeting a specific threshold.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

rekey [frequency ***data_amount*** **[gbytes | kbytes | mbytes]] [interval** ***time*** **[days | hours | minutes | seconds | weeks]]**

no qos dscp

default qos dscp

Parameters

- **rekey frequency** ***data_amount*** - Specify the quantity of data sent through the SSH session before triggering a rekey. Use one of the following units:
  - **gbytes** - Specify Gigabytes.
  - **kbytes** - Specify Kilobytes.
  - **mbytes** - Specify Megabytes.
- **interval** ***time*** - Specify an interval in time using one of the following units:
  - **days** - Specify the interval in days.
  - **hours** - Specify the interval in hours.
  - **minutes** - Specify the interval in minutes.
  - **seconds** - Specify the interval in seconds.
  - **weeks** - Specify the interval in weeks.

Examples

Use the following commands to set the rekey frequency to 10 Gigabytes on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# rekey frequency 10 gbytes
            switch(config-mgmt-ssh)#
```

Use the following commands to set the rekey interval to 8 hours on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# rekey interval 8 hours
switch(config-mgmt-ssh)#
```

3.7.62 reset system storage secure

Use the **reset system storage secure** command to trigger the secure erase mechanism. Secure erase is a command that deliberately, permanently, and irreversibly removes and destroys the data stored on a storage device, rendering that data unrecoverable.

Command Mode

EXEC

Command Syntax

```
reset system storage secure
```

Examples

- To trigger the secure erase mechanism, use the **reset system storage secure** command.

```
switch# reset system storage secure
WARNING! This will destroy all
data and will NOT be recoverable.
Device will reboot into Aboot, and
execution may take up to one hour.
Would you like to proceed? [y/N]
```

- If a particular platform does not support the **reset system storage secure** command , the following message appear:

```
switch#reset system storage secure
% Unavailable command (not supported on this hardware platform)
```

3.7.63 show inventory

The **`show inventory`** command displays the hardware components installed in the switch. Each component has a serial number and a description.

Command Mode

EXEC

Command Syntax

```
show inventory
```

Example

This command displays the hardware installed in a DCS-7150S-52 switch.

```
switch> show inventory
System information
  Model                     Description
  ------------------------- ----------------------------------

  52   Arista Networks  SFP-10G-SR       XCW1225FD753     0002 switch>
```

3.7.64 server-port

The **server-port** command in the SSH Management Configuration Mode defines the TCP port or ports that SSH servers listen for incoming connections.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

server-port ***port_number***

no server-port

default server-port

Parameters

- **server-port*****port_number*** - Specify a port number from 1 to 32767 with a default of 22 to listen for incoming SSH connections on the switch.

Example

Use the following commands to set the port number to 80 on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# server-port 80
switch(config-mgmt-ssh)#
```

3.7.65 service configuration access-list

The **service configuration access-list** command configures how the switch compiles, stages, or validates access lists when the lists receive modifications or pushed to the hardware ASICs.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service configuration access-list symbols

no service configuration access-list symbols

default service configuration access-list symbols

Parameters

- **access-list** - Specify access list configuration parameters.
- **symbols** - When enabled, if you configure an ACL using port numbers, the switch automatically translates recognizable ports into symbolic names when issuing the **show ip access-lists** command.

  When disabled, the switch removes human-readable text and forces all entries to display the literal numeric values.

Example

When the switch has symbols enabled, and you configure an access list with port 80, the display output for an access list has the following output:

```
switch(config-acl-TEST)# permit tcp any any eq 80
```

```
switch# show running-config section TEST
ip access-list TEST
    10 permit tcp any any eq www
```

When the switch has symbols disabled, the output removes human-readable text and all entries display literal numeric values:

```
switch# show running-config section TEST
ip access-list TEST
   10 permit tcp any any eq 80
```

3.7.66 service configuration checkpoint

The **service configuration checkpoint** command configures the number of system configuration checkpoints on the switch. By default, EOS tracks and retains a maximum of 20 system configuration checkpoints.

If you make frequent configuration changes or want a deeper historical safety net of snapshots, you can increase or decrease the retention limits.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service configuration checkpoint max saved ***max_number***

no service configuration checkpoint max

default service configuration checkpoint max

Parameters

- **checkpoint** - Create a new checkpoint limit on the switch.
- **max** - Configure the maximum number of checkpoints.
- **saved** ***max_number*** - Configure the number of saved checkpoints on the switch.

Example

Use the following command to increase the number of saved checkpoints to 50:

```
switch(config)# service configuration checkpoint max saved 50
switch(config)#
```

To display the new limit, use the **show configuration checkpoints** command:

```
switch# show configuration checkpoints
```

```
Maximum number of checkpoints: 50
Hash    Name  Date                 User
------- ---- ------------------- -----
b8ad7c5      2025-01-06 23:11:28  eos
04fc850      2025-03-25 00:07:47  eos
a4d90e4      2025-03-25 00:07:48  admin
62e76ba      2025-03-25 01:36:30  eos
c812e22      2025-03-25 01:36:32  admin
932c042      2025-03-25 01:37:06  admin
dfbb566      2025-04-04 05:56:06  eos
e09ea3a      2025-04-04 05:56:07  admin
263fa99      2025-04-24 15:51:25  eos
3cfd199      2025-04-24 15:51:25  admin
278367f      2025-05-22 13:28:27  eos
f25f264      2025-05-22 13:28:28  admin
ce72f7f      2025-06-10 11:36:27  eos
889fe0e      2025-06-10 11:36:29  admin
```

If you decrease the saved checkpoint limit from your current limit, EOS purges the extra saved checkpoint files to meet your new limit.

3.7.67 service configuration session commit

The **service configuration session** command manages the system limits for configuration sessions. Configuration sessions allow you to stage, review, and test commands in a temporary workspace before committing them to the active running configuration. Use this command to configure the number of saved sessions in the switch memory.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service configuration session [commit [merge [save startup-config] [timer default ***hh:mm:ss*** **interactive**

no service configuration session

default service configuration session

Parameters

- **session** - Configure session settings.
- **merge** - Perform a three-way merge on the commit.
- **save startup-config** - Autosave the session to the startup configuration.
- **timer default** ***hh:mm:ss*** **interactive** - Commit the session with a timeout. If not committed within the time limit, the configuration reverts to the original configuration.

Example

Use the following command to configure a default timer of 1 hour apply it to the current running configuration:

```
switch(config)# service configuration session commit timer default 01:00:00 interactive
switch(config)#
```

3.7.68 service configuration session logging

The **service configuration session logging** command configures the switch to print the results, verification checks, or error logs of the session to the screen as the switch processes a commit.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service configuration session logging terminal

no service configuration session logging terminal

default service configuration session logging terminal

Parameters

- **terminal** - Print to the console any configuration session state changes.

Example

Use the following command to enable the feature:

```
switch(config)# service configuration session logging terminal
switch(config)#
```

3.7.69 service configuration session max

The **service configuration session max** command sets the retention and concurrency limits for system configuration sessions. Configure the limit for pending and completed sessions.

Command Mode

Global Configuration

Command Syntax

service configuration session max completed ***num_sessions*** **pending** ***num_sessions***

no service configuration session max

default service configuration session max

Parameters

- **session max** - Configure the maximum number of configuration sessions on the switch.
- **completed** ***num_sessions*** - Specify the maximum number of completed sessions kept in memory from 0 to 20 sessions. After staging and committing a session, EOS saves a record of that session for auditing and rollback purposes. By default, EOS retains a limited number of historical commits, 1 by default, and increasing the limit creates a deeper audit trail.
- **pending** ***num_sessions*** - Specify the maximum number of pending sessions kept in memory from 1 to 20 sessions. By default, EOS limits the sessions to 1 pending session to prevent multiple administrators from staging conflicting changes at the same time. Once reaching the limit, the switch blocks creation of new sessions until committing or aborting an old one.

Examples

Use the following command to increase the number of pending sessions from 1 to 5:

```
switch(config)# service configuration session max pending 5
switch(config)#
```

Use the following command to increase the number of completed sessions from 1 to 15:

```
switch(config)# service configuration session max completed 15
switch(config)#
```

To display the configured maximums, use the **`show configuration sessions`** command:

```
switch# show configuration sessions
Maximum number of completed sessions: 50
Maximum number of pending sessions: 5

Name        State           User       Terminal    Time
----------- --------------- ---------- ----------- -------------------
BGP_PEER    pending         admin      vty3        2026-04-28 11:45:12
OSPF_TUNE   completed       automation vty1        2026-04-27 09:12:45
```

3.7.70 service configuration terminal

The **service configuration terminal** command disables standard live configuration mode and dictates the use of configuration sessions instead. Before disabling the terminal feature, administrators can make immediate changes to the running configuration and alter the forwarding plane of the switch. When disabled, administrators must create configuration sessions to build a staged workplace to make changes and then explicitly use **commit** to add the configuration changes to the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service configuration terminal disabled

no service configuration terminal

default service configuration terminal

Parameters

- **terminal disabled**- Disable the standard terminal behavior on the switch.

Examples

Use the following command to disable the standard terminal behavior on the switch:

```
switch(config)# service configuration terminal disabled
switch(config)#
```

3.7.71 service configuration verification

The **service configuration verification** command dictates if the switch pre-validates the Quality of Service (QoS) configuration against the hardware physical capabilities before allowing you to successfully commit the change.

The physical silicon on the switch has deep ties to the QoS capabilities. When you create QoS policies, such as policy maps, class maps, or port shaping rates, the CLI may accept the commands, but the underlying hardware might not have enough TCAM space, hardware queues, or buffer memory to support it.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
service configuration verification qos

no service configuration verification qos

default service configuration verification qos
```

Parameters

- **verification qos** - Enable strict QoS verification on the hardware during commits.

Examples

Use the following command to enable the strict QoS verification on the switch:

```
switch(config)# service configuration verification qos
switch(config)#
```

3.7.72 service interface inactive

The **service interface inactive** command forces system level visibility and default state toggles to expose subordinate lanes.

By default, if you configure a port for breakout mode but have not physically plugged in the cable yet, EOS suppresses the inactive subordinate lanes.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service interface inactive expose [port-id allocation disabled]

no service interface inactive

default service interface inactive

Parameters

- **inactive expose** - Expose subordinate lanes in the CLI even if physically down or missing the proper cabling.
- **port-id allocation disabled** - Specify to stop assigning port IDs to inactive interfaces and dynamically allocate port IDs only to actively linked ports or participating in the forwarding plane.

Examples

Use the following command to expose subordinate lanes in the CLI:

```
switch(config)# service interface inactive expose
switch(config)#
```

Use the following command to free up unused IDs on the switch:

```
switch(config)# service interface inactive port-id allocation disabled
switch(config)#
```

3.7.73 service interface shutdown

The **service interface shutdown** command introduces a global, system-wide buffer window between entering a shutdown command and physically shutting down the link. During the delay, the physical link stays alive just long enough for the control plane to warn the connected neighbor of the intentional shutdown.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service interface shutdown delay ***milliseconds***

no service interface shutdown delay

default service interface shutdown delay

Parameters

- **interface shutdown delay** ***milliseconds*** - Specify the time to delay shutting down the interface. Configure a value from 1 to 1000 milliseconds.

Example

Use the following command to configure a shutdown delay of 10 milliseconds:

```
switch(config)# service interface shutdown delay 10
switch(config)#
```

3.7.74 service interface unconnected

The **service interface unconnected** command exposes Ethernet interfaces that do not physically exist on the switch, but instead exist as internally hardwired loopback ports. In EOS, the interfaces have the designation Unconnected Ethernet (Ue) ports and used by the hardware ASIC for packet recirculation. By default, EOS does not display these interfaces, but in some cases, exposing them may assist with troubleshooting hardware recirculation and identify interfaces dropping packets on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

service interface unconnected expose

no service interface shutdown delay

default service interface shutdown delay

Parameters

- **interface unconnected expose** - Expose unconnected interfaces on the switch.

Example

Use the following command to expose unconnected interfaces:

```
switch(config)# service interface unconnected expose
switch(config)#
```

Use the **show interfaces status** command to display the interface status:

```
switch# show interfaces status
Port       Name         Status       Vlan     Duplex Speed  Type
...
Et48                    notconnect   1        auto   auto   10GBASE-CR
Ue1                     connected    1        full   10G    Unconnected
Ue2                     connected    1        full   10G    Unconnected
```

3.7.75 service routing configuration

The **service routing configuration** command dictates the backend architecture of the routing daemon and determines how the switch parser compiles control-plane logic.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
service routing configuration [bgp no-equals-default] [route-map [no-set-
community explicit-members] [set-operations [merged | sequential]

no service routing configuration

default service routing configuration
```

Parameters

- **verification qos** - Enable strict QoS verification on the hardware during commits.
- **bgp no-equals-default** - Removes the default behavior from the running configuration output and displays only configured behavior.
- **route-map** - Configures route map behavior on the switch.
  - **no-set-community explicit-members** - Negates specific community values from an existing list and cleans up the running-configuration output.
  - **set-operations [merged | sequential]** - If selecting **sequential**, EOS enforces the execution of the set commands in strict top to bottom sequence.

Examples

Use the following command to remove BGP default behavior from the running configuration output:

```
switch(config)# service routing configuration bgp no-equals-default
switch(config)#
```

3.7.76 service routing protocols

The **service routing protocols** command dictates the underlying software architecture that the switch uses to process all Layer 3 routing protocols.

The **default** version of the command causes the switch to use the underlying software architecture.

> **Warning:** Enabling this feature requires a reboot of the switch. If you commit the command, the running-config updates immediately, but the changes do not take effect until the switch completes a full system reload.

Command Mode

Global Configuration

Command Syntax

```
service routing protocols model multi-agent

default routing protocols
```

Parameters

- **routing protocols** - Enable the underlying software to process all Layer 3 routing protocols.
- **model multi-agent** - Enable using the ArBGP architecture to completely decouple the routing stack into independent, multi-threaded processes. Each protocol uses a separate process to provide significantly faster convergence and natively supports multi-tenant architectures such as EVPN, VXLAN overlays, and IPv6 underlays.

Example

Use the following command to enable multi-agent processing for routing protocols:

```
switch(config)# service routing protocols model multi-agent
switch(config)#
```

3.7.77 service running-config

The **service running-config** command manages how the switch generates, processes, and displays the running configuration file. Executing the running configuration file on switches with very large configurations impacts the switch performance by spiking the CPU usage. Use this command to manage the running configuration file.

The **[no | default]** versions of the command cause the switch to dynamically compile the running configuration file for every request.

Command Mode

Global Configuration

Command Syntax

service running-config [cache disabled] [copy use-config-session] [timestamp]

no service running-config

default service running-config

Parameters

- **cache [disabled]** - Enable caching of the running configuration file by instructing the switch to generate and hold a pre-compiled text version of the configuration in memory. Once enabled, use the **disabled** parameter to dynamically generate the configuration when requested.
- **copy use-config-session** - Enable this parameter to override the default merge behavior and enforce a strict replace or enforce session-based validations before applying the copied file.
- **timestamp** - Enable to inject a timestamp in the header of the running-config file.

Note: EOS disables **timestamp** by default as constantly updating the timestamp breaks idempotency in certain environments. If enabled, using tools such as Ansible, Terraform, or Git flags the configuration as changed every time polling the switch occurs even if no changes occur on the switch.

Example

Use the following command to enable caching of the running-config file:

```
switch(config)# service running-config cache
switch(config)#
```

3.7.78 session-limit

The **session-limit** command in the Telnet Management Configuration Mode configures the maximum number of Telnet sessions from a single host and the maximum number of sessions.

The **no** version of the command removes the configuration from the ***running-config***.

Command Mode

Telnet Management Configuration

Command Syntax

session-limit ***num_sessions*** **[per-host** ***num_sessions*****]**

no session-limit

default session

Parameters

- **session-limit** ***num_sessions*** - Configure the maximum number of global Telnet sessions. Sets it to 20 by default.
- **per-host** ***num_sessions*** - Configure the maximum number of global Telnet sessions per host. Sets it to 20 by default.

Example

Use the following commands to configure a global Telnet sessions limit of 25:

```
switch(config)# managment telnet
switch(config-mgmt-telnet)# session-limit 25
switch(config-mgmt-telnet)#
```

3.7.79 show configuration checkpoints

The **show configuration checkpoints** command displays a high level table of all saved configuration snapshots currently stored on the switch.

Command Mode

EXEC

Command Syntax

show configuration checkpoints

Example

Use the following command to display all saved configuration snapshots:

```
switch# show configuration checkpoints
Maximum number of checkpoints: 20
Filename                        Date                User
------------------------------- ------------------- ------
ckp-20231024-0                  2023-10-24 14:00:01  admin
ckp-20231024-1                  2023-10-24 15:30:22  admin
PRE_BGP_CHANGE                  2023-10-25 09:15:00  automation
```

The output displays the following information:

- **Maximum number of checkpoints** - Indicates the current system limit for the number of historical snapshots allowed for retention in memory. By default, EOS limits 20 snapshots, but you can adjust it using the command **service configuration checkpoint max**. If the switch reaches the limit of snapshots, EOS begins automatically purging the oldest checkpoints using a First-In, First-Out (FIFO) method.
- **Filename** - Displays the name of the checkpoint file stored in the flash memory.
  - **Auto-generated checkpoints** - If the switch creates the checkpoint automatically, for example, during a configuration session commit or an automated rollback, the file uses a standard naming convention of `ckp-YYYYMMDD-X`
  - **Manual checkpoints** - If an administrator or automated script generated the snapshot, EOS uses a custom string as the filename.
- **Date** - The exact system timestamp in the format `YYYY-MM-DD HH:MM:SS` when created.
- **User** - Identifies the specific username or script name that executed the command or triggered the automated process to create the snapshot.

3.7.80 show configuration sessions

The **`show configuration sessions`** command displays information about configuration sessions created on the switch. If you rely on configuration sessions instead of live terminal configuration, use the output to manage the lifecycle of your staged configuration workspaces.

Command Mode

EXEC

Command Syntax

`show configuration sessions [detail]`

Example

Use the following command to display all saved configuration snapshots:

```
switch# show configuration sessions
Maximum number of completed sessions: 10
Maximum number of pending sessions: 5

  Name               State           User       Terminal
  ------------------ --------------- ---------- -----------
  ADD_BGP_PEER       pending         admin      vty1
  vlan-changes       completed       admin      vty1
  ansible_10928      completed       automation eAPI
  sess-20260430-1    aborted         jdoe       vty3
```

The output displays the following information:

- **Maximum number of completed sessions** - Displays the number of historical committed session diffs allowed in memory before overwriting the oldest ones (FIFO).
- **Maximum number of pending sessions** - Displays the number of active and uncommitted staging workspaces open concurrently on the switch.
- **Name** - Displays the identifier for the session. If using a name for the session, the output displays that information. By default, EOS generates a name with the format `sess-YYYMMDD-X`.
- **State** - Displays the current lifecycle of the session:
  - **`pending`** - Session currently open with actively staged commands but not applied to the control plane yet.
  - **`completed`** - Session successfully committed and applied to the running-config.
  - **`aborted`** - Session manually canceled or failed a pre-check validation. Changes discarded.
- **User** - The specific local or TACACs/RADIUS username that created the session.
- **Terminal** - Displays the entry point used to connect to the switch.

- **vtyx** - Indicates a standard SSH session.
- **console** - Indicates a physical serial connection.
- **eAPI** - Indicates the session built programmatically using the Arista eAPI.

3.7.81 shutdown (API Management)

The **shutdown** command disables management over API on the switch in API Management Configuration Mode. EOS disables API Management by default.

The **no shutdown** command enables the API management access in mgmt-api configuration mode.

The **default shutdown** command disables the management API access in mgmt-api configuration mode.

Command Mode

Mgmt-API Configuration

Command Syntax

```
shutdown

no shutdown

default shutdown
```

Related Command

management api http-commands places the switch in ***mgmt-api*** configuration mode.

Examples

- These commands disable API access to the HTTP server.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# shutdown
switch(config-mgmt-api-http-cmds)#
```

- These commands enable API access to the HTTP server.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# no shutdown
switch(config-mgmt-api-http-cmds)#
```

3.7.82 shutdown (Telnet Management)

The **shutdown** command disables or enables Telnet on the switch. EOS disables by default. The management telnet command places the switch in the Telnet Management Configuration Mode.

- To enable Telnet, enter **no shutdown** at the Telnet Management prompt.
- To disable Telnet, enter **shutdown** at the Telnet Management prompt.

Command Mode

Telnet Management Configuration

Command Syntax

```
shutdown
```

```
no shutdown
```

Examples

- These commands enable Telnet and return the switch to the Global Configuration Mode.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# no shutdown
switch(config-mgmt-telnet)# exit
switch(config)#
```

- This command disables Telnet.

```
switch(config-mgmt-telnet)# shutdown
```

3.7.83 shutdown

The **shutdown** command in the SSH or Telnet Management Configuration Mode disables the SSH or Telnet service on the switch.

Command Mode

SSH Management Configuration

Telnet Management Configuration

Command Syntax

shutdown

Parameters

- **shutdown** - Disable the SSH or Telnet service on the switch.

Example

Use the following commands to disable the SSH service.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# shutdown
switch(config-mgmt-ssh)#
```

3.7.84 shutdown

The **shutdown** command in the SSH Management Configuration Mode and SSH VRF Configuration Mode shuts down the SSH service on the switch.

Command Mode

SSH Management Configuration

SSH VRF Configuration

Command Syntax

shutdown

Parameters

- **shutdown** - Shuts down the SSH service.

Example

Use the following commands to shut down the SSH service on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# shutdown
switch(config-mgmt-ssh)#
```

Use the following commands to shut down the SSH service for VRF `bluengreen` on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# vrf bluengreen
switch(config-mgmt-ssh-vrf-bluengreen)# shutdown
```

3.7.85 timeout

The **timeout** command in the SSH, Telnet, or Console Management Configuration Mode specifies the maximum length of a management session regardless of activity during the session. It prevents sessions from remaining open indefinitely on the switch and provides a separate behavior from the parameter **idle-timeout**. Both timers operate independently and the timer with the shortest session time ends the session.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Console Management Configuration

SSH Management Configuration

Telnet Management Configuration

Command Syntax

management [console | ssh | telnet] timeout ***timeout_period*** **warning** ***warning_time***

[no | default] management [console | ssh | telnet] timeout

Parameters

- **timeout** ***timeout_period*** - Configure a timeout session from 1 to 86400 minutes. Setting the timeout to 0 disables the timeout session.
- **warning** ***warning_time*** - Configure a warning that notifies you that the session ends at a specific time. Configure from 0 to 3599 minutes and setting the timeout to 0 disables the warning.

Examples

Use the following commands to set the console timeout to *60* minutes.

```
switch(config)# management console
switch(config-mgmt-console)# timeout 60
switch(config-mgmt-console)#
```

Use the following commands to set the SSH timeout to *60* minutes.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# timeout 60
switch(config-mgmt-ssh)#
```

Use the following commands to set the Telnet timeout to *60* minutes.

```
switch(config)# management telnet
switch(config-mgmt-telnet)# timeout 60
switch(config-mgmt-telnet)#
```

3.7.86 trusted-ca

The **trusted-ca** command in the SSH Management Configuration Mode allows the switch to validate the identity of connections using standard X.509 PKI certificates.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

trusted-ca key public ***cert_filename***

no trusted-ca

default trusted-ca

Parameters

- **trusted-ca** - Configure trusted CA parameters.
- **key** - Configure a CA public key.
- **public** ***cert_filename*** - Add the CA public key filename.

Example

Use the following commands to add the CA certificate, MyCert, on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# trusted-ca key public MyCert
switch(config-mgmt-ssh)#
```

3.7.87 user-keys

The **user-keys** command in the SSH Management Configuration Mode globally manages external files for user authentication and security.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

user-keys revoke-list ***list_name***

no user-keys revoke-list

default user-keys revoke-list

Parameters

- **user-keys** - Configure user keys settings.
- **revoke-list** ***cert_filename*** - Specify a list of revoked SSH user keys.

Example

Use the following commands to add the revoked list, NoAccess, on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# user-keys revoke-list NoAccess
switch(config-mgmt-ssh)#
```

3.7.88 username ssh-key

The **username ssh-key** command in the SSH Management Configuration Mode enters the Username Configuration Mode and allows the application of specific SSH key to a user when they connect to SSH.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

SSH Username Configuration

SSH Authorized Key Configuration

Command Syntax

username ***username*** **[ssh-key** ***key_name*****] [option [agent-forwarding | cert-authority | command | environment | expiry-time | from | no-agent-forwarding | no-port-forwarding | no-pty | no-touch-required | no-user-rc | no-x11-forwarding | permit-listen | permit-open | port-forwarding | principals | pty | restrict | tunnel | user-rc | verify-required | x11-forwarding]] [public-key** ***ssh_keystring***

no username ssh-key

default username ssh-key

Parameters

- **username** ***username*** - Specify a username to apply the SSH policies.
- **ssh-key** ***key_name*** - Specify an SSH key name.
- **option** - Specify any of the following options:
  - **agent-forwarding** ***ssh_options_value*** - Specify a value to enable authentication agent forwarding.
  - **cert-authority** ***ssh_options_value*** - Specify a value for the certificate authority.
  - **command** ***ssh_options_value*** - Specify a command to execute during authentication.
  - **environment** ***ssh_options_value*** - Specify a value to add a string to the environment during authentication.
  - **expiry-time** ***ssh_options_value*** - Specify a value for the expiration time of the key.
  - **from** ***ssh_options_value*** - Specify a value for patterns.

- **`no-agent-forwarding`** ***ssh_options_value*** - Specify a value to forbid agent forwarding.
- **`no-port-forwarding`** ***ssh_options_value*** - Specify a value to forbid port forwarding.
- **`no-pty`** ***ssh_options_value*** - Specify a value to prevent TTY allocation.
- **`no-touch-required`** ***ssh_options_value*** - Specify a value to not require demonstration of user presence.
- **`no-user-rc`** ***ssh_options_value*** - Specify a value to prevent execution on `~/.ssh/rc`.
- **`no-x11-forwarding`** ***ssh_options_value*** - Specify a value to prevent .X11 forwarding.
- **`permit-listen`** ***ssh_options_value*** - Specify a value to permit listening only on a specified host and port.
- **`permit-open`** ***ssh_options_value*** - Specify a value to connect only to a specified host and port.
- **`port-forwarding`** - Specify a value to enable port forwarding.
- **`principals`** - Specify allowed principals for certificate authentication.
- **`pty`** - Specify to permit PTY allocation.
- **`restrict`** - Specify to enable all restrictions.
- **`tunnel`** - Specify to force a tunnel device on the server.
- **`user-rc`** - Specify to enable execution on `~/.ssh/rc`
- **`verify-required`** - Specify to require users to verify signatures using this key.
- **`x11-forwarding`** - Specify a value to allow .X11 forwarding.

- **`public-key`** ***ssh_keystring*** - Specify a public SSH key string.

Example

Use the following commands to apply the SSH key to a user `admin` on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# username admin
switch(config-mgmt-ssh-user-admin)# ssh-key mykey
switch(config-mgmt-ssh-user-admin-mykey)#
```

3.7.89 username ssh-principal

The **username ssh-principal** command in the SSH Management Configuration Mode enters the Username Configuration Mode and defines which principals in a presented SSH certificate can login as the local user.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

SSH Username Configuration

SSH Authorized Principal Configuration

Command Syntax

username *username* [ssh-principal *key_name*] [option [agent-forwarding | cert-authority | command | environment | expiry-time | from | no-agent-forwarding | no-port-forwarding | no-pty | no-touch-required | no-user-rc | no-x11-forwarding | permit-listen | permit-open | port-forwarding | principals | pty | restrict | tunnel | user-rc | verify-required | x11-forwarding]]

no username ssh-principal

default username ssh-principal

Parameters

- **username *username*** - Specify a username to add SSH principals.
- **ssh-principal *key_name*** - Specify SSH one or more SSH principals.
- **option** - Specify any of the following options:
  - **agent-forwarding *ssh_options_value*** - Specify a value to enable authentication agent forwarding.
  - **cert-authority *ssh_options_value*** - Specify a value for the certificate authority.
  - **command *ssh_options_value*** - Specify a command to execute during authentication.
  - **environment *ssh_options_value*** - Specify a value to add a string to the environment during authentication.
  - **expiry-time *ssh_options_value*** - Specify a value for the expiration time of the key.

- **`from`** ***ssh_options_value*** - Specify a value for patterns.
- **`no-agent-forwarding`** ***ssh_options_value*** - Specify a value to forbid agent forwarding.
- **`no-port-forwarding`** ***ssh_options_value*** - Specify a value to forbid port forwarding.
- **`no-pty`** ***ssh_options_value*** - Specify a value to prevent TTY allocation.
- **`no-touch-required`** ***ssh_options_value*** - Specify a value to not require demonstration of user presence.
- **`no-user-rc`** ***ssh_options_value*** - Specify a value to prevent execution on `~/.ssh/rc`.
- **`no-x11-forwarding`** ***ssh_options_value*** - Specify a value to prevent .X11 forwarding.
- **`permit-listen`** ***ssh_options_value*** - Specify a value to permit listening only on a specified host and port.
- **`permit-open`** ***ssh_options_value*** - Specify a value to connect only to a specified host and port.
- **`port-forwarding`** - Specify a value to enable port forwarding.
- **`principals`** - Specify allowed principals for certificate authentication.
- **`pty`** - Specify to permit PTY allocation.
- **`restrict`** - Specify to enable all restrictions.
- **`tunnel`** - Specify to force a tunnel device on the server.
- **`user-rc`** - Specify to enable execution on `~/.ssh/rc`
- **`verify-required`** - Specify to require users to verify signatures using this key.
- **`x11-forwarding`** - Specify a value to allow .X11 forwarding.

Example

Use the following commands to add the SSH principal `admin` on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# username admin
switch(config-mgmt-ssh-user-admin)# ssh-principal myprincipal
switch(config-mgmt-ssh-user-admin-myprincipal)#
```

3.7.90 username tcp

The **username tcp** command in the SSH Management Configuration Mode enters the SSH Username Configuration Mode and controls if a specific user has permission to use the switch as a jump host or a tunnel endpoint using SSH Port Forwarding. It allows a user to tunnel a TCP connection through the encrypted SSH session and access devices that may otherwise be inaccessible. EOS disables TCP forwarding by default.

The **[no]** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

SSH Username Configuration

Command Syntax

username ***username*** **tcp forwarding [all | local | remote]**

no username tcp forwarding

default username tcp forwarding

Parameters

- **username** ***username*** - Specify a username and enter the SSH Username Configuration Mode.
- **tcp forwarding** - Configure TCP forwarding options.
  - **all** - Specify to allow TCP forwarding for local and remote SSH servers.
  - **local** - Specify to allow TCP forwarding for local SSH servers only.
  - **remote** - Specify to allow TCP forwarding for remote SSH servers only.

Example

Use the following commands for the user, `admin`, to allow TCP forwarding for local and remote SSH servers on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# username admin
switch(config-mgmt-ssh-user-admin)# tcp forwarding all
```

3.7.91 verify

The **verify** command in the SSH Management Configuration Mode implements the SSH Fingerprint (SSHFP) verification mechanism and allows the switch to use DNS records to validate the identify of a remote server.

The **[no]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

Command Syntax

verify dns

no verify dns

Parameters

- **verify** - Set options related to SSHD verification..
- **dns** - Configure the SSH Daemon to verify the DNS check.

Example

Use the following commands to implement SSH Fingerprint verification on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# verify dns
switch(config-mgmt-ssh)#
```

3.7.92 vrf

The **vrf** command in the SSH or Telnet Management Configuration Mode applies the SSH or Telnet service to a specific VRF or the default VRF on the switch.

Command Mode

SSH Management Configuration

Telnet Management Configuration

Command Syntax

vrf [default | *vrf_name*]

Parameters

- **default** - Apply the SSH or Telnet service to the default VRF on the switch.
- ***vrf_name*** - Apply the SSH or Telnet service to a specific VRF on the switch.

Example

Use the following commands to apply the SSH service to the VRF, *bluengreen*:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# vrf bluengreen
switch(config-mgmt-ssh)#
```

3.7.93 vrf known-hosts

The **vrf known-hosts** command in the SSH VRF Configuration Mode allows you to define a specific trusted host key file for each routing domain. By assigning a unique known hosts file to a VRF, the switch trusts that only specific identities of servers within that network segment.

The **[no]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH VRF Configuration

Command Syntax

known-hosts ***hostname_ip*** **[dsa | ecdsa-nistp256 | ecdsa-nistp521 | ed25519 | rsa]** ***base64_string***

no vrf known-hosts

Parameters

- **known-hosts** ***hostname_ip*** - Specify the known host using a hostname or an IPv4 or IPv6 address.
- **dsa** - Specify the Digital Signature Algorithm algorithm.
- **ecdsa-nistp256** - Specify the Elliptic Curve Digital Signature Algorithm NIST-P256.
- **ecdsa-nistp521** - Specify the Elliptic Curve Digital Signature Algorithm NIST-P521.
- **ed25519** - Specify the Edwards-curve Digital Signature Algorithm 25519.
- **rsa** - Specify the RSA Encryption Algorithm.
- ***base64_string*** - Specify a base64 string.

Example

Use the following commands to add the host, `172.16.21.23`, and the algorithm, `dsa`, to the VRF, `bluengreen`, on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# vrf bluengreen
switch(config-mgmt-ssh-vrf-bluengreen)# known-hosts 172.16.1.23 dsa SGVsbG8gV29ybGQh
switch(config-mgmt-ssh-vrf-bluengreen)#
```

3.7.94 vrf

The **vrf** command in the SSH Management Configuration Mode enters the SSH VRF Configuration mode and allows the configuration of specific VRF parameters.

The **[no]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

SSH Management Configuration

SSH VRF Configuration

Command Syntax

vrf [default | *vrf_name*] [tunnel *vrf_name*]

no vrf

Parameters

- **vrf [default | *vrf_name*** - Specify the default VRF or a specific VRF.

Example

Use the following commands to enter the SSH VRF Configuration Mode for the VRF, `bluengreen`, on the switch:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# vrf bluengreen
switch(config-mgmt-ssh-vrf-bluengreen)#
```

3.7.95 vrf (API Management)

The **vrf** command places the switch in the server's VRF configuration mode. If the named VRF does not already exist, this command creates it.

Command Mode

API Management Configuration

Command Syntax

`vrf` **VRF_INSTANCE**

Parameters

VRF_INSTANCE - Specifies the VRF instance.

- **default** - Instance created in the default VRF.
- ***vrf_name*** - Instance created in the specified user-defined VRF.

Related Command

management api http-commands places the switch in API Management Configuration.

Example

This command creates a VRF named management-vrf and places the switch in ***VRF*** configuration mode for the new VRF.

```
switch(config)# management api http-commands
switch(config-mgmt-api-http-cmds)# vrf management-vrf
switch(config-mgmt-api-http-cmds-vrf-management-vrf)#
```

Chapter 4

Administering the Switch

This chapter describes administrative tasks typically performed only after initially configuring the switch or after recovery procedures.

This chapter includes these sections:

- Managing the Switch Name
- System Clock and Time Protocols
- Managing Display Attributes
- System Event Logging
- Event Monitor
- Managing EOS Extensions
- Switch Administration Commands

4.1 Managing the Switch Name

These sections describe how to configure the switch's domain and host name.

- Assigning a Name to the Switch describes assigning an FQDN to the switch.
- Specifying DNS Addresses describes adding name servers to the configuration.

4.1.1 Assigning a Name to the Switch

A Fully Qualified Domain Name (FQDN) labels the switch and defines its organization ID in the Domain Name System hierarchy. The switch FQDN consists of a host name and domain name.

The host name uniquely associates with one device within an IP-domain. The default host name is ***localhost***. You can configure the prompt to display the host name as described in prompt.

- To assign a host name to the switch, use the `hostname` command. To return the switch host name to the default value of *localhost*, use the `no hostname` command.
- To specify the domain location of the switch, use the `dns domain` command.

Examples

- This command assigns the string *main-host* as the switch host name.

```
switch(config)# hostname main-host
main-host(config)#
```

- This command configures *aristanetworks.com* as the switch domain name.

```
switch(config)# dns domain aristanetworks.com
switch(config)#
```

- This procedure configures ***sales1.samplecorp.org*** as the switch FQDN.

```
switch(config)# dns domain samplecorp.org
switch(config)#
```

- The following ***running-config*** extract contains the switch host name and IP-domain name:

```
switch# show running-config
! Command: show running-config
! device: switch (DCS-7150S-64-CL, EOS-4.13.2F)
!

vlan 3-4
!
username john secret 5 $1$a7Hjept9$TIKRX6ytkg8o.ENja.na50
!
hostname sales1
ip name-server vrf default 172.17.0.22
dns domain samplecorp.org
!

end switch#
```

4.1.2 Specifying DNS Addresses

The Domain Name Server (DNS) maps FQDN labels to IP addresses and provides addresses for network devices. Each network requires at least one server to resolve addresses. The configuration file can list a maximum of three server addresses.

To add name servers to the configuration, use the ip name-server command. Each command can add multiple servers. All server addresses support multiple VRFs and a priority may be specified for each server named. If all name servers have the default priority (***0***), the configuration uses the default DNSmasq behavior. It queries all name servers simultaneously and forwards the requests to the first name server for 50 queries or 20 seconds, whichever expires sooner for answering. If any priorities contain non-zero entries, EOS issues queries in order with a five second timeout between unresponsive name servers.

Note: DNSmasq does not fulfill in-flight requests to unresponsive name servers.

Example

Use the following command to display the configuration file:

```
switch(config)# show ip name-server
IP Address VRF     Priority
---------- ------- --------
10.0.0.1   default        0
10.0.0.2   default        1
10.0.0.1   vrf1           2
10.0.0.2   vrf1           3
fc00::1    default        4
```

The switch assigns source IP addresses to outgoing DNS requests. To force the switch to use a single, user-defined source interface for all requests, use the `ip domain lookup` command.

Examples

- Use the following command to force the switch to use ***VLAN 5*** as the source interface for DNS requests originating from the default VRF.

```
switch(config)# ip domain lookup source-interface Vlan5
switch(config)#
```

- This command forces the switch to use ***VLAN 10*** as the source interface for DNS requests originating from VRF purple.

```
switch(config)# ip domain lookup vrf purple source-interface Vlan10
switch(config)#
```

- This command configures a name server with a priority of 4 on VRF purple.

```
switch(config)# ip name-server vrf purple 10.1.1.24 priority 4
switch(config)#
```

- This command removes the name servers.

```
switch(config)# no ip name-server vrf purple 10.1.1.24
switch(config)#
```

- This command removes all configured name in all VRFs.

```
switch(config)# no ip name-server
switch(config)#
```

Note: **`NXDOMAIN`** is considered a valid reply for the query.

4.2 System Clock and Time Protocols

The switch uses the system clock to time-stamp all events, logs, and system messages. Setting the system clock to Coordinated Universal Time (UTC) allows the switch to calculate and display the local time for administrative purposes based on the configured time zone. The system clock can be set manually, but the preferred method for synchronization uses Network Time Protocol (NTP). Any properly configured NTP servers on the switch override manually entered clock settings.

Use the following sections for the configuration of the system clock and NTP. For information on the Precision Time Protocol (PTP), see Timing Protocols.

- Configuring the Time Zone
- Setting the System Clock Manually
- Displaying the Time
- Network Time Protocol (NTP)

4.2.1 Configuring the Time Zone

EOS uses a fundamental system clock based on UTC and you cannot change the system clock UTC base. Instead, configure the time zone and EOS converts the UTC base time to the local time displayed in the Command Line Interface (CLI). Then, the system clock time stamps the logs with the local time.

To specify the time zone, use the **`clock timezone`** command.

Examples

- Use the following commands to configure the switch for the United States Pacific Time Zone:

```
switch(config)# clock timezone US/Pacific
switch(config)# show clock
Tue Nov 11 12:39:16 2025
Timezone: US/Pacific
Clock source: NTP server (1.8.11.24)
switch(config)#
```

- To view the predefined time zone labels, enter **`clock timezone`** with a question mark:

```
switch(config)# clock timezone ?
            Africa/      Africa timezones
            America/     America timezones
            Antarctica/  Antarctica timezones
            Arctic/      Arctic timezones
            Asia/        Asia timezones
            Atlantic/    Atlantic timezones
            Australia/   Australia timezones
            Brazil/      Brazil timezones
            CET          CET timezone
            CST6CDT      CST6CDT timezone
            Canada/      Canada timezones
            Chile/       Chile timezones
            Cuba         Cuba timezone
            EET          EET timezone
            EST          EST timezone
            EST5EDT      EST5EDT timezone
            Egypt        Egypt timezone
```

```
             Eire         Eire timezone
             Etc/         Etc timezones
             Europe/      Europe timezones
            --More--

switch(config)#clock timezone
```

- Use the following command to display all time zone labels that start with **America**.

```
switch(config)# clock timezone America/?
America/Adak           America/Anchorage       America/Anguilla
America/Antigua        America/Araguaina       America/Argentina/
America/Aruba          America/Asuncion        America/Atikokan
America/Atka           America/Bahia           America/Bahia_Banderas
America/Barbados       America/Belem           America/Belize
America/Blanc-Sablon   America/Boa_Vista       America/Bogota
America/Boise          America/Buenos_Aires    America/Cambridge_Bay
--More--
switch(config)#clock timezone AMERICA
```

- Use the following command to display all time zone labels that begin with *Europe*:

```
switch(config)# clock timezone Europe/?
Europe/Amsterdam   Europe/Andorra      Europe/Astrakhan    Europe/Athens
Europe/Belfast     Europe/Belgrade     Europe/Berlin       Europe/Bratislava
Europe/Brussels    Europe/Bucharest    Europe/Budapest     Europe/Busingen
Europe/Chisinau    Europe/Copenhagen   Europe/Dublin       Europe/Gibraltar
Europe/Guernsey    Europe/Helsinki     Europe/Isle_of_Man  Europe/Istanbul
Europe/Jersey      Europe/Kaliningrad  Europe/Kiev         Europe/Kirov
Europe/Kyiv        Europe/Lisbon       Europe/Ljubljana    Europe/London
Europe/Luxembourg  Europe/Madrid       Europe/Malta        Europe/Mariehamn
Europe/Minsk       Europe/Monaco       Europe/Moscow       Europe/Nicosia
Europe/Oslo        Europe/Paris        Europe/Podgorica    Europe/Prague
Europe/Riga        Europe/Rome         Europe/Samara       Europe/San_Marino
Europe/Sarajevo    Europe/Saratov      Europe/Simferopol   Europe/Skopje
Europe/Sofia       Europe/Stockholm    Europe/Tallinn      Europe/Tirane
Europe/Tiraspol    Europe/Ulyanovsk    Europe/Uzhgorod     Europe/Vaduz
Europe/Vatican     Europe/Vienna       Europe/Vilnius      Europe/Volgograd
Europe/Warsaw      Europe/Zagreb       Europe/Zaporozhye   Europe/Zuric
```

4.2.2 Setting the System Clock Manually

The clock set command manually configures the system clock time and date in local time. Manually enter any properly configured NTP servers on the switch to override the time.

Example

This command manually sets the switch time.

```
switch# clock set 08:15:24 14 Jan 2026
Mon Jan 14 08:15:25 2026
timezone is US/Central
```

4.2.3 Displaying the Time

Enter the `show clock` command to display the local time and configured time zone.

Example

This command displays the switch time.

```
switch(config)# show clock
Mon Jan 14 16:32:46 2013
timezone is America/Los_Angeles
```

4.2.4 Network Time Protocol (NTP) Overview

EOS enables Network Time Protocol (NTP) on the switch by default, and time settings from any properly configured NTP server override the manual setting of the system clock.

NTP servers synchronize time settings of systems running an NTP client. The switch supports NTP versions 1 through 4, and uses version 4 by default. After configuring the switch to synchronize with an NTP server, it may take up to ten minutes for the switch to set the clock. Select the configured ***running-config*** lists of the NTP servers that the switch uses.

The following sections describe NTP configuration on the switch:

- Configuring the NTP Server
- Configuring the NTP Source
- Configuring the Switch as an NTP Server
- Configuring NTP Authentication
- Viewing NTP Settings and Status

Overview of Network Time Security (NTS)

Network Time Security (NTS) provides a cryptographic security mechanism for Network Time Protocol (NTP). NTS ensures that a client receives the accurate time from a verified source and the time has not altered in transit. This prevents attacks such as spoofing and Man-in-the-Middle (MITM).

NTS separates key establishment from time synchronization by using a TLS-based NTS Key Establishment (NTS-KE) protocol to negotiate symmetric keys and encrypted cookies. Subsequent NTS packets include the cookies to enable stateless authentication by the server. NTS-KE manages the initial connection, server authentication, and key exchange in the following process:

- **Secure Connection** - The client connects to the NTS-KE server using a TCP connection.
- **Authentication and Key Exchange** - The server and client perform a Transport Layer Security (TLS) handshake and the server proves its identity to the client, providing server authentication.
- **Key Material and Cookies** - During the TLS session, the server and client negotiate cryptographic parameters and exchange the necessary key material in the form of symmetric encryption keys. The server also sends opaque cookies with the per-client state necessary for the next phase.

- **Close Connection** - The TLS connection then closes since it only required the connection for initial setup.

EOS disables the feature by default. To enable it, a valid SSL profile must be provided when configuring NTP.

4.2.4.1 Configuring the NTP Server

The ntp server command adds a server to the list or modifies the parameters of a previously listed address. When the system contains multiple NTP servers, the **prefer** keyword can be used to specify a preferred NTP server and uses it as the NTP server.

Note that all NTP servers must be in the same VRF and added in the default VRF if you do not specify a VRF.

NTP sets the system clock if enabled and if the switch has one properly configured NTP server. NTP overrides the manual setting of the system clock. EOS enables NTP by default. To disable NTP, select the **no ntp** command.

Example

Use the following commands to add three NTP servers and designate the second server as the preferred NTP server.

```
switch(config)# ntp server local-NTP
switch(config)# ntp server 172.16.0.23 Prefer
switch(config)# ntp server 172.16.0.25
```

4.2.4.2 Configuring the NTP Source

A local interface can be specified as the source in outgoing NTP packets using the ntp local-interface command to control the address to send NTP responses to the switch. The IP address of that interface uses the source address in all outgoing NTP packets unless the switch acts as an NTP server and a server-specific source configured using the **source** option of the **ntp server** command.

Example

This command configures the IP address of ***VLAN interface 25*** as the source specified in all outgoing NTP packets.

```
switch(config)# ntp local-interface vlan 25
switch(config)#
```

4.2.4.3 Configuring the Switch as an NTP Server

To configure the switch to accept NTP requests on all interfaces, use the ntp serve all command to enable NTP server mode globally on the switch. To configure an individual interface to accept or deny NTP requests, use the ntp serve command. Interface level settings override the global settings, and changing the settings

at either the global or interface level also causes the switch to re-synchronize with its upstream NTP server. Disable the NTP server mode by default.

Examples

- This command configures the switch to act as an NTP server, accepting NTP requests.

```
switch(config)# ntp serve all
switch(config)#
```

- These commands configure ***interface ethernet 5*** to accept NTP requests regardless of global settings.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ntp serve
switch(config-if-Et5)#
```

4.2.4.4 Configuring NTP Authentication

The switch can be configured to accept NTP packets only from an authenticated server or client. Disable the NTP authentication by default.

To configure the switch to authenticate NTP packets, create one or more authentication keys using the ntp authentication-key command, and specify trusted keys by using the ntp trusted-key command. Use the ntp authenticate command to enable NTP authentication, and specify to use the trusted-key for a specific server. The NTP server must be configured to select the same authentication key and key ID number.

Note: Enable when NTP authentication on a switch. All NTP servers upstream of the switch and all NTP clients of the switch should have matching keys configured, and clients must have NTP authentication enabled.

Example

These commands configure the switch to authenticate NTP packets using key 328 with the plaintext password timeSync.

```
switch(config)# ntp authentication-key 328 md5 timeSync
switch(config)# ntp trusted key 328
switch(config)# ntp authenticate
switch(config)#
```

4.2.4.5 Configuring Network Time Security (NTS)

EOS provides NTS as an optional feature for both client and server modes and disables it by default. To enable it, you must provide a valid SSL profile for the configuration. See **insert link to Control Plane Security**.

Configuring a Client Connection to an NTP Server

The **ntp server** command configures a persistent association with a remote server. When specifying an SSL profile with the configuration, the remote server must support NTS.

Note: If the remote server does not support NTS, then synchronization between the switch and server cannot occur on the network.

To specify the SSL profile, use the parameter, **`ssl profile`** ***profile_name*** and add the profile to the configuration. You must have a configured trust certificate configured for the profile.

Use the following commands to establish an SSL profile, *nts_profile*, with a certificate, *CaCert*, and using TLS version 1.3:

```
switch(config)# mangement security
switch(config-mgmt-security)# ssl profile nts_profile
switch(config-mgmt-sec-ssl-profile-nts_profile)# trust certificate CaCert
switch(config-mgmt-sec-ssl-profile-nts_profile)# tls versions 1.3
switch(config-mgmt-sec-ssl-profile-nts_profile)# ntp server mycompany.com ssl profile nts_profile
```

Configuring the Switch as an NTP Server

EOS enables an NTP server for all interfaces on the switch using the **`ntp serve all`** command, or for individual interfaces by applying the **`ntp serve`** command in the Interface Configuration Mode. For both types of server configuration, enable NTS using an SSL profile and applying the command, **`ntp serve ssl profile`** ***profile_name***.

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile nts_profile
switch(config-mgmt-sec-ssl-profile-nts_profile)# certificate serverCert key serverKey
switch(config-mgmt-sec-ssl-profile-nts_profile)# tls versions 1.3
switch(config)# ntp server mycompany.com
switch(config)# ntp serve all
switch(config)# ntp serve ssl profile nts_profile
```

4.2.4.6 Viewing NTP Settings and Status

To display the status of Network Time Protocol (NTP) on the switch, use the show ntp status command. To display the status of connections to NTP servers, use the show ntp associations command.

Note: In the output for **`show ntp associations`**, the reference ID identifies the time source of the NTP server as either the IPv4 address of the time source or, if that source has an IPv6 address, the first four octets of the MD5 hash of the IPv6 address. In EOS releases prior to *4.23.2*, the **`show ntp status`** command identified the system peer by its reference ID as described above. Still, in later releases, it shows the IPv4 address or IPv6 address.

Examples

- This command displays the status of the switch's NTP connection.

```
switch# show ntp status
synchronised to NTP server (192.168.78.62) at stratum 3
   time correct to within 66 ms
   polling server every 1024 s
```

```
switch #
```

- This command displays data about the NTP servers in the configuration.

```
switch# show ntp associations
remote           refid          st t when  poll reach   delay   offset  jitter
==============================================================================
+1.ntp.arista.co 125.157.10.11   2 u  539  1024  377  121.748   -0.345   0.893
-3.ntp.arista.co 127.31.152.34   2 u  868  1024  377  101.671    2.434   1.529
+2.ntp.arista.co 176.131.12.185  2 u  676  1024  377  116.505     0.03   0.768
*4.ntp.arista.co 120.181.192.192 2 u  696  1024  377   48.431   -0.416    0.15 switch#
```

4.2.4.7 Displaying Network Time Security (NTS)

Use the **show ntp status** command to display information about the NTS configuration:

```
switch# show ntp status
synchronised to NTP server (10.0.1.2) at stratum 2
   time correct to within 939 ms
   polling server every 64 s

NTS client sends: 5
NTS client recvs good: 5
NTS client recvs w error: 0
NTS server sends: 0
NTS server recvs good: 0
NTS server recvs w error: 0
NTS-KE serves good: 0
NTS-KE serves bad: 0
NTS-KE client probes good: 1
NTS-KE client probes bad: 0
```

The output displays the following information about the NTS-KE configuration:

- **NTS client sends** - The number of client requests sent with NTS.
- **NTS client recvs good** - The number of valid responses with NTS received from servers.
- **NTS client recvs w error** - The number of invalid responses with NTS received from servers.
- **NTS server sends** - The number of responses with NTS sent by EOS as a server.
- **NTS server recvs good** - The number of valid client requests with NTS received by EOS as a server.
- **NTS server recvs w error** - The number of invalid client requests with NTS received by EOS as a server.
- **NTS-KE serves good** - The number of successful NTS-KE negotiations performed by the server.
- **NTS-KE serves bad** - The number of unsuccessful NTS-KE negotiations performed by the server.
- **NTS-KE client probes good** - The number of successful NTS-KE negotiations performed by the client.
- **NTS-KE client probes bad** - The number of unsuccessful NTS-KE negotiations performed by the client.

EOS re-attempts unsuccessful negotiations until successfully negotiating with the client or server. NTP synchronization only occurs after a successful NTS-KE negotiation. When operating correctly, the entries for NTS clients and servers increment consistently.

4.3 Managing Display Attributes

Display commands control the content of the banner and the command line prompt.

4.3.1 Banners

The switch can display two banners:

- **Login banner** - The login banner precedes the login prompt. Use a login banner to warn against unauthorized network access attempts or other messages to users.
- **motd banner** - After the user logs into the switch, the Message of the Day (MoTD) banner displays.

This output displays both banners in bold:

```
This is a login banner
switch login: john
Password:
Last login: Mon Jan 14 09:24:36 2013 from aristanetworks.com
This is an motd banner
switch>
```

Use the following commands to create a login and **motd** banner:

```
switch(config)# banner login
Enter TEXT message. Type 'EOF' on its line to end.
This is a login banner
EOF
switch(config)# banner motd
Enter TEXT message. Type 'EOF' on its own line to end.
This is an motd banner
EOF
switch(config)#
```

Use the following steps to create a banner:

1. Enter global configuration mode.

   ```
   switch# config
   switch(config)#
   ```

2. Enter Banner Configuration Mode by typing the desired command:
   - To create a **login** banner, type `banner login`.
   - To create a **motd** banner, type `banner motd`

The switch responds with instructions about entering the banner text.

```
switch(config)# banner login
Enter TEXT message. Type 'EOF' on its own line to end.
```

3. Enter the banner text.

```
This is the first line of banner text.

This is the second line of banner text.
```

4. Press **Enter** to place the cursor on a blank line after completing the banner text.
5. Exit banner edit mode by typing EOF.

```
EOF
switch(config)#
```

4.3.2 Configuring the CLI Prompt

The CLI prompt provides an entry point for EOS commands. The `prompt` command configures the contents of the prompt. The **`no prompt`** command returns the prompt to the default of **`%H%P`**.

Characters allowed in the prompt include A-Z, a-z, 0-9, and the following additional characters:

! @ # $ % Âˆ & * ( ) - = + f g [ ] ; : < > , . ? / Â˜ n

The prompt supports these control sequences:

- %s “ - Space character
- %t “ - Tab character
- %% “ - Percent character
- %H “ - Host Name
- %D “ - Time and Date
- %D{*f_char*} “ - time and date, format specified by the BSD **strftime** (f_char) time conversion function.
- %h “ - Host name up to the first.
- %P “ - Extended command mode
- %p “ - Command mode
- %r “ - Redundancy status on modular systems (has no effect on a fixed system)
- %R “ - Extended redundancy status on modular systems â€“ includes status and slot number (has no effect on a fixed system)

Examples

- Use the following command to create a prompt that displays **system 1** and the Command Mode.

```
switch(config)# prompt system%s1%P
system 1(config)#
```

- Use the following command to create a prompt that displays the Command Mode.

```
switch(config)# prompt %p
(config)#
```

- These equivalent commands create the Default prompt.

```
% prompt %H%P
host-name.dut103(config)#

%no prompt
host-name.dut103(config)#
```

4.4 System Event Logging

Arista switches log Event Notifications using the Syslog protocol. By default, EOS logs the event notifications internally to the folder, `/var/log/messages` but can also display them on the console or log them to an external server. Configure severity levels and log message destinations using the CLI, and configure individual processes and protocols to adjust or limit the messages from them. Use the **`show logging`** command to obtain visibility into the buffered and persistent logs which contain critical system, process, and operational messages.

For a full list of Syslog messages, visit Arista Support. Once on the site, click **Software Downloads**, and then navigate to **EOS** > **Active Releases** > ***latest_release***.

Click on the latest released version, and select **Docs.** Once expanded, select the *latest_release-SysMsgGuide.pdf*. The ***SysMsgGuide*** contains the latest version of the Syslog Messages in EOS.

System Event Logging Guidelines

Consider the following guidelines when configuring system logging on the switch:

- **Buffer Size** - Configure the number of messages stored in the buffer using the **`logging buffered`** ***size*** command. By default, EOS retains a large, but volatile, buffer and discards messages upon reboot unless you configure persistent logging.
- **Severity** - When you specify a severity level, EOS only processes messages with that severity and higher. When filtering with a severity level, EOS only displays messages with that severity and lower.
- **Real-time Output** - To view messages as they occur during your terminal session, enable terminal monitoring with the command, **`terminal monitor`**.
- **Custom Prefixes** - Configure custom prefixes for system log messages.

Severity Thresholds

Specifying a severity sets the minimum threshold of messages logged using an integer from 0 to 7, or a string from the following list:

- **0** - Emergency: System unusable
- **1** - Alert: Take immediate action
- **2** - Critical: Critical conditions
- **3** - Error: Error conditions
- **4** - Warning: Warning conditions
- **5** - Notice: Normal but significant conditions
- **6** - Informational: Informational messages
- **7** - Debug: Debug level messages

For example, if you configure a logging level of 6, EOS logs everything with levels 0-6.

Logging Locations

EOS logs system events in several locations depending on the nature of the log event. Logging occurs in the following locations and includes different types of events:

- Buffer Logging
- Console Logging
- Persistent Logging
- Monitor logging
- Synchronous Logging
- Trap Logging

Buffer Logging

Use **logging buffered** to retain logs in the buffer space on the switch. Set the syslog level as well as the buffer size. Arista Networks recommends a larger buffer size to retain messages for a week or longer.

Console Logging

Displays system notifications directly on the switch console or terminal session to provide real-time visibility into the health and operational status of the switch as events occur.

Persistent Logging

Enable persistent logging to write system logs to non-volatile flash and retain them after a switch reloads. However, utilizing persistent logging may fill up the flash when lots of log events occur on the switch.

To enable persistent logging with a maximum buffer size of 10,000 bytes, use the following command:

```
switch(config)# logging persistent 10000
```

Synchronous Logging

Synchronous logging ensures logging messages appear on the console but do not interrupt CLI output from command output. The log messages display after the CLI completes the command output.

The **logging synchronous** has the following format:

```
switch(config)# logging synchronous [ level severity | all]
```

level severity specify log messages of a lower severity level to log synchronously and specifies all log messages to log synchronously

Trap Logging

Enable trap logging to send log messages to a remote server. Specifying a severity level logs only log messages with a severity at or above that level to the remote server. To add a remote server IPv4 address, *192.168.96.147*, use the following commands:

```
switch(config)# logging host 192.168.96.147
switch(config)#
```

To add a fully qualified domain name (FQDN), *mycompany.com*, as the remote server, use the following command:

```
switch(config)# logging host mycompany.com
```

Use the following command to enable trap logging with severity 6:

```
switch(config)# logging trap system 4
```

The **logging trap system** command has the following parameters:

- **contain** - Specify text contained in a log message.
- **facility** - Specify one of 23 facilities, such as 1, for user-level messages.
- **severity** - Specify a severity from 0 (emergencies) to 7 (debugging).
- **tag** - Specify a tag that correlates with a program name.

Enabling System Logging

Use the following command to enable system logging on the switch:

```
switch(config)# logging on
switch(config)#
```

The **no | default** version of the command disables system logging on the switch and removes the configuration from the ***running-config***.

Configuring the Source Interface

After enabling a remote server to receive log messages, specify a local interface to derive the source IP address using the following syntax:

```
logging vrf vrf_name local-interface interface
```

Configuring Custom Prefixes for System Log Messages

Add custom prefixes to system log messages to create a format for syslog messages sent to syslog servers. The custom prefix can consist of any combination of underscores, numbers and upper and lower case letters, but does not allow other characters including whitespace.

Note: You cannot configure the parameters, **hostname** and **prefix**, at the same time. Configuring one automatically disables the other command.

Use the following command to add the prefix, *router_1a*, to syslog messages:

```
switch(config)# logging format prefix router_1a
switch(config)#
```

Configuring Active Standby Syslog Servers

EOS supports a standby server in addition to the existing logging mechanism for UDP syslog servers. Specify a logging group and then add remote syslog servers. The first configured syslog server becomes the active server and receives forwarded syslog messages when reachable through ICMP. The second configured host server becomes the backup server and receives syslog messages when the active syslog server becomes unreachable on the network.

The syslog server works with Connectivity Monitor to determine server liveliness by periodically sending ICMP probes at a configurable interval. Syslog servers configured in the active-standby mode start the Connectivity Monitor agent to probe the configured servers, and allows the syslog servers to work with the connectionless UCP protocol.

Configure syslog servers and related options in the Logging Group Configuration mode. Use the following commands to configure the logging group, `Group_1` on vrf `bluengreen`, and host `172.16.21.23`, with port `80`:

```
switch(config)# logging group server Group_1
switch(config-logging-group-Group_1)# logging vrf bluengreen host 172.16.21.23 port 80
switch(config-logging-group-Group_1)#
```

Configure the second syslog server, `192.168.1.3`:

```
switch(config-logging-group-Group_1)# host 192.168.1.3
switch(config-logging-group-Group_1)#
```

The host, `172.16.21.23`, becomes the active server, and the host, `192.168.1.3`, becomes the standby server on port `514`, the default port.

Configure a local interface, if not already configured on the VRF, to derive the source IP address of ICMP probes and syslog messages. Any host configured on the VRF then use the interface, `Ethernet1`. Use the following commands to configure an interface, `Ethernet1`:

```
switch(config)# logging vrf bluengreen local-interface Ethernet1
switch(config)#
```

Configuring ICMP Probes

An ICMP probe determines the syslog server status and by default, sends one every 5 seconds. The probe consists of 5 ICMP echo packets, and if all of the packets fail, the syslog server has a down status. Use the following commands to configure sending an ICMP probe every 10 seconds:

```
switch(config-logging-group-Group_1)# probe interval 10
switch(config-logging-group-Group_1)#
```

The interval can be configured from 1 to 600 seconds.

Configuring Success Thresholds

When a syslog server becomes unavailable, sending a number of sequentially passing probes determines the health of the server. If configured to 5, then 5 successful probes must be received before returning the status to available. This becomes useful when the server has a high variability of liveliness and helps prevent erroneous state changes and syslogs. The threshold has a default value of 0 which means that a syslog server has a status of available as long as it receives one probe successfully.

Use the following commands to configure a success threshold of 5:

```
switch(config-logging-group-Group_1)# probe threshold success 5
switch(config-logging-group-Group_1)
```

Displaying Syslog Server Status

The **`show logging group server`** command displays the status of the syslog servers. It also indicates the primary and standby servers and the recipient of the syslog messages.

```
switch# show logging group server Group_1
switch(config)#show logging group server
Logging group group1
Logging to 172.16.21.23 port 80 vrf bluengreen via udp (primary), state: probing
Last available: n/a
Logging to 192.168.1.3 vrf default via udp (standby), state: active
Last available: 0:00:10 ago
```

The output displays the primary status as probing because the syslog server has no availability, and the standby server as active with the endpoint status of 10 seconds indicating the last time the server received syslog messages.

Displaying System Logging Information

To display information about the system logging configuration, use the **`show logging`** command:

```
switch# show logging
```

```
Syslog logging: enabled
Buffer logging: level notifications
Console logging: level debugging
Persistent logging: level debugging
Monitor logging: level debugging
Synchronous logging: disabled
Trap logging: level informational
    Logging to '192.168.93.147' port 6514 in VRF default via udp
    Logging to '192.168.96.147' port 514 in VRF default via udp
    Logging to '192.168.96.147' port 6514 in VRF default via udp
    Logging to '192.168.96.147' port 514 in VRF purple via udp
Sequence numbers: disabled
Syslog facility: local4
Hostname format: Hostname only
Repeat logging interval: disabled
Repeat messages: disabled
Root login logging: disabled

External configuration:
    active:
    inactive:

Facility                    Severity            Effective Severity
---------------------       -------------       ------------------
aaa                         debugging           debugging
accounting                  debugging           debugging
acl                         debugging           debugging
agent                       debugging           debugging
ale                         debugging           debugging
arp                         debugging           debugging
bfd                         debugging           debugging
bgp                         debugging           debugging
<------>
vrf                         debugging           debugging
vrrp                        debugging           debugging
vxlan                       debugging           debugging
ztp                         debugging           debugging
```

The output displays the level of logging for each type of logging location and the configuration on the switch. Each feature displays the severity and effective severity of the log messages.

4.4.1 Managing TCAM Capacity Warnings

Strata chipsets, present in the 7010, 7050X, 7060X, 7250X, 7260X, and 7300X series switches, provide event logging for the hardware capacity of TCAM tables on a per-slice basis, and trigger a capacity warning by default whenever any TCAM slice exceeds 90% capacity. As a result, default TCAM logging can generate high levels of syslog messages on these platforms. The **hardware capacity alert table** command can adjust the capacity levels for the warnings above the 90% default. In that case, this adjustment can be made per TCAM resource and per slice. The command can also disable TCAM hardware capacity messages at the level ***Warning*** and below for a given slice. To disable messages, set the threshold to 0 or use the **no** version of the command.

Examples

- This command reduces hardware capacity Syslog warnings by increasing the capacity threshold to 99% for EFP table monitoring in slice 2.

```
switch(config)# hardware capacity alert table EFP feature Slice-2 threshold 99
```

- This command reduces messages by disabling hardware capacity Syslog warnings entirely for the IFP table in slice 5.

```
switch(config)# hardware capacity alert table IFP feature Slice-5 threshold 0
```

- This command reduces messages by disabling hardware capacity Syslog warnings entirely for the VFP table in all slices.

```
switch(config)# no hardware capacity alert table VFP
```

Note: Hardware capacity messages are user-configurable only at or below the “Warning” level. When depleting TCAM management software, it always sends “Error” messages to Syslog and affected features when all TCAM resources are used.

4.4.2 Layer 2 MAC Learn Failure Detection

A hash collision occurs when two or more distinct pieces of data map to the same entry or slot in the hardware table. It can happen when the hash function used to calculate the index for a MAC address results in the already occupied index and causes a failure of inserting the later MAC address to the hardware table.

Configuring Layer 2 MAC Learn Failure Detection

Use the following commands to enable system logging of MAC Learn Failures on the switch:

```
switch(config)# platform trident hardware mac-address-table collision-tracking
```

Use the **no** version of the command to disable the feature:

```
switch(config)# no platform trident hardware mac-address-table collision-tracking
```

Displaying Layer MAC Learn Failure Information

Use the following command to display missing MAC addresses in the hardware table:

```
switch# show platform trident l2 hardware mac-address-table missing
   Vlan  |   Mac Address         |   Present in SW?   |   Present in HW   | Missing in HW |
---------|-----------------------|--------------------|-------------------|---------------|
   2141  |   00:00:04:00:00:09   |         Y          |                   | Switchcard1/0 |
---------|-----------------------|--------------------|-------------------|---------------|
   2141  |   00:00:03:00:19:0c   |         Y          |                   | Switchcard1/0 |
---------|-----------------------|--------------------|-------------------|---------------|

Total entries missing in software:  0

Total entries missing in hardware:  2
Switchcard1/0:  2
```

Sample Syslog Message for L2 MAC Learn Failure

```
%ETH---MACADDRBANKFULL: Unable to program learned dynamic host table entry
for MAC address MAC address in VLAN VLAN Id due to hardware resource exhaustion.
```

4.5 Event Monitor

The Event Monitor writes system event records to local files for access by SQLite database commands.

> **Note:** The switch does not enable **event-monitor** by default. Use the **event-monitor** command to explicitly enable event-monitor.

4.5.1 Description

The event monitor receives notifications for important events or changes to the enabled event monitor tables. These changes log to a fixed-size circular buffer. The size of this buffer is configurable, but it does not grow dynamically. Buffer contents can be stored to permanent files to increase the event monitor effective capacity. The permanent file size and the number of permanent files is configurable. The buffer is stored at a fixed location on the switch.

Specific event monitor queries are available through CLI commands. For queries not available through specific commands, manual queries are supported through other CLI commands. When the user issues a query command, the relevant events from the circular buffer and permanent files are written to and accessed from a temporary SQLite database file. The database keeps a separate table for each logging type (such as MAC, ARP, route, and others). When the monitor receives notification of a new event, the database file is deleted, then recreated.

4.5.2 Configuring the Event Monitor

Enabling the Event Monitor

The `event-monitor` command enables the Event Monitor and specifies the types of events to log by the switch. The Event Monitor provides an event logging service that records system events to a local database. The Event Monitor records these events:

- All changes to all events.
- ARP changes to the ARP table (IPv4 address to MAC address mappings).
- Neighbor changes to the neighbor table (IPv6 address to MAC address mappings).
- Backed up log files.
- Buffer changes to the local buffer settings.
- IGMP snooping changes to the IGMP snooping table.
- LACP changes to the LACP table events.
- MAC changes to the MAC address table (MAC address to port mappings).
- mRoute changes to the IP multicast routing table.
- Neighbor changes to the neighbor routing table.
- Next-hop group backup-activation events

- Route changes to the IPv4 routing table.
- Route changes to the IPv6 routing table.
- STP unstable events that cause STP instability.

The switch does not enable event monitoring by default. Use the **event-monitor** command to explicitly enable the Event Monitor. The **no event-monitor all** disables the Event Monitor. The **no event-monitor** command, followed by a log type parameter, disables event recording for the specified type.

Example

- This command disables the Event Monitor for all types of events.

```
switch(config)# no event-monitor all
```

- This command enables the Event Monitor for routing table changes.

```
switch(config)# event-monitor route
```

The **event-monitor clear** command removes the contents of the Event Monitor buffer. If enabled, this command removes the contents from all Event Monitor backup files.

Example

This command clears the contents of the Event Monitor buffer.

```
switch# event-monitor clear
switch(config)#
```

Configuring the Buffer

The **event-monitor buffer max-size** command specifies the size of the Event Monitor buffer. The Event Monitor buffer has a fixed-size circular data structure that receives event records from the Event Monitor. When enabling Event Monitor backup, the buffer copies the events to a backup file before each rollover. Buffer size ranges from 6 Kb to 50 Kb with a default size of 32 Kb.

Example

This command configures a buffer size of ***48 Kb***.

```
switch(config)# event-monitor buffer max-size 48
switch(config)#
```

Configuring Permanent Files

The `event-monitor backup path` command enables storage of the Event Monitor buffer to permanent switch files and specifies the path and name of these files. The command references file location either from the flash drive root directory where the CLI operates (**`/mnt/flash`**) or from the switch root directory (/).

The Event Monitor buffer becomes circular after the buffer fills, new data replaces older data at the beginning of the buffer. The switch copies the buffer into a new backup file after each buffer writing cycle before the switch starts re-writing the buffer.

Example

These commands configure the switch to store the Event Monitor buffer in `sw-event.log`, then display the new file in the flash directory.

```
switch(config)# event-monitor backup path eventmon_backup_dir/event.log
switch(config)#
bash-4.3# ls /mnt/flash/eventmon_backup_dir/

arpevent.log.1  lacpevent.log.1  neighborevent.log.1  routeevent.log.1
igmpsnoopingevent.log.1  macevent.log.1   route6event.log.1
stpunstableevent.log.1
```

The `event-monitor backup max-size` command specifies the quantity of Event Monitor backup files the switch maintains. The switch appends an extension number to the file name when it creates a new file. After every 500 events, the switch deletes the oldest backup file after exceeding the file limit.

Example

These commands configure the switch to back up the event buffer to a series of files named ***sw-event.log***. The switch can store a maximum of four files.

```
switch(config)# event-monitor backup path sw-event.log
switch(config)# event-monitor backup max-size 4
switch(config)#
```

The switch creates these first five files to store Event Monitor buffer contents:

`sw-event.log.0`

`sw-event.log.1`

`sw-event.log.2`

`sw-event.log.3`

`sw-event.log.4`

The switch deletes **`sw-event.log.0`** the first time it verifies the number of existing backup files after the creation of **`sw-event.log.4`**.

4.5.3 Querying the Event Monitor

These CLI commands perform SQL-style queries on the Event Monitor database:

- The **show event-monitor arp** command displays ARP table events.
- The **show event-monitor mac** command displays MAC address table events.
- The **show event-monitor route** command displays routing table events.

Example

This command displays all events triggered by MAC address table events.

```
switch# show event-monitor mac
% Writing 0 Arp, 0 Route, 1 Mac events to the database
2012-01-19 13:57:55|1|0808.0808.0808|Ethernet1|configuredStaticMac|added|0
```

For other database queries, the **show event-monitor sqlite** command performs an SQL-style query on the database, using the statement specified in the command.

Example

This command displays all entries from the route table.

```
switch# show event-monitor sqlite select * from route;
2019-09-30 14:01:21.659428|16.16.16.255/32|default|receiveBcast|0|0|updated|20
2019-09-30 14:01:21.659464|192.168.201.12/30|default|connected|1|0|updated|21
2019-09-30 14:01:21.659497|192.168.1.255/32|default|receiveBcast|0|0|updated|22
2019-09-30 14:01:21.659503|192.168.201.8/32|default|receiveBcast|0|0|updated|23
2019-09-30 14:01:21.659512|16.16.16.0/32|default|receiveBcast|0|0|updated|24
2019-09-30
14:01:21.659517|192.168.201.12/32|default|receiveBcast|0|0|updated|25
2019-09-30
14:01:21.659524|192.168.201.15/32|default|receiveBcast|0|0|updated|26
2019-09-30 14:01:21.659541|192.168.201.8/30|default|connected|1|0|updated|27
2019-09-30 14:01:21.659564|16.16.16.0/24|default|connected|1|0|updated|28
2019-09-30 14:01:21.659578|192.168.201.9/32|default|receive|0|0|updated|29
```

4.5.4 Accessing Event Monitor Database Records

The **event-monitor sync** command combines the event monitor buffer with all backup logs and synchronizes them into a single SQLite file. The data can be accessed through SQLite or by using the **show event-monitor** commands.

Example

- This command synchronizes the buffer and backup logs into a single SQLite file.

```
switch(config)# event-monitor sync
switch(config)#
```

4.6 Managing EOS Extensions

The most simple and efficient way to make the most of the extensibility in EOS through the use of extensions. An extension provides a pre-packaged optional feature or a set of scripts in an RPM Package Manager (RPM) or Software image extension (SWIX) format. Arista provides a variety of extensions on the EOS Software Downloads page.

These sections describe basic EOS extension tasks:

- Installing EOS Extensions
- Installing EOS Extensions on a Dual-Supervisor Switch
- Verifying EOS Extensions Installation
- Uninstalling an EOS Extension

4.6.1 Installing EOS Extensions

Complete the following steps to install an EOS extension.

1. Download the desired extension and copy it onto the devices flash storage.

```
switch# dir
Directory of flash:/
-rwx 479183792 Jun 23 09:46 EOS-4.13.3F.swi
-rwx 21280296 Feb 6 16:48 arista-splunk-extension.swix
-rwx 27 Jun 23 10:08 boot-config  drwx 4096 Sep 26 2012 schedule
-rwx 1481 Jun 27 05:54 startup-config
```

2. Copy the file from the flash storage to the extensions partition.

```
switch# copy flash:arista-splunk-extension.swix extension:
Copy completed successfully.
```

3. Install the EOS extension.

```
switch# extension arista-splunk-extension.swix
If this extension modifies the behavior of the Cli, any running Cli sessions will
need to be reset in order for the Cli modifications to take effect.
```

4. If you require extension persistence across rebooting the switch, copy the extension into the boot-extensions partition.

```
switch# copy installed-extensions boot-extensions
```

5. Run the extension. As the CloudVision extension adds additional CLI commands to EOS, the CLI session must be restarted so that the additional commands become available. To achieve this, close the SSH or the Telnet session and open a new session.

4.6.2 Installing EOS Extensions on a Dual-Supervisor Switch

Automated SWIX Installation on Dual Supervisor Systems

This feature automates the end-to-end workflow for EOS extensions by copying the source file from a remote or local location, installing it into the switch extension partition, and ensures adding it to the `boot-extensions` list so it persists across reloads. On dual-supervisor systems, the switch handles peer synchronization internally, removing the need for `session peer-supervisor` manual intervention.

The command has the following syntax:

`install extension source` ***URL*** **`[ {force | signature-verification ignored | delay-restart-agents } ]`**

- **`source`** ***URL*** - Specify a remote or local URL for an SWIX or RPM extension.
- **`force`** - Override dependency checks.
- **`signature-verification ignored`** - Ignores verification of an SWIX extension.
- **`delay-restart-agents`** - Delays restarting agents in the SWIX.

Use the command only on the active supervisor switch. If used on a standby supervisor, the command exits with an error.

Note: This method is applicable to release versions 4.35.1 and later. For earlier versions, please refer to the section on Manual SWIX Installation on Dual Supervisor Systems.

Complete the following to install the extension across the active and standby supervisors.

Copy the source file from a remote or local location, and install it into the extension partition on the active switch. Then, add it to the boot extensions list to persist the extensions across reloads.

```
switch# install extension source flash:/docker.x86_64.swix
Copying extension from flash:/docker.x86_64.swix to temporary file flash:/docker.x86_64.swix_
tmpd4a3
Copy completed successfully.
Copying docker.x86_64.swix from active to standby supervisor
Copy completed successfully.
Copying docker.x86_64.swix to extensions on standby supervisor
Installing docker.x86_64.swix on standby supervisor
Adding to boot-extensions on standby supervisor
Removing temporary file on standby supervisor
Copying extension from temporary file to extension:/docker.x86_64.swix
Copy completed successfully.
Installing docker.x86_64.swix
Adding to boot extensions
Removing file at flash:/docker.x86_64.swix_tmpd4a3
```

Repeat the steps listed in the Verifying EOS Extensions Installation to verify the extension installation.

Manual SWIX Installation on Dual Supervisor Systems

For EOS versions released prior to 4.35.1, follow these steps to manually install an EOS extension on a dual-supervisor switch:

1. Copy the extension from the primary supervisor to the standby supervisor's flash directory.

```
switch(s1)# copy flash:<filename>.swixsupervisor-peer://mnt/flash/
```

2. Establish a session to the standby supervisor from the primary supervisor.

```
switch(s1)# session peer-supervisor
Warning: Permanently added '[127.1.0.2]:3601' (RSA) to the list of known hosts.
Last login: Mon Aug 27 17:32:00 2018 from supervisor1
```

```
WARNING - you are currently logged in to the standby supervisor. Not all cli commands are
 available or supported. Any configurationdone from this cli will not be reflected in the
 active supervisor's
running config and will be lost when the active supervisor writes its startup config.
switch(s2)#
```

3. Repeat the steps outlined in **Installing EOS Extensions** to complete the installation.
4. Repeat the steps outlined in **Verifying EOS Extensions Installation** to verify the installation.
5. Exit the standby supervisor.

```
switch(s2)# exit
Connection to 127.1.0.1 closed.
switch(s1)#
```

4.6.3 Verifying EOS Extensions Installation

Complete the steps to verify that the EOS extensions installed correctly.

1. Run the **`show extensions`** command to verify that the EOS extensions are available and installed correctly.

```
switch# show extensions
Name Version/Release Status Extension
---------------------------------------- -------------------------
EosSdk-1.2.1-fl.boca-1943435.i686.rpm 1.2.1/1943435.flbocaeossd A, NI 1
arista-splunk-extension.swix 0.95/1498976.2013ltdsplun A, I 2
fping-2.4b2-10.fc12.i686.rpm 2.4b2/10.fc12 A, I 1
gnuplot.swix 1.10.0/1.fc14 A, I 16
splunkforwarder-5.0.9-213964.i386.rpm 5.0.9/213964 A, NI 1
```

```
A: available | NA: not available | I: installed | NI: not installed | F: forced
```

2. Run the **`show boot-extensions`** command to verify that the EOS extensions are enabled for boot persistence.

```
switch# show boot-extensions
arista-splunk-extension.swix
fping-2.4b2-10.fc12.i686.rpm
gnuplot.swix
```

4.6.4 Uninstalling an EOS Extension

Complete the following steps to uninstall an EOS extension.

1. Uninstall the existing EOS extension using the **`no extension`** command.

```
switch# no extension fping-2.4b2-10.fc12.i686.rpm
switch#show extensions
Name                                       Version/Release              Status extension
------------------------------------------ -------------------------    ----------
EosSdk-1.2.1-fl.boca-1943435.i686.rpm      1.2.1/1943435.flbocaeossd A,  NI 1
arista-splunk-extension.swix               0.95/1498976.2013ltdsplun A,  I 2
fping-2.4b2-10.fc12.i686.rpm               2.4b2/10.fc12 A,              NI 1
gnuplot.swix                               1.10.0/1.fc14 A,              I 16
splunkforwarder-5.0.9-213964.i386.rpm      5.0.9/213964 A,               NI 1
```

```
A: available | NA: not available | I: installed | NI: not installed | F: forced
```

2. Remove the extension from the boot-extension using the **`copy installed-extensions boot-extensions`** command.

```
switch# copy installed-extensions boot-extensions
```

Note: If you have a Dual-Supervisor Switch, connect to the secondary supervisor using the session peer-supervisor command, repeat steps 1 and 2, and finally exit from the secondary supervisor.

4.6.5 EOS Extensions Log Messages

The following Log Messages display during EOS Extensions installation or after uninstalling EOS Extensions:

Table 6: EOS Extensions System Log Messages

Message	Severity	Explanation	Recommended Action
INSTALL: Extension % has been installed.	Info	The extension has been installed.	No action is required – this message is for information only.
INSTALLING: Installing extension %s, version %s, SHA-1 %s	Info	EOS has started to install the extension.	No action is required – this message is for information only.
INSTALL_ERROR: Extension %s failed to install: %s	Error	The extension failed to install. The log message may contain a reason why installation failed, such as a missing dependency.	Determine why the extension failed to install. If a dependency is missing, install it. If you are unsure how to proceed, contact the developer of the extension or your support representative.
LOAD_ERROR: Extension failed to load: %	Error	The extension failed to load. The log message or extension load log file may contain a reason why it failed, such as a broken config file.	Determine why the extension failed to load. If you are unsure how to proceed, contact the developer of the extension or your support representative.
RESTARTING_AGENTS: Extension installation finalization: restarting agents: %s	Info	Agents are being restarted by operator request, in order to cause a software upgrade/patch to become effective.	No action is required – this message is for information only.
SIGNATURE_INVALID: Extension %s has an invalid signature: %s	Warning	The extension has an invalid signature, or the signature could not be determined. The log message may contain a reason for the error	Examine the extension and determine if the contents are correct. If the contents are not as expected, uninstall the extension immediately. If you are unsure how to proceed, contact the developer of the extension or your support representative.
SIGNATURE_VALID: Extension %s has a valid signature.	Info	The extension has a valid digital signature.	No action is required – this message is for information only.
STATUS_SAVE_ERROR: Failed to write extension status to %s: %s	Error	Cannot write extension status to the filesystem. Extension status may not be restored if Sysdb restarts.	Check if the filesystem is full.
UNINSTALLED: Extension %s has been uninstalled.	Info	The extension has been uninstalled.	No action is required – this message is for information only.

Message	Severity	Explanation	Recommended Action
UNINSTALLING: Uninstalling extension %s	Info	EOS has started to uninstall the extension.	No action is required – this message is for information only.
UNINSTALL_ERROR: Extension %s failed to uninstall: %s	Error	The extension failed to uninstall. The message may contain a reason why uninstallation failed, such as a dependency from another installed extension.	Determine why the extension failed to uninstall. Some extensions may not support uninstall, requiring a reboot of the switch to remove the extension. If you are unsure how to proceed, contact the developer of the extension or your support representative.

4.7 Monitoring Latency

The Monitoring Latency feature allows the measurement and display of end-to-end packet latency as seen at egress interfaces. EOS measures packet latency from switch ingress to switch egress and provides two modes of operation:

- **Maximum Load** - Record and display the maximum end-to-end latency experienced by any packet egressing from the switch at each egress interface and traffic class.
- **Histogram** - For each egress interface and traffic class combination, record and display a histogram of up to 4 bins counting packets. Configure the bin boundaries to your custom parameters, and packets with a latency between the lower and upper boundaries for a bin count in that bin.

Note: Supported on the 7280R3A, 7289R3A, and 7800R3A series of platforms.

Monitoring Latency Configuration

Use the following command to enter the Monitor Latency Configuration Mode:

```
switch(config)# monitor latency
switch(config-mon-latency)#
```

Use the following command to enable maximum mode and begin recording latency data for the mode:

```
switch(config-mon-latency)# measurement end-to-end maximum
switch(config-mon-latency)#
```

Use the following command to enable histogram mode and begin recording latency data for the mode:

```
switch(config-mon-latency)# measurement end-to-end histogram
switch(config-mon-latency)#
```

The **maximum** and **histogram** modes can be enabled together in a single command.

```
switch(config-mon-latency)# measurement end-to-end histogram maximum
switch(config-mon-latency)#
```

The **[no | default]** versions of the command disables the feature.

Configuring Histogram Bin Boundaries for a Profile

The End-to-End Binning Profile defines a set of increasing boundary values that groups latency values into a histogram with up to 4 bins. Specify up to 5 boundary values, in milliseconds, microseconds, or nanoseconds, for the 4 bins. You must configure explicit minimum and maximum boundary values of zero and infinity. Packets experiencing latency with a value between the lower and upper boundaries count for that bin.

The following restrictions apply to the configuration of a binning profile:

- Boundaries must be specified in increasing order.
- Specify at least 2 bins with 3 values: 0, boundary value, and infinity.
- EOS supports up to 4 bins with boundary values of 0 and infinity plus 3 other boundary values.
- In the switch hardware, the binning boundary values consist of 32-bit values specifying nanoseconds even if specified as milliseconds, microseconds, or nanoseconds. The maximum configurable value is approximately 4.29 seconds.
- EOS does not support boundary values using sub-nanosecond precision. If specifying a boundary with sub-nanosecond precision, EOS truncates the nanosecond portion of the value and uses the truncated value as the boundary value.

Changing the binning profile clears existing histogram data and the message, "Changing histogram boundaries clears the histogram counters."

If you do not specify a binning profile, the configuration uses a default profile:

```
binning profile end-to-end microseconds 0 10 50000 infinity
```

Example Profiles

```
switch(config-mon-latency)#binning profile end-to-end milliseconds 0 0.01 0.2 50.3 infinity
switch(config-mon-latency)#binning profile end-to-end microseconds 0 10 200 50300 infinity
switch(config-mon-latency)#binning profile end-to-end nanoseconds 0 10000 200000 50300000 infinity
```

Use the **clear** command to clear recorded latency data and restart updating it.

Displaying the Latency Data Histogram

The output of the **show monitor latency measurement end-to-end histogram** displays the following information:

- **Latency(nanoseconds)** - For each histogram bin, it displays the range of packet latencies assigned to the bin.
- **Count** - The number of packets experiencing latency in this range since clearing the last count.
- **Cumulative%** - The cumulative percentage of total packets received on the interface and traffic class combination accounted for by the row and previous rows.
- **Histogram** - The count value displayed as a string of "*" characters with a maximum of 20 characters.

```
switch# show monitor latency measurement end-to-end histogram
Interface: Ethernet3/2/1
Traffic class: 0
Latency histogram:
Latency (nanoseconds)       Count       Cumulative %    Histogram
--------------------------- ----------- ------------------ ----------------------
           0 -  9999        1234               23.1    |**********
       10000 - 19999        2468               69.3    |********************
       20000 - 29999         702               82.5    |******
       30000+                936              100.0    |********

Interface: Ethernet3/2/1
Traffic class: 1
Latency histogram:
Latency (nanoseconds)       Count       Cumulative %    Histogram
--------------------------- ----------- ------------------ ----------------------
           0 -  9999        1234               23.1    |**********
       10000 - 19999        2468               69.3    |********************
       20000 - 29999         702               82.5    |******
       30000+                936              100.0    |********
```

Displaying the Latency Data Maximum Mode Information

The output of the **show monitor latency measurement end-to-end maximum** displays the following information:

- **Interface** - Displays the interface configured for maximum mode.
- **TC** - Displays the traffic class with the maximum value.
- **Maximum Latency(nanoseconds)** - The largest latency experienced by any packet egressing the switch from the indicated interface and traffic class since clearing the last maximum values.
- **Last seen** - Displays the time when the maximum value was last seen.

```
switch# show monitor latency measurement end-to-end maximum
                            Maximum latency
Interface           TC         (nanoseconds)    Last seen
----------------- -------- --------------------- -----------
Ethernet2            0                 10000    0:00:02 ago
Ethernet2            7                  3000    0:01:12 ago
Ethernet13           0                 10000    0:00:02 ago
Ethernet13           7                  3000    0:01:12 ago
```

4.8 Switch Administration Commands

Switch Name Configuration Commands

- clear ptp interface counters
- dns domain
- hostname
- ip domain-list
- ip domain lookup
- ip host
- ip name-server
- ipv6 host
- show hostname
- show hosts
- show ip domain-name
- show ip name-server
- show local-clock time-properties

Banner Configuration Commands

- banner login
- banner motd
- show banner

Prompt Configuration Command

- prompt

Event Manager Commands

- event-monitor
- event-monitor backup max-size
- event-monitor backup path
- event-monitor buffer max-size
- event-monitor clear
- event-monitor sync

- no event-monitor
- show event-monitor arp
- show event-monitor igmpsnooping
- show event-monitor mac
- show event-monitor mroute
- show event-monitor neighbor
- show event-monitor nexthop-group backup-activation
- show event-monitor route6
- show event-monitor route
- show event-monitor sqlite
- show event-monitor stpunstable

Email Configuration Command

- email

System Clock Commands

- clock set
- clock timezone
- show clock

NTP Commands

- ntp authenticate
- ntp authentication-key
- ntp local-interface
- ntp serve
- ntp serve all
- ntp server
- ntp trusted-key
- show ntp associations
- show ntp status

Syslog Configuration Commands

- logging buffered

- logging console
- logging event
- logging facility
- logging format
- logging host
- logging level
- logging local-interface
- logging message
- logging monitor
- logging persistent
- logging policy
- logging qos
- logging relogging-interval
- logging repeat-messages
- logging source-interface
- logging synchronous
- logging trap
- logging vrf host
- logging vrf local-interface
- logging vrf source-interface

Power Configuration Commands

- power enable module

Monitor Latency Commands

- binning
- measurement end-to-end
- monitor latency

4.8.1 banner login

The **banner login** command configures a message that the switch displays before login and password prompts. The login banner is available on console, telnet, and ssh connections.

The **no banner login** and **default banner login** commands delete the login banner.

Command Mode

Global Configuration

Command Syntax

banner login

no banner login

default banner login

Parameters

- ***banner_text*** To configure the banner, enter a message when prompted. The message may span multiple lines. Banner text supports the following keywords:
  - **$(hostname)** displays the switch's host name.
- **EOF** To end the banner editing session, type EOF on its own line and press **enter**.

Examples

- These commands create a two-line login banner.

```
switch(config)# banner login
Enter TEXT message. Type 'EOF' on its own line to end.
This is a login banner for $(hostname).
Enter your login name at the prompt.
EOF
switch(config)#
```

- This output displays the login banner.

```
This is a login banner for switch.
Enter your login name at the prompt.
switch login:john
Password:
Last login: Mon Jan 14 09:05:23 2013 from adobe-wrks.aristanetworks.com switch>
```

4.8.2 banner motd

The **banner motd** command configures a message of the day (motd) that the switch displays after a user logs in. The motd banner is available on console, telnet, and ssh connections.

The **no banner motd** and **default banner motd** commands delete the motd banner.

Command Mode

Global Configuration

Command Syntax

```
banner motd

no banner motd

default banner motd
```

Parameters

- ***banner_text*** To configure the banner, enter a message when prompted. The message may span multiple lines. Banner text supports this keyword:
  - **$(hostname)** displays the switch's host name.
- **EOF** To end the banner editing session, type EOF on its own line and press **enter**.

Examples

- These commands create an motd banner.

```
switch(config)# banner motd
Enter TEXT message. Type 'EOF' on its own line to end.
This is an motd banner for $(hostname)
EOF
switch(config)#
```

- This output displays the motd banner.

```
switch login: john
Password:
Last login: Mon Jan 14 09:17:09 2013 from adobe-wrks.aristanetworks.com
This is an motd banner for Switch switch>
```

4.8.3 binning

The **binning** command in the Monitor Latency Configuration Mode allows configuration of histogram bin boundaries on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

binning profile end-to-end [microseconds 0 ***value value*** **infinity] [milliseconds 0** ***value value*** **infinity] [nanoseconds 0** ***value value*** **infinity]**

no binning profile end-to-end

default binning profile end-to-end

Parameters

- **binning profile end-to-end** - Configure the histogram binning boundaries.
- **microseconds 0** ***value value*** **infinity** - Configure the boundaries with 0 as the starting point and monotonically increase the bin value ending with infinity to terminate. Decimals are allowed.
- **milliseconds 0** ***value value*** **infinity** - Configure the boundaries with 0 as the starting point and monotonically increase the bin value ending with infinity to terminate. Decimals are allowed.
- **nanoseconds 0** ***value value*** **infinity** - Configure the boundaries with 0 as the starting point and monotonically increase the bin value ending with infinity to terminate. Decimals are not allowed.

The binning profile has the following constraints:

- Boundary values must be specified in increasing order.
- At least 2 bins must be specified using 3 boundary values: 0, *boundary_value*, infinity.
- At most, 4 bins can be specified using 0, infinity, and 3 boundary values.

If you do not configure a binning profile, EOS uses the following default profile:

```
binning profile end-to-end microseconds 0 10 100 50000 infinity
```

Examples

Use the following examples to configure binning profiles on the switch in Monitor Latency Configuration Mode:

```
switch(config)# monitor latency
switch(config-mon-latency)# binning profile end-to-end milliseconds 0 0.01 0.2 50.3 infinity
switch(config-mon-latency)# binning profile end-to-end microseconds 0 10 200 50300 infinity
switch(config-mon-latency)# binning profile end-to-end nanoseconds 0 10000 200000 50300000
 infinity
```

4.8.4 clear ptp interface counters

The **clear ptp interface counters** command resets the Precision Time Protocol (PTP) packet counters.

Command Mode

Privileged EXEC

Command Syntax

`clear ptp interface` [**INTERFACE_NAME**] `counters`

Parameters

INTERFACE_NAME Interface type and numbers. Options include:

- ***no parameter*** Displays information for all interfaces.
  - **ethernet *e_range*** Ethernet interface range specified by ***e_range***.
  - **loopback *l_range*** Loopback interface specified by ***l_range***.
  - **management *m_range*** Management interface range specified by ***m_range***.
  - **port-channel *p_range*** Port-Channel Interface range specified by ***p_range***.
  - **vlan *v_range*** VLAN interface range specified by ***v_range***.
  - **VXLAN *vx_range*** VXLAN interface range specified by ***vx_range***.

Valid parameter formats include number, number range, or comma-delimited list of numbers and ranges.

Example

This command clears all PTP counters.

```
switch# clear ptp counters
switch#
```

4.8.5 clock set

The **clock set** command sets the system clock time and date. If the switch is configured with an NTP server, NTP time synchronizations override manually entered time settings.

Time entered by this command is local, as configured by the **clock timezone** command.

Command Mode

Privileged EXEC

Command Syntax

`clock set` *hh:mm:ss date*

Parameters

- ***hh:mm:ss*** is the current time (24-hour notation).
- ***date*** is the current date. Date formats include:
  - **mm/dd/yy** example: 05/15/2012
  - example: May 15 2012
  - example: 15 May 2012

Example

This command manually sets the switch time.

```
switch# clock set 08:15:24 14 Jan 2013
Mon Jan 14 08:15:25 2013
timezone is US/Central
```

4.8.6 clock timezone

The **clock timezone** command specifies the UTC offset that converts system time to local time. The switch uses local time for time displays and to time-stamp system logs and messages.

The **no clock timezone** and **default clock timezone** commands delete the **timezone** statement from ***running-config***, setting local time to UTC.

Command Mode

Global Configuration

Command Syntax

clock timezone ***zone_name***

no clock timezone

default clock timezone

Parameters

zone_name the time zone. Settings include a list of predefined time zone labels.

Examples

- This command configures the switch for the United States Central Time Zone.

```
switch(config)# clock timezone US/Central
switch(config)# show clock
Fri Jan 11 18:42:49 2013
timezone is US/Central
switch(config)#
```

- To view the predefined time zone labels, enter **clock timezone** with a question mark.

```
switch(config)# clock timezone ?
  Africa/Abidjan                    Africa/Accra
  Africa/Addis_Ababa                Africa/Algiers
  Africa/Asmara                     Africa/Asmera
  Africa/Bamako                     Africa/Bangui

  W-SU                              W-SU timezone
  WET                               WET timezone
  Zulu                              Zulu timezone

switch(config)#clock timezone
```

- This command displays all time zone labels that start with **America**.

```
switch(config)# clock timezone AMERICA?
America/Adak                    America/Anchorage
America/Anguilla                America/Antigua
America/Araguaina               America/Argentina/Buenos_Aires

America/Virgin                  America/Whitehorse
America/Winnipeg                America/Yakutat
America/Yellowknife

switch(config)#clock timezone AMERICA
```

4.8.7 dns domain

The **dns domain** command configures the switchs domain name. The switch uses this name to complete unqualified host names.

The **no dns domain** and **default dns domain** commands delete the domain name by removing the **dns domain** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`dns domain` *string*

`no dns domain`

`default dns domain`

Parameter

string domain name (text string).

Example

This command configures ***aristanetworks.com*** as the switchs domain name.

```
switch(config)# dns domain aristanetworks.com
switch(config)#
```

4.8.8 email

The **email** command places the switch in email client configuration mode. If you configure a from-user and an outgoing SMTP server on the switch, you can then use an email address as an output modifier to a **show** command and receive the output as email.

Command Mode

Global Configuration

Command Syntax

```
email
```

Example

This command places the switch in email client configuration mode.

```
switch(config)# email
switch(config)#
```

4.8.9 event-monitor backup max-size

The **event-monitor backup max-size** command specifies the quantity of event monitor backup files the switch maintains. Values range from 1 to 200 files with a default of ten files.

The **event-monitor backup path** command specifies the path/name of these files. The switch appends an extension to the file name that tracks the creation order of backup files. When the quantity of files exceeds the configured limit, the switch deletes the oldest file.

The **no event-monitor backup max-size** and **default event-monitor backup max-size** command restores the default maximum number of backup files the switch can store to ten by removing the corresponding **event-monitor backup max-size** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`event-monitor backup max-size` *file_quantity*

`no event-monitor backup max-size`

`default event-monitor backup max-size`

Parameter

file_quantity maximum number of backup files. Value ranges from ***1*** to ***200***. Default is ***10***.

Example

These commands configure the switch to back up the event buffer to a series of files named sw-event.log. The switch can store a maximum of four files.

```
switch(config)# event-monitor backup path sw-event.log
switch(config)# event-monitor backup max-size 4
switch(config)#
```

The first five files that the switch creates to store event monitor buffer contents are:

sw-event.log.0

sw-event.log.1

sw-event.log.2

sw-event.log.3

sw-event.log.4

The switch deletes **sw-event.log.0** the first time it verifies the number of existing backup files after the creation of **sw-event.log.4**.

4.8.10 event-monitor backup path

The **event-monitor backup path** command enables the storage of the event monitor buffer to switch files and specifies the path/name of these files. The command references the file location either from the flash drive root directory (/mnt/flash) where the CLI operates or from the switch root directory (/).

The event monitor buffer is circular after the buffer is filled, new data is written to the beginning of the buffer, replacing old data. At the conclusion of each buffer writing cycle, it is copied into a new backup file before the switch starts re-writing the buffer. The switch appends a extension number to the file name when it creates a new file. After every 500 events, the switch deletes the oldest backup file if the file limit specified by the event-monitor backup max-size command is exceeded.

running-config can contain a maximum of one **event-monitor backup path** statement. Subsequent **event-monitor backup path** commands replace the existing statement in ***running-config***, changing the name of the file where event monitor backup files are stored.

The **no event-monitor backup path** and **default event-monitor backup path** commands disable the storage of the event monitor buffer to switch files by deleting the **event-monitor backup path** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
event-monitor backup path URL_FILE

no event-monitor backup path

default event-monitor backup path
```

Parameters

URL_FILE path and file name of the backup file:

- ***path_string*** specified path is appended to **/mnt/flash/**.
- **file:** ***path_string*** specified path is appended to /.
- **flash:** ***path_string*** specified path is appended to **/mnt/flash/**.

Example

These commands configure the switch to store the event monitor buffer in sw-event.log, then display the new file in the flash directory.

```
switch(config)# event-monitor backup path eventmon_backup_dir/event.log
switch(config)#
bash-4.3# ls /mnt/flash/eventmon_backup_dir/

arpevent.log.1  lacpevent.log.1  neighborevent.log.1  routeevent.log.1
igmpsnoopingevent.log.1  macevent.log.1   route6event.log.1
stpunstableevent.log.1
```

4.8.11 event-monitor buffer max-size

The **`event-monitor buffer max-size`** command specifies the size of the event monitor buffer. The event monitor buffer is a fixed-size circular data structure that receives event records from the event monitor. When event monitor backup is enabled (`event-monitor backup path`), the buffer is copied to a backup file before each rollover.

Buffer size ranges from ***6 Kb*** to ***50 Kb***. The default size is ***32 Kb***.

The **`no event-monitor buffer max-size`** and **`default event-monitor buffer max-size`** commands restore the default buffer size of 32 Kb by removing the **`event-monitor buffer max-size`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`event-monitor buffer max-size` *buffer_size*

`no event-monitor buffer max-size`

`default event-monitor buffer max-size`

Parameters

buffer_size buffer capacity (Kb). Values range from ***6*** to ***50***. Default value is ***32***.

Example

This command configures a buffer size of ***48 Kb***.

```
switch(config)# event-monitor buffer max-size 48
switch(config)#
```

4.8.12 event-monitor clear

The **event-monitor clear** command removes the contents of the event monitor buffer. If event monitor backup is enabled, this command removes the contents from all event monitor backup files.

Command Mode

Privileged EXEC

Command Syntax

```
event-monitor clear
```

Example

This command clears the contents of the event monitor buffer.

```
switch# event-monitor clear
switch#
```

4.8.13 event-monitor sync

The **event-monitor buffer sync** command combines the event monitor buffer and all backup logs and synchronizes them into a single SQLite file, which is stored at **/var/log/eventMon.db**.

Command Mode

Privileged EXEC

Command Syntax

```
event-monitor sync
```

Example

This command synchronizes the buffer and backup logs into a single SQLite file.

```
switch(config)# event-monitor sync
switch(config)#
```

4.8.14 event-monitor

The **event-monitor** command enables the event monitor and specifies the types of events that are logged. The event monitor is an event logging service that records system events to a local database.

The database maintains a separate table for each event type.

The event monitor is disabled by default.

- The **no event-monitor all** command disables the event monitor.
- The **no event-monitor** command, followed by a log type parameter, disables event recording for the specified type.
- The **event-monitor** command enables the specified event logging type by removing the corresponding **no event-monitor** command from ***running-config***.

The **no event-monitor** and **default event-monitor** commands, without a **LOG_TYPE** parameter, restore the default event monitor settings by deleting all event monitor related commands from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`event-monitor` **LOG_TYPE**

`no event-monitor` **LOG_TYPE**

`default event-monitor` **LOG_TYPE**

Parameters

LOG_TYPE specifies the event logging type. Options include:

- **all** all event logging types.
- **arp** changes to ARP table.
- **backup** backed up log files.
- **buffer** changes to the local buffer settings.
- **igmpsnooping** changes to IGMP snooping table.
- **lacp** changes to the LACP table events.

- **mac** changes to MAC address table.
- **mroute** changes to multicast routing table.
- **neighbor** changes to the neighbor routing table.
- **route** changes to IP routing table.
- **route6** changes to IP route6 table.
- **stpunstable** events that cause STP instability.

Related Command

`no event-monitor`

Examples

- This command disables the event monitor for all types of events.

```
switch(config)# no event-monitor all
switch(config)#
```

- This command enables the event monitor for routing table changes.

```
switch(config)# event-monitor route
switch(config)#
```

4.8.15 hostname

The **hostname** command assigns a text string as the switch's host name. The default host name is ***localhost***.

The prompt displays the host name when appropriately configured through the **prompt** command.

The **no hostname** and **default hostname** commands return the switch's host name to the default value of ***localhost***.

Command Mode

Global Configuration

Command Syntax

`hostname` *string*

`no hostname`

`default hostname`

Parameter

string host name assigned to the switch.

Example

This command assigns the string ***main-host*** as the switchs host name.

```
switch(config)# hostname main-host
main-host(config)#
```

The prompt was previously configured to display the host name.

4.8.16 ip domain lookup

The **ip domain lookup** command specifies the source interface for all DNS requests sent from the specified VRF.

The **no ip domain lookup** and **default ip domain lookup** commands return the switch to its default state, in which the switch selects source IP addresses for each DNS request from the specified VRF.

Command Mode

Global Configuration

Command Syntax

`ip domain lookup` [**VRF_INSTANCE**] `source-interface` **INTF_NAME**

`no ip domain lookup` [**VRF_INSTANCE**] `source-interface`

`default ip domain lookup` [**VRF_INSTANCE**] `source-interface`

Parameters

- **VRF_INSTANCE** specifies the VRF instance being modified.
  - ***no parameter*** changes are made to the default VRF.
  - **vrf *vrf_name*** changes are made to the specified VRF.
- **INTF_NAME** name of source interface to be used for DNS requests. Options include:
  - **ethernet *e_num*** Ethernet interface specified by ***e_num***.
  - **loopback *l_num*** Loopback interface specified by ***l_num***.
  - management ***m_num*** Management interface specified by ***m_num***.
  - **port-channel *p_num*** Port-channel interface specified by ***p_num***.
  - vlan ***v_num*** VLAN interface specified by ***v_num***.

Examples

- This command specifies ***VLAN 5*** as the source interface for DNS requests originating from the default VRF.

```
switch(config)# ip domain lookup source-interface Vlan5
switch(config)#
```

- This command specifies ***VLAN 10*** as the source interface for DNS requests originating from VRF purple.

```
switch(config)# ip domain lookup vrf purple source-interface Vlan10
switch(config)#
```

4.8.17 ip domain-list

The **ip domain-list** command specifies a domain name to add to the IP domain list.

The **no ip domain-list** and **default ip domain-list** commands return the IP domain list to its default state, in which the switch selects source IP addresses for each DNS request from the specified VRF.

Command Mode

Global Configuration

Command Syntax

`ip domain-list` [**IP_DOMAIN_NAME**]

`no ip domain-list` [**IP_DOMAIN_NAME**]

`default ip domain-list` [**IP_DOMAIN_NAME**]

Parameter

IP_DOMAIN_NAME specifies the IP domain name.

Examples

- This command specifies foo.com as the IP domain name to add to the IP domain list.

```
switch(config)# ip domain-list foo.com
switch(config)#
```

- This command removes foo.com and returns the IP domain list to its default state.

```
switch(config)# no ip domain-list foo.com
switch(config)#
```

4.8.18 ip host

The **ip host** command associates a hostname to an IPv4 address. This command supports local hostname resolution based on local hostname IP address maps. Multiple hostnames can be mapped to an IP address. IPv4 and IPv6 addresses can be mapped to the same hostname. To map an IPv6 address to a hostname, use the **ipv6 host** command. The **show hosts** command displays the local hostname IP address mappings.

The **no ip host** and **default ip host** commands remove hostname IP address maps by deleting the corresponding **ip host** command from ***running-config***, as specified by the following command parameters:

- ***no parameters*** - Removes all hostname IP address maps.
- ***hostname*** - Removes all IP address maps for the specified hostname.
- ***hostname*** and ***IP address*** - Removes specified hostname IP address maps.

Command Mode

Global Configuration

Command Syntax

`ip host` *hostname hostadd_1* [*hostadd_2*] ...[*hostadd_X*]

`no ip host` [*hostname*] [*hostadd_1* [*hostadd_2*] [*hostadd_X*]

`default ip host` [*hostname*] [*hostadd_1* [*hostadd_2*] [*hostadd_X*]

Parameters

- ***hostname*** - hostname (text).
- ***hostadd_N*** - IPv4 address associated with hostname in dotted decimal notation.

Related Commands

- `ipv6 host`
- `show hosts`

Examples

- This command associates the hostname ***MyTestLab*** with the IP addresses ***10.24.18.5*** and ***10.24.16.3***.

```
switch(config)#ip host MyTestLab 10.24.18.5 10.24.16.3
```

- This command removes all IP address maps for the hostname ***production_lab***.

```
switch(config)#no ip host production_lab
switch(config)#
```

4.8.19 ip name-server

The **ip name-server** command adds name server addresses to ***running_config***. The switch uses name servers for name and address resolution. The switch can be configured with up to 32 name servers: 16 IPv4 addresses and 16 IPv6 addresses. Although a command can specify multiple name server addresses, ***running_config*** stores each address in a separate statement.

Name server addresses can be configured in the different VRFs. When adding IP addresses, also set the priority for the name server.

The **no ip name-server** and **default ip name-server** commands remove specified name servers from ***running_config***. Commands that do not list an address remove all name servers.

Command Mode

Global Configuration

Command Syntax

`ip name-server vrf [`*vrf_instance*`] [server_ip_address] [priority` *priority*

`no ip name-server vrf [`*vrf_instance*`] [server_ip_address] [priority` *priority*

`default ip name-server vrf [`*vrf_instance*`] [server_ip_address] [priority` *priority*

Parameters

- **vrf*vrf_instance*** - Specify the VRF instance with the IP addresses.
  - ***no parameter*** - If you do not specify a VRF, the default VRF becomes the name server.
- ***server_ip_address*** IP address of the name server in dotted decimal notation. Options include the following:
  - ***ipv4_addr*** - IPv4 address in `A.B.C.D` format up to a maximum of 16 servers.
  - ***ipv6_addr*** - IPv4 address in `A:B:C:D:E:F:G:H` format up to a maximum of 16 servers. A command can contain both IPv4 and IPv6 address types.
- **priority *priority*** - Specify a priority from 0 (highest) to 15 (lowest) for the name server. If not specified, the priority sets to 0 by default.

Guidelines

Multiple VRFs can be configured as a name server. Specify up to 16 IPv4 or 16 IPv6 addresses per VRF.

Examples

- This command adds two name servers to the default VRF configuration.

```
switch(config)# ip name-server 172.0.14.21 3:4F21:1902::
switch(config)#
```

- This command adds two name servers to the VRF, *kindablue*:

```
switch(config)# ip name-server vrf kindablue 172.21.16.35 192.168.1.101
```

- This command attempts to add a name server when the configuration already lists 16 servers.

```
switch(config)# ip name-server 172.1.10.22
% Maximum number of nameservers reached. '172.1.10.22' not added
switch(config)#
```

4.8.20 ipv6 host

The **`ipv6 host`** command associates a hostname to an IPv6 address. This command supports local hostname resolution based on local hostname IP address maps. Multiple hostnames can be mapped to an IPv6 address. IPv4 and IPv6 addresses can be mapped to the same hostname. To map IPv4 addresses to a hostname, use the `ip host` command. The `show hosts` command displays the local hostname IP address mappings.

The **`no ipv6 host`** and **`default ipv6 host`** commands remove hostname IP address maps by deleting the corresponding **`ipv6 host`** command from ***running-config***, as specified by command parameters:

- ***no parameters*** - Removes all hostname IPv6 address maps.
- ***hostname*** - Removes all IPv6 address maps for the specified hostname.
- ***hostname*** and ***IP address*** - Removes specified hostname IP address maps.

Command Mode

Global Configuration

Command Syntax

`ipv6 host` *hostname hostadd1* [*hostadd2*] ...[*hostaddX*]

`no ipv6 host` [*hostname*] [*hostadd1* [*hostadd2*] [*hostaddX*]

`default ipv6 host` [*hostname*] [*hostadd1* [*hostadd2*] [*hostaddX*]

Parameters

- ***hostname*** - hostname in a text format.
- ***hostaddN*** IPv6 addresses associated with the hostname in dotted decimal notation.

Related Commands

- `ip host`
- `show hosts`

Example

This command associates the hostname ***MySupportLab*** with the IPv6 address ***2001:0DB8:73:ff:ff:26:fd:90***.

```
switch(config)#ipv6 host MySupportLab 2001:0DB8:73:ff:ff:26:fd:90
switch(config)#
```

4.8.21 logging buffered

The **logging buffered** command in the Global Configuration Mode configures the system logging buffer on the switch. The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging buffered [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***severity_level logging_buffer_size***

no ->

logging buffered [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***severity_level logging_buffer_size***

Parameters

- **alerts** - Log events that require immediate action.
- **critical** - Log events with critical conditions.
- **debugging** - Log debugging messages.
- **emergencies** - Log emergency events.
- **errors** - Log error conditions.
- **informational** - Log informational messages.
- **notifications** - Log events with normal but significant conditions.
- **warnings** - Log log messages with warning conditions.
- ***severity_level*** - Log messages with a specific severity level from 0 to 7.
- ***logging_buffer_size*** - Specify the size of the logging buffer in the number of messages from 10 to 214,748,364.

Example

Use the following commands to set the logging buffer to log up to 5000 notifications :

```
switch(config)# buffered notifications
switch(config)# buffered 5000
```

4.8.22 logging console

The **logging console** command in Global Configuration Mode controls which system log events display directly on the switch physical console port or on an administrator's remote terminal session such as SSH or Telnet. It acts as a real-time filter and destination for log events.

Configuring this parameter sets the primary role of **logging console** as setting a severity threshold for log events. The switch displays any log event with the severity set to equal or lower than the configured setting. By default, EOS sets the severity to 3 (errors). If you set the severity to 7 (debugging), the maximum number of log messages display on the console as 7 has the least severe level of logging.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
logging console [alerts | critical | debugging | emergencies | informational
| notifications | warnings]
```

```
no | default logging console [alerts | critical | debugging | emergencies |
informational | notifications | warnings]
```

Parameters

- **console** - Specify console logging parameters.
- **alerts (severity=1)** - Immediate action needed
- **critical (severity=2)** - Critical conditions
- **debugging (severity=7)** - Debugging messages
- **emergencies (severity=0)** - System is unusable
- **errors (severity=3)** - Error conditions
- **informational (severity=6)** - Informational messages
- **notifications (severity=5)** - Normal but significant conditions
- **warnings (severity=4)** - Warning conditions
- ***0_7*** - Specify a severity level.

Example

Use the following command to specify a severity level of *3*:

```
switch(config)# logging console 3
```

4.8.23 logging event

The **logging event** command in the Global Configuration Mode configures specify logging events not included in system logging on the switch. These events include congestion drops and spanning tree as well as others.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging event [congestion-drops interval *seconds*] [link-status global] [login root] [port-channel member-status global] [spanning-tree global] [storm-control discards [global | interval *seconds*]

[no | default] logging event [congestion-drops interval *seconds*] [login root] [port-channel member-status global] [spanning-tree global] [storm-control discards [global | interval *seconds*]>

Parameters

- **event** - Configure logging events.
- **congestion-drops interval *seconds*** - Specify the interval between congestion drop event messages from 1 to 65535 seconds.
- **link-status global** - Specify to globally log link status messages.
- **login root** - Specify to log root login activities.
- **port-channel member-status global** - Specify to globally log port-channel member status.
- **spanning-tree global** - Specify to globally log spanning tree events.
- **storm-control discards** - Specify to log storm-control discard events.
  - **global** - Specify to globally log events.
  - **interval *seconds*** - Specify an interval between log events in seconds from 10 to 65535.

Example

Use the following command to log link-status events to the system logging:

```
switch(config)# log event link-status global
switch(config)#
```

4.8.24 logging facility

The **logging facility** command in the Global Configuration Mode categorizes the source of a system log event using a facility code from 0 to 23.

When specifying a **local** facility, configure a remote server to collect logs with the tag and send the message to a file.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging facility ***source_name facility_code***

[no | default] logging facility ***source_name facility_code***

Parameters

- **facility** ***source_name facility_value*** - Configure logging messages with a specific facility value from 0 to 23:
  - **auth (facility=4)** - Authorization messages
  - **cron (facility=15)** - Clock daemon
  - **daemon (facility=3)** - System daemons
  - **kern (facility=0)** - Kernel messages
  - **local0 (facility=16)** - Local use 0
  - **local1 (facility=17)** - Local use 1
  - **local2 (facility=18)** - Local use 2
  - **local3 (facility=19)** - Local use 3
  - **local4 (facility=20)** - Local use 4
  - **local5 (facility=20)** - Local use 5
  - **local6 (facility=21)** - Local use 6
  - **local7 (facility=22)** - Local use 7

- **`lpr (facility=2)`** - Line printer subsystem
- **`mail (facility=7)`** - Mail system
- **`news (facility=7)`** - Network news subsystem
- **`sys10 (facility=10)`** - System use 10
- **`sys11 (facility=11)`** - System use 11
- **`sys12 (facility=12)`** - System use 12
- **`sys13 (facility=13)`** - System use 13
- **`sys14 (facility=14)`** - System use 14
- **`sys9 (facility=9)`** - System use 9
- **`syslog (facility=5)`** - Internal syslogd messages
- **`user (facility=1)`** - User-level messages
- **`uucp (facility=8)`** - UUCP subsy

Example

Use the following command to log system daemons, *daemon*, to the system logging messages:

```
logging facility daemon
```

4.8.25 logging format

The **logging format** command in the Global Configuration Mode to format log messages on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging format [hostname [fqdn |ipv4]] [prefix ***prefix*** **[rfc5424] [sequence-numbers] [timestamp high-resolution [traditional timezone| year]]**

[no | default] logging format [hostname [fqdn |ipv4]] [rfc5424] [sequence-numbers] [timestamp high-resolution [traditional timezone| year]]

Note: You cannot configure the parameters, **hostname** and **prefix**, at the same time. Configuring one automatically disables the other command.

Parameters

- **format** - Configure the format of the system log messages.
- **hostname [fqdn |ipv4]** - Specify the host name format as a Fully Qualified Domain Name (FQDN) or as an IPv4 address.
- **prefix** ***prefix*** - Configure a custom logging prefix for system logging messages. The custom prefix can consist of any combination of underscores, numbers and upper and lower case letters. No other characters including whitespace are allowed.
- **rfc5424** - Specify the log message format in the format described in RFC5424 (Modern Format) which provides greater precision and flexibility.
- **sequence-numbers** - Configure the log messages to use sequence numbers.
- **timestamp high-resolution [traditional timezone| year]** - Configure the log message format to use a timestamp in high-resolution (RFC5424) or a traditional timestamp with a timezone and year.

Example

Use the following command to configure the log message in the format `rfc5424`:

```
switch(config)# logging format rfc5424
switch(config)#
```

4.8.26 logging group

The **logging group** command creates a Logging Group name and enters the Logging Group Configuration Mode.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging group server ***group_name***

no logging group server

default logging group server

Parameters

- **server** ***group_name*** - Configure the logging group name.

Example

Use the following commands to configure a logging group, Group_1:

```
switch(config)# logging group server Group_1
switch(config-logging-group-Group_1)#
```

4.8.27 logging group host

The **logging group host** command configures a Logging Group host and enters the Logging Group Configuration Mode.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Logging Group Configuration

Command Syntax

logging [vrf ***vrf_name*****] [host** ***host_name*****] port** ***port***

no logging [vrf | host]

default logging [vrf | host]

Parameters

- **vrf** ***vrf_name*** - Configure the VRF for the logging group.
- **host** ***host_name*** - Configure the host with a name or IP address for the logging group.
- **port** ***port*** - Configure the port with a value from 1 to 65535 or the default, 514.

Example

Use the following commands to configure a VRF, bluengreen, and host IP address, 172.16.21.23, for Group_1:

```
switch(config-logging-group-Group_1)# logging vrf bluengreen host 172.16.21.23
            switch(config-logging-group-Group_1)#
```

4.8.28 logging group probe

The **logging group probe** command in the Logging Group Configuration Mode configures the number of ICMP probes sent to the syslog server to determine the server status. The ICMP probe uses 5 ICMP echo packets, and if all of them fail, it returns a status of server down. Configure the parameter for each logging group.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Logging Group Configuration

Command Syntax

probe [interval ***seconds*** **[threshold success** ***count*****]**

no probe

default probe

Parameters

- **interval** ***seconds*** - Configure an interval, between 1 and 600 seconds, for sending probes. The default value is 5 seconds.
- **threshold success** ***count*** - Configure the number of successful probes to return the syslog server status as available. Use a value between 1 and 100.

Examples

Use the following commands to configure a probe interval, 10 seconds, for logging group, Group_1:

```
switch(config-logging-group-group1)# probe interval 10
```

Use the following commands to configure a threshold success, 10, for logging group, Group_1:

```
switch(config-logging-group-group1)# probe threshold success 10
```

4.8.29 logging host

The **logging host** command in Global Configuration Mode configures remote syslog server IP addresses and parameters.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging host ***syslog_name*** **[add** ***port_number*** **protocol [tcp | tls | udp]] [protocol [tcp | tls | udp] [remove** ***port_number*** **[protocol [tcp | tls | udp]]** ***port_number***

[no | default] logging host ***syslog_name***

Parameters

- **host** - Configure the syslog server IP address and parameters.
- **add protocol [tcp | tls | udp]** ***port_number*** - Add a protocol and specify a port number.
  - **tcp** - Specify Transmission Control Protocol (TCP).
  - **tls** - Specify Transport Layer Protocol (TLS).
  - **udp** - Specify User Datagram Protocol (UDP).
  - ***port_number*** - Specify a port number from 1 to 65535 for the syslog server. By default, the syslog server uses port 514.
- **protocol [tcp | tls | udp]** - Specify a protocol used to communicate with the syslog server.
  - **tcp** - Specify Transmission Control Protocol (TCP).
  - **tls** - Specify Transport Layer Protocol (TLS).
  - **udp** - Specify User Datagram Protocol (UDP).
- **remove [protocol [tcp | tls | udp]** ***port_number*** - Specify a protocol to remove from the configuration.
  - **tcp** - Specify Transmission Control Protocol (TCP).
  - **tls** - Specify Transport Layer Protocol (TLS).
  - **udp** - Specify User Datagram Protocol (UDP).

- ***port_number*** - Specify a port number from 1 to 65535 for the syslog server. By default, the syslog server uses port 514.

Example

Use the following commands to add the protocol, *TCP*, with port *6514* (modern syslog security), to host *192.168.96.147*:

```
switch(config)# logging host 192.168.96.147 add 6514 protocol tcp
```

4.8.30 logging level

The **logging level** command in the Global Configuration Mode configures the level of logging severity at the feature level to add to the syslog.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging level ***facility*** **[all | default] [alerts | critical | debugging | emergencies | informational | notifications | warnings |** ***0_7*****]**

[no | default] logging level ***feature_name*** **[all | default]**

Parameters

- **level** - Configure logging severity for a specified feature.
- ***facility*** - Specify the facility to configure for log messages.
- **all | default** - Specify **all** to generate log messages for all facilities or the default value for the level.
- **alerts (severity=1)** - Immediate action needed
- **critical (severity=2)** - Critical conditions
- **debugging (severity=7)** - Debugging messages
- **emergencies (severity=0)** - System is unusable
- **errors (severity=3)** - Error conditions
- **informational (severity=6)** - Informational messages
- **notifications (severity=5)** - Normal but significant conditions
- **warnings (severity=4)** - Warning conditions
- ***0_7*** - Specify a severity level.

Example

Use the following command to set the severity to notifications for the feature, *AAA*:

```
switch(config)# logging level AAA notifications
```

Setting the level to notifications sends all AAA log messages with a severity of 5 or lower to the syslog.

4.8.31 logging local-interface

The **logging local-interface** command in the Global Configuration Mode configures an IP address of an interface as a source IP of log messages.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging local-interface [Ethernet ***port_number*** **| Loopback** ***inf_number*** **| Management** ***port_number*** **| Port Channel** ***lag sub_inf*** **| Tunnel** ***inf_number*** **| VLAN** ***inf_number*****]**

[no | default] logging local-interface

Parameters

- **Ethernet** ***port_number*** - Specify the Ethernet interface and port number.
- **Loopback** ***inf_number*** - Specify the Loopback interface number.
- **Management** ***port_number*** - Specify the Management interface and port number.
- **Port-Channel** ***lag sub_inf*** - Specify the Port Channel as Link Aggregation Group (LAG) or Port-Channel subinterface.
- **Tunnel** ***inf_number*** - Specify the Tunnel interface number.
- **VLAN** ***inf_number*** - Specify the VLAN interface number.

Example

Use the following command to add the interface, *Ethernet1/1*, as a local interface for log messages:

```
switch(config)# logging local-interface Ethernet1/1
switch(config)#
```

4.8.32 logging message

The **logging message** command in the Global Configuration Mode configures the second half of the crucial identifier used within a system log message to categorize the source and event type. It allows you to quickly understand which part of the switch generated the message and what specific event occurred on the system.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging message ***facility_mnenonic*** **severity [alerts | critical | debugging | emergencies | informational | notifications | warnings]** ***0_7***

[no | default] logging local-interface

Parameters

- **message** ***facility_mnenonic*** - Configure the severity for specific log messages. The *facility_mnenonic* has the following sections:
  - `facility` - Identifies the application or system originating the message.
  - `severity` - Describes the urgency level of the message.
  - `mnenonic` - Uses a short descriptive keyword identifying the specific event that triggered the log message.

  For example, the message, `%OSPF-5-ADJCHANGE`, describes an OSPF change, neighbor adjacency, with a severity of 5.
- **severity** - Specify the severity for the log message.
  - **alerts (severity=1)** - Immediate action needed
  - **critical (severity=2)** - Critical conditions
  - **debugging (severity=7)** - Debugging messages
  - **emergencies (severity=0)** - System is unusable
  - **errors (severity=3)** - Error conditions
  - **informational (severity=6)** - Informational messages
  - **notifications (severity=5)** - Normal but significant conditions

- **warnings (severity=4)** - Warning conditions
- ***0_7*** - Specify a severity level.

Example

Use the following command to change the message, *%OSPF-5-ADJCHANGE*, from severity 5 to severity 3:

```
switch(config)# logging message %OSPF-5-ADJCHANGE severity 3
switch(config)#
```

4.8.33 logging monitor

The **logging monitor** command in Global Configuration Mode controls the display of system log events on a switch, specifically for remote terminal sessions such as SSH or Telnet. You must enable this feature for each session open in SSH or Telnet.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging monitor [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***0_7***

[no | default] logging monitor [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***0_7***

Parameters

- **monitor** - Configure the display of log events on remote terminal sessions.
- **severity** - Specify the severity of the log messages to send to the remote session:
  - **console** - Specify console logging parameters.
  - **alerts (severity=1)** - Immediate action needed
  - **critical (severity=2)** - Critical conditions
  - **debugging (severity=7)** - Debugging messages
  - **emergencies (severity=0)** - System is unusable
  - **errors (severity=3)** - Error conditions
  - **informational (severity=6)** - Informational messages
  - **notifications (severity=5)** - Normal but significant conditions
  - **warnings (severity=4)** - Warning conditions
  - ***0_7*** - Specify a severity level.

Example

Use the following command to configure the syslog to send log messages with severity notifications to the remote terminal sessions:

```
switch(config)# logging monitor notifications
switch(config)#
```

4.8.34 logging persistent

The **`logging persistent`** command logs the files stored on the flash disk. It can store upto 30MB logs.

The **`no logging persistent`** command disables the logging from the ***running-config***.

Command Mode

Global Configuration Mode

Command Syntax

`logging persistent` *logging file size*

`no logging persistent` *logging file size*

Parameter

- ***logging file size*** The maximum size (in bytes) of logging file stored on flash disk. The value ranges from 1024 to 2147483647.

Example

- This command configures logging persistent on the switch.

```
switch# config
switch(config)# logging persistent 1024
! Note: writing system log message on non-volatile flash will affect the life
expectancy of the flash drive due to heavy writing. Please disable persistent logging unless
 needed.
```

4.8.35 logging policy

The **logging policy** command in the Global Configuration Mode creates a set of rules and guidelines that dictate what, when, where, and how the system log handles events.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging policy match [invert-result] match-list ***list_name*** **discard**

[no | default] logging policy match

Parameters

- **policy match** - Configure logging message filtering on matching messages.
- **invert-result** - Specify to invert the match of the match list.
- **match-list** ***list_name*** - Specify the name of the match list.
- **discard** - Specify to discard the matching messages.

Example

Use the following command to match the list, *test_match*, and discard the messages:

```
switch(config)# logging policy match match-list test_match discard
            switch(config)#
```

4.8.36 logging qos

The **logging qos** command in Global Configuration Mode describes how the Quality of Service (QoS) log events apply to the system log and manage the traffic policy and internal buffers.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging qos dscp ***dscp_value***

[no | default] logging qos

Parameters

- **qos** - Configure QoS parameters.
- **dscp** ***dscp_value*** - Specify a DSCP value between 0 and 63.

Example

Use the following command to set the DSCP value to *25*:

```
switch(config)# logging qos dscp 25
switch(config)#
```

4.8.37 logging relogging-interval

The **logging relogging-interval** command in the Global Configuration Mode configures the interval between relogging critical log messages. This prevents the log buffer or console from a flood of the exact same rapidly occurring log messages.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging relogging-interval ***minutes***

[no | default] logging relogging-interval

Parameters

- **relogging-interval** ***minutes*** - Specify the relogging interval in seconds for critical log messages. Configure the number of minutes from 1 to 720.

Example

Use the following command to configure a relogging interval of *30* minutes:

```
switch(config)# logging relogging-interval 30
```

4.8.38 logging repeat-messages

The **logging repeat-messages** command configures repetition of syslog messages instead of summarizing the count of repeats.

The **no logging repeat-messages** and **default logging repeat-messages** commands disable the functionality to repeat logging messages in ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
logging repeat-messages

no logging repeat-messages

default logging repeat-messages
```

Examples

- This command repeats syslog messages instead of summarizing the count of repeats.

```
switch(config)# logging repeat-messages
switch(config)#
```

- This command displays the status of logging repeat messages command.

```
switch(config)# show logging
Syslog logging: enabled
    Buffer logging: level debugging
    Console logging: level debugging
    Monitor logging: level debugging
    Synchronous logging: disabled
    Trap logging: level informational
    Sequence numbers: disabled
    Syslog facility: local4
    Hostname format: Hostname only
    Repeat logging interval: disabled
    Repeat messages: enabled

Facility             Severity           Effective Severity
--------------       -------------      ------------------
aaa                  debugging          debugging
accounting           debugging          debugging

switch(config)#
```

4.8.39 logging source-interface

The **logging source-interface** command in Global Configuration Mode configures an interface as the source IP of log messages. This can be crucial for maintaining consistency, reachability, and filtering of logs in large environments.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging source-interface [Ethernet ***port_number*** **| Loopback** ***inf_number*** **| Management** ***port_number*** **| Port Channel** ***lag sub_inf*** **| Tunnel** ***inf_number*** **| VLAN** ***inf_number*****]**

[no | default] logging source-interface

Parameters

- **source-interface** - Specify the interface to use for source IP addresses in log messages.
  - **Ethernet** ***port_number*** - Specify the Ethernet interface and port number.
  - **Loopback** ***inf_number*** - Specify the Loopback interface number.
  - **Management** ***port_number*** - Specify the Management interface and port number.
  - **Port-Channel** ***lag sub_inf*** - Specify the Port Channel as Link Aggregation Group (LAG) or Port-Channel subinterface.
  - **Tunnel** ***inf_number*** - Specify the Tunnel interface number.
  - **VLAN** ***inf_number*** - Specify the VLAN interface number.

Example

Use the following command to specify using *Loopback0* as the source interface:

```
switch(config)# logging source-interface Loopback0
switch(config)#
```

4.8.40 logging synchronous

The **logging synchronous** command in Global Configuration Mode ensures that system log messages do not disrupt or interfere with command line input. This maintains a clean, usable command line environment by synchronizing the display of log messages with user activity.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration Mode

Command Syntax

logging synchronous level [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***0_7***

[no | default] logging synchronous

Parameters

- **synchronous** - Configure synchronizing log messages on the command line.
- **level** - Specify the severity of the log messages to send to synchronize:
  - **all** - Synchronize all log messages.
  - **alerts (severity=1)** - Immediate action needed
  - **critical (severity=2)** - Critical conditions
  - **debugging (severity=7)** - Debugging messages
  - **emergencies (severity=0)** - System is unusable
  - **errors (severity=3)** - Error conditions
  - **informational (severity=6)** - Informational messages
  - **notifications (severity=5)** - Normal but significant conditions
  - **warnings (severity=4)** - Warning conditions
  - ***0_7*** - Specify a severity level.

Example

Use the following command to synchronize notifications on the command line:

```
switch(config)# logging synchronous level notifications
switch(config)#
```

4.8.41 logging trap

The **logging trap** command in Global Configuration Mode controls the minimum severity level of system log events eligible to forward to a remote syslog server. The switch only sends log events to hosts with a severity equal or lower than the specified trap.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging trap

[no | default] logging trap [alerts | critical | debugging | emergencies | informational | notifications | warnings] ***0_7***

Parameters

- **trap** - Configure the level of severity for the trap.
  - **alerts (severity=1)** - Immediate action needed
  - **critical (severity=2)** - Critical conditions
  - **debugging (severity=7)** - Debugging messages
  - **emergencies (severity=0)** - System is unusable
  - **errors (severity=3)** - Error conditions
  - **informational (severity=6)** - Informational messages
  - **notifications (severity=5)** - Normal but significant conditions
  - **system** - Configure the system log buffer.
    - **contain** - Specify the text contained in a log message.
    - **facility** - Specify a facility for the system buffer.
      - **auth (facility=4)** - Authorization messages
      - **cron (facility=15)** - Clock daemon
      - **daemon (facility=3)** - System daemons
      - **kern (facility=0)** - Kernel messages

- **local0 (facility=16)** - Local use 0
- **local1 (facility=17)** - Local use 1
- **local2 (facility=18)** - Local use 2
- **local3 (facility=19)** - Local use 3
- **local4 (facility=20)** - Local use 4
- **local5 (facility=20)** - Local use 5
- **local6 (facility=21)** - Local use 6
- **local7 (facility=22)** - Local use 7
- **lpr (facility=2)** - Line printer subsystem
- **mail (facility=7)** - Mail system
- **news (facility=7)** - Network news subsystem
- **sys10 (facility=10)** - System use 10
- **sys11 (facility=11)** - System use 11
- **sys12 (facility=12)** - System use 12
- **sys13 (facility=13)** - System use 13
- **sys14 (facility=14)** - System use 14
- **sys9 (facility=9)** - System use 9
- **syslog (facility=5)** - Internal syslogd messages
- **user (facility=1)** - User-level messages
- **uucp (facility=8)** - UUCP subsy

- **severity** - Specify the severity.
  - **alerts (severity=1)** - Immediate action needed
  - **critical (severity=2)** - Critical conditions
  - **debugging (severity=7)** - Debugging messages
  - **emergencies (severity=0)** - System is unusable
  - **errors (severity=3)** - Error conditions
  - **informational (severity=6)** - Informational messages
  - **notifications (severity=5)** - Normal but significant conditions
  - **warnings (severity=4)** - Warning conditions
- **tag** - Specify a program name to tag for log messages.

- ***0_7*** - Specify a severity level.

Example

Use the following command to configure the level of the trap to errors

```
switch(config)# logging trap errors
switch(config)#
```

4.8.42 logging vrf host

The **logging vrf** command in the Global Configuration Mode ensures that syslog messages use a specific, non-default Virtual Routing and Forwarding (VRF) instance when sent to a remote syslog servers. Without specifying a VRF, the switch attempts to send syslog packets using the default global routing table. Specifying a VRF configures the switch to generate, encapsulate, and route the syslog messages within the specified VRF routing table.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging vrf ***vrf_name*** **host** ***ip_address*** **[add** ***port_number*** **protocol [tcp | tls | udp]] [protocol [tcp | tls | udp]] [remove** ***port_number*** **protocol [tcp | tls | udp]]**

no logging vrf ***vrf_name***

default logging vrf ***vrf_name***

Parameters

- **vrf** ***vrf_name***
- **host** ***ip_address***
  - **add** ***port_number***
  - **protocol [tcp | tls | udp]** - Specify a protocol used to communicate with the syslog server.
    - **tcp** - Specify Transmission Control Protocol (TCP).
    - **tls** - Specify Transport Layer Protocol (TLS).
    - **udp** - Specify User Datagram Protocol (UDP).
  - **[remove** ***port_number***
  - **protocol [tcp | tls | udp]** - Specify a protocol used to communicate with the syslog server.
    - **tcp** - Specify Transmission Control Protocol (TCP).
    - **tls** - Specify Transport Layer Protocol (TLS).
    - **udp** - Specify User Datagram Protocol (UDP).

Example

Use the following command to add the VRF, *purple*, host IPv4 address, *192.168.96.147*, with port number, *443*, to the configuration:

```
switch(config)# logging vrf purple host 192.168.96.147 443
```

4.8.43 logging vrf local-interface

The **logging vrf local-interface** command in the Global Configuration Mode associates a local interface with a VRF where the event originated. This ensures that the internal logs related to a specific VRF tag properly and possibly handled differently with the switch local logging system than the global VRF.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging vrf ***vrf_name*** **local-interface [Ethernet** ***port_number*** **| Loopback** ***inf_number*** **| Management** ***port_number*** **| Port Channel** ***lag sub_inf*** **| Tunnel** ***inf_number*** **| VLAN** ***inf_number*****]**

[no | default] logging vrf> ***vrf_name*** **local-interface**

Parameters

- **vrf** ***vrf_name*** - Specify the name of the VRF for logging system messages.
- **local-interface** - Specify the local interface to use for logging system messages.
  - **Ethernet** ***port_number*** - Specify the Ethernet interface and port number.
  - **Loopback** ***inf_number*** - Specify the Loopback interface number.
  - **Management** ***port_number*** - Specify the Management interface and port number.
  - **Port-Channel** ***lag sub_inf*** - Specify the Port Channel as Link Aggregation Group (LAG) or Port-Channel subinterface.
  - **Tunnel** ***inf_number*** - Specify the Tunnel interface number.
  - **VLAN** ***inf_number*** - Specify the VLAN interface number.

Example

Use the following commands to specify *Ethernet1/1* as the local interface for VRF, *purple*:

```
switch(config)# logging vrf purple local-interface Ethernet1/1
switch(config)#
```

4.8.44 logging vrf source-interface

The **logging vrf local-interface** command in the Global Configuration Mode associates a source interface, usually a Loopback interface, with a VRF to provide a consistent and correctly isolated source IP address for system log messages.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

logging vrf ***vrf_name*** **source-interface [Ethernet** ***port_number*** **| Loopback** ***inf_number*** **| Management** ***port_number*** **| Port Channel** ***lag sub_inf*** **| Tunnel** ***inf_number*** **| VLAN** ***inf_number*****]**

[no | default] logging vrf> ***vrf_name*** **local-interface**

Parameters

- **vrf** ***vrf_name*** - Specify the name of the VRF for logging system messages.
- **source-interface** - Specify the source interface to use for logging system messages.
  - **Ethernet** ***port_number*** - Specify the Ethernet interface and port number.
  - **Loopback** ***inf_number*** - Specify the Loopback interface number.
  - **Management** ***port_number*** - Specify the Management interface and port number.
  - **Port-Channel** ***lag sub_inf*** - Specify the Port Channel as Link Aggregation Group (LAG) or Port-Channel subinterface.
  - **Tunnel** ***inf_number*** - Specify the Tunnel interface number.
  - **VLAN** ***inf_number*** - Specify the VLAN interface number.

Example

Use the following commands to specify *Loopback0* as the source interface for VRF, *purple*:

```
switch(config)# logging vrf purple source-interface Loopback0
            switch(config)#
```

4.8.45 measurement end-to-end

The **measurement end-to-end** command in the Monitor Latency Configuration Mode allows configuration of monitoring packet latency on the switch and collects latency data using a histogram or maximum end to end output.

You can enable both histogram and maximum monitoring on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Monitor Latency Configuration

Command Syntax

measurement end-to-end [histogram | maximum}

no measurement end-to-end

default measurement end-to-end

Parameters

- **measurement end-to-end** - Configure latency measurement types.
  - **histogram** - Enable end-to-end latency histogram monitoring on the switch.
  - **maximum** - Enable end-to-end latency maximum monitoring on the switch.

Example

Use the following command to place the switch in Monitor Latency Configuration Mode and enable histogram end-to-end monitoring:

```
switch(config)# monitor latency
switch(config-mon-latency)# measurement end-to-end histogram
switch(config-mon-latency)#
```

4.8.46 monitor latency

The **monitor latency** command places the switch in the Monitor Latency Configuration Mode and allows configuration of monitoring packet latency on the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

monitor latency

no monitor latency

default monitor latency

Parameters

- **monitor latency** - Places the switch in Monitor Latency Configuration Mode.

Example

Use the following command to place the switch in Monitor Latency Configuration Mode:

```
switch(config)# monitor latency
        switch(config-mon-latency)#
```

4.8.47 no event-monitor

The **no event-monitor** and **default event-monitor** commands remove the specified **event-monitor** configuration statements from ***running-config***, returning the switch to the specified default state.

- **no event-monitor** with ***no parameters***, restores all default setting states:
  - event monitor is enabled.
  - buffer backup is disabled.
- The **no event-monitor backup** disables the backup.

To disable the event monitor, enter the **no event-monitor all** command (event-monitor).

Command Mode

Global Configuration

Command Syntax

no event-monitor [**PARAMETER**]

default event-monitor [**PARAMETER**]

Parameters

PARAMETER the event monitor property that is returned to the default state.

- ***no parameter*** all event monitor properties.
- **backup** event monitor buffer backup is disabled.

Example

This command removes all event monitor configuration statements from ***running-config***.

```
switch(config)# no event-monitor
switch(config)#
```

4.8.48 ntp authenticate

The **ntp authenticate** command enables the authentication of incoming NTP packets. When authentication is enabled, NTP packets will be used to synchronize time on the switch only if they include a trusted authentication key. Authentication keys are created on the switch using the **ntp authentication-key** command, and the **ntp trusted-key** command is used to specify which keys are trusted. NTP authentication is disabled by default.

The **no ntp authenticate** and **default ntp authenticate** commands disable NTP authentication on the switch by removing the corresponding **ntp authenticate** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
ntp authenticate

no ntp authenticate

default ntp authenticate
```

Examples

- This command enables NTP authentication on the switch.

```
switch(config)# ntp authenticate
switch(config)#
```

- This command disables NTP authentication on the switch.

```
switch(config)# no ntp authenticate
switch(config)#
```

4.8.49 ntp authentication-key

The **ntp authentication-key** command creates an authentication key for use in authenticating incoming NTP packets. For the key to be used in authentication:

- It must be configured as a trusted key using the ntp trusted-key command.
- NTP authentication must be enabled on the switch using the ntp authenticate command.
- The same key must be configured on the NTP server.

The **no ntp authentication-key** and **default ntp authentication-key** commands remove the specified authentication key by removing the corresponding **ntp authentication-key** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

ntp authentication-key*key_id* **ENCRYPT_TYPE** *password_text*

no ntp authentication-key *key_id*

default ntp authentication-key *key_id*

Parameters

- ***key_id*** key ID number. Value ranges from ***1*** to ***65534***.
- **ENCRYPT_TYPE** encryption method. Values include:
  - **md5** ***key_text*** is MD5 encrypted.
  - **sha1** ***key_text*** is SHA-1 encrypted.
- ***password_text*** the authentication-key password.

Examples

- This command creates an NTP authentication key with ***ID 234*** and password ***timeSync*** using MD5 encryption.

```
switch(config)# ntp authentication-key 234 md5 timeSync
```

Running-config stores the password as plain text.

- This command removes ***NTP authentication key 234***.

```
switch(config)# no ntp authentication-key 234
```

4.8.50 ntp local

The **ntp local** command in the Global Configuration Mode instructs the switch to use the internal hardware clock as an authoritative time source and allows serving the time to other devices without an external connection.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Note: Arista recommends only using this command in isolated networks, air-gapped data centers, or out-of-band management islands where reaching an Internet NTP server is impossible.

Command Mode

Global Configuration

Command Syntax

ntp local [stratum *number*]

no ntp local

Parameters

- **local** - Configure the switch to use the internal hardware clock.
- **stratum *number*** - Force downstream devices to prefer the local hardware clock. Specify a number between 1 and 15. A lower number indicates higher priority and accuracy. For instance, stratum 1 uses a literal atomic clock or GPS receiver.

Example

Use the following command to set the internal clock to use stratum 4:

```
switch(config)# ntp local stratum 4
switch(config)#
```

4.8.51 ntp local-interface

The **ntp local-interface** command configures an interface as the local NTP source. The IP address of that interface will then be used as the source address in NTP packets sent by the switch. If the switch is acting as an NTP server and a server-specific source interface has been configured using the **source** option of the ntp server command, the server-specific source address will take precedence.

The **no ntp local-interface** and **default ntp local-interface** commands remove the **ntp local-interface** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
ntp local-interface [VRF_INSTANCE] INT_PORT

no ntp local-interface

default ntp local-interface
```

Parameters

- **VRF_INSTANCE** the VRF instance to be used for connection to the specified server. Options include:
  - ***no parameter*** connects using the default VRF.
  - **vrf *vrf_name*** connects using the specified user-defined VRF.
- **INT_PORT** the interface port that specifies the NTP local interface. Settings include:
  - **ethernet *e_range*** Ethernet interface list.
  - **loopback *l_range*** loopback interface list.
  - **management *m_range*** management interface list.
  - **port-channel *c_range*** port channel interface list.
  - **vlan *v_range*** VLAN interface list.

Examples

- This command configures ***ntp local-interface vlan 25*** as the local NTP source. NTP packets exiting the switch use the IP address of ***VLAN interface 25*** as their source address.

```
switch(config)# ntp local-interface vlan 25
switch(config)#
```

- This command removes the **ntp local-interface** command from the configuration.

```
switch(config)# no ntp local-interface
switch(config)#
```

4.8.52 ntp serve all

The **ntp serve all** command configures the switch to act as an NTP server by accepting incoming NTP requests.

Using this command also causes the switch to re-synchronize with its upstream NTP server.

Individual interfaces can be configured separately to accept or deny NTP requests by using the `ntp serve` command, and these settings override the global setting.

Command Mode

Global Configuration

Command Syntax

```
ntp serve all

no ntp serve all

default ntp serve all
```

Examples

- This command configures the switch to accept incoming NTP requests.

```
switch(config)# ntp serve all
switch(config)#
```

- This command configures the switch to deny incoming NTP requests.

```
switch(config)# no ntp serve all
switch(config)#
```

4.8.53 ntp serve

The **ntp serve** command configures the command mode interface to accept incoming NTP requests regardless of the global setting.

The **no ntp serve** command configures the command mode interface to refuse incoming NTP requests regardless of the global setting. The **default ntp serve** command configures the command mode interface to follow the global setting.

Using this command also causes the switch to re-synchronize with its upstream NTP server.

Command Modes

Interface-Ethernet Configuration

Interface-Loopback Configuration

Interface-Management Configuration

Interface-Port-channel Configuration

Interface-VLAN Configuration

Interface-VXLAN Configuration

Command Syntax

```
ntp serve

no ntp serve

default ntp serve
```

Examples

- These commands configure ***interface ethernet 5*** to accept incoming NTP requests regardless of global settings.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ntp serve
switch(config-if-Et5)#
```

- These commands configure ***interface ethernet 5*** to deny incoming NTP requests regardless of global settings.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ntp serve
```

```
switch(config-if-Et5)#
```

- These commands configure ***interface ethernet 5*** to use global settings in responding to incoming NTP requests.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)#default ntp serve
switch(config-if-Et5)#
```

4.8.54 ntp server

The **ntp server** command adds a Network Time Protocol (NTP) server to the ***running-config***. If the command specifies an existing server in the ***running-config***, it modifies the server settings. The switch synchronizes the system clock with an NTP server when ***running-config*** contains at least one valid NTP server.

The switch supports NTP versions 1 through 4. The default is version 4.

The **prefer** option specifies a preferred NTP server to use as the NTP server if not discarded by NTP.

The **no ntp server** and **default ntp server** commands remove the specified NTP server from ***running-config***. To remove an NTP server configured in a user-defined VRF, include the VRF name in the **no ntp server** command.

Command Mode

Global Configuration

Command Syntax

`ntp server [ vrf`*vrf_instance* | *host_name*] `refresh` [`version` *ntp_version*] [`source-address [` [*ipv4_address* | *ipv6_address*] `burst` [`iburst [ key` *auth_key* `][ maxpoll` *max_poll_interval*][`] [ minpoll` *min_poll_interval* `] prefer source` *interface_name*

`no ntp server` [*vrf_instance*] *host_name*

`default ntp server` [*vrf_instance*] *host_name*

All parameters except **vrf** and ***hostname*** can be placed in any order.

Parameters

- **vrf** ***vrf_instance*** - Specify the VRF instance to use for the connection to the specified server.
- ***host_name*** Specify the name or IP address of the NTP server. Options include:
  - ***ip_address*** - Specify an IPv4 or IPv6 address in dotted decimal notation.
  - ***host_name*** - Specify the hostname of the NTP server.
- **prefer** - Indicates the priority of this server when the switch selects a synchronizing server.
  - ***no parameter*** - The server has no special priority.
  - **prefer** - This server has priority when the switch selects a synchronizing server.

- **`refresh`** - Specifies sending periodic DNS queries for the NTP server. If the DNS response doesn't include the resolved IP address of the NTP server, then a request selects the next available IP address and restarts the service with an updated configuration.

- **`version`** ***ntp_version*** - Specifies the NTP version. Settings include:
  - ***no parameter*** - Sets NTP version to 4 (default).
  - **`version`** ***number*** - Specify a version ***number*** from ***1*** to ***4***.

- **`source-address`** ***ip_source*** - Specifies the source IPv4 address or IPv6 address for NTP updates for the specified NTP server. This option overrides global settings created by the `ntp local-interface` command.

- **`burst`** - Indicates that when the switch reaches the NTP server, the switch sends packets to the server in bursts of eight instead of the usual one. Recommended only for local servers. Disabled by default.

- **`iburst`** - Indicates that the switch sends packets to the server in bursts until reaching the server. Recommended for general use to speed synchronization. Disabled by default.

- **`key`** ***auth_key*** - Specify the authentication key to use when authenticating NTP packets from the server.
  - ***no parameter*** - Specify no authentication key.
  - **`key`** ***1*** **to** ***65534*** - The switch uses the specified key to authenticate NTP packets from the server.

- ***max_poll_interval*** - Specifies the maximum polling interval for the server as the base-2 logarithm of the interval in seconds. Settings include the following:
  - ***no parameter*** - Sets the maximum polling interval to ***10***. (***1,024*** seconds, the default).
  - **maxpoll** ***number*** - Specifies to use the ***number*** as the base-2 logarithm of the interval in seconds. Values range from ***3*** (***8*** seconds) to ***17*** (***131,072*** seconds, approximately ***36*** hours).

- **`minpoll`** ***min_poll_interval*** - Specifies the minimum polling interval for the server as the base-2 logarithm of the interval in seconds. Settings include the following:
  - ***no parameter*** - Sets the minimum polling interval to ***6*** (***64*** seconds, the default).
  - ***number***, where ***number*** is the base-2 logarithm of the interval in seconds. Values range from ***3*** (***8*** seconds) to ***17*** (***131,072*** seconds, approximately ***36*** hours).

Guidelines

To configure multiple parameters for a single server, include them all in a single **`ntp server`** command. Using the command again for the same server overwrites parameters previously configured in ***running-config***.

All NTP servers must use the same VRF. If you do not specify a VRF, the server uses the default VRF. To use a user-defined VRF for connection to an NTP server, first use the **`no ntp server`** command to remove any NTP servers configured in the default VRF.

When specifying a source interface, choose an interface in the same VRF as the server. If the source interface does not exists on the same VRF, the ***running-config*** includes the source data but does not add it to the NTP packets.

An NTP server may be configured using an invalid or inactive VRF, but the status of the NTP server remains inactive until the VRF becomes active.

Examples

- This command configures the switch to update the time with the NTP server at address ***172.16.0.23*** and designates it as a preferred NTP server.

```
switch(config)# ntp server 172.16.0.23 prefer
```

- This command configures the switch to update the time through an NTP server named ***local-nettime***.

```
switch(config)# ntp server local-nettime
```

- This command configures the switch to update the time through a ***version 3*** NTP server.

```
switch(config)# ntp server 171.18.1.22 version 3
```

- These commands reconfigure the switch to access the above NTP servers through VRF magenta.

```
switch(config)# no ntp server 172.16.0.23
switch(config)# no ntp server local-nettime
switch(config)# no ntp server 171.18.1.22
switch(config)# ntp server vrf magenta 172.16.0.23 prefer
switch(config)# ntp server vrf magenta local-nettime
switch(config)# ntp server vrf magenta 171.18.1.22 version 3
switch(config)#
```

4.8.55 ntp trusted-key

The **ntp trusted-key** command specifies which authentication keys will be trusted for authentication of NTP packets. A packet with a trusted key will be used to update the local time if authenticated.

The **no ntp trusted-key** and **default ntp trusted-key** commands remove the specified authentication keys from the trusted key list by removing the corresponding **ntp trusted-key** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ntp trusted-key` **key_list**

`no ntp trusted-key`

`default ntp trusted-key`

Parameter

key_list specified one or more keys. Formats include a number (***1*** to ***65534***), number range, or comma-delimited list of numbers and ranges.

Example

This command configures the switch to trust authentication keys ***234*** and ***237*** for authentication of NTP packets.

```
switch(config)# ntp trusted-key 234,237
switch(config)#
```

4.8.56 power enable module

The **power enable module** command powers up the specified module. The **no power enable module** command powers down the specified module.

Command Mode

Global Configuration

Command Syntax

`power enable module` {**fabric**|**linecard**|**supervisor**|**switchcard**} *module_number*

`no power enable module` {**fabric**|**linecard**|**supervisor**|**switchcard**} *module_number*

`default power enable module` {**fabric**|**linecard**|**supervisor**|**switchcard**} *module_number*

Parameters

fabric specifies a fabric card

linecard specifies a linecard

supervisor specifies a supervisor

switchcard specifies a switch card

module_number specifies the number of the module

Examples

- This command powers down linecard 3.

```
switch(config)# no power enable module linecard 3
switch(config)#
```

- These commands reload fabric module 2.

```
switch(config)# no power enable module fabric 2
switch(config)# power enable module fabric 2
switch(config)#
```

4.8.57 prompt

The **`prompt`** command specifies the contents of the CLI prompt. Characters allowed in the prompt include A-Z, a-z, 0-9, and these punctuation marks:

! @ # $ % # & * ( ) - = + f g [ ] ; : < > , . ? / # n

The prompt supports these control sequences:

- %s – space character
- %t – tab character
- %% – percent character
- %D – time and date
- %D{*f_char*} – time and date, format specified by the BSD **strftime** (f_char) time conversion function.
- %H – host name
- %h – host name up to the first '.'
- %P – extended command mode
- %p – command mode
- %r [1] – redundancy status on modular systems.
- %R [2] – extended redundancy status on modular systems – includes status and slot number.

[1] When logged into a fixed system or a supervisor on a modular system, this option has no effect.
[2] When logged into a fixed system, this option has no effect.

Table 7: Command Mode Prompt Examples

Command Mode	Command Mode Prompt	Extended Command Mode Prompt
Exec	>	>
Privileged Exec	#	#
Global Configuration	(config)#	(config)#
Ethernet Interface Configuration	(config-if)#	(config-if-ET15)#
VLAN Interface Configuration	(config-if)#	(config-if-Vl24)#
Port Channel Interface Configuration	(config-if)#	(config-if-Po4)#
Management Interface Configuration	(config-if)#	(config-if-Ma1)
Access List Configuration	(config-acl)#	(config-acl-listname)#
OSPF Configuration	(config-router)#	(config-router-ospf)#
BGP Configuration	(config-router)#	(config-router-bgp)#

The **`no prompt`** and **`default prompt`** commands return the prompt to the default of ***%H%R%P***.

Command Mode

Global Configuration

Command Syntax

`prompt` ***p_string***

`no prompt`

`default prompt`

Parameters

p_string prompt text (character string). Elements include letters, numbers, and control sequences.

Examples

- This command creates a prompt that displays ***system 1*** and the command mode.

```
host-name.dut103(config)# prompt system%s1%P
system 1(config)#
```

- This command creates a prompt that displays the command mode.

```
host-name.dut103(config)# prompt %p
(config)#
```

- These equivalent commands create the default prompt.

```
% prompt %H%P
host-name.dut103(config)#
```

```
% no prompt
host-name.dut103(config)#
```

4.8.58 show banner

The **show banner** command displays the specified banner.

Command Mode

Privileged EXEC

Command Syntax

show banner **BANNER_TYPE** [login | motd]

Parameters

BANNER_TYPE banner that the command displays. Options include:

- **login** command displays login banner.
- **motd** command displays message of the day banner.

Example

These commands configure and display the message of the day banner.

```
switch(config)# banner motd
Enter TEXT message. Type 'EOF' on its own line to end.
This is an motd banner for $(hostname)
EOF

switch(config)# show banner motd
This is an motd banner for $(hostname)
switch(config)#
```

4.8.59 show clock

The **show clock** command displays the current system clock time and configured time zone. The switch uses the system clock for system log messages and debugging traces.

Command Mode

EXEC

Command Syntax

```
show clock
```

Example

This command displays the current system clock time and configured time zone.

```
switch> show clock
Wed Nov  2 10:29:32 2011
timezone is America/Los_Angeles switch>
```

4.8.60 show event-monitor arp

The **`show event-monitor arp`** command performs an SQL-style query on the event monitor database and displays ARP table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor arp` [**GROUP**] [**MESSAGES**] [**INTERFACE**] [**IP**] [**MAC**] [**TIME**] [**VRF**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group by interface** results are grouped by interface.
  - **group by ip** results are grouped by IP address.
  - **group by mac** results are grouped by MAC address.
  - **group by vrf** results are grouped by VRF.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - ***no parameter*** result-set not restricted by interface.
  - **match-interface ethernet *e_range*** Ethernet interface list.
  - **match-interface loopback *l_range*** loopback interface list.
  - **match-interface management *m_range*** management interface list.
  - **match-interface port-channel *c_range*** port channel interface list.
  - **match-interface tunnel *t_range*** tunnel interface list.
  - **match-interface VXLAN *vx_range*** VXLAN interface list.

- **match-interface port-channel *c_range*** port channel interface list.

- **IP** restricts result-set to events that include specified IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ip *ip_address_rex*** IP address, as represented by regular expression.

- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific MAC addresses.
  - **match-mac *mac_address_rex*** MAC address, as represented by regular expression.

- **TIME** restricts result-set to events generated during specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

- **VRF** restricts result-set to events that include a specific VRF.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-vrf *vrf_name*** the VRF name.

Example

This command displays ARP table events listed in the event monitor database.

```
switch# show event-monitor arp
% Writing 220017 Arp, 234204 Route, 1732559 Mac events to the database
2012-11-06 12:36:10|10.33.6.159|Vlan1417|0000.00dc.cc0d|0|added|2186271

```

4.8.61 show event-monitor igmpsnooping

The **`show event-monitor igmpsnooping`** command performs an SQL-style query on the event-monitor database, using the statement specified in the command.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor igmpsnooping` [**GROUP**] [**MESSAGES**] [**MAC**] [**INTERFACE**] [**VLAN**] [**TIME**]

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group-by interface** results are grouped by interface.
  - **group-by mac** results are grouped by MAC address.
  - **group-by vlan** results are grouped by VLAN.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific MAC addresses.
  - **match-mac *mac_address_rex*** MAC address, as represented by regular expression.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - ***no parameter*** result-set not restricted by interface.
  - **match-interface ethernet *e_range*** Ethernet interface list.
  - **match-interface loopback *l_range*** loopback interface list.
  - **match-interface management *m_range*** management interface list.
  - **match-interface port-channel *c_range*** port channel interface list.
  - **match-interface vlan *v_range*** VLAN interface list.
  - **match-interface tunnel *t_range*** tunnel interface list.

- **match-interface VXLAN *vx_range*** VXLAN interface list.

- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

- **VLAN** restricts result-set to events that include a specific VLAN (SQL Like command).
  - ***no parameter*** result-set not restricted by time of event.
  - **match-vlan vlan** VLAN interface number.

Example

```
switch# show event-monitor igmpsnooping
switch#
```

4.8.62 show event-monitor mac

The **`show event-monitor mac`** command performs an SQL-style query on the event monitor database and displays MAC address table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor mac` [**GROUP**] [**MESSAGES**] [**INTERFACE**] [**MAC**] [**TIME**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group-by interface** results are grouped by interface.
  - **group-by mac** results are grouped by MAC address.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - ***no parameter*** result-set not restricted by interface.
  - **match-interface ethernet *e_range*** Ethernet interface list.
  - **match-interface loopback *l_range*** loopback interface list.
  - **match-interface management *m_range*** management interface list.
  - **match-interface port-channel *c_range*** port channel interface list.
  - **match-interface vlan *v_range*** VLAN interface list.
  - **match-interface tunnel *t_range*** tunnel interface list.
  - **match-interface VXLAN *vx_range*** VXLAN interface list.
- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).

- ***no parameter*** result-set not restricted to specific MAC addresses.
- **match-mac *mac_address_rex*** MAC address, as represented by regular expression.

- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

Examples

- This command displays all events triggered by MAC address table events.

```
switch# show event-monitor mac
% Writing 0 Arp, 0 Route, 1 Mac events to the database
2012-01-19 13:57:55|1|0808.0808.0808|Ethernet1|configuredStaticMac|added|0
```

- This command displays events triggered by MAC address table changes.

```
switch# show event-monitor mac match-mac 08:08:08:%
2012-01-19 13:57:55|1|0808.0808.0808|Ethernet1|configuredStaticMac|added|0
```

4.8.63 show event-monitor mroute

The **`show event-monitor mroute`** command performs an SQL-style query on the event-monitor database, using the statement specified in the command.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor mroute` [**GROUP**] [**MESSAGES**] [**IP**] [**INTERFACE**] [**SRC_IP**] [**TIME**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group-by interface** results are grouped by interface.
  - **group-by ipv6** results are grouped by IPv6 address.
  - **group-by mac** results are grouped by MAC address.
  - **group-by vrf** results are grouped by VRF.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **IP** restricts result-set to events that include specified IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ipv6 *ip_address_rex*** IP address, as represented by regular expression.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - ***no parameter*** result-set not restricted by interface.
  - **match-interface ethernet *e_range*** Ethernet interface list.
  - **match-interface loopback *l_range*** loopback interface list.
  - **match-interface management *m_range*** management interface list.
  - **match-interface port-channel *c_range*** port channel interface list.

- **match-interface vlan *v_range*** VLAN interface list.
- **match-interface tunnel *t_range*** tunnel interface list.
- **match-interface VXLAN *vx_range*** VXLAN interface list.

- **SRC_IP** restricts result-set to events that include specified Source IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ip *ip_address_rex*** IP address, as represented by regular expression.

- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

Example

This command displays neighbor table events listed in the event monitor database.

```
switch# show event-monitor mroute
2011-07-28 12:33:28|default|16.17.18.19/32|225.0.0.1/32|||added|30
2011-07-28 12:33:28|default|16.17.18.19/32|225.0.0.1/32|Vlan2|iif|join|31
2011-07-28 12:33:28|default|16.17.18.19/32|225.0.0.1/32|Vlan3|oif|join|32
2011-07-28 12:33:28|default|16.17.18.19/32|225.0.0.1/32|Vlan4|oif|join|33
2011-07-28 12:33:28|default|10.11.12.13/32|225.0.0.2/32|||added|34
2011-07-28 12:33:28|default|10.11.12.13/32|225.0.0.2/32|Vlan3|iif|join|35
2011-07-28 12:33:28|default|10.11.12.13/32|225.0.0.2/32|Vlan2|oif|join|36
2011-07-28 12:33:28|default|16.17.18.19/32|225.0.0.1/32|Vlan4||leave|37

```

4.8.64 show event-monitor neighbor

The **`show event-monitor neighbor`** command performs an SQL-style query on the event monitor database and displays neighbor table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor neighbor` [**GROUP**][**MESSAGES**][**INTERFACE**][**IP6**][**MAC**][**TIME**][**VRF**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group-by interface** results are grouped by interface.
  - **group-by ip6** results are grouped by IPv6 address.
  - **group-by mac** results are grouped by MAC address.
  - **group-by vrf** results are grouped by VRF.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - ***no parameter*** result-set not restricted by interface.
  - **match-interface ethernet *e_range*** Ethernet interface list.
  - **match-interface loopback *l_range*** loopback interface list.
  - **match-interface management *m_range*** management interface list.
  - **match-interface port-channel *c_range*** port channel interface list.
  - **match-interface vlan *v_range*** VLAN interface list.
  - **match-interface tunnel *t_range*** tunnel interface list.

- **match-interface VXLAN *vx_range*** VXLAN interface list.

- **IP6** restricts result-set to events that include specified IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ipv6 *ip6_address_rex*** IPv6 address, as represented by regular expression.

- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific MAC addresses.
  - **match-mac *mac_address_rex*** MAC address, as represented by regular expression.

- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

- **VRF** restricts result-set to events that include a specific VRF (SQL Like command).
  - ***no parameter*** result-set not restricted by time of event.
  - **match-vrf *vrf_name*** VRF name, as represented by a regular expression.

Example

This command displays neighbor table events listed in the event monitor database.

```
switch# show event-monitor neighbor
2019-09-30 14:37:32.894147|def0::1|Vlan1|default|0005.0005.0005|1|added|1

```

4.8.65 show event-monitor nexthop-group backup-activation

The **`show event-monitor nexthop-group backup-activation`** command displays Nexthop Group backup activation events produced by forwarding agents. Nexthop groups supports configuring the backup paths through EOS RPC APIs and CLI. Whenever the route or prefix begins pointing to configured backup paths, the event monitor database logs a backup activation event with the nexthop group name, timestamp, and other attributes.

The **[no | default] show event-monitor nexthop-group backup-activation** commands disable event monitoring and remove the configuration from the ***running-config***.

Command Mode

EXEC

Command Syntax

show event-monitor nexthop-group backup-activation

Parameters

- **nexthop-group** - Display Nexthop Group Events.
- **backup-activation** - Display the Nexthop Group backu activation events table.

Example

Use the following command to display Nexthop Group backup-activation events:

```
switch# show event-monitor nexthop-group backup-activation
2025-01-06 00:17:09.266517|NHG-1|111|2025-01-06 00:17:09.245674|backup|allProgrammed
2025-01-06 00:18:09.266517|NHG-2|121|2025-01-06 00:18:09.245674|backup|allProgrammed
2025-01-06 00:19:09.266517|NHG-3|131|2025-01-06 00:19:09.245674|backup|allProgrammed
```

The output displays the following information:

- **Timestamp** - Displays the timestamp when recording the event.
- **Nexthop Group Name** - Displays the Nexthop Group Name.
- **Nexthop Group Version ID** - Displays the Nexthop Group Version ID.
- **Activation Timestamp** - Displays the time backup paths programmed into hardware and began carrying traffic.
- **ViaType** - Displays if the traffic went through backup routes.
- **Hardware Programmed State** - Displays the state as Drop, partiallyProgrammed, or allProgrammed.

4.8.66 show event-monitor route6

The **`show event-monitor route6`** command performs an SQL-style query on the event monitor database and displays routing6 table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor route6` [**GROUP**][**MESSAGES**][**IP6**][**TIME**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group by interface** results are grouped by interface.
  - **group by ip6** results are grouped by IPv6 address.
  - **group by mac** results are grouped by MAC address.
  - **group by vrf** results are grouped by VRF.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **IP6** restricts result-set to events that include specified IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ipv6 *ip6_address_rex*** IPv6 address, as represented by regular expression.
- TIME restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.

- **match-time last-week** includes events generated during last week.

Example

This command displays neighbor table events listed in the event monitor database.

```
switch# show event-monitor route6
2019-09-30 14:59:30.660447|def1::1:0/128|default|receive|0|1|updated|41
2019-09-30 14:59:30.660720|def1::2:0/128|default|attached|0|1|updated|42

```

4.8.67 show event-monitor route

The **`show event-monitor route`** command performs an SQL-style query on the event monitor database and displays routing table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor route` [**GROUP**][**MESSAGES**][**IP**][**TIME**]

Optional parameters can be placed in any order.

Parameters

- **GROUP** used with aggregate functions to group results. Analogous to SQL **group by** command.
  - ***no parameter*** results are not grouped.
  - **group-by ip** results are grouped by IPv4 address.
- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **IP** restricts result-set to events that include specified IP address (SQL Like command).
  - ***no parameter*** result-set not restricted to specific IP addresses.
  - **match-ip *ip_address_rex*** IP address, as represented by regular expression.
- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

Example

This command displays 10 routing table events listed in the event monitor database.

```
switch# show event-monitor route limit 10
2019-09-30 14:01:21.659428|16.16.16.255/32|default|receiveBcast|0|0|updated|20
2019-09-30 14:01:21.659464|192.168.201.12/30|default|connected|1|0|updated|21
2019-09-30 14:01:21.659497|192.168.1.255/32|default|receiveBcast|0|0|updated|22
2019-09-30 14:01:21.659503|192.168.201.8/32|default|receiveBcast|0|0|updated|23
2019-09-30 14:01:21.659512|16.16.16.0/32|default|receiveBcast|0|0|updated|24
2019-09-30
14:01:21.659517|192.168.201.12/32|default|receiveBcast|0|0|updated|25
2019-09-30

2019-09-30 14:01:21.659578|192.168.201.9/32|default|receive|0|0|updated|29 switch#
```

4.8.68 show event-monitor sqlite

The **show event-monitor sqlite** command performs an SQL-style query on the event monitor database, using the statement specified in the command.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor sqlite` *statement*

Parameter

statement SQLite statement.

Example

This command displays all entries from the route table.

```
switch# show event-monitor sqlite select * from route;
2019-09-30 14:01:21.659428|16.16.16.255/32|default|receiveBcast|0|0|updated|20
2019-09-30 14:01:21.659464|192.168.201.12/30|default|connected|1|0|updated|21
2019-09-30 14:01:21.659497|192.168.1.255/32|default|receiveBcast|0|0|updated|22
2019-09-30 14:01:21.659503|192.168.201.8/32|default|receiveBcast|0|0|updated|23
2019-09-30 14:01:21.659512|16.16.16.0/32|default|receiveBcast|0|0|updated|24
2019-09-30
14:01:21.659517|192.168.201.12/32|default|receiveBcast|0|0|updated|25
2019-09-30
14:01:21.659524|192.168.201.15/32|default|receiveBcast|0|0|updated|26
2019-09-30 14:01:21.659541|192.168.201.8/30|default|connected|1|0|updated|27
2019-09-30 14:01:21.659564|16.16.16.0/24|default|connected|1|0|updated|28
2019-09-30 14:01:21.659578|192.168.201.9/32|default|receive|0|0|updated|29 switch#
```

4.8.69 show event-monitor stpunstable

The **`show event-monitor stpunstable`** command performs an SQL-style query on the event-monitor database, using the statement specified in the command.

Command Mode

Privileged EXEC

Command Syntax

`show event-monitor stpunstable` [**MESSAGES**][**TIME**]

Optional parameters can be placed in any order.

Parameters

- **MESSAGES** number of messages returned from query. Analogous to SQL **limit** command.
  - ***no parameter*** result-set size is not limited.
  - **limit *msg_quantity*** number of results that are displayed. Values range from ***1*** to ***15,000***.
- **TIME** restricts result-set to events with specified period.
  - ***no parameter*** result-set not restricted by time of event.
  - **match-time last-minute** includes events generated during last minute.
  - **match-time last-day** includes events generated during last day.
  - **match-time last-hour** includes events generated during last hour.
  - **match-time last-week** includes events generated during last week.

Example

```
switch# show event-monitor stpunstable limit 5
2019-02-07 07:22:10.286164|Cist|Ethernet5|forward-delay-while|1
2019-02-07 07:22:10.286651|Cist|Ethernet6|forward-delay-while|2
2019-02-07 07:22:10.286844|Cist|Ethernet8|forward-delay-while|3
2019-02-07 07:22:10.287030|Cist|Ethernet14|forward-delay-while|4
2019-02-07 07:22:10.287215|Cist|Ethernet21|forward-delay-while|5 switch#
```

4.8.70 show hostname

The **show hostname** command displays the hostname and the Fully Qualified Domain Name (FQDN) of the switch.

Command Mode

EXEC

Command Syntax

```
show hostname
```

Example

This command displays the hostname and FQDN of the switch.

```
switch> show hostname
Hostname: switch_1
FQDN:     switch_1.aristanetworks.com switch>
```

4.8.71 show hosts

The **show hosts** command displays the default domain name, name lookup service style, a list of name server hosts, and the static hostname-IP address maps.

Command Mode

EXEC

Command Syntax

show hosts

Example

This command displays the switch's IP domain name:

```
switch> show hosts
Default domain is: aristanetworks.com
Name/address lookup uses domain service
Name servers are: 172.22.22.40, 172.22.22.10
Static Mappings:

Hostname                        IP     Addresses

TEST_LAB                       IPV4    10.24.18.6
PRODUCTION_LAB                 IPV4    10.24.18.7
SUPPORT_LAB                    IPV6    2001:0DB8:73:ff:ff:26:fd:90 switch>
```

4.8.72 show ip domain-name

The **show ip domain-name** command displays the switchs IP domain name that is configured with the ip domain name command.

Command Mode

EXEC

Command Syntax

```
show ip domain-name
```

Example

This command displays the switch's IP domain name:

```
switch> show ip domain-name
aristanetworks.com switch>
```

4.8.73 show ip name-server

The **`show ip name-server`** command displays the ip addresses of name-servers in ***running-config***. The name servers are configured by the **`ip name-server`** command.

Command Mode

EXEC

Command Syntax

`show ip name-server`

Example

This command displays the IP address of name servers configured on the switch and the priority assigned to it.

```
switch> show ip name-server
IP Address   VRF     Priority
------------ ------- --------
172.22.22.10 default        0
172.22.22.40 default        0
172.21.16.35 kindablue      1 switch>
```

4.8.74 show local-clock time-properties

The **`show local-clock time-properties`** command displays the Precision Time Protocol (PTP) clock properties.

Command Mode

Privileged EXEC

Command Syntax

```
show local-clock time-properties
```

Example

This command shows the PTP clock properties.

```
switch# show local-clock time-properties
Current UTC offset valid: False
Current UTC offset: 0
Leap 59: False
Leap 61: False
Time Traceable: False
Frequency Traceable: False
PTP Timescale: False
Time Source: 0x0 switch#
```

4.8.75 show logging

The **show logging** command displays information about the current system logging configuration.

Command Mode

EXEC

Command Syntax

show logging

Parameters

- **alerts** - Display events that require immediate action.
- **all** - Display all lines in the logging buffer.
- **counters** - Display counter statistics of each logging host.
- **critical** - Display events with critical conditions.
- **debugging** - Display debugging messages.
- **emergencies** - Display emergency events.
- **errors** - Display error conditions.
- **follow** - Keep following the buffer as it grows.
- **informational** - Display informational messages.
- **last** - Display messages in the last *number* of time-units,
- **mce** - Display the contents of the Machine Check Exception/Error (MCE) buffer.
- **notifications** - Display events with normal but significant conditions.
- **persistent** - Display persistent logging messages stored on a flash drive.
- **system** - Display the contents of the system log buffer.
- **threshold** - Display only log messages at the threshold level or above.
- **time-range** - Filter messages by the begin and end time.
- **warnings** - Display log messages with warning conditions.
- ***1_9999*** - Display the last number of messages in the logging buffer.

Examples

Use the following command to display log counter statistics:

```
switch# show logging counters
IP Address         Protocol Bytes Sent Processed Failed Suspended Suspended Duration Resumed
 Last Refreshed
------------------ -------- ---------- --------- ------ --------- ------------------ -------
 -------------------
192.168.96.147:514 udp               0        12     12        12           00:06:00     119
 2025-11-06 18:12:32
```

Use the following command to display information about the system logging configuration:

```
switch# show logging
Syslog logging: enabled
Buffer logging: level debugging
Console logging: level errors
Persistent logging: disabled
Monitor logging: level errors
Synchronous logging: disabled
Trap logging: level informational
Logging local-interface 'Ethernet1/1' (unavailable), no IP address assigned to interface in VRF
 default (config error)
Logging to '192.168.96.147' port 514 in VRF default via udp
Sequence numbers: disabled
Syslog facility: local4
Hostname format: Hostname only
Repeat logging interval: disabled
Repeat messages: disabled
Root login logging: disabled

    External configuration:
    active:
    inactive:

Facility                  Severity            Effective Severity
--------------------      -------------       ------------------
aaa                       debugging           debugging
accounting                debugging           debugging
acl                       debugging           debugging
agent                     debugging           debugging
ale                       debugging           debugging
arp                       debugging           debugging
bfd                       debugging           debugging
bgp                       debugging           debugging
bmp                       debugging           debugging
capacity                  debugging           debugging
capi                      debugging           debugging
card                      debugging           debugging
classification            debugging           debugging
clear                     debugging           debugging
cvx                       debugging           debugging
dataplane                 debugging           debugging
dhcp                      debugging           debugging
dmf                       debugging           debugging
dot1x                     debugging           debugging
dot1xhttp                 debugging           debugging
dscp                      debugging           debugging
```

4.8.76 show logging group

The **show logging group** command displays the status of the syslog servers, and indicates if the server acts as the primary or the standby server. The state identifies the server receiving the syslog messages. The status, probing, indicates an unreachable server, and the status, Active, indicates a server acting as the syslog server for the group.

Command Mode

EXEC

Command Syntax

show logging group server ***group_name***

Parameters

- **server** ***group_name*** - Displays the logging group server definitions.

Example

Use the following command to display the status of the logging group, Group_1, syslog servers:

```
switch# show logging group server
Logging group Group_1
   Logging to 172.16.21.23 port 80 vrf bluengreen via udp (primary), state: probing
   Last available: n/a
   Logging to 192.168.1.3 vrf default via udp (standby), state: active
   Last available: 0:00:10 ago
```

4.8.77 show ntp associations

The **`show ntp associations`** command displays the status of connections to NTP servers.

Command Mode

EXEC

Command Syntax

```
show ntp associations
```

Display Values

- **refid (reference ID)**: the reference ID of the configured NTP server's time source. The reference ID is either the IPv4 address of the source or (if the source has an IPv6 address) the first four octets of the MD5 hash of the IPv6 address.
- **st (stratum)**: number of steps between the switch and the reference clock.
- **t (transmission type)**: u unicast; b broadcast; l local.
- **when**: interval since reception of last packet (seconds unless unit is provided).
- **poll**: interval between NTP poll packets. Maximum (1024) reached as server and client syncs.
- **reach**: octal number that displays status of last eight NTP messages (377 - all messages received).
- **delay**: round-trip delay of packets to the NTP server.
- **offset**: difference between local clock and the server's clock.
- **jitter**: nominal offset estimation error.

Example

This command displays the status of the switch's NTP associations.

```
switch> show ntp associations
     remote           refid      st t when  poll reach   delay   offset  jitter
==============================================================================
+1.ntp.arista.co 125.157.10.11   2 u  539  1024  377  121.748   -0.345   0.893
-3.ntp.arista.co 127.31.152.34   2 u  868  1024  377  101.671    2.434   1.529
+2.ntp.arista.co 176.131.12.185  2 u  676  1024  377  116.505     0.03   0.768
*4.ntp.arista.co 120.181.192.192 2 u  696  1024  377   48.431   -0.416    0.15 switch#
```

4.8.78 show ntp [ip | ipv6]

The **show ntp [ip | ipv6]** command provides a quick, consolidated view of every IPv4 Access Control List (ACL) currently bound to the switch NTP daemon. The output displays active ACLs filtering NTP traffic, the applied direction, and the tenant routing domains (VRF) protected by the ACL list.

Command Mode

EXEC

Command Syntax

show ntp [ip | ipv6] access-lists [***name*****] [detail | dynamic | summary]**

Parameters

- **access-lists** ***name*** - Displays a specific access-list bound to the NTP daemon.
- **detail** - Displays all of the ACLs and prints the actual Access Control Entries (ACEs).
- **dynamic** - Displays ACLs dynamically generated by the switch.
- **summary** - Displays an administrative overview of all ACLs protecting the NTP daemon.

Example

Use the following command to display a summary of NTP ACLs on the switch:

```
switch# show ntp ip access-list summary
NTP IPv4 Access Lists:

VRF: default
  Direction In: DENY-UNTRUSTED
    Total rules configured: 4
    Dynamic rules: 0

VRF: MGMT
  Direction In: TRUSTED-NTP-CLIENTS
    Total rules configured: 12
    Dynamic rules: 0
  Direction Out: ALLOW-NTP-REPLIES
    Total rules configured: 2
    Dynamic rules: 0
```

The output displays the following information:

- **VRF** - Displays the routing domain for the NTP ACL.
- **Direction In/Out** - Direction the traffic flows on the switch.
- **Total rules configured** - Number of rules configured for NTP.

- **`Dynamic rules`** - Indicates the number of rules generated by the switch.

4.8.79 show ntp status

The **`show ntp status`** command displays the status of NTP on the switch. If the switch clock has not synchronized to an NTP server, the status reads “unsynchronised” and displays the server polling interval. If the clock synchronized to an NTP server, the status displays the IP address and stratum of the server, the precision of the synchronization, and the polling interval.

Note: In EOS releases prior to *4.23.2*, this command identified system peers with IPv6 addresses by the reference IDs, the first four octets of the MD5 hash of the IPv6 address. In later releases, this command always displays the IP address of the system peer, whether IPv4 or IPv6.

Command Mode

EXEC

Command Syntax

`show ntp status`

Example

This command displays the switch NTP status.

```
switch# show ntp status
synchronized to NTP server (192.168.78.62) at stratum 3
   time correct to within 66 ms
   polling server every 1024 s switch>
```

Chapter 5

7130 Platform Layer 1 Configuration

This section describes the purpose, behavior, and configuration of the 7130 platform and includes the following topics:

- Configuring Layer 1 on 7130 Platform Interface
  - Addressing 7130 Platform Speed Mismatch
  - Configuring the 7130 Platform and Multilane Sourcing
  - Using Show Commands to Confirm Source Configurations
- 7130 Platform Layer 1 Commands

7130 Platform Overview

The Arista 7130 Series provides a comprehensive set of platforms to service ultra-low latency networking, in-network applications, and composable custom packet processing. The product family contains a broad selection of powerful hardware, FPGA-based network applications and developer toolkits.

The series contains the following features:

- The 7130 Connect Layer 1+ network devices with port-to-port ultra low latencies.
- The FPGA-enabled devices of the 7130E and L Series, programmable switches hosting up to 3 FPGAs, and running Arista and third party network applications.
- The 7130 network applications which feature capabilities for low latency multiplexing using a MetaMux interface, tapping, tap aggregation, and sub-nanosecond precision timestamping on a MetaWatch interface. Capabilities also include Layer 2 switching on a SwitchApp, filtering on a MetaProtect interface, inline timestamping on an ExchangeApp interface, and segmented multiplexing for multi-tenant environments on a MultiAccess interface. Arista also provides development toolkits and IP Cores for users to develop applications.

This chapter provides information about configuring a 7130 Layer 1 interface to connect on your network.

5.1 Configuring Layer 1 on the 7130 Platform

Switch interfaces can be used instead of the application interfaces for creating connections between app interfaces and front panel ports. Configure Layer 1 traffic between front panel ports, application FPGA ports, and switch interfaces using the l1 source command.

Adding this connection does not affect previously configured destinations.

This section contains the following topics:

- Addressing 7130 Platform Speed Mismatch
- Configuring the 7130 Platform and Multilane Sourcing
- Using Show Commands to Confirm Source Configurations

On DCS-7130 series switches, change the default connections dynamically by using the **`l1 source`** and configuring the switch interfaces as a source or destination. Connect bidirectional network traffic on a Switch1/26 and an Ethernet 36 interface when using a Layer 2 full profile.

Example

```
switch(config)# l1 connect Switch1/26 Ethernet36
```

Configuring Layer 1 on an Interface

Use the following command to connect Layer 1 traffic from the Ethernet interface ***et2***.

```
switch(config)# interface ethernet1
switch(config-if-Et1)# l1 source interface et2
```

Configuring Layer 1 for a MetaMux Interface

MetaMux is an FPGA-based feature available on Arista 7130 platforms. It performs ultra-low latency Ethernet packet multiplexing with or without packet contention queuing. The port to port latency functions as the selected MetaMux profile, using the front panel ingress port, the front panel egress port, the FPGA connector ingress port, and the platform.

Use the **`l1 source`** and **`l1 connect`** commands to connect the ***MuxIn*** and ***MuxOut*** ports to Ethernet ports. In this example, the commands connect the first two Mux1 inputs, ***MuxIn2/1/1*** and ***MuxIn2/1/2*** of the MetaMux instance 2 to the ingress ports of Ethernet 17 and 20 and the Mux1 output, ***MuxOut2/1*** of the same instance to the egress port of Ethernet 22.

Example

Use the following commands to configure a Layer 1 topology for a MetaMux interface:

```
switch(config)# interface MuxIn 2/1/1
switch(config-if-MuI2/1/1)# l1 source interface Eth5
switch(config-if-MuI2/1/1)# interface MuxIn 2/1/2
switch(config-if-MuI2/1/2)# l1 source interface Eth6
switch(config-if-MuI2/1/2)# interface eth11
switch(config-if-Et22)# l1 source interface muxout 2/1
```

To verify the configuration, use the `show l1 path` or `show l1 matrix` commands:

```
switch# show l1 path int et17,20,22
Source                  Destination             Type
----------------------- ----------------------- -------
Ethernet17              MuxIn2/1/1 (Ap2/1)      dynamic
Ethernet20              MuxIn2/1/2 (Ap2/2)      dynamic
MuxOut2/1 (Ap2/4)       Ethernet22              dynamic

switch# show l1 matrix int et5,6,11
                Ethernet   MuxIn
                5 6 11     2/1/1* 2/1/2*
        Et5 -> -|-|-|------+      |
        Et6 -> -|-|-|-------------+
        MuO2/1* -> -|-|-+
        MAC -> -+-+
   * indicates interface is a function interface
```

For more information about MetaMux interfaces, see Software Downloads for the 7130 platform.

Configuring Layer 1 for MultiAccess

7130 platforms provide support for MultiAccess, an FPGA-based feature. It performs low-latency Ethernet multiplexing with optional packet contention queuing, storm control, VLAN tunneling, and packet access control. The interface to interface latency provides functionality for the selected MultiAccess profile, front panel interfaces, MultiAccess interfaces, configuration settings, and platform used. The MultiAccess feature uses the Downstream and Upstream interfaces to connect to Ethernet interfaces.

Example

To configure Multiaccess Layer 1 topology, use the following commands. In this case, you have an active Multiaccess instance with an ID of 2 to bidirectionally connect the two Downstream interfaces from Group 2 to Ethernet interfaces, 17 and 20.

```
switch(config)# interface Ethernet17
switch(config-if-Et17)# l1 source interface Downstream2/1/1
switch(config-if-Et17)# interface Downstream2/1/1
switch1(config-if-Dn2/1/1)# l1 source interface Ethernet17
switch(config-if-Dn2/1/1)#

switch(config)# interface Ethernet20
switch(config-if-Et20)# l1 source interface Downstream2/1/2
switch(config-if-Et20)# interface Downstream2/1/2
switch(config-if-Dn2/1/2)# l1 source interface Ethernet20
switch(config-if-Dn2/1/2)#
```

Next, add the Upstream interface, ***Upstream2/1***, to the configuration:

```
oml201(config)# interface Ethernet25
switch(config-if-Et25)# l1 source interface Upstream2/1
switch(config-if-Et25)# interface Upstream2/1
switch(config-if-Up2/1)# l1 source interface Ethernet25
switch(config-if-Up2/1)#
```

To display the configuration, use the **`show l1 path`** and the **`show l1 matrix`** command:

```
switch# show l1 path interface Ethernet17,20,25
Source                        Destination                   Type
----------------------------- ----------------------------- -------
Ethernet17                    Downstream2/1/1 (Ap1/5)       dynamic
Ethernet20                    Downstream2/1/2 (Ap1/6)       dynamic
Ethernet25                    Upstream2/1 (Ap1/12)          dynamic
Downstream2/1/1 (Ap1/5)       Ethernet17                    dynamic
Downstream2/1/2 (Ap1/6)       Ethernet20                    dynamic
Upstream2/1 (Ap1/12)          Ethernet25                    dynamic

switch# show l1 matrix interface Ethernet17,20,25
            Ethernet   Downstream      Upstream
            17 20 25   2/1/1* 2/1/2*   2/1*
   Et17 -> -|--|--|----+      |        |
   Et20 -> -|--|--|-----------+        |
   Et25 -> -|--|--|--------------------+
Dn2/1/1* -> -+  |  |
Dn2/1/2* -> ----+  |
Up2/1* -> ---------+
* indicates interface is a function interface
```

For more information about MultiAccess interfaces, see Software Downloads for the 7130 platform.

5.1.1 Addressing 7130 Platform Speed Mismatch

When configuring the L1 source of an interface, the following speed restrictions should be considered:

- The configuration for an L1 source only applies if the source and destination interfaces have the same speed configuration.
- If you configure an interface and a single lane with a multilane speed, such as 40Gbps, all other lanes must also be sourced individually. In the config mode, display the additional lanes with the `service interface inactive expose` command.

If you configure the two interfaces with mismatched speeds, the mapping does not apply to the configuration. When running the **`l1 source`** command, the console does not display any warnings that a speed mismatch exists. When you execute the **`l1 source`** command, you can see if the configuration accepts the parameters.

```
(config)#int sw1/1/1
        (config-if-sw1/1/1)#speed 10g
        (config-if-sw1/1/1)#int et1/1
        (config-if-et1/1)#speed 1g
        (config-if-et1/1)#l1 source int sw1/1/1

        Interface        Source Interface       Type
        ---------------- ---------------------- -------
        Ethernet1/1                             dynamic
```

Check the **`show logging`** output for warnings about speed mismatch. In this example, you see the following syslog text:

```
L1SOURCE-6-SPEED_MISMATCH: Speed mismatch found between Layer1 source Switch1/1/1 and destination
 Ethernet1/1, configuration has not been applied.
```

If you attempt to configure an unsupported interface, such as a static interface, as a source, the **show logging** output displays the following log message:

```
L1SOURCE-6-UNSUPPORTED: The configured Layer1 source for interface name is unsupported.
```

When you resolve the misconfiguration, the **show logging** output displays the following log message:

```
L1SOURCE-6-OK: Layer1 sourcing has been successfully applied between source source interface and
 destination destination interface>.
```

5.1.2 Configuring the 7130 Platform and Multilane Sourcing

Source the lanes individually if an interface configuration has a multi-lane speed, such as 40Gbps. Display the individual lanes using the **service interface inactive expose** command while in the configure mode. Configure the individual lanes with a corresponding interface name. To learn more about configuring port speeds, see speed.

See the example for an Ethernet interface connecting to a switch interface at 40Gbps.

Example

The following commands expose the individual lanes on interface ***sw1*** and set the sources and speed.

```
(config)# service interface inactive expose
(config)# int sw1/1/1
(config-if-sw1/1/1)# speed 40g
(config-if-sw1/1/1)# int et1/1
(config-if-et1/1)# speed 40g
(config-if-et1/1)# l1 source int sw1/1/1
(config-if-et1/1)# int et1/2
(config-if-et1/2)# l1 source int sw1/1/2
(config-if-et1/2)# int et1/3
(config-if-et1/3)# l1 source int sw1/1/3
(config-if-et1/3)# int et1/4
(config-if-et1/4)# l1 source int sw1/1/4
(config-if-et1/4)# show l1 source int et1/1-4

Interface          Source Interface        Type
------------------ ---------------------- -------
Ethernet1/1         Switch1/1/1            dynamic
Ethernet1/2         Switch1/1/2            dynamic
Ethernet1/3         Switch1/1/3            dynamic
Ethernet1/4         Switch1/1/4            dynamic
```

5.1.3 Using Show Commands to Confirm Source Configurations

If the interfaces have matching speeds and the configuration applies to the interface, confirm the configuration by running the show l1 source command on the destination interface.

```
(config-if-et1/1)# l1 source int sw1/1/1
(config-if-et1/1)#show l1 source int et1/1
Interface           Source Interface       Type
```

```
------------------ ---------------------- -------
Ethernet1/1        Switch1/1/1            dynamic
```

If a speed mismatch occurs, the **show l1 source** output does not display mapping for the mismatched interface. To display the speed of the source before the mismatch occurs, use the show active command and check the output. View the mismatched speeds by running the show interface status command for each interface.

```
(config-if-et1/1)# l1 source int sw1/1/1
(config-if-et1/1)# show l1 source int et1/1

Interface           Source Interface       Type
------------------ ---------------------- -------
Ethernet1/1                           dynamic

(config-if-et1/1)# show active
interface Ethernet1
l1 source interface Switch1/1/1
```

```
(config-if-et1/1)# show interface et1/1 status
Port   Name    Status   Vlan        Duplex      Speed   Type       Flags Encapsulation
----- ------ --------- ----------- ------------ ----- ----------- --------------------
Et1            signal  Not Bridged  full        10G   10GBASE-CR

(config-if-et1/1)# show interface sw1/1/1 status

Port      Name    Status        Vlan   Duplex       Speed  Type    Flags Encapsulation
-------- ------- ------------- ------ ------------ ------ ------  --------------------
Sw1/1/1           notconnect     1     full         1G     N/A
```

Static Mappings and Speed Mismatches

Some configurations may appear even if a speed mismatch occurs on the interfaces. You may see the configurations when reviewing the static interface mappings. You cannot change the static mappings using the CLI and the **l1 source** command or change the speed. Compare this to dynamic mappings, which can be configured and updated based on speed changes.

The example output displays the static mappings between the switch and application interfaces on a DCS-7130LBR series device:

```
#show l1 source interface sw1/25/1-8

Interface          Source Interface       Type
------------------ ---------------------- ------
Switch1/25/1       Application1/25        static
Switch1/25/2       Application1/26        static
Switch1/25/3       Application1/27        static
Switch1/25/4       Application1/28        static
Switch1/25/5       Application1/57        static
Switch1/25/6       Application1/58        static
Switch1/25/7       Application1/59        static
Switch1/25/8       Application1/60        static
```

L1 Configuration Considerations

The following information should be considered when using the L1 source suite of commands:

- EOS only enforces speed mismatch on Ethernet to Ethernet, switch to switch, and Ethernet to switch connections. Be sure both sides of a connection have matching speeds to avoid linking between 10G and 40G interfaces. Currently, EOS does not enforce speed checks on the following interface:
  - **Cpu**

- The **`show l1 source`** command does not display a mapping for a mismatched interface. Run the **`show active`** command to display the source before speeds mismatched. The default source is configured if the output does not display a mapping.

For more information, refer to https://www.arista.com/en/support/toi/eos-4-27-1f/14877-switchapp-ultra-low-latency-packet-switch.

5.2 7130 Layer 1 Commands

Layer 1 Configuration Commands

- l1 source

Layer 1 Show Commands

- show l1 destination
- show l1 matrix
- show l1 path
- show l1 source
- show l1 source capabilities

5.2.1 l1 source

The **`l1 source`** command configures the source for patching Layer 1 traffic between various front panel interfaces and Switch Application (SwitchApp) ports in the Ethernet Interface configuration mode.

The **`no l1 source`** and **`default l1 source`** commands remove the source configurations and return to the default platform configurations.

Command Mode

Interface-Ethernet Configuration

Command Syntax

`l1 source` [interface | mac | none]

Parameters

- **interface** patches the Layer 1 traffic from the specified interface.
  - **Application** *1-1* - Application FPGA connector interface
  - **CPU** *1-4* - CPU interface
  - **Downstream** *1-255* - Downstream interface
  - **Ethernet** *1-96* - Ethernet interface
  - **MuxIn** *1-24* - Metamux input interface
  - **MuxOut** *1-24* - Metamux output interface
  - **Ptp** *1-2* - MetaWatch PIP interface
  - **Switch** *1-7* Switch interface
  - **TrafficGen** *1-256* - Traffic Generation interface
  - **Upstream** *1-255* - Upstream interface
  - **WatchIn** *1-255* - WatchIn interface
  - **WatchOut** *1-255* - WatchOut interface
  - **WatchPassthrough** *1-255* - Watch passthrough interface
  - **WhiteRabbit** *1-255* - White Rabbit interface
- **mac** patches the Layer 1 traffic from the specified MAC address.
- **none** unpatches the Layer 1 traffic source.

Examples

- This command patches the Layer 1 traffic from the Ethernet interface ***et2***.

```
switch(config)# interface ethernet1
switch(config-if-Et1)# l1 source interface et2
switch(config-if-Et1)#
```

- This command unpatches the Layer 1 traffic source.

```
switch(config)# interface ethernet1
switch(config-if-Et1)# l1 source none
```

```
(config)# int sw1/1/1
(config-if-sw1/1/1)# speed 10g
(config-if-sw1/1/1)# int et1/1
(config-if-et1/1)# speed 1g
(config-if-et1/1)# l1 source int sw1/1/1
(config-if-et1/1)# show l1 source int et1/1

Interface           Source Interface       Type
------------------ ---------------------- -------
Ethernet1/1                         dynamic
```

5.2.2 show l1 destination

The **`show l1 destination`** command displays the list of all destinations for all interfaces.

Command Mode

Privileged EXEC

Command Syntax

`show l1 destination` [interface]

Parameters

interface lists the destination interfaces to connect for the specified interface.

- **application** - Application FPGA connector interface.
- **cpu** - CPU interface.
- **ethernet** - Ethernet interface.
- **switch** - Switch interface.

Examples

- This command displays the list of all interfaces to connect in the crosspoint and the specific destination ports.

```
switch> show l1 destination

Interface             Destination Interface(s) Type
------------------    ------------------------ ------
Ethernet1             App1/1, Sw1              dynamic
Ethernet2             Ethernet3, Ethernet4     dynamic
Ethernet3
Ethernet4
Ethernet5
App1/1                Ethernet1                dynamic
App1/2                Sw17                     static
Sw1
Sw2
Sw3
Sw4
Sw5
Sw17                  App1/2                   static
Cpu1
Cpu2
```

Note: Interfaces without a destination port are listed, but the Destination Interface and Type columns appear as blanks.

- This command displays the list of destination interfaces to connect for the Ethernet interface ***et1***.

```
switch# show l1 destination interface et1

Interface             Destination Interfaces   Type
--------------------- ------------------------ ------
Ethernet1             App1/1, Sw1              dynamic
```

5.2.3 show l1 matrix

The **`show l1 matrix`** command displays the matrix representation of Layer 1 paths for available interfaces in the privileged EXEC mode.

Command Mode

Privileged EXEC

Command Syntax

`show l1 matrix` [all | interface | detail | physical]

Parameters

- **all** displays the matrix of Layer 1 paths for possible interface types even if they do not have a connection.
- **interface** displays the matrix of Layer 1 paths for the specified interface.
  - **Application** *1-1* - Application FPGA connector interface
  - **CPU** *1-4* - CPU interface
  - **Downstream** *1-255* - Downstream interface
  - **Ethernet** *1-96* - Ethernet interface
  - **MuxIn** *1-24* - Metamux input interface
  - **MuxOut** *1-24* - Metamux output interface
  - **Ptp** *1-2* - MetaWatch PIP interface
  - **Switch** *1-7* Switch interface
  - **TrafficGen** *1-256* - Traffic Generation interface
  - **Upstream** *1-255* - Upstream interface
  - **WatchIn** *1-255* - WatchIn interface
  - **WatchOut** *1-255* - WatchOut interface
  - **WatchPassthrough** *1-255* - Watch passthrough interface
  - **WhiteRabbit** *1-255* - White Rabbit interface
- **detail** displays the detailed matrix of Layer 1 paths.
- **physical** displays the Layer 1 matrix for physical interfaces only.

Examples

- This command displays the matrix of Layer 1 paths for all available interface types.

```
switch> show l1 matrix
Ethernet   Switch     App
1 3 4      1 17       1/1 1/2
| | |      | |        |   |
Et1 -> -|-|-|------+-|--------+   |
Et2 -> -|-+-+        |            |
Sw17 -> -|------------|------------+
App1/1 -> -+            |
App1/2 -> --------------+
```

- This command displays the matrix of Layer 1 paths for all available interface types even if the interfaces do not have a connection.

```
switch> show l1 matrix all
Ethernet                                    Switch
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16   1 2 3 4 5 6 7 8 9 10
|   | |                                   |

Et14 ->                    |        |
Et15 ->                    |        |
```

```
Et16 ->                      |         |
Sw1 ->                      |         |
Sw2 ->                      |         |
Sw3 ->                      |         |
Sw4 ->                      |         |
Sw5 ->                      |         |
Sw6 ->                      |         |
Sw7 ->                      |         |
Sw8 ->                      |         |
Sw9 ->                      |         |
Sw10 ->                      |         |
Sw11 ->                      |         |
Sw12 ->                      |         |
Sw13 ->                      |         |
Sw14 ->                      |         |
Sw15 ->                      |         |
Sw16 ->                      |         |
Sw17 -> --------------------|---------+
App1/1 ->                     |
App1/2 -> --------------------+
Cpu1 ->
Cpu2 ->
```

- This command displays the matrix of Layer 1 paths for the specific Ethernet interfaces ***et1*** and ***et4***.

```
switch> show l1 matrix interface et1, et4
Ethernet   Switch   App
1 4        1        1/1
| |        |        |
Et1 -> -|-|---------+---------+
Et2 -> -|-+
App1/1 -> -+
```

5.2.4 show l1 path

The **`show l1 path`** command displays the source and destination paths for all interfaces in the system.

Command Mode

Privileged EXEC

Command Syntax

`show l1 path` [interface]

Parameters

- **interface** lists the connections available for the specified interface.
  - **Application** *1-1* - Application FPGA connector interface
  - **CPU** *1-4* - CPU interface
  - **Downstream** *1-255* - Downstream interface
  - **Ethernet** *1-96* - Ethernet interface
  - **MuxIn** *1-24* - Metamux input interface
  - **MuxOut** *1-24* - Metamux output interface
  - **Ptp** *1-2* - MetaWatch PIP interface
  - **Switch** *1-7* Switch interface
  - **TrafficGen** *1-256* - Traffic Generation interface
  - **Upstream** *1-255* - Upstream interface
  - **WatchIn** *1-255* - WatchIn interface
  - **WatchOut** *1-255* - WatchOut interface
  - **WatchPassthrough** *1-255* - Watch passthrough interface
  - **WhiteRabbit** *1-255* - White Rabbit interface

Examples

- This command displays the source and destination paths for all interfaces in the system.

```
switch# show l1 path
Source               Destination          Type
-------------------  -------------------- -------
Ethernet1             App1/1              dynamic
Ethernet1             Sw1                 dynamic
Ethernet2             Ethernet3           dynamic
```

```
Ethernet2             Ethernet4           dynamic
App1/1                Ethernet1           dynamic
App1/2                Sw17                static
Sw17                  App1/2              static
```

- This command displays the list of all connections that include the Ethernet interfaces ***et1*** and ***et4***.

```
switch# show l1 path interface et1, et4
Source                 Destination           Type
---------------------- --------------------- -------
Ethernet1              App1/1                dynamic
Ethernet1              Sw1                   dynamic
Ethernet2              Ethernet4             dynamic
App1/1                 Ethernet1             dynamic
```

5.2.5 show l1 source

The **`show l1 source`** command displays the list of all source interfaces to connect for specific interfaces such as Ethernet ports, switch, FPGA ports, or CPU ports.

Command Mode

Privileged EXEC

Command Syntax

`show l1 source` [interface | capabilities]

Parameters

- **interface** lists the source interfaces available to connect for the specified interface.
  - **Application** *1-1* - Application FPGA connector interface
  - **CPU** *1-4* - CPU interface
  - **Downstream** *1-255* - Downstream interface
  - **Ethernet** *1-96* - Ethernet interface
  - **MuxIn** *1-24* - Metamux input interface
  - **MuxOut** *1-24* - Metamux output interface
  - **Ptp** *1-2* - MetaWatch PIP interface
  - **Switch** *1-7* Switch interface
  - **TrafficGen** *1-256* - Traffic Generation interface
  - **Upstream** *1-255* - Upstream interface
  - **WatchIn** *1-255* - WatchIn interface
  - **WatchOut** *1-255* - WatchOut interface
  - **WatchPassthrough** *1-255* - Watch passthrough interface
  - **WhiteRabbit** *1-255* - White Rabbit interface
- **capabilities** lists the Layer 1 source capabilities for the specified switch.

Examples

- This command displays the list of all source interfaces to connect in the crosspoint and the specific interfaces.

```
switch# show l1 source
Interface             Source Interface    Type
--------------------- ---------------------- -------
Ethernet1             App1/1              dynamic
Ethernet2
Ethernet3             Ethernet2           dynamic
Ethernet4             Ethernet2           dynamic
Ethernet5             MAC                 dynamic
App1/1                Ethernet1           dynamic
App1/2                Sw17                static
Sw1                   Ethernet1           dynamic
Sw2
Sw3
Sw4
Sw5
Sw17                  App1/2              static
Cpu1
Cpu2
```

Note: Interfaces without a source port are listed as well, but the Source Interface and Type columns appear as blanks.

- This command displays the list of source interfaces to connect for the Ethernet interface ***et1***.

```
switch# show l1 source interface et1
Interface             Source Interface    Type
--------------------- ------------------- -------
Ethernet1             App1/1              dynamic
```

5.2.6 show l1 source capabilities

The **`show l1 source capabilities`** command displays the list of all interfaces available to connect in the crosspoint and the possible source ports.

Command Mode

Privileged EXEC

Command Syntax

```
show l1 source capabilities
```

Examples

- This command displays the list of all possible source interfaces available to connect in the crosspoint and the specific interfaces.

```
switch# show l1 source capabilities
Interface             Possible Source Interface(s)
--------------------- --------------------------------
Ethernet1             Ap1/1,Cpu1-2,Et1-16,Sw1-16
Ethernet2             Ap1/1,Cpu1-2,Et1-16,Sw1-16
Ethernet3             Ap1/1,Cpu1-2,Et1-16,Sw1-16
Ethernet4             Ap1/1,Cpu1-2,Et1-16,Sw1-16
Ethernet5             Ap1/1,Cpu1-2,Et1-16,Sw1-16
Application1/1        Ap1/1,Cpu1-2,Et1-16,Sw1-16
Application1/2        Sw17
Switch1               Ap1/1,Cpu1-2,Et1-16,Sw1-16
Switch2               Ap1/1,Cpu1-2,Et1-16,Sw1-16
Switch3               Ap1/1,Cpu1-2,Et1-16,Sw1-16
Switch4               Ap1/1,Cpu1-2,Et1-16,Sw1-16
Switch5               Ap1/1,Cpu1-2,Et1-16,Sw1-16
Switch17              Ap1/2
Cpu1                  Ap1/1,Cpu1-2,Et1-16,Sw1-16
Cpu2                  Ap1/1,Cpu1-2,Et1-16,Sw1-16
```

- This command displays the list of possible source interfaces available to connect for the Ethernet interface ***et1***.

```
switch# show l1 source interface et1 capabilities
Interface             Possible Source Interface(s)
--------------------- --------------------------------
Ethernet1             Ap1/1,Cpu1-2,Et1-16,Sw1-16
```

- This command displays the list of possible source interfaces available to connect for the FPGA port ***fpga***.

```
switch# show l1 source fpga capabilities
Interface             Possible Source Interface(s)
--------------------- ------------------------------
Application1/1        Ap1/1,Cpu1-2,Et1-16,Sw1-16
Application1/2        Sw17
```

Chapter 6

Timing Protocols

The Precision Time Protocol (PTP) provides clock accuracy for networked devices, allowing clocks to be synchronized locally in increments of less than a microsecond. PTP uses a primary-secondary hierarchy similar to that used by NTP. The primary clock provides the most precise time, and the secondary devices use the signal to synchronize their clocks.

The master clock sends a **sync** request, called an **announce** message by the IEEE 1588-2008 standard, at a regular interval. The slave clock responds with a time-stamped delay request message in order to measure and compensate for packet delays between the devices. The slave then receives a message from the master specifying the time of the delay message and allows the slave to calculate final values for clock synchronization. The time maintains synchronization by regularly exchanging PTP packets between master and slave.

Note: Arista switches do not support setting the system clock using PTP. Use the NTP service on the PTP grandmaster for system clock synchronization.

EOS disables PTP globally by default. Enabling PTP on an interface requires the following steps:

- Setting the PTP Mode
- Enabling PTP on an Interface

Optional PTP global configurations include the following:

- Configuring the PTP Domain
- Configuring the Offset Hold Time
- Setting the PTP Priority
- Configuring the Source IP
- Configuring the TTL for PTP Packets
- Configuring PTP Monitoring

Optional PTP interface-level configurations include the following:

- Setting the PTP Announce Interval
- Setting the PTP Timeout Interval
- Configuring the PTP Delay Mechanism
- Setting the Delay Request Interval
- Setting the Peer Delay Request Interval

- Setting the Peer Link Propagation Threshold
- Setting the Interval for Sending Synchronization Messages
- Setting the PTP Transport Type
- Viewing PTP Settings and Status
- Precision Time Protocol (PTP) Commands

6.1 Setting the PTP Mode

To enable PTP on switch interfaces, set the PTP mode using the **`ptp mode`** command. PTP mode options include the following:

- **boundary** - The device acts as a boundary clock and runs and participates in the best master clock algorithm.
- **disabled** - Disables PTP, and the device forwards all PTP packets as normal traffic.
- **end-to-end transparent** - The device acts as an end-to-end transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time.
- **peer-to-peer transparent** - The device acts as a peer-to-peer transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time and inbound path delays.
- **generalized Precision Time Protocol (gPTP)** - The device runs generalized Precision Time Protocol (gPTP), participating in the best master clock algorithm but also updating the interval field of forwarded PTP packets using switch residence time and inbound path delays.

To disable PTP globally on the switch, use the **no** or **default** forms of the **`ptp mode`** command.

Example

This command configures the device as a PTP boundary clock.

```
switch(config)# ptp mode boundary
switch(config)#
```

6.2 Enabling PTP on an Interface

To enable PTP on a specific interface on the device, use the **`ptp enable`** command.

Example

This command enables PTP on ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)#ptp enable
```

6.3 Configuring the PTP Domain

To set the domain number to use for the clock, use the **`ptp domain`** command.

Example

This command configures the ***domain 1*** to use with a clock.

```
switch(config)# ptp domain 1
switch(config)#
```

6.4 Configuring the Offset Hold Time

To set the PTP offset hold time, use the **`ptp hold-ptp-time`** command.

Example

This command configures the PTP offset hold time to ***600*** seconds.

```
switch(config)# ptp hold-ptp-time 600
switch(config)#
```

6.5 Setting the PTP Priority

To set the priority 1 value, use the `ptp priority1` command. Lower values take precedence.

This command configures the priority 1 value of ***120*** to use when advertising the clock.

```
switch(config)# ptp priority1 120
switch(config)#
```

To set the priority 2 value for the clock, use the `ptp priority2` command.

This command configures the priority 2 value of ***128***.

```
switch(config)# ptp priority2 128
switch(config)#
```

6.6 Configuring the Source IP

To set the source IP address for all PTP packets, use the `ptp source` command.

Example

This command configures the source IP address of `10.0.2.1` for all PTP packets.

```
switch(config)# ptp source ip 10.0.2.1
switch(config)#
```

This command configures the source IP address of `2001:db8:ac10:fe01::` for all PTP packets.

```
switch(config)# ptp source ip 2001:db8:ac10:fe01::
switch(config)#
```

6.7 Configuring the TTL for PTP Packets

To set the Time To Live (TTL) of PTP packets, use the `ptp ttl` command. TTL is the maximum number of hops that a PTP packet may make.

Example

This command configures a TTL of ***64*** hops for PTP packets.

```
switch(config)# ptp ttl 64
switch(config)#
```

6.8 Configuring PTP Monitoring

PTP Monitoring records PTP information, including the offset from the master, mean path delay, and skew values, which you view using a **show** command. PTP Syslog messages generate the metrics with threshold values configured on the switch when enabled. EOS enables PTP Monitoring by default.

Enabling and Disabling PTP Monitoring

Use the `ptp monitor` command to enable PTP monitoring on the device. The **no** form of the command disables PTP monitoring and clears all of the recorded PTP data.

Example

This command disables PTP monitoring and clears all recorded PTP data from the switch.

```
switch(config)# no ptp monitor
```

Configuring the Offset-from-master Threshold

The offset is the difference in nanoseconds between master and slave time. Use the `ptp monitor threshold offset-from-master` command to specify the offset-from-master threshold in nanoseconds. EOS generates a Syslog message if the most recently calculated time offset from the PTP master occurs outside the configured range. The maximum offset threshold is one second. The **no** form of the command clears the threshold value and prevents further Syslog messages from generating for this parameter.

Example

This command sets an offset-from-master threshold value of ***500*** nanoseconds.

```
switch(config)# ptp monitor threshold offset-from-master 500
```

Configuring the Mean-path-delay Threshold

Mean path delay is the mean time in nanoseconds PTP packets take to travel between master and slave. Use the `ptp monitor threshold mean-path-delay` command to specify the mean-path-delay threshold in nanoseconds. EOS generates a Syslog message if the value of the most recently calculated mean path delay becomes greater than or equal to this threshold. The maximum mean-path-delay threshold is one second. The **no** form of the command clears the threshold value and prevents further Syslog messages from generating for this parameter.

Note: Mean path delay is always non-negative.

Example

This command sets a mean-path-delay threshold value of ***2000*** nanoseconds.

```
switch(config)# ptp monitor threshold mean-path-delay 2000
```

Configuring the Skew Threshold

PTP skew is the clock frequency difference between master and slave. Use the `ptp monitor threshold skew` command to configure the value of the skew-threshold percentage. A Syslog message generates if the value of the most recently calculated skew does not fall within the range (1/(1+<threshold>), 1*(1+<threshold>)). Skew threshold percentage represents a double precision (16 digit) real number ranging from ***0*** (0%) to ***10*** (1000%). The **no** form of the command clears the threshold value and prevents further Syslog messages from generating for this parameter.

Example

This command sets a skew threshold value of ***5*** (500%).

```
switch(config)# ptp monitor threshold skew 5
```

6.9 Setting the PTP Announce Interval

To set the interval at which an interface sends PTP **announce** messages, use the `ptp announce interval` command. EOS measures the interval in log seconds. This value also affects the timeout interval.

This command configures the interval between PTP announcement messages on ***interface ethernet 5*** to ***4*** seconds.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp announce interval 2
switch(config-if-Et5)#
```

6.10 Setting the PTP Timeout Interval

To set the timeout multiplier for an interface, use the **`ptp announce timeout`** command. The timeout multiplier is the number of announcement intervals that the interface waits without receiving a PTP announcement before a timeout occurs. The values range from ***2*** to ***255***. The default multiplier is ***3***, which results in a ***6***-second timeout interval when setting the announcement interval to the default of ***2*** seconds.

This command sets timeout multiplier for the interface to ***5***. The announcement interval has just been set to ***2*** (***4*** seconds), and the interface times out if it doesn't receive a PTP announcement for ***20*** seconds.

```
switch(config-if-Et5)# ptp announce timeout 5
switch(config-if-Et5)#
```

6.11 Configuring the PTP Delay Mechanism

To set the delay mechanism used in boundary-mode, use the `ptp delay-mechanism` command.

Example

This command sets the delay mechanism in boundary clock mode for the interface to peer-to-peer.

```
switch(config-if-Et5)# ptp delay-mechanism p2p
switch(config-if-Et5)#
```

6.12 Setting the Delay Request Interval

To set the time for the slave devices to send delay request messages, use the **`ptp delay-req interval`** command.

Example

This command sets the time the slave devices to send delay request messages to the master state to ***3*** for the interface.

```
switch(config-if-Et5)# ptp delay-request interval 3
switch(config-if-Et5)#
```

6.13 Setting the Peer Delay Request Interval

To set the minimum interval between the PTP peer delay-request messages, use the **`ptp pdelay-req interval`** command.

Example

This command sets the interval between PTP peer delay-request messages on the interface to ***3***.

```
switch(config-if-Et5)# ptp pdelay-request interval 3
switch(config-if-Et5)#
```

6.14 Setting the Peer Link Propagation Threshold

To set the delay threshold for which the peer cannot run generalized Precision Time Protocol (gPTP), use the **ptp pdelay-neighbor-threshold** command.

Example

This command sets the link propagation delay threshold on the interface to ***200000*** nanoseconds..

```
switch(config-if-Et5)# ptp pdelay-neighbor-threshold 200000
switch(config-if-Et5)#
```

6.15 Setting the Interval for Sending Synchronization Messages

To set the interval (in log seconds) for sending synchronization messages, use the **ptp sync-message interval** command. Value ranges and defaults vary based on the PTP mode of the switch.

Example

This command configures the interval for sending synchronization messages on the interface to ***3*** (***8*** seconds).

```
switch(config-if-Et5)# ptp sync-message interval 3
switch(config-if-Et5)#
```

6.16 Setting the PTP Transport Type

To set the PTP transport type, use the **ptp transport** command.

- This command configures the PTP transport type for the interface to IPv4.

```
switch(config-if-Et5)# ptp transport ipv4
switch(config-if-Et5)#
```

- This command configures the PTP transport type for the interface to IPv6.

```
switch(config-if)# ptp transport ipv6
switch(config-if)#
```

Setting the Local Priority of the Clock and Interfaces

To set the local priority of the clock and interfaces to control the topology, use the **ptp local-priority** command.

```
switch(config)# ptp local-priority 1
switch(config-if)# ptp local-priority 255
```

Setting up as a Slave to another PTP Device

Each interface may be configured with a candidate grantor IP address to send requests and potentially become the slave device to another PTP device. After configuration, the switch starts negotiating with the candidate grantor, and depending on the Announce messages received, it may start requesting Sync and Delay Response to sync the clock. Each grantor may be associated with a unicast negotiation profile. If the configuration omits the profile, the device uses the default interval of one second and a duration of 60 seconds for all message types. If the profile does not exist, the switch uses the default values until the profile gets added.

Use the **ptp unicast-negotiation candidate-grantor** command to set up the profile. The following commands set up the candidate grantor profile.

```
switch(config-if)# ptp unicast-negotiation candidate-grantor 10.0.0.1
switch(config-if)# ptp unicast-negotiation candidate-grantor 10.0.0.1 profile fastProfile
```

Setting up as a Master to another PTP Device

Each interface may be configured with a range of IP addresses of remote grantees to grant incoming requests and potentially become a master to another PTP device. By default, the interface denies incoming requests outside the configured range of IP addresses. Each grantee may be associated with a unicast negotiation profile. If the configuration omits the profile, the interface grants incoming requests with an interval of ***0*** or longer for all message types. If you specify a profile, it compares it to the configured interval. If the profile does not exist, the switch uses the default values until you add the profile.

Use the **ptp unicast-negotiation remote-grantee** command to set up the profile. The following commands set up the remote grantee profile.

```
switch(config-if)# ptp unicast-negotiation remote-grantee 10.0.0.1/24
switch(config-if)# ptp unicast-negotiation remote-grantee 10.0.0.1/24 profile fastProfile
```

Setting the masterOnly Flag

For ports that should not be a slave regardless of other attributes, use the **ptp role master** command.

```
switch(config-if)# ptp role master
```

Configuring the Unicast Profile

A Unicast negotiation profile may be configured to change message rates and durations. The following tables displays the default value and the configurable range of each value.

Table 8: Default Values and Configuration Parameters

Field	Range	Default
Announce interval	[-3, 0]	0
Announce duration	[60, 1000]	60
Sync interval	[-7, 0]	0
Sync duration	[60, 1000]	60
Delay Response interval	[-7, 0]	0
Delay Response duration	[60, 1000]	60

When you apply a profile to a remote grantee on a Grant port, it uses the profile values to determine if the given request should be granted or denied. If the requested interval is shorter than the profile, the port denies the request. When a profile applies to a candidate grantor on a Request port, it requests the candidate grantor using the values in the profile.

The following configures a typical Unicast negotiation profile.

```
switch(config)# ptp unicast-negotiation profile fastProfile
switch(config-unicast-negotiation-profile-fastProfile)# announce interval -2
switch(config-unicast-negotiation-profile-fastProfile)# announce duration 500
switch(config-unicast-negotiation-profile-fastProfile)# sync interval -3
switch(config-unicast-negotiation-profile-fastProfile)# sync duration 300
switch(config-unicast-negotiation-profile-fastProfile)# delay-resp interval -3
switch(config-unicast-negotiation-profile-fastProfile)# delay-resp duration 300
```

Displaying Unicast Negotiation Configurations

The **`show ptp unicast-negotiation profile`** command displays all user configured profiles and their values.

```
(switch)# show ptp unicast-negotiation profile
Unicast Negotiation Profile fastProfile
Announce interval: 0.25 seconds
Announce duration: 500 seconds
Sync interval: 0.125 seconds
Sync duration: 300 seconds
Delay Response interval: 0.125 seconds
Delay Response duration: 300 seconds
```

The **`show ptp unicast-negotiation candidate-grantor`** command displays all configured candidate grantors, associated profile name and latest update.

```
(switch)# show ptp unicast-negotiation candidate-grantor
 Interface    Address      Profile       Grantor Status
----------- ---------- -------------- ------------------
 Ethernet1    4::1       fastProfile    Master
 Ethernet1    4::2       fastProfile    Candidate Master
 Ethernet2    4::2       fastProfile    Blacklisted
```

The **show ptp unicast-negotiation remote-grantee** command displays all configured remote grantees, associated profile name and latest update.

```
(switch)# show ptp unicast-negotiation remote-grantee
Interface    Address      Profile
------------ ---------- -------------
 Ethernet1    4::1/96    fastProfile
 Ethernet1    4::2/96    fastProfile
 Ethernet2    4::2/96    fastProfile
```

The **show ptp unicast-negotiation granted** command displays to which remote grantees each port has granted and some detail.

```
(switch)# show ptp unicast-negotiation granted
Interface    Address    Message     Interval        Duration       Expires In
------------ ---------- ------------ -------------- -------------- -------------
 Ethernet2    4::1       Announce    0.25 seconds    300 seconds    30 seconds
 Ethernet2    4::1       Sync        2.0 seconds     300 seconds    30 seconds
```

The **show ptp unicast-negotiation requested** command displays to which candidate grantors each port has requested and some detail.

```
(switch)# show ptp unicast-negotiation requested
 Interface    Address    Message     Interval        Duration       Expires In
------------ --------- ----------- --------------- -------------- -------------
 Ethernet2    4::2       Announce    0.25 seconds    600 seconds    250 seconds
 Ethernet2    4::2       Sync        2.0 seconds     300 seconds    denied
```

The **show ptp local-clock** command displays the clock local priority in G8275.2 mode.

```
(switch)# show ptp local-clock
 PTP Mode: Boundary Clock
Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Clock Domain: 44
Number of PTP ports: 64
Priority1: 128
Priority2: 128
Local Priority: 128
Clock Quality:
   Class: 248
   Accuracy: 0x30
   OffsetScaledLogVariance: 0xffff
Offset From Master: -5
Mean Path Delay: 416 nanoseconds
Steps Removed: 1
Skew: 1.00000006399
Last Sync Time: 23:42:33 UTC Nov 01 2018
Current PTP System Time: 23:42:33 UTC Nov 01 2018
```

The **show ptp interface** command displays the interface local priority in G8275.2 mode.

Note: The Announce, Sync and Delay request message intervals are for multicast mode. Since G8275.2 operates in unicast mode, those values should be ignored.

```
(switch)# show ptp interface Ethernet 42 | nz  Interface Ethernet42
PTP: Enabled
Port state: Slave
Sync interval: 1.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 3
Delay mechanism: end to end
Delay request message interval: 0.25 seconds
Local Priority: 128
Transport mode: ipv4
Announce messages received: 2964
Sync messages received: 2558
Follow up messages received: 2558
Delay request messages sent: 2540
Delay response messages received: 2540
Signaling messages sent: 98
Signaling messages received: 101
```

6.17 Configuring a PTP Grandmaster Clocks List

In a PTP network, multiple clocks may be capable of serving as the primary source of time. The Best Master Clock Algorithm (MBCA) to select the single best clock to become the single active Grandmaster (GM) for the PTP domain. Typically, the list specifies the MAC addresses or EUI-64 bit number of clocks on the network.

To delete the GM clocks list, use the **no** version of the command to delete the GM list. If no list exists, EOS considers all potential GM clocks by default.

To add the MAC addresses, *00:00:79:ff:ff:01:00:00* through *00:00:79:ff:ff:03:00:00*, use the following commands:

```
switch(config)# ptp grandmasters
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:01:00:00
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:02:00:00
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:03:00:00
```

To delete a clock from the acceptable grandmaster list, use the following commands:

```
switch(config)# ptp grandmasters
switch(config-ptp-grandmasters)# no clock-identity accepted 00:00:79:ff:ff:01:00:00
```

To delete the entire list, use the **no** version of the command:

```
switch(config)# no ptp grandmasters
```

Displaying Grandmaster List Information

When configured and other announce messages from clocks rejected, the messages count towards the drop counters.

```
switch# show ptp interface ethernet4 counters drop
   Endpoint       Dir       Reason                                                    Count
          Last Seen
-------------- --------- ------------------------------------------------------- -----------
 ------------------------
   Et4            rx        Announce message with less than foreign master              1
 2025-10-01 UTC 02:59:05
                          threshold value.

   Et4            rx        Sync message with received port is not slave.               60
 2025-10-01 UTC 03:00:18
```

6.18 Viewing PTP Settings and Status

The following commands display the status of the switch PTP server connections:

- Displaying General PTP Information
- Displaying PTP Local Clock and Offset
- Displaying PTP Masters Information
- Displaying PTP Clock Properties
- Displaying PTP Information for all Interfaces
- Displaying PTP Interface Counters
- Displaying PTP Foreign Master
- Displaying PTP Monitoring Information
- Displaying PTP Source IP

6.18.1 Displaying General PTP Information

To display general Precision Time Protocol (PTP) information, use the **`show ptp`** command.

```
switch# show ptp
PTP Mode: gptp - Generalized PTP Clock
Clock Identity: 2001:0DB8:73:ff:ff:26:fd:90
Grandmaster Clock Identity: 2001:0DB8:96:ff:fe:6c:ed:02
Number of slave ports: 1
Number of master ports: 6
Slave port: Ethernet33
Mean Path Delay (nanoseconds): 718
Steps Removed: 1
Neighbor Rate Ratio: 1.00000007883
Rate Ratio: 1.00000007883
```

```
Interface  State    ASTime  Since LastNeighbor Mean        Path        Residence
Capable    Changed  Rate    Ratio              Delay (ns)  Time (ms)
---------  -------- ------- ------------------ ----------- ----------- ---------
Et1        Disabled No      Never              1.0         00
Et2        Disabled No      Never              1.0         00
Et3        Disabled No      Never              1.0         00
Et4        Disabled No      Never              1.0         00
Et5        Disabled No      Never              1.0         00
Et6        Disabled No      Never              1.0         00
Et7        Master   Yes                        0:21:08     1.000000094200
```

6.18.2 Displaying PTP Clock Properties

To display PTP clock properties, use the Displaying PTP Clock Properties command.

```
switch# show local-clock time-properties
Current UTC offset valid: False
Current UTC offset: 0
Leap 59: False
Leap 61: False
Time Traceable: False
Frequency Traceable: False
PTP Timescale: False
Time Source: 0x0 switch#
```

6.18.3 Displaying PTP Foreign Master

To display information about foreign masters (PTP sources not designated as the switch's master from which the switch has received sync packets), use the **show ptp foreign-master-record** command.

```
switch# show ptp foreign-master-record
No Foreign Master Records switch#
```

6.18.4 Displaying PTP Information for all Interfaces

To display PTP information for specified interfaces, use the **show ptp interface** command.

```
switch# show ptp interface
Interface Ethernet1
PTP: Disabled
Port state: Disabled
Sync interval: 1.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 3
Delay mechanism: end to end
Delay request message interval: 32.0 seconds
Transport mode: ipv4

Interface Ethernet5
PTP: Disabled
Port state: Disabled
Sync interval: 8.0 seconds
```

```
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 5
Delay mechanism: peer to peer
Peer delay request message interval: 8.0 seconds
Peer Mean Path Delay: 0
Transport mode: ipv4
```

6.18.5 Displaying PTP Interface Counters

To display PTP interface counters for specified interfaces, use the **show ptp interface counters** command.

```
switch# show ptp interface ethernet 5 counters
Interface Ethernet5
Announce messages sent: 0
Announce messages received: 0
Sync messages sent: 0
Sync messages received: 0
Follow up messages sent: 0
Follow up messages received: 0
Delay request messages sent: 0
Delay request messages received: 0
Delay response messages sent: 0
Delay response messages received: 0
Peer delay request messages sent: 0
Peer delay request messages received: 0
Peer delay response messages sent: 0
Peer delay response messages received: 0
Peer delay response follow up messages sent: 0
Peer delay response follow up messages received: 0
```

6.18.6 Displaying PTP Local Clock and Offset

To display the local PTP clock and offset, use the **show ptp local-clock** command.

```
switch# show ptp local-clock
PTP Mode: Boundary Clock
Clock Identity: 0x00:1c:73:ff:ff:1e:83:24
Clock Domain: 1
Number of PTP ports: 24
Priority1: 128
Priority2: 128
Clock Quality:
   Class: 248
   Accuracy: 0x30
   OffsetScaledLogVariance: 0xffff
Offset From Master: 0
Mean Path Delay: 0
Steps Removed: 0
```

6.18.7 Displaying PTP Masters Information

To display the PTP clocks master and grandmaster identity and configuration, use the **show ptp masters** command.

```
switch# show ptp masters
Parent Clock:
Parent Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Parent Port Number: 0
Parent IP Address: N/A
Observed Parent Offset (log variance): N/A
Observed Parent Clock Phase Change Rate: N/A

Grandmaster Clock:
Grandmaster Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Grandmaster Clock Quality:
   Class: 248
   Accuracy: 0x30
   OffsetScaledLogVariance: 0xffff
   Priority1: 128
   Priority2: 128
```

6.18.8 Displaying PTP Monitoring Information

To display the list of up to 100 recorded entries of offset from master, mean path delay and skew values, the current PTP mode, whether or not the feature is enabled, the number of entries displayed, and the configured thresholds for each metric, use the **show ptp monitor** command. Entries are sorted by the system time at which the value was calculated, starting with the most recent data at the top.

```
switch# show ptp monitor
PTP Mode: Boundary Clock
Ptp monitoring: enabled
Number of entries: 5
Offset from master threshold: 1500
Mean path delay threshold: not configured
Skew threshold: 0.5
Interface  Time                          Offset from   Mean Path    Skew
                                         Master (ns)   Delay (ns)
---------- ----------------------------- ------------ ------------ -----------
Et8        21:23:12.901 UTC Feb 22 2018  71           5849         1.003159918
Et1        21:23:12.901 UTC Feb 22 2018  113          3672         1.004990621
Et2        21:23:12.901 UTC Feb 22 2018  706          7799         1.002744199
Et1        21:23:12.901 UTC Feb 22 2018  803          5861         1.003432049
Et1        21:23:12.901 UTC Feb 22 2018  610          3415         0.998974658
```

6.18.9 Displaying PTP Source IP

To display PTP IP source information, use the **show ptp source ip** command.

```
switch# show ptp source ip
PTP source IP: 10.0.2.1
```

6.19 Precision Time Protocol (PTP) Commands

PTP Commands

- ptp announce interval
- ptp announce timeout
- ptp delay-mechanism
- ptp delay-req interval
- ptp domain
- ptp enable
- ptp forward-v1
- ptp hold-ptp-time
- ptp local-priority
- ptp mode
- ptp monitor
- ptp monitor threshold mean-path-delay
- ptp monitor threshold offset-from-master
- ptp monitor threshold skew
- ptp pdelay-neighbor-threshold
- ptp pdelay-req interval
- ptp priority1
- ptp priority2
- ptp role
- ptp source
- ptp sync timeout
- ptp sync-message interval
- ptp transport
- ptp ttl
- ptp unicast-negotiation

PTP Show Commands

- show ptp foreign-master-record
- show ptp interface
- show ptp interface counters
- show ptp local-clock

- show ptp masters
- show ptp monitor
- show ptp source ip
- show ptp unicast-negotiation
- show ptp unicast-negotiation profile
- show ptp

6.19.1 ptp announce interval

The **ptp announce interval** command configures the interval at which the configuration mode interface sends PTP **announce** messages. The **no ptp announce interval** command resets the announce interval to its default of 1 (2 seconds).

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp announce interval ***log_interval***

no ptp announce interval

default ptp announce interval

Parameters

log_interval - The number of log seconds between PTP announce messages (base *2* log (seconds)). Value ranges from *-3* (*1/8* second) to *4* (*16* seconds) with a default value of *1* (*2* seconds).

Examples

- These commands set the interval between PTP announce messages sent by ***interface ethernet 5*** to ***4*** seconds.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp announce interval 2
switch(config-if-Et5)#
```

- These commands reset the PTP announce interval on ***interface ethernet 5*** to the default value of ***1*** (***2*** seconds).

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp announce interval
switch(config-if-Et5)#
```

6.19.2 ptp announce timeout

The **ptp announce timeout** sets the timeout multiplier for an interface. The timeout multiplier uses the number of announcement intervals that the interface waits without receiving a PTP **announce** message before a timeout occurs. It uses a range from ***2*** to ***255***. The default multiplier is 3, which results in a 6-second timeout interval when setting the announce interval to the default of 2 seconds. To configure the announce interval, use the **ptp announce interval** command.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp announce timeout ***multiplier***

no ptp announce timeout

default ptp announce timeout

Parameter

multiplier - Configure the number of announce intervals before the interface times out if it does not receive a PTP **announce** message. The range is from ***2*** to ***255***; default value is ***3***.

Examples

- This command sets the timeout multiplier for ***interface ethernet 5*** to ***5***. This means that the interface times out if it doesn't receive a PTP **announce** message within five announce intervals.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp announce timeout 5
switch(config-if-Et5)#
```

- These commands reset the PTP timeout interval on ***interface ethernet 5*** to the default value of ***3***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp announce timeout
switch(config-if-Et5)#
```

6.19.3 ptp clock-accuracy

The **ptp clock-accuracy** command in the Global Configuration Mode allows you to manually configure the accuracy of the switch timeclock in the PTP Announce messages.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp clock-accuracy ***decimal***

no ptp clock-accuracy

default ptp clock-accuracy

Parameters

- **clock-accuracy** ***decimal*** - Configure a decimal value from 0 to 255:
  - **254** - Unknown accuracy
  - **48** - Accuracy within 100 nanoseconds
  - **33** - Accuracy within 100 picaseconds, usually reserved for highly accurate atomic clocks.

Example

Use the following command to set the clock accuracy to 48:

```
switch(config)# ptp clock-accuracy 48
switch(config)#
```

6.19.4 ptp clock-identity

The **ptp clock-identity** command in the Global Configuration Mode configures the hexadecimal identifier and serves as the tiebreaker in a Grandmaster Election. The switch with the lower hexadecimal value wins the election.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp clock-identity [*EUI-64 bit number H.H.H*]

no ptp clock-identity

default ptp clock-identity

Parameters

- ***EUI-64 bit number*** - Specify the clock identity in EUI-64 bit format.
- ***H.H.H*** - Specify the clock identity in MAC address format.

Example

Use the following command to configure the clock identity with a MAC address:

```
switch(config)# ptp clock-identity 01:02:03:04:05:06:07:08
switch(config)#
```

6.19.5 ptp delay-mechanism

The **ptp delay-mechanism** command configures the delay mechanism in boundary clock mode. The **no ptp delay-mechanism** command disables the feature.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp delay-mechanism ***mech_type***

no ptp delay-mechanism

default ptp delay-mechanism

Parameters

mech_type - Configure the type of delay mechanism. Options include the following:

- **e2e** - end-to-end delay mechanism.
- **p2p**- peer-to-peer mechanism.

Examples

- This command sets the delay mechanism to peer-to-peer in the boundary clock mode.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp delay-mechanism p2p
switch(config-if-Et5)#
```

- This command sets the delay mechanism to end-to-end in the boundary clock mode.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp delay-mechanism e2e
switch(config-if-Et5)#
```

- This command removes the delay mechanism configuration from ***Ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp delay-mechanism e2e
switch(config-if-Et5)#
```

6.19.6 ptp delay-req interval

The **ptp delay-req interval** command specifies the time in log seconds recommended to the slave devices to send delay request messages. You must enable PTP on the switch first and configure the source IP address for PTP communication. The **no ptp delay-req interval** command resets the interval to its default of ***5*** (***32*** seconds).

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp delay-req interval ***log_interval***

no ptp delay-req interval

default ptp delay-req interval

Parameter

log_interval - Specify from ***-1*** to ***8*** log seconds (base ***2*** log (seconds)). The default is ***5*** (***32*** seconds).

Examples

- These commands set the minimum interval allowed between PTP delay request messages on ***interface ethernet 5*** to ***3*** (***8*** seconds).

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp delay-request interval 3
switch(config-if-Et5)#
```

- These commands reset the minimum interval allowed between PTP delay-request messages to the default of ***5*** (***32*** seconds).

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp delay-request interval
switch(config-if-Et5)#
```

6.19.7 ptp domain

The **ptp domain** command sets the domain number to use for the clock. The **no ptp domain** command resets or restores the domain to the default number 0.

Command Mode

Global Configuration

Command Syntax

ptp domain ***domain_number***

no ptp domain

default ptp domain

Parameter

domain_number Configure a value from ***0*** to ***255***. Default number is 0.

Examples

- This command shows how to configure ***domain 1*** for use with a clock.

```
switch(config)# ptp domain 1
switch(config)#
```

- This command removes the configured ***domain 1*** for use with a clock.

```
switch(config)# no ptp domain 1
switch(config)#
```

6.19.8 ptp enable

The **ptp enable** command enables PTP on the interface. The **no ptp enable** command disables PTP on the interface.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

```
ptp enable

no ptp enable

default ptp enable
```

Examples

- This command enables PTP on ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp enable
```

- This command disables PTP on ***Ethernet interface 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp enable
```

6.19.9 ptp forward-unicast

The **ptp forward-unicast** command in the Global Configuration Mode configures the switch to pass Unicast PTP packets through a multicast Boundary Clock without the CPU dropping them.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp forward-unicast

no ptp forward-unicast

default ptp forward-unicast

Parameters

- **forward-unicast** - Configure the switch to forward dataplane PTP unicast packets in PTP boundary mode.

Example

Use the following command to configure forwarding unicast packets:

```
switch(config)# ptp forward-unicast
switch(config)#
```

6.19.10 ptp forward-v1

The **ptp forward-v1** command configures the switch to forward Precision Time Protocol version 1 packets as regular multicast traffic. By default, PTP v1 packets are trapped by the CPU, logged and discarded.

The **no ptp forward-v1** and **default ptp forward-v1** commands restore the default forwarding behavior by removing the corresponding **ptp forward-v1** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp forward-v1

no ptp forward-v1

default ptp forward-v1

Examples

- This command configures the switch to forward PTP v1 packets as regular multicast traffic.

```
switch(config)# ptp forward-v1
switch(config)#
```

- This command configures the switch to log and discard PTP v1 packets.

```
switch(config)# no ptp forward-v1
switch(config)#
```

6.19.11 ptp free-running

The **ptp free-running** command in Global Configuration Mode, by default, enters into a free running state after rebooting the switch or when upstream links fail on the network. It starts counting time using an unsynchronized internal clock. This behavior causes network disruptions. To prevent this behavior, use the **no ptp free-running**ccommand.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

no ptp free-running

Parameters

- **no ptp free-running** - Explicitly disable the feature on the switch.

Example

Use the following command to disable the feature:

```
switch(config)# no ptp free-running
switch(config)#
```

6.19.12 ptp grandmasters

The **ptp grandmasters** command in the PTP Configuration Mode allows the configuration of a list of grandmaster clocks for PTP. Typically, the list specifies the MAC addresses or EUI-64 bit number of clocks on the network.

To delete the GM clocks list, use the **no** version of the command to delete the GM list. If no list exists, EOS considers all potential GM clocks by default.

To delete a single clock, use the **no ptp grandmasters clock-identity accepted** ***address_format***.

Command Mode

PTP Configuration

Command Syntax

ptp grandmasters clock-identity accepted ***address_format***

no ptp grandmasters

Parameters

- **ptp grandmasters** - Specify creating a list of Grandmasters clocks.
- **clock-identity accepted** - Specify the clock identity accepted.
- ***address_format*** - Specify the clock in MAC address format (IPv4) or EUI-64 bit format (IPv6).

Example

To add the MAC addresses, *00:00:79:ff:ff:01:00:00* through *00:00:79:ff:ff:03:00:00*, use the following commands:

```
switch(config)# ptp grandmasters
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:01:00:00
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:02:00:00
switch(config-ptp-grandmasters)# clock-identity accepted 00:00:79:ff:ff:03:00:00
```

To delete a clock from the acceptable grandmaster list, use the following commands:

```
switch(config)# ptp grandmasters
switch(config-ptp-grandmasters)# no clock-identity accepted 00:00:79:ff:ff:01:00:00
```

To delete the entire list, use the **no** version of the command:

```
switch(config)# no ptp grandmasters
```

6.19.13 ptp hold-ptp-time

The **ptp hold-ptp-time** command configures the PTP offset hold time in seconds. The **no ptp hold-ptp-time** command resets or restores the PTP hold time to the default value.

Command Mode

Global Configuration

Command Syntax

ptp hold-ptp-time ***offset***

no ptp hold-ptp-time

default ptp hold-ptp-time

Parameter

offset - Specify a value from ***0*** to ***86400***.

Examples

- This command shows how to configure the PTP offset hold time.

```
switch(config)# ptp hold-ptp-time 600
switch(config)#
```

- This command resets or restores the PTP offset hold time to the default value.

```
switch(config)# no ptp hold-ptp-time
switch(config)#
```

6.19.14 ptp ip

The **ptp ip** command in the Global Configuration Mode allows you to bind a standard or extended IP ACL directly to the PTP daemon and guarantees that the switch control plane only processes timing packets from Grandmasters and known Boundary Clocks.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp ip access-list ***name*** **in**

no ptp ip access-list

default ptp ip access-list

Parameters

- **ip access-list** ***name*** - Specify the name of the IPv4 address Access Control List (ACL).
- **in** - Evaluates incoming PTP incoming PTP requests and announcements.

Example

Use the following command to use the ACL, MyPTP, on incoming packets:

```
switch(config)# ptp ip access-list MyPTP in
switch(config)#
```

6.19.15 ptp local-priority

The **`ptp local-priority`** command configures the local priority of the clock and interfaces to control the topology.

Command Mode

Interface-Ethernet Configuration

Command Syntax

`ptp local-priority` ***priority_num***

Parameter

priority_num - Specify a priority number from ***1*** to ***255***.

Example

This command sets the priority for the subinterface.

```
switch(config)# ptp local-priority 1
switch(config-if)# ptp local-priority 255
```

6.19.16 ptp management

The **ptp management** command in the Global Configuration Mode configures PTP to process PT Management Messages used by external devices by sending them to the CPU. After receiving the messages, the switch actively processes the administrative instructions inside the messages. In some networks, the fabric drops these messages to prevent hijacking of them.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp management all

no ptp management

default ptp management

Parameters

- **management all** - Specify processing all PTP Management Messages.

Example

Use the following command to process PTP Management Messages:

```
ptp management all
```

6.19.17 ptp message-type

The **ptp message-type** command in Global Configuration Mode allows you to manually configure the Differentiated Services Code Point (DSCP) values injected into the IP headers of the outgoing packets. This guarantees that your timing packets map to the correct strict-priority QoS queues as they traverse the rest of your network.

The configuration uses one of two packet types:

- Event - Highly time-critical packets that require exact nanosecond hardware timestamping at the moment they physically enter or leave the switch.
- General - Administrative or informational packets that do not require hardware timestamping and maintain the synchronization hierarchy.

Command Mode

Global Configuration

Command Syntax

ptp message-type [event | general] dscp *value* default

no ptp message-type

default ptp message-type

Parameters

- **event** - Specify Event messages.
- **general** - Specify General messages.
- **dscp *value*** - Set the DSCP value for PTP IPv4 packets as a number between 0 and 63.
- **default** - Apply the DSCP value to all interfaces.

Example

Use the following command to set the DSCP value as 46 on Event messages:

```
switch(config)# ptp message-type event dscp 46 default
switch(config)#
```

6.19.18 ptp mode

The **ptp mode** command configures the Precision Time Protocol (PTP) packet forwarding mode for the switch. By default, PTP is disabled globally, and the mode must be changed to use PTP on switch interfaces.

The **no ptp mode** and **default ptp mode** commands return the forwarding mode to **disabled** by removing the **ptp mode** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp mode ***mode_name***

no ptp mode

default ptp mode

Parameters

mode_name Default mode is **disabled**. Options include:

- **boundary one-step** - The One-Step PTP Boundary Clock (BC) streamlines the PTP synchronization process by embedding the precise OriginTimestamp directly into the PTP sync message's originTimestamp field, thereby eliminating the need for a separate Follow-Up message. This optimization reduces control plane traffic, enabling the BC to support more PTP master ports while maintaining full functionality.
  - **disabled** The default mode. PTP is disabled, and the device forwards all PTP packets as normal traffic.
  - **e2etransparent one-step** The device acts as an end-to-end transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time. Add the **one-step** parameter to handle PTP packets in the forwarding plane and remove scaling limitations such as packet drops due to high packet intervals and reduces CPU utilization.
  - **ordinarymaster** - The device acts as the Grandmaster. It generates and transmits PTP Announce, Sync, and Follow_up messages from the PTP-enabled interface.
  - **p2ptransparent** The device acts as a peer-to-peer transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time and inbound path delays.
  - **gptp** The device runs generalized Precision Time Protocol (gPTP), participating in the best master clock algorithm but also updating the interval field of forwarded PTP packets using switch residence time and inbound path delays.

Examples

- This command configures the switch to act as a One-Step PTP Boundary Clock (BC).

```
switch(config)# ptp mode boundary one-step
switch(config)#
```

- These commands configure the switch to operate as a one-step end-to-end transparent clock. This configuration enables both ingress and egress timestamping for PTP packets.

```
switch#configure
switch(config)#ptp mode e2etransparent one-step
switch(config)#interface Ethernet1/1
switch(conf-if-Et1/1)#ptp enable
```

Note: Enabling PTP on an interface is required for the switch to apply both ingress and egress timestamping to PTP packets. Accurate calculation of the correction field depends on PTP being enabled on both the ingress and egress interfaces.

- This command restores PTP to disabled mode.

```
switch(config)# no ptp mode
switch(config)#
```

6.19.19 ptp mpass

The **ptp mpass** command in the Global Configuration Mode enables Multi-Path Synchronization Support and creates a bridge between two MLAG peers. When enabled, Switch A and Switch B constantly synchronize their PTP states and timestamps over the MLAG peer link. If Switch B receives a `Delay_Req` packet for a session initiated by Switch A, Switch B can hand off the timestamping logic or proxy the response. To the downstream host, the two physical switches appear as a single logical PTP Boundary Clock.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp mpass

no ptp mpass

default ptp mpass

Parameters

- **mpass** - Enable Multi-Path Synchronization Support.

Example

Use the following command to enable Multi-Path Synchronization Support:

```
switch(config)# ptp mpass
switch(config)#
```

6.19.20 ptp monitor threshold mean-path-delay

Mean path delay is the mean time in nanoseconds that PTP packets take to travel between PTP master and slave. The **ptp monitor threshold mean-path-delay** command configures the mean-path-delay threshold in nanoseconds. When this threshold is configured, a Syslog message is generated if the value of the most recently calculated mean path delay is greater than or equal to this value.

The **no ptp monitor threshold mean-path-delay** and **default ptp monitor threshold mean-path-delay** commands clear the threshold value and prevent further Syslog messages from being generated for this parameter.

Command Mode

Global Configuration

Command Syntax

ptp monitor threshold mean-path-delay ***threshold***

no ptp monitor threshold mean-path-delay

default ptp monitor threshold mean-path-delay

Parameter

threshold - Configure a threshold in nanoseconds. Values range from ***0*** to ***1000000000*** (***1*** second).

Example

This command sets a mean-path-delay threshold value of ***2000*** nanoseconds.

```
switch(config)# ptp monitor threshold mean-path-delay 2000
```

6.19.21 ptp monitor threshold missing-message

The **ptp monitor threshold missing-message** command in the Global Configuration Mode allows you to proactively track the timing domain health by monitoring the exact sequence of the packets.

Every PTP message sent between a master and a client contains a Sequence ID in the header that increments by 1 with each transmission. The PTP daemon tracks the counter and if it receives a Sync packet with the Sequence ID 100, and receives the next packet with the Sequence ID 104, the switch immediately detects three packets dropped in transit. If the drops exceed your configured threshold, the switch sends a telemetry alert or Syslog message warning of packet loss before the switch drops the timing.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp monitor threshold missing-message {announce | delay-resp | follow-up | sync} ***threshold-value***

no ptp monitor threshold missing-message

default ptp monitor threshold missing-message

Parameters

- **ptp monitor threshold missing-message** - Specify tracking the following types of messages:
  - **announce** - Specify tracking packets used for the Best Master Clock Algorithm (BMCA).
  - **delay-resp** - Specify tracking the master reply to the switch path delay request.
  - **follow-up** - Specify tracking packets containing the actual two-step hardware timestamp.
  - **sync** - Specify tracking packets used by the primary timing heartbeat.
- ***threshold-value*** - Specify a number between 2 and 255.

Example

Use the following command to specify a threshold of 10 for sync packets:

```
switch(config)# ptp monitor threshold missing-message sync 10
switch(config)#
```

6.19.22 ptp monitor threshold offset-from-master

PTP offset is the difference in nanoseconds between master and slave time. The **ptp monitor threshold offset-from-master** command configures the offset-from-master threshold in nanoseconds. A Syslog message is generated if the most recently calculated time offset from the PTP master is outside of the range (-<threshold>, <threshold>). The maximum offset threshold is one second.

The **no ptp monitor threshold offset-from-master** and **no ptp monitor threshold offset-from-master** commands clear the threshold value and prevents further Syslog messages from being generated for this parameter.

Command Mode

Global Configuration

Command Syntax

ptp monitor threshold offset-from-master ***threshold***

no ptp monitor threshold offset-from-master

default ptp monitor threshold offset-from-master

Parameter

threshold - Configure an offset threshold value in nanoseconds. Values range from ***0*** to ***1000000000***.

Example

This command sets an offset-from-master threshold value of ***500*** nanoseconds.

```
switch(config)# ptp monitor threshold offset-from-master 500
switch(config)#
```

6.19.23 ptp monitor threshold skew

PTP skew is the clock frequency difference between master and slave. The **ptp monitor threshold skew** command configures the value of the skew-threshold percentage. A Syslog message is generated if the value of the most recently calculated skew is not in the range (1/(1+*threshold*), 1*(1+*threshold*)).

The **no ptp monitor threshold skew** and **default ptp monitor threshold skew** commands clear the threshold value and prevent further Syslog messages from being generated for this parameter.

Command Mode

Global Configuration

Command Syntax

ptp monitor threshold skew ***threshold***

no ptp monitor threshold skew

default ptp monitor threshold skew

Parameter

threshold - Specify the skew percentage threshold represented as a double precision (16 digit) real number ranging from ***0*** (***0%***) to ***10*** (***1000%***).

Example

This command sets a skew threshold value of ***5*** (***500%***).

```
switch(config)# ptp monitor threshold skew 5
switch(config)#
```

6.19.24 ptp monitor

The **ptp monitor** command enables and disables PTP monitoring on the switch. When PTP monitoring is enabled, the switch records PTP status and configuration information (which can be viewed using the **show ptp monitor** command) and generates Syslog messages for metrics whose threshold values have been configured. PTP monitoring is enabled by default.

The **no ptp monitor** command disables the PTP monitoring and clears all the recorded data from ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp monitor

no ptp monitor

Related Commands

- ptp monitor threshold mean-path-delay
- ptp monitor threshold offset-from-master
- ptp monitor threshold skew
- show ptp monitor

Example

This command disables PTP monitoring on the switch and clears all the recorded data.

```
switch(config)# no ptp monitor
switch(config)#
```

6.19.25 ptp netsync-monitor

The **ptp netsync-monitor** command enables the Netsync Monitor (NSM) protocol and allows an external device to monitor the switch. NSM allows a central monitoring station to probe the switch at specific intervals.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

ptp netsync-monitor delay-request

no ptp netsync-monitor

default ptp netsync-monitor

Parameters

- **delay-request** - Enable the NSM protocol.

Example

Use the following command to enable the NSM protocol:

```
switch(config)# ptp netsync-monitor delay-request
switch(config)#
```

6.19.26 ptp pdelay-neighbor-threshold

The **ptp pdelay-neighbor-threshold** command configures the propagation delay threshold above which the switch will consider the neighbor connected to this port to be incapable of participating in generalized Precision Time Protocol (gPTP).

The **no ptp pdelay-neighbor-threshold** and **default ptp pdelay-neighbor-threshold** commands restore the threshold to 100000 nanoseconds by removing the corresponding **ptp pdelay-neighbor-threshold** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp pdelay-neighbor-threshold ***link_prop***

no ptp pdelay-neighbor-threshold

default ptp pdelay-neighbor-threshold

Parameter

link_prop - Configure a threshold in nanoseconds. Value ranges from ***0*** to ***10000000000*** (ten billion). Default is ***100000***.

Examples

- These commands set the link propagation delay threshold on ***interface ethernet 5*** to ***200000*** nanoseconds.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp pdelay-neighbor-threshold 200000
switch(config-if-Et5)#
```

- These commands restore the link propagation delay threshold on ***interface ethernet 5*** to its default value of ***100000*** nanoseconds.

```
switch(config)# interface ethernet 5s
witch(config-if-Et5)# no ptp pdelay-neighbor-threshold
switch(config-if-Et5)#
```

6.19.27 ptp pdelay-req interval

The **ptp pdelay-req interval** command configures the interval between Precision Time Protocol peer delay-request messages. The **no ptp pdelay-req interval** command removes the configuration.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp pdelay-req interval ***log_interval***

no ptp pdelay-req interval

default ptp pdelay-req interval

Parameter

log_interval - Specify the log interval in seconds (base 2 log (seconds)). Value ranges from ***0*** to ***5***.

Examples

- This command configures the interval allowed between PTP peer delay request messages on ***interface Ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp pdelay-request interval 3
switch(config-if-Et5)#
```

- This command removes the configure the interval allowed between PTP peer delay request messages on ***interface Ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp pdelay-request interval
switch(config-if-Et5)#
```

6.19.28 ptp priority1

The **ptp priority1** command configures the priority 1 value for advertising the switchs PTP clock. Priority 1 is the most significant of the six factors used by devices in the selection of a master clock. Lower values indicate higher priority.

The **no ptp priority1** and **default ptp priority1** commands restore the priority 1 default setting of 128.

Command Mode

Global Configuration

Command Syntax

ptp priority1 ***priority_rate***

no ptp priority1

default ptp priority1

Parameter

priority_rate Specify a value from ***0*** to ***255***. Default is ***128***.

Examples

- This command sets the ***priority 1*** level for the switchs PTP clock to ***120***.

```
switch(config)# ptp priority1 120
switch(config)#
```

- This command restores the default ***priority 1*** level of ***128***.

```
switch(config)# no ptp priority1
switch(config)#
```

6.19.29 ptp priority2

The **ptp priority2** command sets the ***priority 2*** value for the clock. The range is from ***0*** to ***255***. ***Priority 2*** is the fifth most significant of the six factors used by devices in the selection of a master clock. Lower values indicate higher priority.

The **no ptp priority2** and **default ptp priority2** commands restore the ***priority 2*** default setting of ***128***.

Command Mode

Global Configuration

Command Syntax

ptp priority2 ***priority_rate***

no ptp priority2

default ptp priority2

Parameter

priority_rate - Specifies the ***priority 2*** level for the PTP clock. Value ranges from ***0*** to ***255***; default value is ***128***.

Examples

- This command sets the ***priority 2*** level for the switchs PTP clock to ***120***.

```
switch(config)# ptp priority2 120
switch(config)#
```

- This command restores the default ***priority 2*** level of ***128***.

```
switch(config)# no ptp priority2
switch(config)#
```

6.19.30 ptp profile

The **ptp profile** command in the Global Configuration Mode allows the application of a complete set of industry-standard PTP parameters to the switch.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
ptp profile [g8275.1 | g8275.2]

no ptp profile

default ptp profile>
```

Parameters

- **profile** - Specify a profile to apply to the PTP configuration:
  - **g8275.1** - The Telecom profile for Layer 2 (Ethernet) transport. Used in mobile backhaul where every switch in the path provides a Boundary Clock.
  - **g8275.2** - The Telecom profile for Layer 3 (IP/Unicast) transport. Used in wide-area networks where not every hop supports PTP.

Example

Use the following command to apply the profile, `g8275.1`, to the PTP configuration:

```
switch(config)# ptp profile 8275.1
! Announce message rate will be fixed to 8/s
! Sync/FollowUp message rate will be fixed to 16/s
! Delay-req message rate will be fixed to 16/s
! Only E2E delay mechanism will be supported
switch(config)#
```

6.19.31 ptp role

The **ptp role** command configures a port to operate either in the master mode or the dynamic mode when it is executed in the interface configuration mode.

The **no ptp role** command removes the master or dynamic mode if it was previously configured on an interface.

Command Mode

Interface-Ethernet Configuration

Command Syntax

ptp role [dynamic | master]

no ptp role

default ptp role

Parameters

- **dynamic** - Specify the dynamic mode.
- **master** - Specify the master clock mode with the most precise time.

Related Commands

- ptp enable
- ptp enable
- show ptp interface

Examples

- This command configures a port to operate in the master mode for ***interface ethernet 1***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# ptp role master
```

- This command configures a port to operate in the dynamic mode for ***interface ethernet 1***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# ptp role dynamic
```

6.19.32 ptp source

The **ptp source** command configures the source IP address for all PTP packets. The IP address can be in IPv4 or IPv6 format. The **no ptp source ip** command removes this configuration.

Command Mode

Global Configuration

Command Syntax

ptp source ip {ip|ipv6} ***ip_addr***

no ptp source ip

default ptp source ip

Parameters

ip - Specifies an IPv4 source address.

ipv6 - Specifies an IPv6 source address.

ip_addr - Specify the source IP address.

Examples

- This command configures the source IP address `10.0.2.1` for all PTP packets.

```
switch(config)# ptp source ip 10.0.2.1
switch(config)#
```

- This command configures the source IP address `2001:db8:ac10:fe01::` for all PTP packets.

```
switch(config)# ptp source ip 2001:db8:ac10:fe01::
switch(config)#
```

- This command removes any configured source IP address for all PTP packets.

```
switch(config)# no ptp source ip
switch(config)#
```

6.19.33 ptp sync timeout

A PTP synchronization timeout occurs if a sync message is not received for a specified period of time, calculated as a multiple of the PTP sync-message interval. The **ptp sync timeout** command configures the sync timeout multiplier. The range is ***2*** to ***255***, with a default of ***20*** (20 times the sync interval). To configure the sync interval, use the **ptp sync-message interval** command.

The **no ptp sync timeout** and **default ptp sync timeout** commands restore the PTP sync timeout multiplier to its default value of ***20***.

Command Mode

Interface-Ethernet Configuration

Command Syntax

ptp sync timeout ***interval_multiplier***

no ptp sync timeout

default ptp sync timeout

Parameter

interval_multiplier - Specify the number of sync intervals that must pass without the configuration mode interface receiving a PTP sync message before a timeout occurs. Value ranges from ***2*** to ***255***. Default value is ***20***.

Example

These commands configure the sync timeout on ***interface ethernet 5*** to ten times the configured sync interval.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp sync timeout 10
switch(config-if-Et5)#
```

6.19.34 ptp sync-message interval

The **ptp sync-message interval** command configures the time for sending synchronization messages by specifying its log2 value. Default values and ranges depend on the PTP mode set using the **ptp mode** command.

The **no ptp sync-message interval** and **default ptp sync-message interval** commands restore the sync interval to its default (***1*** second in **boundary** mode, ***1/8*** second in **gptp** mode) by removing the corresponding **ptp sync-message interval** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp sync-message interval ***log_interval***

no ptp sync-message interval

default ptp sync-message interval

Parameter

log_interval - Specify the interval between PTP synchronization messages sent from the master to the slave (base 2 log (seconds)). Values vary according to PTP mode: in **boundary** mode, the range is from ***-7*** (***1/128*** second) to ***3*** (***8*** seconds) and the default value is ***0*** (***1*** second). In **gptp** mode, the range is from ***-3*** (***1/8*** second) to ***17*** (***131072*** seconds, approximately ***36*** hours) with a default of ***-3***.

Examples

- These commands set the interval for PTP synchronization messages on ***interface ethernet 5*** to ***3*** (***8*** seconds).

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp sync-message interval 3
switch(config-if-Et5)#
```

- In **boundary** mode, these commands restore the interval for PTP synchronization messages on ***interface ethernet 5*** to its default of ***0*** (***1*** second).

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp sync-message interval
switch(config-if-Et5)#
```

6.19.35 ptp transport

The **ptp transport** command configures the PTP transport type for a specific interface. Any values set in interface PTP configuration mode override the settings in the PTP configuration profile associated with the interface. The **no ptp transport** command removes the stetting from the ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

ptp transport ***transport_type***

no ptp transport

default ptp transport

Parameters

transport_type - Specify the transport mode in boundary clock mode. Options include:

- **ipv4** - Use the IPv4 address as the transport type on the interface.
- **ipv6** - Use the IPv6 address as the transport type on the interface.
- **layer2** - Use the Layer 2 protocol as the transport type on the interface.

Examples

- This command overrides the transport type in the profile and sets it to be IPv4 for the interface.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp transport ipv4
switch(config-if-Et5)#
```

- This command removes the interval for PTP synchronization messages on ***interface Ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp transport
switch(config-if-Et5)#
```

6.19.36 ptp ttl

The **`ptp ttl`** command configures the Time To Live (TTL) value of the PTP packets. The **`no ptp ttl`** resets the TTL value to the default value of ***1*** hop by removing the **`ptp ttl`** command from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ptp ttl` ***hop_count***

`no ptp ttl`

`default ptp ttl`

Parameter

hop_count - Configure the TTL value measured in hops. The value ranges from ***1*** to ***255*** with a default of ***1***.

Examples

- This command sets the time to live of the PTP packets to ***60*** hops.

```
switch(config)# ptp ttl 60
switch(config)#
```

- This command resets the time to live of the PTP packets to the default value of ***1*** hop.

```
switch(config)# no ptp ttl
switch(config)#
```

6.19.37 ptp unicast-negotiation

The **ptp unicast-negotiation** command configures the master slave profiles for PTP devices.

Command Mode

Interface-Ethernet Configuration

Command Syntax

ptp unicast-negotiation

ptp unicast-negotiation remote-grantee

Parameters

- **candidate-grantor** - Becomes a slave to another PTP device.
- **remote-grantee** - Becomes a master to another PTP device.

Examples

- This command sets up an interface as a potential master.

```
switch(config-if)# ptp unicast-negotiation remote-grantee 10.0.0.1/24
switch(config-if)# ptp unicast-negotiation remote-grantee 10.0.0.1/24 profile fastProfile
```

- This command sets up an interface as a potential slave.

```
switch(config-if)# ptp unicast-negotiation candidate-grantor 10.0.0.1
switch(config-if)# ptp unicast-negotiation candidate-grantor 10.0.0.1 profile fastProfile
```

6.19.38 show ptp

The **show ptp** command displays summary Precision Time Protocol (PTP) information and PTP status of switch ports.

Command Mode

EXEC

Command Syntax

show ptp

Example

This command displays summary PTP information.

```
switch#show ptp
PTP Mode: gptp - Generalized PTP Clock
Clock Identity: 2001:0DB8:73:ff:ff:26:fd:90
Grandmaster Clock Identity: 2001:0DB8:96:ff:fe:6c:ed:02
Number of slave ports: 1
Number of master ports: 6
Slave port: Ethernet33

```

6.19.39 show ptp foreign-master-record

The **show ptp foreign-master-record** command displays information about foreign masters (PTP sources not designated as the switch's master from which the switch has received sync packets).

Command Mode

EXEC

Command Syntax

show ptp foreign-master-record

Example

This command displays information about PTP foreign masters.

```
switch# show ptp foreign-master-record
No Foreign Master Records switch#
```

6.19.40 show ptp interface counters

The **show ptp interface counters** command displays PTP interface counters for all interfaces.

Command Mode

EXEC

Command Syntax

show ptp [***interface_name***] **counters**

Parameters

interface_name - Interface type and numbers. Options include:

- ***no parameter*** - Display information for all interfaces.
- **ethernet** ***e_range*** - Ethernet interface range specified by ***e_range***.
- **loopback** ***l_range*** - Loopback interface specified by ***l_range***
- **management** ***m_range*** - Management interface range specified by ***m_range***.
- **port-channel** ***p_range*** - Port-Channel Interface range specified by ***p_range***.
- **vlan** ***v_range*** - VLAN interface range specified by ***v_range***.
- **VXLAN** ***vx_range*** - VXLAN interface range specified by ***vx_range***.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

Example

This command displays the PTP interface counters.

```
switch# show ptp interface ethernet 5 counters
Interface Ethernet5
Announce messages sent: 0
Announce messages received: 0
Sync messages sent: 0
Sync messages received: 0
Follow up messages sent: 0
Follow up messages received: 0
Delay request messages sent: 0
Delay request messages received: 0
Delay response messages sent: 0
Delay response messages received: 0
Peer delay request messages sent: 0
Peer delay request messages received: 0
Peer delay response messages sent: 0
Peer delay response messages received: 0
Peer delay response follow up messages sent: 0
```

```
Peer delay response follow up messages received: 0
switch#
```

6.19.41 show ptp interface

The **show ptp interface** command displays PTP information for all the interfaces on the device.

Command Mode

EXEC

Command Syntax

show ptp [***interface_name***][***status_filter***]

Parameters

- ***interface_name*** - Interface type and numbers. Options include:
  - **no parameter** - Display information for all interfaces.
  - **ethernet** ***e_range*** - Ethernet interface range specified by ***e_range***.
  - **loopback** ***l_range*** - Loopback interface specified by ***l_range***.
  - **management** ***m_range*** - Management interface range specified by ***m_range***.
  - **port-channel** ***p_range*** - Port-Channel Interface range specified by ***p_range***.
  - **vlan** ***v_range*** - VLAN interface range specified by ***v_range***.

  Valid range formats include number, number range, or comma-delimited list of numbers and ranges.
- ***status_filter*** - Filters interfaces by configuration status. Options include:
  - **no parameter** - all interfaces.
  - **enabled** - PTP configured interfaces.

Example

This command displays PTP information for all the interfaces on the device.

```
switch# show ptp interface
Interface Ethernet1
PTP: Disabled
Port state: Disabled
Sync interval: 1.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 3
Delay mechanism: end to end
Delay request message interval: 32.0 seconds
Transport mode: ipv4

Interface Ethernet5
PTP: Disabled
```

```
Port state: Disabled
Sync interval: 8.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 5
Delay mechanism: peer to peer
Peer delay request message interval: 8.0 seconds
Peer Mean Path Delay: 0
Transport mode: ipv6 switch#
```

6.19.42 show ptp local-clock

The **`show ptp local-clock`** command displays the Precision Time Protocol (PTP) clock information.

Command Mode

EXEC

Command Syntax

`show ptp local-clock`

Example

This command shows how to display the PTP local clock and offset.

```
switch# show ptp local-clock
PTP Mode: Boundary Clock
Clock Identity: 0x00:1c:73:ff:ff:1e:83:24
Clock Domain: 1
Number of PTP ports: 24
Priority1: 128
Priority2: 128
Clock Quality:
   Class: 248
   Accuracy: 0x30
   OffsetScaledLogVariance: 0xffff
Offset From Master: 0
Mean Path Delay: 0
Steps Removed: 0 switch#
```

6.19.43 show ptp masters

The **show ptp masters** command displays information about the switch's PTP master and grand master clocks.

Command Mode

Privileged EXEC

Command Syntax

show ptp masters

Example

This command displays information about the switch PTP master and grand master clocks.

```
switch# show ptp masters
Parent Clock:
Parent Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Parent Port Number: 0
Parent IP Address: N/A
Observed Parent Offset (log variance): N/A
Observed Parent Clock Phase Change Rate: N/A

Grandmaster Clock:
Grandmaster Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Grandmaster Clock Quality:
   Class: 248
   Accuracy: 0x30
   OffsetScaledLogVariance: 0xffff
   Priority1: 128
   Priority2: 128 switch#
```

6.19.44 show ptp monitor

The **show ptp monitor** command to displays the list of up to 100 recorded entries of offset from master, mean path delay and skew values, along with current PTP mode, whether or not the feature is enabled, number of entries displayed and the configured thresholds for each metric. Entries are sorted by the system time at which the value was calculated, starting with the most recent data at the top.

Command Mode

EXEC

Command Syntax

show ptp monitor

Example

This command displays the information recorded by PTP monitoring.

```
switch# show ptp monitor
PTP Mode: Boundary Clock
Ptp monitoring: enabled
Number of entries: 5
Offset from master threshold: 1500
Mean path delay threshold: not configured
Skew threshold: 0.5
Interface  Time                          Offset from   Mean Path     Skew
                                         Master (ns)   Delay (ns)
---------- ----------------------------- ------------  ------------- -----------
Et8        21:23:12.901 UTC Feb 22 2018  71            5849           1.003159918
Et1        21:23:12.901 UTC Feb 22 2018  113           3672           1.004990621
Et2        21:23:12.901 UTC Feb 22 2018  706           7799           1.002744199
Et1        21:23:12.901 UTC Feb 22 2018  803           5861           1.003432049
Et1        21:23:12.901 UTC Feb 22 2018  610           3415           0.998974658
```

6.19.45 show ptp source ip

The **`show ptp source ip`** command displays the PTP source IP for the device.

Command Mode

Privileged EXEC

Command Syntax

`show ptp source ip`

Example

This command shows the PTP source IP to be `10.0.2.1`

```
switch# show ptp source ip
PTP source IP: 10.0.2.1
```

This command shows the PTP source IP to be `2001:db8:ac10:fe01::`.

```
switch# show ptp source ip
PTP source IP: 2001:db8:ac10:fe01::
```

6.19.46 show ptp unicast-negotiation

The **show ptp unicast-negotiation** command displays PTP unicast negotiation information for the switch.

Command Mode

EXEC

Command Syntax

show ptp unicast-negotiation profile

show ptp unicast-negotiation [*details*]

Parameters

details - Details requested. Options include:

- **candidate-grantor** - Display all configured candidate grantors, associated profile name and latest update.
- **remote-grantee** - Display all configured remote grantees, associated profile name and latest update.
- **granted** - Display to which remote grantees each port has granted and some detail.
- **requested** - Display to which candidate grantors each port has requested and some detail.

Examples

- This command displays the unicast negotiation profiles configured on the switch.

```
switch# show ptp unicast-negotiation profile
Unicast Negotiation Profile fastProfile
Announce interval: 0.25 seconds
Announce duration: 500 seconds
Sync interval: 0.125 seconds
Sync duration: 300 seconds
Delay Response interval: 0.125 seconds
Delay Response duration: 300 seconds
```

- This command displays all configured candidate grantors, associated profile name and latest update.

```
switch# show ptp unicast-negotiation candidate-grantor
 Interface  Address    Profile        Grantor Status
---------- ---------- -------------- ------------------
 Ethernet1  4::1       fastProfile    Master
 Ethernet1  4::2       fastProfile    Candidate Master
 Ethernet2  4::2       fastProfile    Blacklisted
```

- This command displays all configured remote grantees, associated profile name and latest update.

```
switch# show ptp unicast-negotiation remote-grantee
 Interface    Address    Profile
------------ ---------- -------------
 Ethernet1    4::1/96    fastProfile
 Ethernet1    4::2/96    fastProfile
 Ethernet2    4::2/96    fastProfile
```

- This command displays to which remote grantees each port has granted and some detail.

```
switch# show ptp unicast-negotiation granted
Interface    Address    Message     Interval       Duration       Expires In
---------- ---------- ------------ -------------- -------------- -----------
 Ethernet2   4::1       Announce    0.25 seconds   300 seconds    30 seconds
 Ethernet2   4::1       Sync        2.0 seconds    300 seconds    30 seconds
```

- This command displays to which candidate grantors each port has requested and some detail.

```
switch# show ptp unicast-negotiation requested
Interface    Address   Message     Interval       Duration       Expires In
------------ --------- ----------- -------------- -------------- ------------
 Ethernet2   4::2      Announce    0.25 seconds    600 seconds    250 seconds
 Ethernet2   4::2      Sync        2.0 seconds     300 seconds    denied
```

6.19.47 show ptp unicast-negotiation profile

The **show ptp unicast-negotiation profile** command displays all user configured profiles and their values.

Command Mode

EXEC

Command Syntax

show ptp unicast-negotiation profile

Example

This command displays the PTP profiles.

```
switch# show ptp unicast-negotiation profile
Unicast Negotiation Profile fastProfile
Announce interval: 0.25 seconds
Announce duration: 500 seconds
Sync interval: 0.125 seconds
Sync duration: 300 seconds
Delay Response interval: 0.125 seconds
Delay Response duration: 300 seconds
```

Chapter 7

Switch Environment Control

The following sections describe the commands that display temperature, fan, and power supply status:

- Environment Control Introduction
- Environment Control Overview
- Configuring and Viewing Environment Settings
- Environment Commands

The switch chassis, fans, power supplies, line cards, and supervisors also provide LEDs that signal status and conditions that require attention. The Quick Start Guide for the individual switches provides information about their LEDs.

7.1 Environment Control Introduction

Arista switching platforms are designed to work reliably in common data center environments.

To ensure their reliable operation and to monitor or diagnose the switch's health, Arista provides a set of monitoring capabilities available through the CLI or SNMP entity MIBs to monitor and diagnose potential problems with the switching platform.

7.2 Environment Control Overview

This section contains the following topics:

- Temperature
- Fans
- Power

7.2.1 Temperature

Arista switches include internal temperature sensors. The number and location of the sensors vary with each switch model. Each sensor is assigned temperature thresholds that denote alert and critical conditions. Temperatures that exceed the threshold trigger the following:

- **Alert Threshold**: All fans run at maximum speed, and a warning message is logged.
- **Critical Threshold**: The component is shut down immediately, and its Status LED flashes orange.

In modular systems, cards are shut down when their temperatures exceed the critical threshold. The switch is shut down if the temperature remains above the critical threshold for three minutes.

7.2.2 Fans

Arista switches include fan modules that maintain internal components at proper operating temperatures. The number and type of fans vary with switch chassis type:

- **Fixed configuration switches** contain hot-swappable independent fans. Fan models with different airflow directions are available, but all fans within a switch must have the same airflow direction.
- **Modular switches** contain independent fans that circulate air from the front to the rear panel. The power supplies for modular switches also include fans that cool the power supply and supervisors.

The switch operates normally when one fan is not operating. Non-functioning modules should only be removed from the switch if they are immediately replaced; adequate switch cooling requires the installation of all components, including a non-functional fan.

Two non-operational fans trigger an ***insufficient fan shutdown*** condition. Under normal operations, this condition initiates a switch power-down procedure.

Fans are accessible from the rear panel.

7.2.3 Power

Arista switches contain power supplies that provide power to internal components.

- **Fixed configuration switches** contain two power supplies, providing 1+1 redundancy.
- **Modular switches** contain four power supplies, providing a minimum of 2+2 redundancy.

Power supply LED indicators are visible from the rear panel.

7.3 Configuring and Viewing Environment Settings

This section contains the following topics:

- Overriding Automatic Shutdown
- Viewing Environment Status
- Locating Components on the Switch

7.3.1 Overriding Automatic Shutdown

This section contains the following topics:

- Overheating
- Insufficient Fans
- Fan Speed

7.3.1.1 Overheating

The switch can be configured to continue operating during temperature shutdown conditions. Ignoring a temperature shutdown condition is strongly discouraged because operating at high temperatures can damage the switch and void the warranty.

Temperature shutdown condition actions are specified by the environment overheat action command. The switch displays this warning when configured to ignore shutdown temperature conditions.

```
switch(config)# environment overheat action ignore
======================================================================
WARNING: Overriding the system shutdown behavior when the system
is overheating is unsupported and should only be done under
the direction of an Arista Networks engineer. You risk damaging
hardware by not shutting down the system in this situation, and doing
so without direction from Arista Networks can be grounds for voiding
your warranty. To re-enable the shutdown-on-overheat behavior, use
the 'environment overheat action shutdown' command.
======================================================================
switch(config)#
```

The ***running-config*** contains the **`environment overheat action`** command when set to **ignore**. When the command is not in ***running-config***, the switch shuts down when an overheating condition exists.

The following ***running-config*** file lists the **`environment overheat action`** command.

```
switch# show running-config
! Command: show running-config
! device: switch (DCS-7150S-64-CL, EOS-4.13.2F)

ip route 0.0.0.0/0 10.255.255.1
!
environment overheat action ignore
!
!
end
```

7.3.1.2 Insufficient Fans

The switch can be configured to ignore the ***insufficient fan shutdown*** condition. This is strongly discouraged because continued operation without sufficient cooling may lead to a critical temperature condition that can damage the switch and void the warranty.

Insufficient-fans shutdown override is configured by the environment insufficient-fans action command. The switch displays this warning when configured to ignore insufficient-fan conditions.

```
switch(config)# environment insufficient-fans action ignore
```

```
======================================================================
WARNING: Overriding the system shutdown behavior when the system
has insufficient fans inserted is unsupported and should only be done
under
the direction of an Arista Networks engineer. You risk damaging
hardware by not shutting down the system in this situation, and doing
so without direction from Arista Networks can be grounds for voiding
your warranty. To re-enable the shutdown-on-overheat behavior, use
the 'environment insufficient-fans action shutdown' command.
======================================================================
switch(config)#
```

The ***running-config*** contains the **`environment insufficient-fans action`** command when set to ***ignore***. When ***running-config*** does not contain this command, the switch shuts down when it detects an insufficient-fans condition.

7.3.1.3 Fan Speed

The switch can be configured to override the automatic fan speed. The switch normally controls the fan speed to maintain optimal operating temperatures. The fans can be configured to operate at a constant speed regardless of the switch temperature conditions.

Fan speed override is configured by the environment fan-speed command. The switch displays this warning when its control of fan speed is overridden.

```
switch(config)# environment fan-speed override 50
======================================================================
WARNING: Overriding the system fan speed is unsupported and should only
be done under the direction of an Arista Networks engineer.
You can risk damaging hardware by setting the fan speed too low
and doing so without direction from Arista Networks can be grounds
for voiding your warranty.
To set the fan speed back to automatic mode, use the
'environment fan-speed auto' command
======================================================================
switch(config)#
```

The ***running-config*** contains the **`environment fan-speed override`** command if it is set to override. When ***running-config*** does not contain this command, the switch controls the fan speed.

7.3.2 Viewing Environment Status

This section contains the following topics:

- Power Status
- Temperature Status
- Fan Status
- System Status

7.3.2.1 Power Status

The show environment power command displays the status of the power supplies.

Example

This command displays the status of the power supplies.

```
switch> show environment power
Power Input Output Output
Supply  Model         Capacity  Current  Current  Power    Status
------- ------------- --------- -------- -------- -------- -------
1       PWR-650AC      650W      0.44A    10.50A  124.0W   Ok
```

7.3.2.2 Temperature Status

To display internal temperature sensor status, enter show environment temperature.

```
switch> show environment temperature
System temperature status is: Ok
                                                 Alert      Critical
Sensor  Description               Temperature  Threshold  Threshold
------- ------------------------- ------------ ---------- ----------
1       Front-panel temp sensor   22.000C       65C        75C
2       Fan controller 1 sensor   23.000C       75C        85C
3       Fan controller 2 sensor   28.000C       75C        85C
4       Switch chip 1 sensor      40.000C       105C       115C
5       VRM 1 temp sensor         48.000C       105C       110C
```

System temperature status is the first line that the command displays. **System temperature status** values indicate the following:

- **Ok:** All sensors report temperatures below the alert threshold.
- **Overheating:** At least one sensor reports a temperature above its alert threshold.
- **Critical:** At least one sensor reports a temperature above its critical threshold.
- **Unknown:** The switch is initializing.
- **Sensor Failed:** At least one sensor is not functioning.

7.3.2.3 Fan Status

The show system environment cooling command displays the cooling and fan status.

Example

This command displays the fan and cooling status:

```
switch> show system environment cooling
System cooling status is: Ok
Ambient temperature: 22C
Airflow: port-side-intake
Fan Tray  Status          Speed
--------- --------------- ------
1 Ok 35%
2 Ok 35%
3 Ok 35%
4 Ok 35%
5 Ok 35%
switch>
```

7.3.2.4 System Status

The show system environment all command lists the temperature, cooling, fan, and power supply information the individual show environment commands display, as described in Temperature Status, Fans, and Power.

Example

This command displays the temperature, cooling, fan, and power supply status:

```
switch> show system environment all
System temperature status is: Ok
                                                 Alert      Critical
Sensor  Description              Temperature     Threshold  Threshold
------- ------------------------ --------------- ---------- ----------
1       Front-panel temp sensor   22.750C         65C        75C
2       Fan controller 1 sensor   24.000C         75C        85C
3       Fan controller 2 sensor   29.000C         75C        85C
4       Switch chip 1 sensor      41.000C         105C       115C
5       VRM 1 temp sensor         49.000C         105C       110C

System cooling status is: Ok
Ambient temperature: 22C
Airflow: port-side-intake
Fan Tray  Status           Speed
--------- ---------------- ------
1         Ok                 35%
2         Ok                 35%
3         Ok                 35%
4         Ok                 35%
5         Ok                 35%

Power                           Input    Output   Output
Supply  Model       Capacity    Current  Current  Power    Status
------- ----------- --------- -------- -------- -------- -------
1       PWR-650AC   650W       0.44A    10.50A   124.0W   Ok
```

7.3.3 Locating Components on the Switch

When a component requires service, the switch administrator may use the locator-led command to assist a technician in finding the component. The command causes the status LED on the specified component to flash and display a “service requested” message on the LCD panel of modular switches or lights the blue locator light on the front of fixed switches. Use the show locator-led command to display all locator LEDs currently enabled on the switch.

Examples

- This command enables the locator LED on fan tray ***3***:

```
switch# locator-led fantray 3
Enabling locator led for FanTray3
```

- This command displays all locator LEDs enabled on the switch:

```
switch# show locator-led
There are no locator LED enabled
```

7.4 Environment Commands

Environment Control Configuration Commands

- environment fan-speed
- environment insufficient-fans action
- environment overheat action
- locator-led

Environment Display Commands

- show environment power
- show environment temperature
- show locator-led
- show system environment all
- show system environment cooling
- show system environment power budget

7.4.1 environment fan-speed

The **`environment fan-speed`** command determines how to control the speed of the switch fans. By default, the switch automatically controls the fan speed.

The switch normally controls the fan speed to maintain optimal operating temperatures. The fans can be configured to operate at a constant speed regardless of the switch temperature conditions.

The **`no environment fan-speed`** and **`default environment fan-speed`** commands restore the default action of automatic fan-speed control by removing the **environment fan-speed override** statement from ***running-config***.

Note: Overriding the system fan speed is unsupported and should only be done under the direction of an Arista Networks engineer. You can risk damaging hardware by setting the fan speed too low. Doing so without direction from Arista Networks can be grounds for voiding your warranty.

Command Mode

Global Configuration

Command Syntax

`environment fan-speed` **ACTION**

`no environment fan-speed`

`default environment fan-speed`

Parameters

ACTION Fan speed control method. Valid settings include:

- **auto** Fan speed is controlled by the switch.

  This option restores the default setting by removing the **`environment fan-speed override`** command from ***running-config***

- **override** ***percent*** Fan speed is set to the specified percentage of the maximum. Valid ***percent*** settings range from ***30*** to ***100***.

Examples

- This command overrides the automatic fan speed control and configures the fans to operate at 50% of maximum speed.

```
switch(config)# environment fan-speed override 50
======================================================================
WARNING: Overriding the system fan speed is unsupported and should
only be done under the direction of an Arista Networks engineer.
You can risk damaging hardware by setting the fan speed too low
and doing so without direction from Arista Networks can be grounds
for voiding your warranty.
To set the fan speed back to automatic mode, use the
'environment fan-speed auto' command
======================================================================
switch(config)#
```

- This command restores control of the fan speed to the switch.

```
switch(config)# environment fan-speed auto
switch(config)#
```

7.4.2 environment insufficient-fans action

The **`environment insufficient-fans`** command controls the switch response to the insufficient fan condition. By default, the switch initiates a shutdown procedure when it senses insufficient fans.

The switch operates normally when one fan is not operating. Non-functioning modules should only be removed from the switch if they are immediately replaced; adequate switch cooling requires the installation of all components, including a non-functional fan.

Two non-operational fans trigger an ***insufficient fan shutdown*** condition. This condition normally initiates a power-down procedure.

The **`no environment insufficient-fans`** and **`default environment insufficient-fans`** commands restore the default shutdown response to the insufficient-fans condition by removing the **`environment insufficient-fans action ignore`** statement from ***running-config***.

Note: Overriding the system shutdown behavior when the system has insufficient fans inserted is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty.

Command Mode

Global Configuration

Command Syntax

`environment insufficient-fans action` **REMEDY**

`no environment insufficient-fans action`

`default environment insufficient-fans action`

Parameters

REMEDY Configures action when the switch senses an insufficient fan condition. Settings include:

- **ignore** Switch continues operating when insufficient fans are operating.
- **shutdown** Switch shuts the power down when insufficient fans are operating.

  The **shutdown** parameter restores default behavior by removing the **`environment insufficient-fans`** command from ***running-config***.

Examples

- This command configures the switch to continue operating after it senses insufficient fan condition.

```
switch(config)# environment insufficient-fans action ignore
======================================================================
WARNING: Overriding the system shutdown behavior when the system
has insufficient fans inserted is unsupported and should only be done
under the direction of an Arista Networks engineer. You risk damaging
hardware by not shutting down the system in this situation, and doing
so without direction from Arista Networks can be grounds for voiding
your warranty. To re-enable the shutdown-on-overheat behavior, use
the 'environment insufficient-fans action shutdown' command.
======================================================================
```

- This command configures the switch to shut down when it senses an insufficient fan condition.

```
switch(config)# environment insufficient-fans action shutdown
switch(config)#
```

7.4.3 environment overheat action

The **`environment overheat`** command controls the switch's response to an overheat condition. By default, the switch shuts down when it senses an overheat condition.

Note: Overriding the system shutdown behavior when the system is overheating is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty.

Arista switches include internal temperature sensors. The number and location of the sensors vary with each switch model. Each sensor is assigned temperature thresholds that denote alert and critical conditions. Temperatures that exceed the threshold trigger the following:

- **Alert Threshold**: All fans run at maximum speed, and a warning message is logged.
- **Critical Threshold**: The component is shut down immediately, and its Status LED flashes orange.

In modular systems, cards are shut down when their temperatures exceed the critical threshold. The switch normally shuts down if the temperature remains above the critical threshold for three minutes.

The **`no environment overheat action`**, and **`default environment overheat action`** commands restore the default shutdown response to the environment overheat condition by removing the **`environment overheat action ignore`** statement from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
environment overheat action REMEDY

no environment overheat action

default environment overheat action
```

Parameters

REMEDY Reaction to an overheat condition. The default value is **shutdown**.

- **shutdown** Switch shuts power down by an overheat condition.
- **ignore** Switch continues operating during an overheat condition.

Examples

- This command configures the switch to continue operating after it senses an overheat condition.

```
switch(config)# environment overheat action ignore
================================================================
WARNING: Overriding the system shutdown behavior when the system
is overheating is unsupported and should only be done under
the direction of an Arista Networks engineer. You risk damaging
hardware by not shutting down the system in this situation, and doing
so without direction from Arista Networks can be grounds for voiding
your warranty. To re-enable the shutdown-on-overheat behavior, use
the 'environment overheat action shutdown' command.
================================================================
switch(config)#
```

- This command configures the switch to shut down when it senses an overheat condition.

```
switch(config)# environment overheat action shutdown
switch(config)#
```

7.4.4 locator-led

When a component requires service, the **`locator-led`** command activates a locator to assist a technician in finding the component. The command causes the status LED on the specified component to flash and display a “service requested” message on the LCD panel of modular switches or lights the blue locator light on the front of fixed switches. The available locators vary by platform; to see a list of the locator LEDs available on the switch, use the **`locator-led ?`** command. To trun off the locator LED, use the **`no locator-led`** command.

Command Mode

Privileged EXEC

Command Syntax

`locator-led` {fantray *tray_num* | interface *interface* | module *module_num* | powersupply *supply_num*}

`no locator-led` {fantray *tray_num* | interface *interface* | module *module_num* | powersupply *supply_num*}

Parameters

- **fantray *tray_num*** Activates the locator LED on specified fan tray.
- **interface *interface*** Activates the locator LED on specified interface.
- **module *module_num*** Activates the locator LED on specified module.
- **powersupply *supply_num*** Activates the locator LED on specified power supply.

Examples

- This command enables the locator LED on ***fantray 3***.

```
switch# locator-led fantray 3
Enabling locator led for FanTray3
```

- This command disables the locator LED on ***fantray 3***.

```
switch# no locator-led fantray 3
Disabling locator led for FanTray3
```

- This command displays the locator LEDs available on the switch.

```
switch# locator-led ?
  fantray      Fan tray LED
  interface    Interface LED
  module       Module LED
  powersupply  Power supply LED
```

7.4.5 show environment power

The **`show environment power`** command displays the status of all power supplies in the switch.

Command Mode

EXEC

Command Syntax

`show environment power` [**INFO_LEVEL**]

Parameters

INFO_LEVEL Specifies level of detail that the command displays. Options include:

- **no parameter** Displays current and power levels for each supply.
- **detail** Also includes status codes that can report error conditions.

Example

This command displays the status of power supplies on the switch.

```
switch> show environment power
Power                          Input    Output   Output
Supply  Model      Capacity  Current  Current  Power    Status
------- ---------- --------- -------- -------- -------- -------
1       PWR-760AC  760W       0.81A    11.00A   132.8W   Ok
2       PWR-760AC  760W       0.00A    0.00A    0.0W AC  Loss
```

7.4.6 show environment temperature

The **`show environment temperature`** command displays the operating temperature of all sensors on the switch.

Command Mode

EXEC

Command Syntax

`show environment temperature` [**MODULE_NAME**] [**INFO_LEVEL**]

Parameters

- **MODULE_NAME** Specifies modules for which data is displayed. This parameter is only available on modular switches. Options include:
  - **no parameter** All modules (identical to **all** option).
  - **fabric *fab_num*** Specified fabric module. Number range varies with switch model.
  - **linecard *line_num*** Line card module. Number range varies with switch model.
  - **supervisor *super_num*** Supervisor module. Number range varies with switch model.
  - ***mod_num*** Supervisor (1 to 2) or line card (3 to 18) module.
  - **all** All modules.
- **INFO_LEVEL** Specifies level of detail that the command displays. Options include:
  - **no parameter** Displays table that lists the temperature and thresholds of each sensor.
  - **detail** Displays data block for each sensor listing the current temperature and historic data.

Display Values

System temperature status is the first line that the command displays. Values report the following:

- ***Ok*** All sensors report temperatures below the alert threshold.
- ***Overheating*** At least one sensor reports a temperature above its alert threshold.
- ***Critical*** At least one sensor reports a temperature above its critical threshold.
- ***Unknown*** The switch is initializing.
- ***Sensor Failed*** At least one sensor is not functioning.

Examples

- This command displays a table that lists the temperature measured by each sensor.

```
switch> show environment temperature
System temperature status is: Ok
                                                Alert      Critical
Sensor  Description              Temperature  Threshold  Threshold
------- ------------------------ ------------ ---------- ----------
1       Front-panel temp sensor   30.750C       65C        75C
2       Fan controller 1 sensor   32.000C       75C        85C
3       Fan controller 2 sensor   38.000C       75C        85C
4       Switch chip 1 sensor      50.000C       105C       115C
5       VRM 1 temp sensor         60.000C       105C       110C switch>
```

- This command lists the temperature detected by each sensor and includes the number of previous alerts, the time of the last alert, and the time of the last temperature change.

```
switch> show environment temperature detail
TempSensor1 - Front-panel temp sensor
                      Current State   Count    Last Change
  Temperature         30.750C
  Max Temperature     35.000C                  4 days, 23:35:24 ago
  Alert                False           0        never

TempSensor2 - Fan controller 1 sensor
                      Current State    Count    Last Change
  Temperature          32.000C
  Max Temperature      36.000C                  4 days, 23:32:46 ago
  Alert                 False           0        never

TempSensor3 - Fan controller 2 sensor
                     Current State    Count     Last Change
  Temperature          38.000C
  Max Temperature      41.000C                   4 days, 23:37:56 ago
  Alert                False            0        never

TempSensor4 - Switch chip 1 sensor
                      Current State    Count    Last Change
  Temperature         51.000C
  Max Temperature     53.000C                    4 days, 23:35:16 ago
  Alert               False              0       never

TempSensor5 - VRM 1 temp sensor
                       Current State     Count    Last Change
  Temperature          60.000C
  Max Temperature      62.000C                    4 days, 22:54:51 ago
  Alert                False             0        never
```

7.4.7 show locator-led

The **`show locator-led`** command displays the status of locator LEDs enabled on the switch.

Command Mode

Privileged EXEC

Command Syntax

```
show locator-led
```

Example

This command displays all locator LEDs enabled on the switch.

```
switch# show locator-led
There are no locator LED enabled switch#
```

7.4.8 show system environment all

The **`show system environment all`** command displays temperature, cooling, and power supply status.

Command Mode

EXEC

Command Syntax

```
show system environment all
```

Example

This command displays the switch's temperature, cooling, and power supply status

```
switch> show system environment all
System temperature status is: Ok
                                                 Alert      Critical
Sensor  Description              Temperature  Threshold  Threshold
------- ------------------------ ------------ ---------- ----------
1       Front-panel temp sensor   31.000C       65C        75C
2       Fan controller 1 sensor   32.000C       75C        85C
3       Fan controller 2 sensor   38.000C       75C        85C
4       Switch chip 1 sensor      50.000C       105C       115C
5       VRM 1 temp sensor         60.000C       105C       110C

System cooling status is: Ok
Ambient temperature: 31C
Airflow: port-side-intake
Fan Tray  Status           Speed
--------- ---------------- ------
1         Ok                 52%
2         Ok                 52%
3         Ok                 52%
4         Ok                 52%
5         Ok                 52%

Power                         Input    Output   Output
Supply  Model       Capacity  Current  Current  Power    Status
------- ----------- --------- -------- -------- -------- -------
1       PWR-760AC    760W     0.81A    11.00A    132.6W  Ok
2       PWR-760AC    760W     0.00A     0.00A      0.0W  AC Loss
```

7.4.9 show system environment cooling

The **`show system environment cooling`** command displays fan status, air flow direction, and ambient temperature on the switch.

Command Mode

EXEC

Command Syntax

`show system environment cooling` [**INFO_LEVEL**]

Parameters

- **INFO_LEVEL** Specifies level of detail that the command displays. Options include:
  - **no parameter** Displays the fan status, air flow direction, and ambient switch temperature.
  - **detail** Also displays actual and configured fan speed of each fan.

Status

- System Cooling Status
  - **`Ok`** No more than one fan has failed or is not inserted.
  - **`Insufficient fans`** More than one fan has failed or is not inserted. This status is also displayed if fans with different airflow directions are installed. The switch shuts down if the error is not resolved.
  - **`Ambient temperature`** Temperature of the surrounding area.
  - **`Airflow`** Indicates the direction of the installed fans:
    - **`port-side-intake`** All fans flow air from the front (port side) to the rear of the chassis.
    - **`port-side-exhaust`** All fans flow air from the rear to the front (port side) of the chassis.
    - **`incompatible fans`** Fans with different airflow directions are inserted.
    - **`Unknown`** The switch is initializing.
- **Fan Tray Status** table Displays the status and operating speed of each fan. Status values indicate the following conditions:
  - **`OK`** The fan is operating normally.
  - **`Failed`** The fan is not operating normally.
  - **`Unknown`** The system is initializing.
  - **`Not Inserted`** The system is unable to detect the specified fan.

- **Unsupported** The system detects a fan that the current software version does not support.

Example

This command displays the fan status, air flow direction, and ambient switch temperature.

```
switch> show system environment cooling
System cooling status is: Ok
Ambient temperature: 30C
Airflow: port-side-intake
Fan Tray  Status           Speed
--------- ---------------- ------
1         Ok                 51%
2         Ok                 51%
3         Ok                 51%
4         Ok                 51%
5         Ok 51%
```

7.4.10 show system environment power budget

The **`show system environment power budget`** command displays the configured power budget for PoE switches and a table to show the current consumption.

Command Mode

EXEC

Command Syntax

```
show system environment power budget
```

Example

This command displays the configured power budget for a PoE switch and a table to show the current consumption.

```
switch> show system environment power budget
Budget is 300.0W out of 1425.2W of total power
Active devices using up to 60.0W

Device                  Consumed
Name                    Power
----------------------- -----------------------
Ethernet37              30.0W
Ethernet38              30.0W
Total                   60.0W
```

Chapter 8

Upgrades and Downgrades

This chapter describes the procedures for upgrading or downgrading the switch software.

This chapter contains these sections:

- Upgrade/Downgrade Overview
- Smart System Upgrade
- Standard Upgrades and Downgrades
- Upgrade/Downgrade Commands

8.1 Upgrade/Downgrade Overview

Upgrade or downgrade the Arista Extensible Operating System (EOS) by replacing the EOS image and reloading the switch. It may be possible to minimize (or virtually eliminate) downtime and packet loss during an upgrade, depending on the switch model and the software change. There are two upgrade methods for the EOS:

Smart System Upgrade: SSU significantly decreases downtime and packet loss during upgrades. SSU is available on selected platforms and is ideal for leaf switches and other non-redundant deployments.

Standard Upgrades and Downgrades: In cases where an accelerated upgrade is not needed or an option (such as software downgrades and on unsupported platforms), performing a standard upgrade or downgrade using the steps described here will minimize downtime and packet loss.

Note: To upgrade the software on switches participating in an MLAG, see Upgrading MLAG Peers.

8.2 Smart System Upgrade

Smart System Upgrade (SSU) dramatically speeds up system upgrades and minimizes network disruptions with:

- **Faster Reloads:** SSU streamlines and optimizes the upgrade process, significantly reducing the reload time.

- **Uninterrupted Connections:** Even while the system reboots, SSU keeps your network connections active by sending LACP PDUs. These PDUs are essential signals that maintain port channels, ensuring your devices stay connected.
- **Minimal Traffic Loss:** SSU uses protocols that support "graceful restart," allowing network services to restart without dropping connections, preventing interruptions to your data flow.

Features capable of hitless restart under SSU include:

- QinQ
- 802.3ad Link Aggregation/LACP
- 802.3x Flow Control
- BGP (you must enable BGP graceful restart; refer to Configuring BGP.)
- MP-BGP (you must enable BGP graceful restart; refer to Configuring BGP.)
- 128-way Equal Cost Multipath Routing (ECMP)
- VRF
- Route Maps
- L2 MTU
- MLAG (you must configure reload delay; refer to Configuring MLAG.)
- QoS
- SRv6 uN
- EVPN VXLAN Multi-homing on the DCS-7050SX3 and DCS-7050CX3
  - 900 VTEPs
  - 10,000 MAC addresses where each address maps to an IPv4 and IPv6 address.
  - 500 VLANs
  - 50 IP VRFs

Note:

- If the host scale is greater than 10,000 including remote and local hosts, traffic loss of more than 1 second may occur during SSU.
- When using OSPF as the underlay, the default graceful restart timer leads to higher traffic loss. Set the graceful restart timer to 600 seconds to observe traffic loss in the sub-second time frame during SSU.
- EOS does not support single active configuration.

- Standalone Layer 2 EVPN-VXLAN VTEP with the following scale on 64-bit DCS-7260CX3 and DCS-7060DX5:
  - MAC Addresses up to 230,000 on the 64-bit DCS-7260CX3 platform

- MAC Addresses up to 100,000 entries on the 64-bit DCS-7060DX5 platform

- Standalone VTEP with EVPN-VXLAN IRB with the following scale on 64-bit DCS-7260CX3 and DCS-7060DX5:
  - 230 VTEPs
  - 10,000 MAC addresses where each address maps to IPv4 and IPv6 address.
  - 500 VLANs
  - 50 IP VRFs

  Note:
  - When the host has a scale greater than 10,000 MAC addresses, remote and local, traffic loss of more than one second occurs during the SSU upgrade.
  - When using OSPF as the underlay, using the default graceful restart timer leads to higher traffic loss. Configure the graceful restart time to 600 seconds to obtain a traffic loss in a sub-second time frame.
  - When connecting a VTEP to a remote multi-homing peer or peers, traffic may be impacted towards the multi-homing peer during SSU of the VTEP.

- SSU supports MLAG with EVPN-VXLAN as well as multi-VTEP MLAG mode with the following scale on 64-bit DCS-7260CX3 and DCS-7060DX5:
  - 200 VTEPs
  - 10,000 MAC Addresses mapped to IPv4 and IPv6 addresses.
  - 500 VLANs
  - 50 IP VRFs

  Note:
  - When the host has a scale greater than 10,000 MAC addresses, remote and local, traffic loss of more than one second occurs during the SSU upgrade.
  - When using OSPF as the underlay, using the default graceful restart timer leads to higher traffic loss. Configure the graceful restart time to 600 seconds to obtain a traffic loss in a sub-second time frame.
  - Traffic on directly connected hosts and orphan ports and configured with storm control may lead to traffic loss of seconds during the SSU.

- SSU supports EVPN-VXLAN and IRB, with or without MLAG, configurations with IPv6 underlay on DCS-7050SX3 and DCS-7050CX3 platforms with the following scale:
  - 900 VTEPs
  - 10,000 MAC addresses with each mapped to IPv4 and IPv6 addresses
  - 500 VLANs
  - 50 IP VRFs

Note:

- If the configuration has more than 10,000 MAC addresses, including local and remote, SSU experiences a traffic loss of more than 1 second.
- If configured with OSPF as the underlay, using the default graceful reset timer causes a higher traffic loss. Set the graceful restart time to 600 seconds and the observed traffic loss during SSU is in the subsecond time frame.

Note:

- SSU and VRRP are not compatible. Use a different upgrade method if you have VRRP configured on the switch.
- SSU and Port Security are not compatible on DCS-7060CX series, DCS-7060CX2, and DCS-7260CX3 series switches.

8.2.1 Upgrading the EOS image with Smart System Upgrade

Using SSU to upgrade the active EOS image requires a five-step process:

1. Preparing the Switch for SSU.
2. Transfer the Image File for SSU. Not required if the desired file already exists on the switch
3. Modify boot-config.
4. Start the SSU Process.
5. Verify Success of the Upgrade.

8.2.1.1 Preparing the Switch for SSU

To prepare the switch for SSU, use the following steps:

- Backing Up Critical Software
- Making Room on the Flash Drive
- Verifying Connectivity
- Verifying Configuration
- Configuring BGP
- Configuring MLAG

Note: Configuring BGP graceful restart resets BGP sessions. If configuring BGP graceful restart as part of the SSU process, ensure you have stable BGP sessions and all BGP routing information has been learned and advertised before proceeding with SSU.

Backing Up Critical Software

Before upgrading the EOS image, be sure you have copies of the currently running EOS version and the **running-config** file available in case of corruption during the upgrade process. To copy the **running-config** file, use the **copy running-config** command. In this example, the system copies the **running-config** contents to a file on the switch flash drive.

```
switch# copy running-config flash:/cfg_06162014
Copy completed successfully.
switch#
```

Making Room on the Flash Drive

Determine the size of the new EOS image. Verify enough space exists on the flash drive for two copies of this image, plus a recommended 240MB (if available) for diagnostic information in case of a fatal error. Use the **dir** command to check the `bytes free` figure.

```
switch# dir flash:
Directory of flash:/
-rwx   293168526      Nov 4    22:17   EOS4.11.0.swi
-rwx          36      Nov 8    10:24   boot-config
-rwx       37339      Jun 16   14:18   cfg_06162014
606638080 bytes total (602841088 bytes free)
```

Verifying Connectivity

Ensure the switch has a management interface configured with an IP address and default gateway. See Assigning a Virtual IP Address to Access the Active Ethernet Management Port and Configuring a Default Route to the Gateway. Confirm network connectivity to the switch using the **show interfaces status** command and pinging the default gateway.

```
switch# show interfaces status
Port    Name      Status     Vlan       Duplex   Speed      Type
Et3/1             notconnect   1         auto    auto     1000BASE-T

<-------OUTPUT OMITTED FROM EXAMPLE-------->
Ma1/1             connected   routed     unconf   unconf    Unknown

switch# ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

Verifying Configuration

Verify the switch has a valid configuration for SSU using the `show reload fast-boot` command. If parts of the configuration block SSU execution, an error message displays explaining the issues. For SSU to proceed, correct the configuration conflicts before issuing the `reload fast-boot` command.

```
switch# show reload fast-boot
switch#'reload fast-boot' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports switch#
```

Note: You can still use the **`show reload hitless`** and **`reload hitless`** commands, but they have the same effect as the commands shown earlier.

Configuring BGP

For hitless restart of BGP and MP-BGP, BGP graceful restart must first be enabled using the **`graceful-restart`** command. The default restart time value (***300*** seconds) is appropriate for most configurations.

The BGP configuration mode issuing the **`graceful-restart`** command determines which BGP connections will restart gracefully.

Note: Configuring BGP graceful restart resets BGP sessions. If configuring BGP graceful restart as part of the SSU process, be sure you have stable BGP sessions and all BGP routing information has been learned and advertised before proceeding with SSU.

For all BGP connections, use the **`graceful-restart`** command in BGP configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# graceful-restart
switch(config-router-bgp)#
```

For all BGP connections in a specific VRF, use the **`graceful-restart`** command in BGP VRF configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# vrf purple
switch(config-router-bgp-vrf-purple)# graceful-restart
switch(config-router-bgp-vrf-purple)# exit
switch(config-router-bgp)#
```

For all BGP connections in a specific BGP address family, use the **`graceful-restart`** command in BGP address-family configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# address-family ipv6
```

```
switch(config-router-bgp-af)# graceful-restart
switch(config-router-bgp-af)# exit
switch(config-router-bgp)#
```

Configuring MLAG

> **Note:** For EOS versions earlier than 4.31.2, configure the **`reload-delay`** parameter. For versions 4.31.2 and later, no configuration required.

Before performing a hitless upgrade on switches configured with MLAG, configure the **`reload-delay`** parameter to ***0*** using the following commands:

```
switch(config)# mlag
switch(config-mlag)# reload-delay 0
```

> **Note:** To minimize the traffic disruption during MLAG SSU, all links remain up to let traffic flow during the upgrade process.

If performing the upgrade on the primary MLAG switch, the switch first transitions to the secondary MLAG switch and becomes the primary switch.

All MLAG port channel interfaces with STP enabled shutdown locally on the MLAG peer undergoing the upgrade.

8.2.1.2 Transfer the Image File for SSU

The target image must be copied to the file system on the switch, typically onto the flash drive:

1. Verify that the flash drive has enough space for two copies of the image plus an optional 240MB for diagnostic information.
2. Use the **`copy`** command to copy the image to the flash drive.
3. Confirm that the system transferred the new image file correctly.

The following command examples illustrate transferring an image file from various locations to the flash drive.

USB Memory

Command

`copy usb1:/`***`sourcefile`*** `flash:/`***`destfile`***

Example

```
switch# copy usb1:/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

FTP Server

Command

```
copy ftp:/ftp-source/sourcefile flash:/destfile
```

Example

```
switch# copy ftp:/user:password@10.0.0.3/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

SCP

Command

```
copy scp://scp-source/sourcefile flash:/destfile
```

Example

```
switch# copy scp://user@10.1.1.8/user/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

HTTP

Command

```
copy http://http-source/sourcefile flash:/destfile
```

Example

```
switch# copy http://10.0.0.10/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

After transferring the file, verify that it is present in the directory, then confirm the MD5 checksum using the **verify** command. The MD5 checksum is available from the EOS download page of the Arista website.

```
switch# dir flash:
Directory of flash:/
-rwx     293168526   Nov 4     22:17     EOS4.14.2.swi
-rwx            36   Nov 8     10:24     boot-config
-rwx         37339   Jun 16    14:18     cfg_06162014
-rwx     394559902   May 30    02:57     EOS4.13.1.swi

606638080 bytes total (208281186 bytes free)
switch# verify /md5 flash:EOS-4.14.4.swi
verify /md5 (flash:EOS-4.14.4.swi) =c277a965d0ed48534de6647b12a86991
```

8.2.1.3 Modify boot-config

After transferring and confirming the desired image file, use the **boot system** command to update the **boot-config** file to point to the new EOS image.

This command changes the **boot-config** file to point to the image file located in flash memory at **EOS-4.14.4.swi**.

```
switch# configure terminal
switch(config)# boot system flash:/EOS-4.14.4.swi
```

Use the **show boot-config** command to verify that the **boot-config** file is correct:

```
switch(config)# show boot-config
Software image: flash:/EOS-4.14.4.swi
Console speed: (not set)
Aboot password (encrypted): $1$ap1QMbmz$DTqsFYeauuMSa7/Qxbi2l1
```

Save the configuration to the **startup-config** file with the **write** command.

```
switch# write
```

8.2.1.4 Start the SSU Process

After updating the **boot-config** file, verify that your configuration supports SSU (if you have not already done so) using the **show reload fast-boot** command. If parts of the configuration are blocking SSU execution, an error message will be displayed explaining what they are.

```
switch# show reload fast-boot
switch#'reload fast-boot' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports
```

Start the SSU process using the **reload fast-boot** command to reload the switch and activate the new image. The CLI will identify any changes that must be made to the configuration before starting SSU, prompt the saving of any modifications to the system configuration, and request confirmation before reloading.

```
switch# reload fast-boot
System configuration has been modified. Save? [yes/no/cancel/diff]:y
Copy completed successfully.
Proceed with reload? [confirm]y
```

Note: You can still use the **show reload hitless** and **reload hitless** commands, but they have the same effect as the commands shown earlier.

8.2.1.5 Verify Success of the Upgrade

Before making any configuration changes to the switch after reloading, verify that the SSU process is complete using the command **show boot stages log**. If it is, the last message should be **Hitless boot stages complete**.

```
switch# show boot stages log
Timestamp           Delta Begin Msg
2022-10-03 12:42:06 000.000000 Asu Hitless boot stages started
2022-10-03 12:42:06 000.001592 stage CriticalAgent started
2022-10-03 12:42:06 000.001834   event CriticalAgent:PhyEthtool completed

[ . . . ]

2022-10-03 12:43:02 056.316874 stage BootSanityCheck is complete
2022-10-03 12:43:02 056.317491 Asu Hitless boot stages complete
```

You can also verify the completion of the SSU process by checking the syslog for the following message:

```
LAUNCHER-6-BOOT_STATUS: 'reload fast-boot' reconciliation complete
```

To verify whether the SSU upgrade was successful, use the **show reload cause** command. Suppose a fatal error occurred during the upgrade process. In that case, the switch will have completely rebooted, and the fatal error details will be displayed along with the directory containing the diagnostic information.

If the SSU upgrade has succeeded, it will read **Hitless reload requested by the user.**

Fatal Error Display

```
switch# show reload cause
Reload Cause 1:
-------------------
Fatal error occurred during Asu Hitless boot. (stageMgr - LinkStatusUpdate timed out)

Reload Time:
------------
Reload occurred at Sun Oct 02 12:06:37 2022 PDT.

Recommended Action:
-------------------
The system rebooted due to a fatal error.
If the problem persists, contact your customer support representative.

Debugging Information:
------------------------------
/mnt/flash/persist/fatalError-2022-10-02_120637
```

Successful Upgrade Display

```
switch# show reload cause
Reload Cause 1:
-------------------
```

```
Hitless reload requested by the user.

Reload Time:
------------
Reload occurred at Mon Oct 03 13:29:31 2022 PDT.

Recommended Action:
-------------------
No action necessary.

Debugging Information:
------------------------------
None available.
```

The **show version** command confirms whether the correct image is loaded. The **Software image version:** line displays the version of the active image file.

```
switch# show version
Arista DCS-7050QX-32-F
Hardware version: 02.00
Serial number: JPE14071098
System MAC address: 001c.7355.556f
Software image version: 4.14.5F-2353054.EOS4145F
Architecture: i386
Internal build version: 4.14.5F-2353054.EOS4145F
Internal build ID: e8748ea7-916d-4217-878f-4bfe2adc7122
Uptime: 4 minutes
Total memory: 3981328 kB
Free memory: 1342408 kB
```

Note: If a fatal error occurs during the SSU process, the new EOS image will still be loaded and booted.

8.2.2 Scheduling an SSU

SSU supports scheduling an upgrade with the **reload fast-boot in** command. If the switch has unsaved configuration changes, or saved configuration changes that block an SSU upgrade, the scheduled reload stops at the scheduled time.

Configuring a Scheduled SSU Upgrade

Use the **reload fast-boot in** command to schedule the upgrade at a specific time. The switch detects any unsaved configuration and prompts you to save the changes first. Replying *no* exits the command and the scheduled upgrade does not proceed.

```
switch# reload fast-boot in 10:00
System configuration has been modified. Save? [yes/no/cancel/diff]:yes
Copy completed successfully.
Proceed with reload? [confirm]y
Reload scheduled for Mon Jan 20 19:31:09 2025 (in 9 hours 59 minutes)
No warnings or unsupported configuration found.
```

Specify the time to reboot in hours, for example, 10:00, as shown in the example.

Override the confirmation prompt by adding the optional parameter **`force`** and specify a reason using the **`reason`**.

```
switch# reload fast-boot in 10:00 force reason scheduled maintenance
Copy completed successfully.
Reload scheduled for Mon Jun 17 19:38:12 2024 (in 9 hours 59 minutes)
Reload reason: scheduled maintenance
No warnings or unsupported configuration found.
```

Note: EOS supports only one pending scheduled SSU, either normal or scheduled, at a time. To schedule a new SSU, cancel the existing scheduled SSU.

Canceling a Scheduled SSU

To cancel a scheduled SSU reload, use the **`reload cancel`** command:

```
switch# reload cancel
Scheduled reload has been canceled.
```

Displaying Scheduled SSU Information

Use the following command to display information about scheduled SSU configurations:

```
switch# show reload fast-boot
Reload scheduled for Mon Jan 20 19:31:09 2025 (in 9 hours 59 minutes)
Reload reason: scheduled maintenance
No warnings or unsupported configuration found.
```

If no scheduled reload exists on the switch, the command returns the following output:

```
switch# show reload fast-boot
No reload is scheduled
No warnings or unsupported configuration found.
```

8.3 Standard Upgrades and Downgrades

Standard software upgrades and downgrades on Arista switches are accomplished by installing a different EOS image and reloading the switch. On switches with redundant supervisors, you must install the EOS image on both supervisors. Using the following procedures will minimize packet loss during a standard upgrade or downgrade.

These sections describe standard switch upgrade and downgrade procedures:

- Upgrading or Downgrading the EOS on a Single-Supervisor Switch
- Upgrading or Downgrading the EOS on a Dual-Supervisor Switch

8.3.1 Upgrading or Downgrading the EOS on a Single-Supervisor Switch

Modifying the active EOS image is a five-step process:

1. Prepare the switch for upgrade (Prepare the Switch for SSU).
2. Transfer the image file to the switch (Transfer the Image File). (This is not required if the desired file is on the switch).
3. Modify the **boot-config** file to point to the desired image file (Modify boot-config for Single-Supervisor Switch).
4. Reload the switch (Reload).
5. Verify the switch is running the new image (Verify the New Image for Single-Supervisor Switch).

8.3.1.1 Preparing the Switch for SSU

To prepare the switch for SSU, use the following steps:

- Backing Up Critical Software
- Making Room on the Flash Drive
- Verifying Connectivity
- Verifying Configuration
- Configuring BGP
- Configuring MLAG

Note: Configuring BGP graceful restart resets BGP sessions. If configuring BGP graceful restart as part of the SSU process, ensure you have stable BGP sessions and all BGP routing information has been learned and advertised before proceeding with SSU.

Backing Up Critical Software

Before upgrading the EOS image, be sure you have copies of the currently running EOS version and the **running-config** file available in case of corruption during the upgrade process. To copy the **running-config** file, use the **copy running-config** command. In this example, the system copies the **running-config** contents to a file on the switch flash drive.

```
switch# copy running-config flash:/cfg_06162014
Copy completed successfully.
switch#
```

Making Room on the Flash Drive

Determine the size of the new EOS image. Verify enough space exists on the flash drive for two copies of this image, plus a recommended 240MB (if available) for diagnostic information in case of a fatal error. Use the **dir** command to check the `bytes free` figure.

```
switch# dir flash:
Directory of flash:/
-rwx   293168526      Nov 4    22:17   EOS4.11.0.swi
-rwx          36      Nov 8    10:24   boot-config
-rwx       37339      Jun 16   14:18   cfg_06162014
606638080 bytes total (602841088 bytes free)
```

Verifying Connectivity

Ensure the switch has a management interface configured with an IP address and default gateway. See Assigning a Virtual IP Address to Access the Active Ethernet Management Port and Configuring a Default Route to the Gateway. Confirm network connectivity to the switch using the **show interfaces status** command and pinging the default gateway.

```
switch# show interfaces status
Port    Name     Status     Vlan       Duplex   Speed      Type
Et3/1            notconnect   1         auto    auto     1000BASE-T

<-------OUTPUT OMITTED FROM EXAMPLE-------->
Ma1/1            connected   routed     unconf   unconf    Unknown

switch# ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

Verifying Configuration

Verify the switch has a valid configuration for SSU using the `show reload fast-boot` command. If parts of the configuration block SSU execution, an error message displays explaining the issues. For SSU to proceed, correct the configuration conflicts before issuing the `reload fast-boot` command.

```
switch# show reload fast-boot
switch#'reload fast-boot' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports switch#
```

Note: You can still use the **show reload hitless** and **reload hitless** commands, but they have the same effect as the commands shown earlier.

Configuring BGP

For hitless restart of BGP and MP-BGP, BGP graceful restart must first be enabled using the **graceful-restart** command. The default restart time value (***300*** seconds) is appropriate for most configurations.

The BGP configuration mode issuing the **graceful-restart** command determines which BGP connections will restart gracefully.

Note: Configuring BGP graceful restart resets BGP sessions. If configuring BGP graceful restart as part of the SSU process, be sure you have stable BGP sessions and all BGP routing information has been learned and advertised before proceeding with SSU.

For all BGP connections, use the **graceful-restart** command in BGP configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# graceful-restart
switch(config-router-bgp)#
```

For all BGP connections in a specific VRF, use the **graceful-restart** command in BGP VRF configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# vrf purple
switch(config-router-bgp-vrf-purple)# graceful-restart
switch(config-router-bgp-vrf-purple)# exit
switch(config-router-bgp)#
```

For all BGP connections in a specific BGP address family, use the **graceful-restart** command in BGP address-family configuration mode:

```
switch# config
switch(config)# router bgp 64496
switch(config-router-bgp)# address-family ipv6
switch(config-router-bgp-af)# graceful-restart
switch(config-router-bgp-af)# exit
switch(config-router-bgp)#
```

Configuring MLAG

Note: For EOS versions earlier than 4.31.2, configure the **reload-delay** parameter. For versions 4.31.2 and later, no configuration required.

Before performing a hitless upgrade on switches configured with MLAG, configure the **reload-delay** parameter to ***0*** using the following commands:

```
switch(config)# mlag
switch(config-mlag)# reload-delay 0
```

Note: To minimize the traffic disruption during MLAG SSU, all links remain up to let traffic flow during the upgrade process.

If performing the upgrade on the primary MLAG switch, the switch first transitions to the secondary MLAG switch and becomes the primary switch.

All MLAG port channel interfaces with STP enabled shutdown locally on the MLAG peer undergoing the upgrade.

8.3.1.2 Transfer the Image File

The target image must be copied to the file system on the switch, typically onto the flash drive. After verifying that there is space for the image, use the CLI **copy** command to copy the image to the flash drive, then confirm that the system transferred the new image file correctly.

The following command examples illustrate transferring an image file from various locations to the flash drive.

USB Memory

Command

```
copy usb1:/sourcefile flash:/destfile
```

Example

```
switch# copy usb1:/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

FTP Server

Command

```
copy ftp:/ftp-source/sourcefile flash:/destfile
```

Example

```
switch# copy ftp:/user:password@10.0.0.3/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

SCP

Command

```
copy scp://scp-source/sourcefile flash:/destfile
```

Example

```
switch# copy scp://user@10.1.1.8/user/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

HTTP

Command

```
copy http://http-source/sourcefile flash:/destfile
```

Example

```
switch# copy http://10.0.0.10/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

After transferring the file, verify that it is present in the directory, then confirm the MD5 checksum using the **verify** command. The MD5 checksum is available from the EOS download page of the Arista website.

```
switch# dir flash:
Directory of flash:/
-rwx     293168526   Nov 4     22:17     EOS4.11.0.swi
-rwx            36   Nov 8     10:24     boot-config
-rwx         37339   Jun 16    14:18     cfg_06162014
-rwx     394559902   May 30    02:57     EOS-4.12.2.swi

606638080 bytes total (208281186 bytes free)
switch#53# verify /md5 flash:EOS-4.13.2.swi
verify /md5 (flash:EOS-4.13.2.swi) =c277a965d0ed48534de6647b12a86991
```

8.3.1.3 Modify boot-config for Single-Supervisor Switch

After transferring and confirming the desired image file, use the **boot system** command to update the **boot-config** file to point to the new EOS image.

This command changes the **boot-config** file to point to the image file located in flash memory at **EOS-4.12.2.swi**.

```
switch# configure terminal
switch(config)# boot system flash:/EOS-4.13.2.swi
```

Use the **show boot-config** command to verify that the **boot-config** file is correct:

```
switch(config)# show boot-config
Software image: flash:/EOS-4.13.2.swi
Console speed: (not set)
Aboot password (encrypted): $1$ap1QMbmz$DTqsFYeauuMSa7/Qxbi2l1
```

Save the configuration to the **startup-config** file with the **write** command.

```
switch# write
```

8.3.1.4 Reload

After updating the **boot-config** file, reset the switch to activate the new image. The **reload** command resets the switch, resulting in temporary downtime and packet loss on single supervisor switches.

The terminal displays all rebooting messages when reloading from the console port. From any port except the console, the CLI displays this text:

```
switch# reload
The system is going down for reboot NOW!
```

Note: The EOS boot process makes a copy of the **.swi** image file in the internal flash while booting, so sufficient space for ***two copies*** must be present when loading the new EOS image. If the switch reloads without adequate space on the flash drive, it boots to the Aboot prompt from which you can delete files from **/mnt/flash** to free up additional space. Exiting Aboot begins the boot process again.

8.3.1.5 Verify the New Image for Single-Supervisor Switch

After the switch finishes reloading, log into the switch and use the **show version** command to confirm the correct image is loaded. The **Software image version** line displays the version of the active image file.

```
switch# show version
Arista DCS-7150S-64-CL-F
Hardware version:    01.01
Serial number:       JPE13120819
System MAC address:  001c.7326.fd0c

Software image version: 4.13.2F
Architecture:           i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                 14 hours and 48 minutes
Total memory:           4017088 kB
Free memory:            1569760 kB
```

8.3.2 Upgrading or Downgrading the EOS on a Dual-Supervisor Switch

Modifying the active EOS image is a four-step process:

1. Prepare the switch for upgrade (Prepare the Switch for Dual-Supervisor Switch).
2. Transfer the image file to the primary supervisor (Transfer the Image File to the Primary Supervisor). (This is not required if the desired file is on the switch).
3. Use the **install** command to install the new EOS image and update **boot-config** (Install the New EOS Image).

4. Verify the switch is running the new image (Verify the New Image).

Note: Due to a change in the supervisor heartbeat timeout, booting one supervisor with a post-SSO image (version ***4.10.0-SSO***, ***4.11.X*** and later) while the other supervisor is running a pre-SSO image will cause the supervisor running the pre-SSO image to reload. This causes a disruption as both supervisors are inactive for a short time. To minimize downtime, upgrade the images on both supervisors and reload the entire chassis using the **install** command.

8.3.2.1 Prepare the Switch for Dual-Supervisor Switch

To prepare the switch for an EOS upgrade, take the following steps:

- Back up all essential files.
- Address and ensure the following:
  - You are logged in to the primary supervisor.
  - Confirm that the primary supervisor is reachable and that the management interfaces are configured.
  - There is enough room on both supervisors for the new image file.
  - Any extensions running on the active supervisor are also available on the standby.

Before upgrading the EOS image, ensure that backup copies of the currently running EOS version and the **running-config** file are available in case of corruption during the upgrade process. To copy the **running-config** file, use the **copy running-config** command. In the following example, the **running-config** file is copied to a file called **backup2** on the flash drive.

```
switch# copy running-config backup2
Copy completed successfully.
switch#
```

Be sure you log into the primary supervisor, not the standby. Use the **show redundancy status** command, and verify that **my status** reads **ACTIVE** and not **STANDBY**.

```
switch# show redundancy status
my status = Active
peer state = STANDBY HOT
Unit = Secondary
Unit ID = 1
Redundancy Protocol (Operational) = Stateful Switchover
Redundancy Protocol (Configured) = Stateful Switchover
Communications = Up
Ready for switchover
Last switchover time = 25 days, 19:51:34 ago
Last switchover reason = Other supervisor stopped sending heartbeats
```

Be sure the switch has a management interface configured with an IP address and default gateway. Refer to the sections Assigning a Virtual IP Address to Access the Active Ethernet Management Port and Configuring a Default Route to the Gateway, and confirm that both management interfaces have an Up state and can ping the default gateway by using the **`show interfaces status`** command and **`ping`** command.

Note: If the management VRF interface is used, use the virtual management interface (management 0) instead of the IP address on the physical management interface.

```
switch# show interfaces status
Port    Name      Status      Vlan       Duplex   Speed      Type
Et3/1             notconnect   1          auto    auto     1000BASE-T

<-------OUTPUT OMITTED FROM EXAMPLE-------->
Ma1/1             connected   routed     unconf   unconf    Unknown

switch# ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

Determine the size of the new EOS image. Then verify that there is enough space available on the flash drive for two copies of this image (use the **`dir`** command to check the bytes free figure).

```
switch# dir flash:
Directory of flash:/
-rwx   293168526      Nov 4    22:17   EOS4.11.0.swi
-rwx          36      Nov 8    10:24   boot-config
-rwx       37339      Jun 16   14:18   cfg_06162014
<-------OUTPUT OMITTED FROM EXAMPLE-------->
606638080 bytes total (602841088 bytes free)
Standby supervisor:
switch# dir supervisor-peer:mnt/flash/
Directory of flash:/
-rwx 293168526 Nov 4 22:17 EOS4.11.0.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014
<-------OUTPUT OMITTED FROM EXAMPLE-------->
606638080 bytes total (602841088 bytes free)
```

Finally, ensure that any extensions running on the primary supervisor are also available on the secondary supervisor.

8.3.2.2 Transfer the Image File to the Primary Supervisor

Load the desired image to the file system on the primary supervisor, typically into the flash. Use the CLI **`copy`** command to load files to the flash on the primary supervisor, then confirm that the system transferred the new image file correctly.

The following command examples illustrate transferring an image file from various locations to the flash drive.

USB Memory

Command

```
copy usb1:/sourcefile flash:/destfile
```

Example

```
switch# copy usb1:/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

FTP Server

Command

```
copy ftp:/ftp-source/sourcefile flash:/destfile
```

Example

```
switch# copy ftp:/user:password@10.0.0.3/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

SCP

Command

```
copy scp://scp-source/sourcefile flash:/destfile
```

Example

```
switch# copy scp://user@10.1.1.8/user/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

HTTP

Command

```
copy http://http-source/sourcefile flash:/destfile
```

Example

```
switch# copy http://10.0.0.10/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

After transferring the file, verify that it is present in the directory, then confirm the MD5 checksum using the **`verify`** command. The MD5 checksum for each available image can be found on the EOS download page of the Arista website.

```
switch# dir flash:
Directory of flash:/
-rwx      293168526     Nov 4    22:17     EOS4.11.0.swi
-rwx             36     Nov 8    10:24     boot-config
-rwx          37339     Jun 16   14:18     cfg_06162014
-rwx      394559902     May 30   02:57     EOS-4.12.2.swi

<-------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (208281186 bytes free)
switch#53# verify /md5 flash:EOS-4.13.2.swi
verify /md5 (flash:EOS-4.13.2.swi) =c277a965d0ed48534de6647b12a86991
```

8.3.2.3 Install the New EOS Image

After the EOS image has been copied to the primary supervisor's flash drive, use the **install** command to update the ***boot-config***, copy the new image to the secondary supervisor, and reload both supervisors. Both supervisors will briefly be unavailable when upgrading to a new image; using the **`install`** command minimizes packet loss during reload.

```
switch(config)# install source EOS-4.13.2.swi reload
Preparing new boot-config... done.
Copying new software image to standby supervisor... done.
Copying new boot-config to standby supervisor... done.
Committing changes on standby supervisor... done.
Reloading standby supervisor... done.
Committing changes on this supervisor... done.
Reloading this supervisor...
```

8.3.2.4 Verify the New Image

After the switch finishes reloading, log in to the switch and use the **`show version`** command to confirm the correct image is loaded. The **`Software image version`** line displays the version of the active image file.

```
switch# show version
Arista DCS-7504
Hardware version:    01.01
Serial number:       JPE13120819
System MAC address:  001c.7326.fd0c

Software image version: 4.13.2F
Architecture:           i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                 1 hour and 36 minutes
Total memory:           4017088 kB
Free memory:            1473280 kB switch#
```

8.4 Upgrade/Downgrade Commands

- install
- reload fast-boot
- reload hitless

8.4.1 install

The **`install`** command copies the specified EOS image onto the switch if the source is external, configures the ***boot-config*** file to point to the specified EOS image, copies the image to the standby supervisor on dual-supervisor switches, and optionally reloads the switch to run the new EOS.

Command Mode

Privileged EXEC

Command Syntax

`install source` ***source_path*** **[destination** ***destination_path*****][now][reload]**

Parameters

- ***source_path*** - Specify the file path and name of EOS image. If no file path specified, the switch looks for the image on the flash drive of the primary supervisor.
- **destination** ***destination_path*** - Specify the destination file path and name of the EOS image. If no destination or name specified, the EOS image stores on the flash drive with its original file name.
- **now** - Specify to execute the command immediately without further prompts.
- **reload** - Reload the supervisor after installing the image and updated ***boot-config*** file. On dual-supervisor switches, reloads both supervisors, after which control returns to the primary supervisor.

Example

This command updates the ***boot-config*** file to point to the **`EOS.swi`** file on the primary supervisors flash drive, copies the image and ***boot-config*** file to the secondary supervisor, and reboots both.

```
switch(config)# install source EOS.swi reload
Preparing new boot-config... done.
Copying new software image to standby supervisor... done.
Copying new boot-config to standby supervisor... done.
Committing changes on standby supervisor... done.
Reloading standby supervisor... done.
Committing changes on this supervisor... done.
Reloading this supervisor...
```

8.4.2 reload fast-boot

Smart System Upgrade (SSU) allows critical switches to be upgraded with minimal downtime and packet loss by optimizing the reload procedure and leveraging protocols capable of graceful restart. The **reload fast-boot** command starts the SSU process using the EOS image specified by the ***boot-config*** file configured by the **boot system** command.

When entering the **reload fast-boot** command, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, then asks the user to confirm the reload request.

Command Mode

Privileged EXEC

Command Syntax

reload fast-boot

Guidelines

- SSU supports upgrades and not downgrades.
- EOS does not support SSU if the EOS upgrade requires an FPGA upgrade.
- Enough free space must be available on the flash drive to store two copies of the target EOS image. Arista also recommends that an additional 240MB be available to store diagnostic information.

Examples

- Use the following command to start the Smart Software Upgrade process.

```
switch# reload fast-boot
Proceed with reload? [confirm]
```

- If the current switch configuration has issues that prevent SSU from performing, the switch lists the changes that must be made before SSU can begin..

```
switch# reload fast-boot
switch#'reload fast-boot' cannot proceed due to the following:
Spanning-tree portfast is not enabled for one or more ports
Spanning-tree BPDU guard is not enabled for one or more ports
```

- After entering the **reload fast-boot** command, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, then asks the user to confirm the reload request.

```
switch# reload fast-boot
System configuration has been modified. Save? [yes/no/cancel/diff]:y
```

```
Copy completed successfully.
Proceed with reload? [confirm]y
```

8.4.3 reload hitless

The **reload hitless** command is a legacy command now identical to the **reload fast-boot** command. It starts the Smart System Upgrade (SSU) process using the EOS image specified by the ***boot-config*** file configured by the using the boot system command.

Command Mode

Privileged EXEC

Command Syntax

reload hitless

Examples

- This command starts the SSU process.

```
switch# reload hitless
Proceed with reload? [confirm]
```

- If the current switch configuration has issues that prevent SSU from performing, the switch lists the changes that must be made before SSU can begin.

```
switch# reload hitless
switch#'reload hitless' cannot proceed due to the following:
Spanning-tree portfast is not enabled for one or more ports
Spanning-tree BPDU guard is not enabled for one or more ports
```

- When you enter the **reload hitless** command, the switch returns a message prompting to save the configuration if it contains unsaved modifications, then asks you to confirm the reload request.

```
switch# reload hitless
System configuration has been modified. Save? [yes/no/cancel/diff]:y
Copy completed successfully.
Proceed with reload? [confirm]y
```

Chapter 9

Security

The Security chapter contains the following sections:

- User Security
- Control Plane Security
- Data Plane Security

9.1 User Security

This section covers the following:

- AAA Configuration

9.1.1 AAA Configuration

This section describes Authentication, Authorization, and Accounting (AAA), and contains these topics:

- Authentication, Authorization, and Accounting Overview
- Configuring the Security Services
- Server Groups
- Role-Based Authorization
- AAA and X.509 Authentication
- Activating Security Services
- TACACS+ Configuration Examples
- AAA Accounting for OpenConfig Remote Procedure Call (RPC) Messages Overview
- AAA Commands

9.1.1.1 Authentication, Authorization, and Accounting Overview

This section contains the following topics:

- Methods
- Configuration Statements
- Encryption

9.1.1.1.1 Methods

The switch authenticates user identity and verifies user authorization to control access to EOS commands. Three data services conduct authentication, authorization, and accounting (AAA) activities: a local security database, TACACS+ servers, and RADIUS servers.

The Configuring the Security Services section provides details about these services.

9.1.1.1.2 Configuration Statements

Enabling AAA on the switch requires two steps:

1. Configure security service parameters.

   The switch provides configuration commands for each security service:

   - A local file supports authentication through **username** and enable password commands.
     - TACACS+ servers provide security services through **`tacacs-server`** commands.
     - RADIUS servers provide security services through **`radius-server`** commands.
   - The Configuring the Security Services section describes the configuration commands for each security service.

2. Activate AAA services.

   EOS uses **`aaa authorization`**, **`aaa authentication`**, and **`aaa accounting`** commands to manage the primary and backup services. The Activating Security Services section provides details on implementing a security environment.

9.1.1.1.3 Encryption

The switch uses clear-text passwords and server access keys to authenticate users and communicate with security systems. To safeguard against accidental disclosure of passwords and keys, **`running-config`** stores encrypted versions of these passwords and keys. The encryption method depends on the type of password or key.

Commands used to configure passwords or keys can accept either the clear-text password or an encrypted string generated by the designated encryption algorithm, using the clear-text password as the basis (seed) for encryption.

9.1.1.2 Configuring the Security Services

The switch can access three security data services to authenticate users and authorize switch tasks: a local file, TACACS+ servers, and RADIUS Servers.

This section contains the following topics:

- Local Security File
- TACACS+

- RADIUS
- AAA with LDAP

9.1.1.2.1 Local Security File

The local file uses passwords to:

- Authenticate users logging into the switch.
- Control access to configuration commands.
- Control access to the switch's root login.

The local file stores username-password combinations for user authentication. Passwords also control access to configuration commands and the switch's root login.

9.1.1.2.1.1 Passwords

The switch recognizes both clear text and encrypted strings as valid passwords.

- **Clear-text passwords** are the text you directly enter to access the CLI, configuration commands, or the switch's root login.
- **Encrypted strings** are SHA-512-encrypted strings generated using the clear text as the seed. The local file stores passwords in this format to prevent unauthorized disclosure. When you enter a clear-text password, the switch generates the corresponding secure hash and compares it to the stored version.

Note: The switch cannot decrypt the encrypted string to recover the original clear text.

Valid passwords can include characters A-Z, a-z, 0-9, and any of the following punctuation characters:

```
! @ # $ % ^ & * ( ) - _ = + { } [ ] ; : < > , . ? / ~ \
```

Note: To use a question mark **(?)** in a password within the CLI, you must first press **Ctrl + V** simultaneously. This is necessary to escape the CLI's normal behavior, which interprets **?** as a request to display the next available command options.

9.1.1.2.1.2 Usernames

Usernames govern access to the EOS and all switch commands. You typically access the switch through an SSH login using a previously defined username and password. Use the username command to create a new username or change an existing one.

Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:

@ # $ % ^ & * - _ = + ; < > , . ~ |

The default username is **admin**, which the section on Admin Username explains.

Examples

- These commands both create the username ***john*** and assign it the password ***x245***. The password is entered in clear text because the ***encrypt-type*** parameter is omitted or zero.

```
switch(config)# username john secret x245
switch(config)# username john secret 0 x245
```

- This command creates the username ***john*** and assigns it to the text password corresponding to the encrypted string ***1sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1***. An MD5 encryption program generated this string using ***x245*** as the seed.

```
switch(config)# username john secret 5 $1$sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1
```

The CLI will prompt for a password; enter ***x245*** to authenticate the username.

- This command creates the username ***jane*** without a password. It also removes a password if the ***jane*** username exists.

```
switch(config)# username jane nopassword
```

- This command removes the username ***william*** from the local file.

```
switch(config)# no username william
```

9.1.1.2.1.3 Logins by Unprotected Usernames

The default switch configuration allows usernames that are not password-protected to log in only from the console. The **aaa authentication policy local allow-nopassword-remote-login** command configures the switch to allow unprotected usernames to log in from any port. To reverse this setting to the default state, use the **no** form of **aaa authentication policy local allow-nopassword-remote-login**.

Note: Allowing remote access to accounts without passwords is a severe security risk. Arista Networks recommends assigning strong passwords to all usernames.

Examples

- This command configures the switch to allow unprotected usernames to log in from any port.

```
switch(config)# aaa authentication policy local allow-nopassword-remote-login
```

- This command configures the switch to allow unprotected usernames to log in only from the console port.

```
switch(config)# no aaa authentication policy local allow-nopassword-remote-login
```

9.1.1.2.1.4 *Enable Command Authorization*

The **enable** command controls access to Privileged EXEC and all configuration command modes. The enable password authorizes users to execute the **enable** command. When the enable password is set, the CLI displays a password prompt when a user attempts to enter ***Privileged EXEC*** mode.

```
main-host> enable
Password:
main-host#
```

If an incorrect password is entered three times in a row, the CLI displays the EXEC mode prompt.

If no enable password is set, the CLI does not prompt for a password when a user attempts to enter ***Privileged EXEC*** mode.

To set the enable password, use the enable password command.

Examples

- These equivalent commands assign ***xyrt1*** as the enable password.

```
switch(config)# enable password xyrt1
switch(config)# enable password 0 xyrt1
```

- This command assigns the enable password to the clear text ***12345*** corresponding to the encrypted string ***$1$8bPBrJnd$Z8wbKLHpJEd7d4tc5Z/6h/***. An MD5 encryption program generated the string using ***12345*** as the seed.

```
switch(config)# enable password 5 $1$8bPBrJnd$Z8wbKLHpJEd7d4tc5Z/6h/
```

- This command deletes the enable password.

```
switch(config)# no enable password
```

9.1.1.2.1.5 *Root Account Password*

The root account accesses the root directory in the underlying Linux shell. When it is not password protected, you can log into the root account only through the console port. After you assign a password to the root account, you can log in through any port.

To set the password for the root account, use the **aaa root** command.

Examples

- These equivalent commands assign ***f4980*** as the root account password.

```
switch(config)# aaa root secret f4980
switch(config)# aaa root secret 0 f4980
```

- This command assigns the text ***ab234*** corresponding to the encrypted string ***1HW05LEY8$QEVw6JqjD9VqDfh.O8r.b***. as the root password.

```
switch(config)# aaa root secret 5 $1$HW05LEY8$QEVw6JqjD9VqDfh.O8r.b
```

- This command removes the password from the root account.

```
switch(config)# aaa root nopassword
```

- This command disables the root login.

```
switch(config)# no aaa root
```

9.1.1.2.2 RADIUS

Remote Authentication Dial-In User Service (RADIUS) consists of a networking protocol that provides centralized AAA services for computers connecting to a network and then using network resources. RADIUS manages access to the Internet, internal networks, wireless networks, and integrated email services.

These sections describe the steps to configure access to RADIUS servers. Before configuring switch parameters, confirm your RADIUS server functionality.

9.1.1.2.2.1 RADIUS Vendor-Specific Attribute-Value Pairs

RADIUS servers and client companies extend basic RADIUS functionality through vendor-specific attributes. A dictionary file includes a list of RADIUS attribute-value pairs that Arista switches use to perform AAA operations through the RADIUS server.

Arista switches use the following attribute values:

- Arista Vendor number: ***30065***
- Attribute: Arista-AVPair 1 string

Acceptable string values for Arista-AVPair include:

- **shell:priv-lvl=<privilege level of a user, 0-15>**
- **shell:roles=<list of roles for a user>**

Example

A dictionary file that identifies Arista RADIUS vendor-specific attribute value pairs may look similar to the following example:

```
#
# dictionary.arista
#
VENDOR          Arista    30065
#   Standard Attribute
BEGIN-VENDOR    Arista
ATTRIBUTE       Arista-AVPair    1    string
END-VENDOR      Arista
```

9.1.1.2.2.2 Configuring RADIUS Defaults

RADIUS policies specify the settings the switch uses to communicate with RADIUS servers. Configure a set of values for each RADIUS server that the switch accesses. Global parameters define settings for communicating with servers without configured individual parameters.

The switch defines the following RADIUS parameters.

Encryption Key

The encryption key, shared between the switch and RADIUS servers, enables secure communication.

- The **radius-server host** command defines the encryption key for a specified server.
- The **radius-server key** command specifies the global encryption key.

Examples

- Configure the switch to communicate with the RADIUS server assigned the host name ***RAD-1*** using the encryption key ***rp31E2v***.

  ```
  switch(config)# radius-server host RAD-1 key rp31E2v
  ```

  Configure ***cv90jr1*** as the global encryption key.

  ```
  switch(config)# radius-server key 0 cv90jr1
  ```

- Assign ***cv90jr1*** as the key by specifying the corresponding encrypted string.

  ```
  switch(config)# radius-server key 7 020512025B0C1D70
  ```

Timeout

Timeout is the duration the switch waits for a successful connection to, or response from, a RADIUS server. The default value is ***5*** seconds.

- The **radius-server host** command defines the timeout for a specified server.
- The **radius-server key** command defines the global timeout.

Examples

- Use the following command to configure the switch to communicate with the RADIUS server assigned the host name ***RAD-1*** and configures the timeout duration as ***20*** seconds.

```
switch(config)# radius-server host RAD-1 timeout 20
```

- Use the following command to configure ***50*** seconds as the duration the server waits for a response from a RADIUS server before issuing an error.

```
switch(config)# radius-server timeout 50
```

Retransmit

Retransmit is the number of times the switch attempts to access the RADIUS server after the first server timeout expires. The default value is ***3*** times.

- The **radius-server host** command defines the retransmit for a specified server.
- The **radius-server retransmit** command defines the global retransmit value.

Examples

- Use the following command to configure the switch to communicate with the RADIUS server assigned the host name ***RAD-1*** and configures the retransmit value as ***2***.

```
switch(config)# radius-server host RAD-1 retransmit 2
```

- Use the following command to configure the switch to attempt five RADIUS server contacts after the initial timeout. If the timeout parameter is set to ***50*** seconds, then the total period the switch waits for a response is ((5+1)*50) = ***300*** seconds.

```
switch(config)# radius-server retransmit 5
```

Deadtime

Deadtime consists of the time period when the switch ignores a non-responsive RADIUS server or a server that does not answer retransmit attempts after timeout expiration. If no value specified, deadtime becomes disabled.

- The **radius-server host** command defines the deadtime for a specified server.
- The **radius-server deadtime** command defines the global deadtime setting.

Examples

- Use the following command to configure the switch to communicate with the RADIUS server assigned the host name ***RAD-1*** and configures the deadtime period as ***90*** minutes.

```
switch(config)# radius-server host RAD-1 deadtime 90
```

- Use the following command to configure the switch to ignore a server for two hours if the server does not respond to a request during the timeout-retransmit period.

```
switch(config)# radius-server deadtime 120
```

Port

The port specifies the port number through which the switch and servers send information.

- The **radius-server host** command specifies the port numbers for an individual RADIUS server.
- The global RADIUS port numbers cannot be changed from the default values of ***1812*** for an authorization port and ***1813*** for an accounting port.

Example

These commands configure the switch to communicate with the RADIUS server named ***RAD-1*** through port number ***1850*** for authorization and port number ***1851*** for accounting.

```
switch(config)# radius-server host RAD-1 auth-port 1850
switch(config)# radius-server host RAD-1 acct-port 1851
```

To remove the configuration for this server, use the **no radius-server host** command and specify the hostname or IP address with both the authorization and accounting port numbers.

MTU

Adjust the MTU of RADIUS requests for 802.1x supplicants using EAP TLS authentication. Adjusting the size may be useful where the hops between the switches and the RADIUS server do not support IP MTU discovery and the switch sends Access Requests based on the interface MTU size. Configuring this feature allows you to select an MTU size compatible with the topology and forces the Dot1x agent to send Access Requests with the configured MTU.

Use the following commands to set the MTU size to 1500 bytes:

```
switch(config)# dot1x
switch(config-dot1x)# radius mtu 1500
switch(config-dot1x)
```

VLANs

EOS supports the inclusion of VLAN information in RADIUS Access-Requests and Accounting-Requests sent to the AAA server, and assists the server with profiling devices and assigning them to the correct VLANs after successful authentication. EOS sends the information in two ways:

- A new Arista VSA, **Arista-Config-Vlan**, with attribute ID 22, that contains the configured VLAN and sent only in the Access-Request.
- The standard RADIUS attribute, **Tunnel-Private-Group-ID**, sent in both Access-Requests and Accounting-Requests with the Tunnel-Type and Tunnel-Medium-Type attributes.

Values Sent in Tunnel-Private-Group-Id

The **Tunnel-Private-Group-Id** attribute in the Accounting-Request always contains the VLAN of the supplicant. The behavior of the **Tunnel-Private-Group-Id** attribute in the Access-Request depends on the current state of the port and the supplicant type.

Unauthorized Port

When a port has an unauthorized state with no authenticated devices, the Access-Request contains the following VLAN information in the behavior of the **Tunnel-Private-Group-Id** attribute:

- **Untagged supplicant** - Configured Access VLAN or Trunk Native VLAN.
- **Untagged phone supplicant** - Statically configured phone VLAN.
- **Tagged supplicant** - 802.1Q tag used by the device.

Supplicants on ports in fallback VLANs, such as `AAA Unresponsive VLAN`, `Guest VLAN`, or `Auth Fail VLAN`, receive treatment similar to those on unauthorized ports.

Authorized Ports

When at least one supplicant authenticates on the port, the following applies:

- **Tagged Supplicant** - If the switch identifies the client as a Tagged Supplicant, it commits to an 802.1Q-tagged data path.
- **New supplicant** - The Access-Request for a new supplicant contains the current dynamic VLAN of the already authenticated device on the port, not the statically configured one.
- **Re-authenticating supplicant** - After successfully authenticating the supplicant, the Access-Request contains the dynamic VLAN received from the AAA server.
- **Untagged Supplicant and Untagged Phone Supplicant** - If no dynamic VLAN received, the untagged supplicant uses the configured VLAN, and the untagged phone supplicant uses the phone VLAN.

Configuring VLANs in AAA Requests

Use the following commands to enable sending the statically configured VLAN in RADIUS Access-Requests messages using the Arista-Config-Vlan VSA:

```
switch(config)# dot1x
switch(config-dot1x)# radius av-pair config-vlan
switch(config-dot1x)#
```

Use the following commands to enable the Tunnel-Private-Group-Id attribute in RADIUS Access-Request messages:

```
switch(config)# dot1x
switch(config-dot1x)# radius av-pair tunnel-private-group-id
switch(config-dot1x)#
```

9.1.1.2.2.3 Configuring a RADIUS Proxy

Enable a RADIUS proxy to send requests from a RADIUS client and forward them to a remote RADIUS server. In return, the RADIUS proxy receives the reply from the remote RADIUS server and forwards it to the client. Dynamic authorization requests initiated by remote servers also proxy to the correct clients based on the user name and calling station ID.

Use the radius proxy command to enter the RADIUS Proxy Configuration Mode.

```
switch(config)# radius proxy
switch(config-radius-proxy)#
```

Configuring RADIUS Client Groups

A client group consists of a set of IPv4 or IPv6 prefixes, addresses, or hostnames. RADIUS proxies the requests from these clients to the configured RADIUS server. A client may belong to a VRF and can be configured with the VRF key.

Example

Configure a client group, *MyClientGroup*, with the IPv4 address, *192.168.1.25*, VRF name, *default*, VRF key, *0*, and line, *password1234*, using the following commands:

```
switch(config)# radius proxy
switch(config-radius-proxy)# client group MyClientGroup
switch(config-radius-proxy-MyClientGroup)# client 192.168.1.25 vrf default key  0 password1234
```

Use one of the following parameters as the **key**:

- **0** - Indicates that the key string is not encrypted.
- **7** - Specifies that a hidden key follows.
- **8a** - Specifies that an AES-256-GCM encrypted key follows.
- **LINE** - Specify the text of the key.

Associating Server Groups with Client Groups

A client group can be associated with one or more server groups. The server groups proxy the client requests in the order of configuration. The following example, the client group, *MyClientGroup* sends all client requests and proxies the request in the order of the configured server groups.

Example

```
switch(config-radius-proxy)# client group MyClientGroup
switch(config-radius-proxy-MyClientGroup)# server group RADIUS1 RADIUS2 RADIUS3
```

Configuring a Global Client Key

The **client key** command configures a global key, up to 128 characters, for all clients in all client groups:

Example

Use the following command to configure a client key, *MySuperSecretKey*:

```
switch(config-radius-proxy)# client key MySuperSecretKey
```

Note: An individual client key takes precedence over a global client key.

Configuring Session Idle Timeout

The **client session idle-timeout** following command to configure the client session idle timeout, in seconds, for dynamic authorization. EOS uses 600 seconds by default. The configuration applies globally to the configuration.

Example

Use the following command to configure the session idle-timeout as *300* seconds:

```
switch(config-radius-proxy)# client session idle-timeout 300 seconds
```

Configuring Dynamic Authorization

The **dynamic-authorization** command enables dynamic authorization for RADIUS proxy server groups configured for client groups. Dynamic authorization uses port 3799 for UDP authorization requests and port 2083 for TLS authorization requests.

Example

Use the following command to enable dynamic authorization for RADIUS server groups:

```
switch(config-radius-proxy)# dynamic-authorization
```

Sending Authentication Requests Using Round Robin

Configure RADIUS to send authentication requests across all reachable or live servers within a RADIUS server group and select a server group using round robin for new authentication requests. The configured dead timer or server probe determines the reachability or liveliness of the RADIUS servers.

Use the following command in the Dot1X Configuration Mode to enable the feature:

```
switch(config)# dot1x
                switch(config-dot1x)# aaa authentication load-balance round-robin
                switch(config-dot1x)#
```

Displaying RADIUS Proxy Information

The **show radius proxy client group** command displays information about the RADIUS proxy configuration on the switch.

Example

Use the following command to display configuration information about RADIUS proxy:

```
switch# show radius proxy client group
Radius Client Group                : MyClientGroup
Last time counters were cleared    : never

     Client                          : 192.168.1.25, authentication port 1812, accounting port
 1813, vrf default
     Resolved IP address             : 192.168.1.25/32
            Messages received:          0
                Messages sent:          0
            Accept response sent:       0
            Reject response sent:       0
        Accounting start received:      0
         Interim updates received:      0
         Accounting stop received:      0
                  Bad requests:         0
            CoA requests sent:          0
             DM requests sent:          0
            CoA ACKs received:          0
             DM ACKs received:          0
            CoA NAKs received:          0
             DM NAKs received:          0
                Bad responses:          0
            Connection errors:          0
```

Use the **show radius proxy server group** to display information about RADIUS proxy server groups:

```
switch# show radius proxy server group
            Radius Server Group: MyServerGroup
                Radius Server 1: RADIUS
            Resolved IP address: 192.168.25.33
                         Status: active
```

To clear the counters, use the **clear radius proxy counters client group** command.

9.1.1.2.2.4 Configuring Per MAC Address Access Lists

Arista EOS implements **Per-MAC Access Lists** (Per-Host ACLs) to provide granular security at the individual device level. Unlike standard port-based ACLs, this feature allows the switch to apply unique IPv4 or IPv6 filtering rules to each 802.1X supplicant, even when they share the same physical interface.

When a device authenticates via 802.1X, the switch identifies the device by the MAC address. The system then applies a specific ACL to that MAC address traffic flow. This ensures that a compromised or unauthorized device cannot access restricted resources, even if located behind a port used by other authorized devices.

You can apply Per-MAC ACLs using two primary methods:

- **Dynamic Application using RADIUS and Change of Authorization (CoA)** - The server sends the ACL name or specific rules within an Arista-AVPair attribute with a vendor code, Vendor-ID: 30065. If the security profile of a device changes, the AAA server can issue a CoA to update the ACL in real time without disconnecting the host.
- **Manual Configuration using MAC Traffic Policies** - For static environments or manual overrides, define policies on the switch. Create a MAC Traffic Policy and map specific MAC Addresses to the respective ACLs.

Use the following commands to configure a MAC field set, MAC8021x, with MAC addresses, 2601:600:c903:5708:3e:3fb0:a22f:fd6a and 2601:600:c903:5708:3e:3fb0:a22f:fe7b:

```
switch(config)# mac traffic-policies
switch(config-mac-traffic-policies)# field-set mac MAC8021x
switch(config-macTp-field-set-mac-MAC8021x)# 2601:600:c903:5708:3e:3fb0:a22f:fd6a
switch(config-macTp-field-set-mac-MAC8021x)# 2601:600:c903:5708:3e:3fb0:a22f:fe7b
```

From the MAC Traffic Policies Configuration Mode, enter the Traffic Policy Configuration Mode:

```
switch(config-macTp-field-set-mac-MAC8021x)# exit
switch(config-mac-traffic-policies)# traffic-policy
switch(config-mac-traffic-policy)#
```

Define the matching rules for the MAC ACL. A match rule, M1, consists of MAC field sets to match and the actions to apply to the matching traffic:

```
switch(config-mac-traffic-policy)# match M1
switch(config-mac-traffic-policy-match-M1)# source mac field-set MAC8021x
switch(config-mac-traffic-policy-match-M1)#
```

To apply ACLs to a set of source MAC address, enter the Actions Configuration Mode and add the ACL, ACL1. For more about configuring ACLs, see Access Control Lists.

```
switch(config-mac-traffic-policy-match-M1)# actions
switch(config-mac-traffic-policy-actions-M1)# access-list ACL1
```

Optionally, you can limit the scope of the MAC Traffic Policy to a specific interface that authenticated the MAC by using the following command:

```
switch(config-mac-traffic-policies)# host move disabled
switch(config-mac-traffic-policies)#
```

Finally, enable MAC Traffic Policies globally:

```
switch(config-mac-traffic-policies)# no disabled
```

Be default, the MAC Traffic Policy applies globally to the configuration, and also applies to all traffic with a specified MAC regardless of the port. If you configure the **`host move disabled`** parameter and an authenticated MAC appears on any other interface other than the authenticated interface, the Per MAC ACL does not apply to it.

9.1.1.2.2.5 DSCP Support for CPU-generated Traffic

The Differentiated Services Code Point (DSCP), a 6-bit field in the IP header, marks traffic to provide Quality of Service (QoS). The switch marks all protocol-specific traffic with the configured DSCP value, which EOS sets individually for the following network management protocols:

- RADIUS
- TACACS
- SNMP
- SSH
- sFlow

Configuring DSCP Value

The following commands apply to all platforms for configuring the DSCP value.

- This command configures the DSCP value of ***62*** for RADIUS-server.

```
switch(config)# radius-server qos dscp 62
```

- This command configures the DSCP value of ***36*** for TACACS-server.

```
switch(config)# tacacs-server qos dscp 36
```

- This command configures the DSCP value of ***36*** for snmp-server.

```
switch(config)# snmp-server qos dscp 36
```

- This command configures the DSCP value of ***36*** for sFlow.

```
switch(config)# sFlow qos dscp 36
```

- This command configures the DSCP value of ***36*** for snmp-server.

```
switch(config)# snmp-server qos dscp 36
```

9.1.1.2.2.6 Monitoring RADIUS Servers

EOS uses Status-Server packets to probe RADIUS servers and configures the format of the packet. EOS considers the Status-Server packets as successful in the following situations:

EOS uses Status-Server packets to probe RADIUS servers and can be configured to change the format of the packet. EOS considers the Status-Server packets as successful in the following situations:

- Receiving valid responses before sending out the next set of probes and treating the probe as a timeout period.
- Valid responses received as RADIUS Access-Accept packets

EOS considers a probe failure, for example, an unresponsive server, under the following situations:

- Response times out without receiving a response before the next probes send out.
- Receives an invalid response instead of a RADIUS Access-Accept packet. EOS silently drops invalid responses and treats them as no response received.

Since a probe can drop or get lost on the network, declaring a server unresponsive after sending a single probe may not be desirable on your network. Use the **`fail count`** parameter to configure the number of probes sent before declaring a server as unresponsive. The parameter has a default value of **`1`**.

EOS does not probe servers configured only for 802.1X accounting, but only servers configured for 802.1X authentication, resulting in the following behaviors:

- A server configured with both accounting and authentication only receives probes on the authentication port. The results of the probes determine the response of the authentication server.
- Servers configured only for accounting do not receive authentication probes and respond only to accounting requests.

Configuring Authentication Probes

Use the following commands to configure authentication probes for all servers configured for IEEE 802.1X authentication:

```
switch(config)# monitor server radius
switch(config-monitor-radius)# service dot1x
switch(config-monitor-radius)#
```

Configuring the Probe Properties

Configure the properties of the probe sent to the server. You can configure any of the three properties:

- **`interval`** - Specify a probe interval in seconds, from 1 to 1000 with a default value of 300 seconds.

- **method** - Specify the method used to probe the server. Select from **access-request** or **server-status** with a default value of server-status. The parameter **access-request** requires a username and password configured on the switch and the RADIUS server.
- **threshold failure** - Specify the number of consecutive failed probes sent before considering a server unresponsive.

Use the following commands to figure a probe with an interval of **600 seconds**, method as **server-status**, and a threshold of **50**:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)# probe interval 600 seconds
switch(config-monitor-server-radius)# probe method server-status
switch(config-monitor-server-radius)# probe threshold failure 50
```

Displaying the RADIUS Server Status

Use the **show monitor server radius** command to display information about the RADIUS servers:

```
switch(config)# show monitor server radius

Probe method: Status-Server packet
RADIUS Server            Messages Sent            Messages Accepted             Messages Dropped
            Status
-------------            -------------            -----------------             ----------------
            ---------
10.0.0.101                     48                       35                            1
             alive
10.0.0.102                     48                       29                            1
             not alive
```

The output displays the following information:

- **RADIUS Server** - Displays the IP addresses of RADIUS servers.
- **Messages Sent** - Displays the total number of probes sent to the server.
- **Messages Accepted** - Displays the total number of successful responses to probes from RADIUS servers.
- **Messages Dropped** - Displays the total number of received responses but failed packet validation.
- **Status** - Displays the status as alive or not alive.

Use the **show monitor server radius detail** command to display details about the RADIUS servers:

```
switch(config)# show monitor server radius detail

Probe method: Status-Server packet

RADIUS server: 10.0.0.101, Authentication port: 33922, Accounting port: 34685
Status: alive, Last changed: 0:02:32 ago
Last probed: 0:00:02 ago
Last successful probe: 0:00:02 ago, Failed probes since then: 0
Messages sent: 47
Messages accepted: 34
Messages dropped: 1
Last time counters were cleared: never

RADIUS server: 10.0.0.102 Authentication port: 34406, Accounting port: 47258
```

```
Status: not alive, Last changed: 0:00:12 ago
Last probed: 0:00:02 ago
Last successful probe: 0:00:27 ago, Failed probes since then: 4
Messages sent: 47
Messages accepted: 29
Messages dropped: 1
Last time counters were cleared: never
```

9.1.1.2.2.7 RADIUS Status

The **show radius** command displays configured RADIUS servers and their interactions with the switch.

Examples

- This command lists the configured RADIUS servers.

```
switch(config)# show radius

server1: 10.1.1.45
Messages sent: 24
Messages received: 20
Requests accepted: 14
Requests rejected: 8
Requests timeout: 2
Requests retransmitted: 1
Bad responses: 1
Last time counters were cleared: 0:07:02 ago
```

To reset the RADIUS status counters, use the **clear aaa counters radius** command.

- This command clears all RADIUS status counters.

```
switch(config)# clear aaa counters radius
```

9.1.1.2.3 TACACS+

Terminal Access Controller Access-Control System Plus (TACACS+), derived from the TACACS protocol defined in RFC 1492, is a network protocol that provides centralized user validation services. A remote database maintains TACACS+ information. EOS requires access to a TACACS+ server to support TACACS+ services.

TACACS+ manages multiple network access points from a single server. The switch defines a TACACS+ server connection by its address and port, allowing it to conduct multiple data streams to a single server by addressing different ports on the server.

These sections describe the steps to configure access to TACACS+ servers. Configuring TACACS+ access is most efficient when TACACS+ is functioning before you configure switch parameters.

9.1.1.2.3.1 Configuring TACACS+ Parameters

TACACS+ parameters define the settings the switch uses to communicate with TACACS+ servers. You can configure a set of values for individual TACACS+ servers that the switch accesses. Global parameters define settings for communicating with servers where you haven't configured individual parameters.

The switch supports the following TACACS+ parameters.

Encryption Key

The encryption key is code that the switch and the TACACS+ server share to facilitate communications.

- The **tacacs-server host** command defines the encryption key for a specified server.
- The **tacacs-server key** command defines the global encryption key.

Examples

- This command configures the switch to communicate with the TACACS+ server assigned the host name ***TAC_1*** using the encryption key ***rp31E2v***.

```
switch(config)# tacacs-server host TAC-1 key rp31E2v
```

- This command configures ***cv90jr1*** as the global encryption key.

```
switch(config)# tacacs-server key 0 cv90jr1
```

- This command assigns ***cv90jr1*** as the global key, using the corresponding encrypted string.

```
switch(config)# tacacs-server key 7 020512025B0C1D70
```

Session Multiplexing

The switch supports multiplexing sessions on a single TCP connection.

- The **tacacs-server host** command configures the multiplexing option for a specified server.
- There is no global multiplexing setting.

Example

This command configures the switch to communicate with the TACACS+ server at ***10.12.7.9*** and indicates the server supports session multiplexing on a TCP connection.

```
switch(config)# tacacs-server host 10.12.7.9 single-connection
```

Timeout

The timeout is the period the switch waits for a successful connection to, or response from, the TACACS+ server. The default is ***5*** seconds.

- The **tacacs-server host** command defines the timeout for a specified server.
- The **tacacs-server timeout** command defines the global timeout.

Examples

- This command configures the switch to communicate with the TACACS+ server assigned the host name ***TAC_1*** and configures the timeout period as ***20*** seconds.

```
switch(config)# tacacs-server host TAC_1 timeout 20
```

- This command configures ***40*** seconds as the period that the server waits for a response from a TACACS+ server before issuing an error.

```
switch(config)# tacacs-server timeout 40
```

Port

The port specifies the port number through which the switch and the servers send information. The TACACS+ default port is ***49***.

- The **tacacs-server host** command specifies the port number for an individual TACACS+ server.
- The global TACACS+ port number cannot be changed from the default value of ***49***.

Example

This command configures the switch to communicate with the TACACS+ server at ***10.12.7.9*** through port ***54***.

```
switch(config)# tacacs-server host 10.12.7.9 port 54
```

9.1.1.2.3.2 TACACS+ Status

To display the TACACS+ servers and their interactions with the switch, use the show tacacs command.

Example

This command lists the configured TACACS+ servers.

```
switch(config)# show tacacs

server1: 10.1.1.45
Connection opens: 15
Connection closes: 6
Connection disconnects: 6
Connection failures: 0
Connection timeouts: 2
Messages sent: 45
Messages received: 14
Receive errors: 2
Receive timeouts: 2
Send timeouts: 3
```

```
Last time counters were cleared: 0:07:02 ago
```

To reset the TACACS+ status counters, use the clear aaa counters tacacs+ command.

Example

This command clears all TACACS+ status counters.

```
switch(config)# clear aaa counters tacacs
```

9.1.1.2.4 AAA with LDAP

The switches support AAA with the LDAP protocol for authentication and authorization. They use Transport Layer Security (TLS) communication with a remote LDAP server and interoperate with Microsoft's Active Directory when configured with LDAP plugins. LDAP authentication configuration is necessary for LDAP to function. The switch sends AAA requests to servers in the order of their configuration. Once marked unreachable, the switch will only retry a server after all other servers are also found unreachable.

Configuring LDAP Authentication

For all platforms, the **`ldap`** command is configured from the management **ldap** mode and requires configuration files to provide remote authentication.

Active Directory Server with LDAP Plugin Configured

The following file extract illustrates a configuration for the authentication for ***rdn attribute user*** and ***search filter***.

```
aaa authentication login default group ldap local
aaa authorization exec default group ldap local
!
management ldap
   server host ldap-server.samplecompany.com
   !
   server defaults
      base-dn dc=samplecompany,dc=com
      rdn attribute user cn
      ssl-profile testProfile
      authorization group policy basic-role-example
      search username cn=ldap-admin-acct,OU=ServiceAccounts,OU=Sample,dc=samplecompany,dc=com
 password 0 secretString
   !
   group policy basic-role-example
      search filter objectclass group attribute member
      group "Network Admin" role network-admin
      group "Network Newbie" role network-operator
!
management security
   ssl profile testProfile
      fips restrictions
      trust certificate caCert
!
```

The following file extract illustrates a configuration for the management **ldap** mode.

```
management ldap
   server host ldap-server.samplecompany.com
      ssl-profile testProfile2
      authorization group policy company1
   !
   Server host ldap-server.company2.com
   !
   server defaults
      base-dn dc=samplecompany,dc=com
      rdn attribute user cn
      ssl-profile testProfile1
      authorization group policy basic-role-example
      search username cn=ldap-admin-acct,OU=ServiceAccounts,OU=Sample,dc=samplecompany,dc=com
 password 0 secretString
   !
   group policy basic-role-example
      search filter objectclass group attribute member
      group "Network Admin" role network-admin
      group "Network Newbie" role network-operator
   !
   group policy company1
      search filter objectclass group attribute member
      group "Network Admin2" role network-admin
      group "Network Newbie2" role network-operator
   !
```

Use LDAP with the following settings as a minimum configuration.

```
aaa authentication login default group ldap
!
management ldap
   server host <ldap server hostname/ip>
   !
   server defaults
      base-dn <base distinguished name>
      rdn attribute user <relative distinguished attribute name>
      search username <full distinguished name> password <password>
```

The configuration sets up AAA authentication with LDAP. The LDAP server supports IPv4, IPv6, hostnames, and VRFs for specifying the address. The **RDN**, relative distinguished name, is typically an attribute/value pair to specify a user. When a user attempts to connect to the switch, the admin username searches recursively for the **RDN**s that match the passed-in username from the base-dn folder to generate a shortened list of potential **DN**s, which are then searched for a match with the provided password.

Configuring LDAP Authorization

Active Directory Server with LDAP Plugin Configured

The following file extract illustrates a configuration of a user authorization.

```
aaa authorization exec default group ldap
!
management ldap
   server defaults
      authorization group policy basic-role-example
   !
   group policy basic-role-example
      search filter objectclass group attribute member
      group "Network Admin" role network-admin
      group "Network Newbie" role network-operator
```

The **group**/**role** maps an LDAP group to an EOS role for RBAC. The matching process ensures that the first matched group results in the role being assigned to the user. Use the **`before`** and **`after`** commands to insert rules in the appropriate priority.

The LDAP admin account uses the **`search filter`** command to search for LDAP groups that contain the user, where **objectclass** defines the object that contains the LDAP group, and **attribute** is the entry attribute name that contains the DN of the group member.

TLS Communication

LDAP supports TLS communication using SSL profiles. A trust certificate, or multiple intermediate certificates, is required to verify the root of trust of the LDAP server. If **ssl profiles** are configured and the server does not support TLS or fails x509 verification, the system will not use the server for authentication. Other **ssl profiles** supported commands are:

- fips restrictions
- crl
- tls version
- cipher-list

Active Directory Server with LDAP Plugin Configured

The following file extract illustrates a configuration for TLS communication.

```
management ldap
   !
   server defaults
      ssl-profile testProfile
management security
   ssl profile testProfile
      trust certificate <root of trust>
```

9.1.1.3 Server Groups

A server group is a collection of servers associated with a single group name. Subsequent authorization and authentication commands can access all servers in a group by invoking the group name. The switch supports ***TACACS+*** and ***RADIUS*** server groups.

The **`aaa group server`** commands create server groups and place the switch in a ***server-group*** configuration mode to assign servers to the group. Commands referencing an existing group place the switch in a ***server-group*** configuration mode to modify the group.

These commands create named server groups and enter the appropriate command mode for the specified group:

- **aaa group server radius**
- **aaa group server tacacs+**

The **server (server-group-RADIUS configuration mode)** commands add servers to the configuration mode server group. Before they are added to a group, servers must have been previously configured with a **radius-server host** or **tacacs-server host** command.

Examples

- This command creates the TACACS+ server group named ***TAC-GR*** and enters ***server-group*** configuration mode for the new group.

```
switch(config)# aaa group server tacacs+ TAC-GR
switch(config-sg-tacacs+-TAC-GR)#
```

- These commands add two servers to the ***TAC-GR*** server group. To add servers to this group, the switch must be in ***sg-tacacs+-TAC-GR*** configuration mode.

  The CLI remains in ***server-group*** configuration mode after adding the ***TAC-1*** server (port ***49***) and the server located at ***10.1.4.14*** (port ***151***) to the group.

```
switch(config-sg-tacacs+-TAC-GR)# server TAC-1
switch(config-sg-tacacs+-TAC-GR)# server 10.1.4.14 port 151
switch(config-sg-tacacs+-TAC-GR)#
```

- This command exits ***server-group*** configuration mode.

```
switch(config-sg-tacacs+-TAC-GR)# exit
switch(config)#
```

- This command creates the RADIUS server group named ***RAD-SV1*** and enters ***server-group*** configuration mode for the new group.

```
switch(config)# aaa group server radius RAD-SV1
switch(config-sg-radius-RAD-SV1)#
```

- These commands add two servers to the ***RAD-SV1*** server group. To add servers to this group, the switch must be in ***sg-radius-RAD-SV1*** configuration mode.

  The CLI remains in server-group configuration mode after adding the RAC-1 server (authorization port ***1812***, accounting port ***1813***) and the server located at ***10.1.5.14*** (authorization port ***1812***, accounting port ***1850***) to the group.

```
switch(config-sg-radius-RAD-SV1)# server RAC-1
switch(config-sg-radius-RAD-SV1)# server 10.1.5.14 acct-port 1850
switch(config-sg-radius-RAD-SV1)#
```

9.1.1.4 Role-Based Authorization

Role-based authorization is a method of restricting access to CLI commands through the assignment of profiles, called ***roles***, to user accounts. Each role consists of rules that permit or deny access to a set of commands within specified command modes.

All roles are accessible to the local security file through a **username** parameter and to remote users through ***RADIUS*** or ***TACACS+*** servers. You can apply each role to multiple user accounts, but only one role to each user.

9.1.1.4.1 Role Types

The switch defines two types of roles: user-defined and built-in.

- User-defined roles are created and edited through CLI commands.
- Built-in roles are supplied with the switch and are not user-editable.

Built-in roles supplied by the switch are ***network-operator*** and ***network-admin***.

9.1.1.4.2 Role Structure

A role is an ordered list of rules that restricts access to specified commands from users to whom it is applied. Roles consist of deny and permit rules. Each rule references a set of command modes and contains a regular expression that specifies one or more CLI commands. Commands are compared sequentially to the rules within a role until a rule's regular expression matches the command.

- Commands that match a regular expression in a permit rule are executed.
- Commands that match a regular expression in a deny rule are disregarded.
- Commands that do not match a regular expression are evaluated against the next rule in the role.

Upon its entry in the CLI, a command is compared to the first rule of the role. Commands that match the rule are ***executed*** (permit rule) or ***disregarded*** (deny rule). Commands that do not match the rule are compared to the next rule. This process continues until the command either matches a rule or the rule list is exhausted. The switch disregards commands that do not match any rule.

9.1.1.4.3 Role Rules

Role rules have four components: sequence number, filter type, mode expression, and command expression.

Sequence Number

The sequence number designates a rule’s placement in the role. Sequence numbers range in value from 1 to 256. Rule commands that do not include a sequence number append the rule at the end of the list, deriving its sequence number by adding 10 to the sequence number of the last rule in the list.

Example

These rules have sequence numbers ***10*** and ***20***.

```
10 deny mode exec command reload
20 deny mode config command (no |default )?router
```

Filter Type

The filter type specifies the disposition of matching commands. The filter types are **`permit`** and **`deny`**. Commands matching permit rules are executed, and commands matching deny rules are disregarded.

Example

These rules are deny and permit rules, respectively.

```
10 deny mode exec command reload
20 permit mode config command interface
```

Mode Expression

The mode expression specifies the command mode under which the command expression is effective. The mode expression may be a regular expression or a designated keyword. Rules support the following mode expressions:

- **exec** - EXEC and Privileged EXEC modes
- **config** - Global Configuration Mode
- **config-all** - All configuration modes, including Global Configuration Mode
- ***short_name*** - short key name of a command mode (exact match)
- ***long_name*** - long key name of a command mode (regular expression match of one or more modes)
- **no parameter** - all command modes

The **prompt** command configures the CLI to display a configuration mode's key name:

- %P - long key name
- %p - short key name

Examples

- These commands use the prompt command to display short key name (**if**) and long key name (**if-Et1**) for ***interface ethernet 1***.

```
switch(config)# prompt switch%p
switch(config)# interface ethernet 1
switch(config-if)# exit
switch(config)# prompt switch%P
switch(config)# interface ethernet 1
switch(config-if-Et1)#
```

  The command supports the use of regular expressions to reference multiple command modes.

- These regular expressions correspond to the listed command modes:
  - **if-Vlan(1|2)** - matches ***interface-VLAN 1*** or ***interface-VLAN 2***.
  - **if** - matches all interface modes.
  - **acl-text1** - matches ACL configuration mode for ***text1*** ACL.

Command Expression

The command expression is a regular expression that corresponds to one or more CLI commands.

Examples

These regular expressions correspond to the specified commands:

- **`reload`** - reload command
- **`(no | default)? router`** - commands that enter routing protocol configuration modes
- **`(no | default)?(ip|mac) access-list`** - commands that enter ACL configuration modes
- **`(no | default)?(ip|mac) access-group`** - commands that bind ACLs to interfaces
- **lacp | spanning-tree** - LACP and STP commands
- **.*** - all commands

9.1.1.4.4 Creating and Modifying Roles

This section contains the following topics:

- Built-in Role
- Managing Roles
- Modifying Roles

9.1.1.4.4.1 Built-in Role

The switch provides the following two built-in roles:

- **network-operator** - Allows all commands in EXEC (Privileged) modes. Commands in all other modes are denied.
- **network-admin** - Allows all CLI commands in all modes.

The **network-admin** role is typically assigned to the **admin** user to allow it to run any command.

Built-in roles are not editable.

Example

These **`show users roles`** commands display the contents of the built-in roles.

```
switch(config)# show users roles network-operator
The default role is network-operator
role: network-operator
        10 deny mode exec command bash|\|
        20 permit mode exec command .*
```

```
switch(config)# show users roles network-admin
The default role is network-operator
role: network-admin
        10 permit command .*
switch(config)#
```

9.1.1.4.4.2 *Managing Roles*

Creating and Opening a Role

Roles are created and modified in ***Role*** configuration mode. To create a role, enter the **role** command with the role's name. The switch enters ***Role*** configuration mode. If the name of an existing role follows the command, subsequent commands edit that role.

Example

This command places the switch in ***Role*** configuration mode to create a role named ***sysuser***.

```
switch(config)# role sysuser
switch(config-role-sysuser)#
```

Saving Role Changes

Role configuration mode is a group-change mode; changes are saved by exiting the mode.

Examples

- These commands create a role, then add a deny rule to the role. Because the changes are not yet saved, the role remains empty, as shown by **show users roles**.

```
switch(config)# role sysuser
switch(config-role-sysuser)# deny mode exec command reload
switch(config-role-sysuser)# show users roles sysuser
The default role is network-operator

switch(config-role-sysuser)#
```

- Type **exit** to save all current changes and exit the role configuration mode.

```
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
switch(config)#
```

Note: To preserve role changes after system restarts, you need to save the **running-config** to the **startup-config** after exiting role mode.

Discarding Role Changes

The **abort** command exits the ***Role*** configuration mode without saving pending changes.

Example

These commands enter the ***Role*** configuration mode to add deny rules but discard the changes before saving them to the role.

```
switch(config)# role sysuser
switch(config-role-sysuser)# deny mode exec command reload
switch(config-role-sysuser)# abort
switch(config)# show users roles sysuser
The default role is network-operator

switch(config)#
```

9.1.1.4.4.3 Modifying Roles

Adding Rules to a Role

The **deny (Role)** command adds a deny rule to the configuration mode role. The **permit (Role)** command adds a permit rule to the configuration mode role.

To append a rule to the end of a role, enter the rule without a sequence number while in Role Configuration Mode. The new rule's sequence number is derived by adding 10 to the last rule's sequence number.

Example

These commands enter the first three rules into a new role.

```
switch(config)# role sysuser
switch(config-role-sysuser)# deny mode exec command reload
switch(config-role-sysuser)# deny mode config command (no |default )?router
switch(config-role-sysuser)# permit command .*
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        20 deny mode config command (no |default )?router
        30 permit command .*
switch(config)#
```

Inserting a Rule

To insert a rule into a role, enter the rule with a sequence number between the existing rules numbers.

Example

This command inserts a rule between the first two rules by assigning it the sequence number 15.

```
switch(config)# role sysuser
switch(config-role-sysuser)# 15 deny mode config-all command lacp
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        15 deny mode config-all command lacp
        20 deny mode config command (no |default )router
        30 permit command .*
switch(config)#
```

Deleting a Rule

To remove a rule from the current role, perform one of these commands:

- Enter **no**, followed by the sequence number of the rule to be deleted.
- Enter **no**, followed by the rule be deleted.
- Enter **default**, followed by the sequence number of the rule to be deleted.
- Enter **default**, followed by the rule to be deleted.

Examples

- These equivalent commands remove rule ***30*** from the list.

```
switch(config-role-sysuser)# no 30
switch(config-role-sysuser)# default 30
switch(config-role-sysuser)# no permit command .*

switch(config-role-sysuser)# default permit command .*
```

- This role results from entering one of the preceding commands.

```
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        15 deny mode config-all command lacp|spanning-tree
        20 deny mode config command (no |default )router
switch(config)#
```

Redistributing Sequence Numbers

Sequence numbers determine the order of the rules in a role. After a list editing session where existing rules are deleted, and new rules are inserted between existing rules, the sequence number distribution may not be uniform. Redistributing rule numbers changes adjusts the sequence number of rules to provide a constant difference between adjacent rules. The **resequence (Role)** command adjusts the sequence numbers of role rules.

Example

The **resequence** command renumbers rules in the sysuser role. The sequence number of the first rule is ***100***; subsequent rules' sequence numbers are incremented by ***20***.

```
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        20 deny mode config-all command lacp|spanning-tree
        25 deny mode config command (no |default )?router
        30 permit command .*
switch(config)# role sysuser
switch(config-role-sysuser)# resequence 100 20
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        100 deny mode exec command reload
        120 deny mode config-all command lacp|spanning-tree
        140 deny mode config command (no |default )?router
        160 permit command .*
switch(config)#
```

9.1.1.4.5 Assigning a Role to a Username

Roles are assigned to local users through the **username** command and to remote users through RADIUS or TACACS+ servers. Each user is assigned one role, which can be assigned to multiple local and remote users.

9.1.1.4.5.1 Default Roles

Users that are not explicitly assigned a role are assigned the default role. The **aaa authorization policy local default-role** command designates the default role. The ***network-operator*** built-in role is the default role when the default role is not configured.

Examples

- These commands assign ***sysuser*** as the default role. The output displays the name of the default role (`The default role is sysuser`).

```
switch(config)# aaa authorization policy local default-role sysuser
switch(config)# show users roles
The default role is sysuser

switch(config)#
```

- These commands restore ***network-operator*** as the default role by deleting the **aaa authorization policy local default-role** statement from ***running-config***. The output displays the default role name (`The default role is network-operator`).

```
switch(config)# no aaa authorization policy local default-role
switch(config)# show users roles
```

```
The default role is network-operator

switch(config)#
```

9.1.1.4.5.2 *Local Security File (Username Command)*

Roles are assigned to users with the **username** command's **role** parameter. A username whose **running-config username** statement does not include a **role** parameter is assigned the default role.

The **role** parameter function in a command creating a username is different from its function in a command to edit an existing name.

Assigning a Role to a New Username

A **username** command creating a username explicitly assigns a role to the username by including the **role** parameter; commands without a **role** parameter assign the default role to the username.

Example

These commands create two usernames. The first user is assigned a role; the second user assumes the default role.

```
switch(config)# username FRED secret 0 axced role sysuser1
switch(config)# username JANE nopassword
switch(config)# show running-config
<-------OUTPUT OMITTED FROM EXAMPLE-------->
!
username FRED role sysuser1 secret 5 $1$dhJ6vrPV$PFOvJCX/vcqyIHV.vd.l20
username JANE nopassword
!
<-------OUTPUT OMITTED FROM EXAMPLE-------->
switch(config)#
```

Editing the Role of an Existing Username

A **username** command may edit the role of a previously configured username without altering its password. However, username commands that do not include a **role** parameter do not change the role assignment of a username.

Examples

- These commands assign a role to a previously configured username.

```
switch(config)# username JANE role sysuser2
switch(config)# show running-config

<-------OUTPUT OMITTED FROM EXAMPLE-------->
!
username FRED role sysuser1 secret 5 $1$dhJ6vrPV$PFOvJCX/vcqyIHV.vd.l20
username JANE role sysuser2 nopassword
!
<-------OUTPUT OMITTED FROM EXAMPLE-------->
switch(config)#
```

- These commands reverts a username to the default role by removing its role assignment.

```
switch(config)# no username FRED role
switch(config)# show running-config
<-------OUTPUT OMITTED FROM EXAMPLE-------->
!

username FRED secret 5 $1$dhJ6vrPV$PFOvJCX/vcqyIHV.vd.l20
username JANE role sysuser2 nopassword
!
<-------OUTPUT OMITTED FROM EXAMPLE-------->
switch(config)#
```

Displaying the Role Assignments

The **show users accounts** command displays role assignment of the configured users. The **show users detail** command displays roles of users that are currently logged into the switch.

Examples

- This command displays the configured users and their role assignments.

```
switch(config)# show users accounts
user: FRED
       role: <unknown>
       privilege level: 1
user: JANE
       role: sysuser2
       privilege level: 1
user: admin
       role: network-admin
       privilege level: 1
switch(config)#
```

- This command displays information about the active AAA login sessions.

```
switch(config)# show aaa session
Session  Username  Roles           TTY    State Duration  Auth          Remote Host
-------  --------- ------------    ------ ----- --------  ------------- ------------
2         admin     network-operator ttyS0   E     0:01:21  local
4         Fred      sysadmin         telnet  E     0:02:01  local         sf.example.com
6         Jane      sysuser2         ssh     E     0:00:52  group radius  ny.example.com
9         admin     network-admin    ssh     E     0:00:07  local         bj.example.com
10        max       network-admin    telnet  E     0:00:07  local         sf.example.com
```

9.1.1.4.5.3 Radius Servers

A role can be assigned to a remote user authenticated through a RADIUS server. Roles are assigned through the vendor-specific Attribute-Value (AV) pair named **Arista-AVPair**. When RADIUS authentication is enabled, the switch extracts the remote user's role upon successful authentication.

Example

This file extract is sample FreeRADIUS server code that includes the AV pair that assigns roles to three remote users.

```
# Sample RADIUS server users file
"Jane"          Cleartext-Password := "Abc1235"
```

```
                Arista-AVPair = "shell:roles=sysuser2",
                Service-Type = NAS-Prompt-User
"Mary"          Cleartext-Password := "xYz$2469"
                Arista-AVPair = "shell:roles=sysadmin",
                Service-Type = NAS-Prompt-User
"Fred"          Cleartext-Password := "rjx4#222"
                Arista-AVPair = "shell:roles=network-operator",
                Service-Type = NAS-Prompt-User
```

The **aaa authentication login** command selects the user authentication service (see Configuring Service Lists).

Example

This command configures the switch to authenticate users through all RADIUS servers.

```
switch(config)# aaa authentication login default group radius
```

9.1.1.4.5.4 Enable Role-Based Access Control

To enable Role-Based Access Control (RBAC) on the switch, apply the following configuration:

```
switch(config)# aaa authorization commands all default local
```

9.1.1.5 AAA and X.509 Authentication

Configure AAA to support X.509 Certificates for Secure Shell (SSH) connections to securely send commands over an unsecured network. X.509 certificates use a type of public key authentication, and must be enabled on the switch.

When a user attempts to log into the network using an X.509 certificate, EOS performs a check to ensure that the certificate grants permissions and compares the username to names extracted from the certificate. By default, an exact match must be located. The configuration extracts subject alternative names (SANs) from the X.509 certificate, and EOS supports uniform resource identifiers (URIs), an email format as defined in RFC822, and the **otherName** format for Microsoft Active Directory User Principal Name (UPN). If a match cannot be located, the common name is extracted and checked.

Table 9: Default Behavior of Validating Usernames

	Name Extracted from the Certificate	
Login User Name	**Username**	**username@example.com**
Username	Valid Match	Match Failure
username@example.com	Match Failure	Valid Match

Successful login attempts must match one of the names on the certificate.

Before configuring X.509 authentication, enable public-key authentication and keyboard interactive on the switch.

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authentication protocol public-key keyboard-interactive
```

Configuring a Secure Socket Layer (SSL) Profile for X.509 Authentication

You must add at least one trusted certificate (CA) to allow X.509 authentication, and specify a Certificate Revocation List (CRL) with revoked certificates.

To enable X.509 on a switch, configure an SSL profile, *x509-profile*, to link to the SSH configuration:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile x509-profile
```

Add the trusted certificate, *trusted-cert*, to the configuration:

```
switch(config-mgmt-sec-profile-x509-profile)# trust trusted-cert
```

Add the name of the applicable Certificate Revocation List (CRL), *my-crl*:

```
switch(config-mgmt-sec-profile-x509-profile)# revocation crl name my-crl
```

Next, enable public-key authentication on the switch, and add the SSL profile, *x509-profile*:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authentication x509
switch(config-mgmt-ssh-auth-x509)# server ssl profile x509-profile
```

Configuring X.509 to Omit Domains from the Usernames

Names extracted from the X.509 certificates include domain names, and in some cases, you may want to omit the domain name from the X.509 certificates when comparing the usernames with the login name. To omit the domain name, use the following commands:

```
switch(config)# management ssh
switch(config-mgmt-ssh)# authentication x509
switch(config-mgmg-ssh-auth-x509)# username domain omit
```

When configured, the following login behavior occurs on the switch:

Table 10: Default Behavior when Omitting Domains from Usernames

	Name Extracted from the Certificate	
Login User Name	**Username**	**username@example.com**
Username	Valid Match	Valid Match
username@example.com	Match Failure	Match Failure

Configuring an Online Certificate Status Profile (OCSP) for X.509 Certificates

Instead of using a CRL to perform certificate validation, use an OCSP query to an authorized server for the revocation status of a certificate. Performing an OCSP lookup requires access to a remote OCSP server, or a local OSCP server. Configure an OCSP profile with the appropriate settings for your network.

Note: The OCSP server must be reachable from the default VRF.

Use the following commands to enable OCSP on the switch, and add the OCSP profile, *myOCSP*:

```
switch(config)# managment security
switch(config-mgmt-security)# ocsp profile myOSCP
```

Link an OCSP profile to an SSL profile by adding the parameter, **`revocation ocsp profile`**.

Specify a timeout in seconds from one (1) to 600 with a default timeout of 30 seconds.

```
switch(config-mgmt-sec-ocsp-profile-myOCSP)# timeout 120
```

Override the OCSP responder and use a URL to a OCSP server for all OCSP queries instead of the values in the X.509 certificate:

```
switch(config-mgmt-sec-ocsp-profile-myOCSP)# url http://www.myocspserver.com
```

Note: EOS only supports HTTP requests for OCSP queries.

Add an extension request and response nonce behavior to the configuration. By default, a response contains a nonce but doesn't treat the absence of one as a failure. Configure this parameter to require a nonce in the request or not send one at all. In this case, disable the nonce request:

```
switch(config-mgmt-sec-ocsp-profile-myOCSP)# extension nonce request disabled
```

Configure certificates in the chain that require validation using OCSP. By default, the profile uses **all**. This requires the entire chain up to but not including the root CA to validate with OCSP. If set to **leaf**, only the client certificate must be validated using OCSP. If set to **none**, then OCSP only performs validation on certificates with an OCSP responder specified.

```
switch(config-mgmt-sec-ocsp-profile-myOCSP)# chain certificate requirement responder all
```

Specify a VRF for OCSPP queries using the parameter, **vrf** and add it to the OCSP profiles:

```
switch(config)# management security
switch(config-mgmt-security)# ocsp profile myOCSP
switch(config-mgmt-security-myOCSP)# vrf VRF2
```

Link an OCSP profile to an SSL profile using the parameter, **revocation ocsp profile** when configuring the SSL profile. If the SSL profile links to a nonexisting OCSP profile, the SSL profile becomes invalid. If no OCSP profile links to the SSL profile, no OCSP profile checking occurs for the SSL profile. The following commands link the SSL profile, *MySSLProfile*, to the OCSP profile, *MyOCSP*:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile MySSLProfile
switch(config-mgmt-security-MySSLProfile)# revocation ocsp profile myOCSP
```

Displaying X.509 Certification Configuration

Use the following command to display the X.509 Authentication configuration:

```
switch(config)# show run section management ssh
management ssh
   authentication X.509
   server ssl profile x509-profile
   username domain omit
```

The command, **show management ssh**, includes additional information about the X.509 authentication configuration:

```
switch(config)# show management ssh
User certificate authentication methods: x509-certificates
SSL profile: X509-profile invalid. See "show management security ssl profile” output for details.
```

To display details about the SSL profile configured for SSH authentication, use the **show management security ssl profile** command:

```
switch(config)# show management security ssl profile
Profile                State   Additional Information
---------------------- ------- ----------------------
ARISTA_DEFAULT_PROFILE valid
x509-profile           invalid Profile has no data
```

To display the SSL profile, the OCSP profile, and VRF information, use the following command:

```
switch(config)# show run section management security
management security
   ocsp profile myOCSP
     chain certificate requirement responder leaf
   extension nonce request response
   timeout 20
   url http://127.0.0.1:8080
   vrf VRF2
   !
   ssl profile X509-profile
    …
   revocation ocsp profile revoke-ocsp
    …
```

In the output, only the leaf certificate validates, and an extension request requires a nonce. The timeout occurs after 20 seconds, and the URL for certificate validation set to the local address.

9.1.1.5.1 X.509 Automatic Certificate Management

X.509 automatic certificate management provides support for retrieving signed X.509v3 certificates from a server using the Enrollment over Secure Transport (EST) protocol. EOS only supports EST as the client protocol.

EOS supports the following capabilities for an EST protocol profile:

- Server URL
- Separate authentication credentials for initial enrollment and re-enrollment
- Request retry behavior
- Server authentication with explicit trust anchor

EOS supports the following capabilities for a certificate profile:

- Distinguished Name
- Subject Alternative Name
- Private key on the switch
- Certificate Signing Requests with digest algorithm
- A renewal interval before certificate expiration

- Assigning an EST protocol profile to the certificate profile

EOS also supports the following additional functionalities:

- Automatic retrieval of the initial signed certificates from the EST server
- Automatic certificate renewal
- Displaying information about the current certificate status and EST protocol profiles
- Using automatically retrieved certificates in SSL profiles

9.1.1.5.1.1 Configuring X.509 Automatic Certificate Management

X.509 Automatic Certificate Management provides two dedicated configuration modes for certificate and Enrollment over Secure Transport (EST) protocol profiles under the Management Security Configuration mode.

- **`profile`** - Configure certificate options for automatic certificate management.
- **`protocol`** - Configure EST protocol options for automatic certificate management.

Use **`protocol`** options to specify the details, such as server identity, validation, or retry behavior, for the EST protocol used to retrieve the certificate.

Use **`profile`** options to specify the parameters for the certificate such as a distinguished name and subject alternative name. Each certificate profile manages a single certificate and multiple certificate profiles can apply to a single protocol profile. However, a single certificate profile cannot apply to multiple protocol profiles.

Configuring an EST Protocol Profile

An EST protocol profile communicates with an EST server based on the configured parameters. Create a new protocol profile or modify an existing EST protocol profile and configure a name for each profile. Use the following commands to create a profile, *EST_1*, on the switch:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)#
```

Configuring EST Protocol Profile Connections

The parameter, **`connection`**, configures the request send and retry behavior, and includes the maximum number of retries with the configured interval between retries. A device continues to send certificate signing requests to the switch until retrieving the certificate or exceeding the number of configured retries. The maximum number of retries resets to the maximum value for each new retry initiation or the retry count changes. By default, the switch allows an infinite number of retries and the interval between each request doubles exponentially to a maximum of 24 hours.

Use the following commands to configure *10* as the maximum number retries with an exponentially increasing interval of *5* seconds:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
```

```
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# connection retry count 10 interval 5 backoff
 exponential
```

Adding the **backoff exponential** parameters doubles the interval between each retry attempt up to 24 hours. Omitting the keywords sets a constant interval, for example:

```
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# connection retry interval 10
```

Configuring EST Protocol Profile Credentials

The **credentials** parameter configures initial enrollment and re-enrollment using a username and secret pair or JSON Web Tokens (JWT). HTTP authentication uses the credentials when sending requests to the server. Configuring a username and secret pair uses basic HTTP authentication and bearer authentication for JWTs. You cannot configure username-secret pairs with JWTs on the same EST protocol profile. Use the following commands to configure a username, *user_1*, with a secret, *myS3cr3t*, for the EST protocol profile, *EST_1*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# credentials enroll username user_1 secret
 myS3cr3t
```

Use the following commands to add the credentials for re-enrollment:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# credentials re-enroll username user_1 secret
 myS3cr3t
```

Configuring the EST Server

The **server** parameters identify the EST server and manage the authentication process by setting the server URL and then validating the server. The server URL must begin with `https://` and only contains the relevant identifying information. When retrieving a new certificate, the server checks the URL against the subject names in the EST server certificate and against the configured hostname or IP address. Otherwise, the server rejects the connection.

The URL can contain an IPv4 or IPv6 address or a DNS and may also contain a port.

Use the following commands to set the server URL to *https://my-est-server.com*

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# server url https://my-est-server.com
```

An SSL option can be used to select an SSL profile with trusted certificates to validate the EST server identity. Use the following commands to use an SSL profile, *SSL_Lab*, and configure the EST protocol profile, *EST_1*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# server ssl profile SSL_Lab
```

Disabling an EST Protocol Profile

The **disabled** parameter temporarily pauses retrieving credentials from the server configured for the selected EST protocol profile. Use this option when EST server errors detected on the network and prevent sending unnecessary requests while resolving issues with the server without changing the EST protocol profile parameters.

Use the following commands to temporarily disable the profile, *EST_1*:

```
switch(config)# management security
switch(mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-est-EST1)# disabled
```

To re-enable the protocol profile, use the **no** parameter:

```
switch(config)# management security
switch(mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-est-EST1)# no disabled
```

9.1.1.5.1.2 Configuring EST Certificate Profiles

Use EST certificate profiles to manage certificates for EST and configure each profile with a unique name. A certificate profile can only manage one certificate. For example, use the following commands to create a certificate profile, *CertAlpha*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

Configuring a Certificate Profile with a Digest Algorithm

Configure the certificate profile to use a digest algorithm to sign Certificate Signing Requests. Select one of the three available algorithms:

- **sha256** - Use a 256 bit SHA digest algorithm, the default value.
- **sha384** - Use a 384 bit SHA digest algorithm.
- **sha512** - Use a 512 bit SHA digest algorithm.

Use the following commands add a 512 bit SHA digest algorithm to the certificate profile, *CertAlpha*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# digest sha512
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

Configuring a Key for a Certificate Profile

The **key** parameter configures the private and public key pair used for creating the certificate. By default, no value exists. Create or copy a key file and store it in the ***sslkey*** directory. For instance, use the following command to copy the key file, *key.pem* from the `/tmp` directory on the switch to the ***sslkey*** directory:

```
switch# copy file:/tmp/ssl/key.pem sslkey:
```

To generate a 2048-bit RSA key with the name, *key.pem*, and save it to the ***sslkey*** directory, use the following command:

```
switch# security pki generate rsa 2048 key.pem
```

Add the key to the certificate profile using the following commands:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# key key.pem
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

The certificate profile configuration requires adding a key. If left empty or contains an invalid key, the configuration marks the profile as mis-configured and does not send certificate signing requests.

Changing the key for the certificate while associated with a certificate profile triggers a **rekey** operation which sends a re-enrollment request to the EST server and uses the new key for creating a new certificate. The old key and certificate pair authenticates the client as well as using the re-enrollment credentials to authenticate.

Configuring Parameters for a Certificate Profile

The **parameters** option configures the **distinguished name** and the **subject alternative name** for the certificate. The **distinguished name** parameter configures the following:

- Common Name
- Country
- Email
- Locality
- Organization
- Organization Unit
- Serial Number
- State

Each field can have only one value, and the field contains no values until configured. Quotation marks (" ") can be used for names with more than one word. For example, use the following commands to include the common name, *"Switch 1"*, and the organization, *Arista*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
```

```
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters distinguished-name common-name
 "Switch 1"
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters distinguished-name organization
 Arista
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

To clear the values from the configuration, use the **no | default** versions of the command.

The **subject alternative name** includes the following fields:

- DNS - Specify a DNS name.
- Email - Add the email address.
- IP address - Add the IPv4 or IPv6 address.
- URI - Specify URIs for the configuration.

By default, these fields contain no values.

Use the following commands to add the IPv4 address, *192.168.1.1*, the IPv6 address, *3FF.FFFF::1*, the email address, *mail@yourcompany.com*, and the URI, *http://example.com/path/etc* to the certificate profile, *CertAlpha*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name ip 192.0.2.1
 192.0.2.2 3FFF:FFFF::1"
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name email
 mail@example.com
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name uri https://
example.com/path/one
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

To clear the values from the configuration, use the **no | default** versions of the command.

Configure at least one option for **parameters**, either the distinguished name or the subject alternative name. If left empty, the configuration marks the profile as misconfigured and does not send certificate signing requests.

Changing the key for the certificate while associated with a certificate profile triggers a **rekey** operation which sends a re-enrollment request to the EST server and uses the new key for creating a new certificate. The old key and certificate pair authenticates the client as well as using the re-enrollment credentials to authenticate.

Set the serial number parameter as a custom value or set it automatically as the device serial number using the parameter **system**.

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters distinguished-name serial-number
 system
```

Assigning a Certificate Profile to an EST Protocol Profile

The **protocol** parameter assigns a certificate profile to an EST profile. Use the following commands to add the *CertAlpha* certificate protocol to the *EST_1* protocol profile:

```
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# protocol instance EST_1
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

You must configure this parameter to assign a valid EST protocol profile to a certificate profile. Multiple certificate profiles can be assigned to a single EST protocol profile.

Renewing Certificates

The **renewal** parameter sets the time to renew the certificate. Configure this parameter as the number of seconds before a certificate expires. By default, the certificate expires after two hours. Use the following commands to configure the renewal time as *3600 seconds*, one hour before the certificate expires:

```
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# renewal 3600 seconds
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

Using the **no** version of the command resets the renewal time to 7200 seconds (2 hours).

9.1.1.5.1.3 Displaying Certificate Profile Information

The **show certificate profile** command displays information about the current status of the certificate profile as well as additional statistics about previous retrievals if you add the **detail** keyword.

```
switch# show management security auto-certificate profile CertAlpha
Auto certificate profile CertAlpha:
    Key:        clientkey.pem
    State:      Valid
    Next request in 89 days, 21:59:47 at: 2025-02-05 01:45:51

switch# show management security auto-certificate profile CertAlpha detail
Auto certificate profile CertAlpha:
    Key:        clientkey.pem
    State:      Valid
    Next request in 89 days, 21:59:37 at: 2025-02-05 01:45:51
    Initial enrollment statistics:
    Number of successes: 1
    Number of failures:  0
    Renewal statistics:
    Number of successes: 0
```

The output displays the following information about the certificate profile:

- **Key** - Displays the current key associated with the retrieved certificate.
- **State** - Displays the current state of the certificate profile. The certificate profile state may be one of the following transient values:
  - **Initiating** - Temporary state displayed after creating a new certificate profile.
  - **Configuration changed** - Temporary state displayed after changing a certificate profile configuration.

- **Invalid configuration** - Displayed when the certificate profile has an invalid configuration and preventing certificate retrievals for this profile.
- **Needs enrolling** - Displayed when the certificate requires enrollment but the process has not begun.
- **Enrolling** - Displayed during the certificate initial enrollment process and changes after retrieving a valid certificate or the process fails after running out of retry attempts.
- **Needs renewing** - Displayed when the certificate requires renewing but the process has not begun
- **Renewing** - Displayed when the certificate renewal process begins and changes after receiving a valid certificate or the process fails after running out of retry attempts.
- **Valid** - Displayed when the certificate profile has a valid configuration and has a valid certificate.
- **Invalid** - Displayed when the certificate renewal process fails or runs out of retry attempts.

- **Last Error** - Displays a timestamp and description of the last error that prevented retrieval of the certificate. Only displays if an error has occurred.
- **Next request** - Displays the timestamp of the next planned request for certificate renewal if a valid certificate profile exists. Or displays the next retrieval attempt with a timestamp if an error occurs during retrieval. Otherwise, displays **Never**.

When adding the **detail** keyword, the output displays the following additional information:

- **Initial enrollment statistics** - Displays counters for successful and failed initial enrollment request attempts.
- **Renewal statistics** - Displays counters for successful and failed renewal request attempts.

Displaying Invalid Configuration Information

The following output displays information about an invalid certificate profile configuration:

```
switch# show management security auto-certificate profile CertAlpha
Auto certificate profile CertAlpha:
    Key:            clientkey.pem
    State:          Invalid configuration
    Last error:
    Message:     Protocol instance not set
    Time:        2024-11-07 04:59:19
Next request at:       Never

switch# show management security auto-certificate profile CertAlpha detail
Auto certificate profile CertAlpha:
Key:    clientkey.pem
State:  Invalid configuration
Last error:
Message:             Protocol instance not set
Time:2024-11-07 04:59:19
Next request at:        Never
Initial enrollment statistics:
Number of successes: 0
Number of failures:  0
Renewal statistics:
Number of successes: 0
Number of failures:  0
```

The profile does not have a valid protocol instance in the configuration and the configuration fails.

Displaying Request Errors

The output displays information about a certificate profile encountering errors when sending requests to the server:

```
switch# show management security auto-certificate profile certProfileCharlie
    Auto certificate profile certProfileCharlie:
    Key:    clientkey.pem
    State:  Enrolling
    Last error:
    Message:             HTTP connection refused
    Time:2024-11-07 05:37:49
    Next request in 0:00:07 at: 2024-11-07 05:37:57

switch# show management security auto-certificate profile certProfileCharlie detail
Auto certificate profile certProfileCharlie:
Key:        clientkey.pem
State:      Enrolling
Last error:
Message:             HTTP connection refused
Time:2024-12-10 05:17:52
Next request in 0:00:04 at: 2024-11-07 05:37:57
Initial enrollment statistics:
Number of successes: 0
Number of failures:  4
Renewal statistics:
Number of successes: 0
Number of failures:  0
```

The certificate request has encountered errors when attempting to reach the EST server.

Displaying All Certificate Profiles

Use the **`show management security auto-certificate profile detail`** to display details about all certificate profiles on the switch:

```
switch# show management security auto-certificate profile detail
Auto certificate profile certProfileCharlie:
    Key:                  clientkey.pem
    State:                Enrolling
    Last error:
    Message:             HTTP connection refused
    Time:                2024-11-07 05:46:19
    Next request in 0:04:41 at: 2024-11-07 05:54:51
    Initial enrollment statistics:
    Number of successes: 0
    Number of failures:  4
    Renewal statistics:
    Number of successes: 0
    Number of failures:  0
Auto certificate profile certProfileAlpha:
    Key:                    clientkey.pem
    State:                  Valid
    Next request in 89 days, 19:55:41 at: 2025-02-05 01:45:51
    Initial enrollment statistics:
    Number of successes: 1
    Number of failures:  0
    Renewal statistics:
    Number of successes: 0
    Number of failures:  0
Auto certificate profile certProfileDelta:
    Key:
    State:              Invalid configuration
    Last error:
    Message:            No parameters set
    Time:               2024-11-07 05:43:07
    Next request at:        Never
    Initial enrollment statistics:
    Number of successes: 0
    Number of failures:  0
    Renewal statistics:
```

```
    Number of successes: 0
    Number of failures:  0
Auto certificate profile certProfileBravo:
    Key:                    clientkey.pem
    State:                  Enrolling
    Last error:
    Message:             HTTP connection refused
    Time:                2024-11-07 05:45:05
    Next request in 0:11:59 at: 2024-11-07 06:02:09
    Initial enrollment statistics:
    Number of successes: 0
    Number of failures:  6
    Renewal statistics:
    Number of successes: 0
    Number of failures:  0
```

9.1.1.5.1.4 *Displaying EST Protocol Profile Information*

The **show management security auto-certificate protocol est** command displays information about the current status of an EST profile. Include the keyword, **detail** to list the certificate profiles managed by each EST protocol profile.

```
switch# show management security auto-certificate protocol est EST_1
Automatic Certificate Management policy EST_1:
    State:      Valid

switch# show management security auto-certificate protocol est EST_1 detail
Automatic Certificate Management policy EST_1:
    State:      Valid
    Managed certificate profile:
    certProfileAlpha:
        Certificate state:   Valid
    certProfileDelta:
        Certificate state:   Invalid configuration
```

The output displays the following information about EST protocol profiles:

- **State** - Displays the current state of the EST protocol profile. The state can be one of the following values:
  - **Configuration changed** - Displays a temporary state present after changing the EST protocol profile configuration.
  - **Valid** - Displays when the switch has a valid EST protocol profile configured.
  - **Invalid** - Displays when the switch has an invalid EST protocol profile configured.
  - **Disabled** - Displays when the EST protocol profile has been temporarily disabled using the **disable** command.
- **Last error** - Displays a timestamp and description of the last error encountered causing the EST protocol profile to be invalid.

The following output for an invalid EST protocol profile displays an error message about the configuration:

```
switch# show management security auto-certificate protocol est EST_2
Automatic Certificate Management policy EST_2:
    State:      Invalid
    Last error:
    Message: Invalid SSL profile
    Time:    2024-11-07 06:28:20

switch# show management security auto-certificate protocol est EST_2 detail
```

```
Automatic Certificate Management policy EST_2:
    State:      Invalid
    Last error:
    Message: Invalid SSL profile
    Time:    2024-11-07 06:28:20
    Managed certificate profile:
    certProfileBravo:
        Certificate state:   Needs enrolling
```

9.1.1.6 Activating Security Services

After configuring the access databases, **`aaa authentication`**, **`aaa authorization`**, and **`aaa accounting`** commands designate active and backup services for handling access requests.

These sections describe the methods of selecting the switch's database to authenticate users and authorize access to network resources.

9.1.1.6.1 Authenticating Usernames and the Enable Password

Service lists specify the services the switch uses to authenticate usernames and the enable password.

9.1.1.6.1.1 Service List Description

Service list elements are service options, ordered by their priority.

Note: When the local file is one of the service list elements, any attempts to locally authenticate a username not included in the local file will result in the switch continuing to the next service list element.

Example

The following is an example service list for username authentication:

1. ***Location_1*** server group - specifies a server group (see Server Groups).
2. ***Location_2*** server group - specifies a server group.
3. TACACS+ servers - specifies all hosts for which a **`tacacs-server host`** command exists.
4. Local file - specifies the local file.
5. None - specifies that no authentication is required and all access attempts succeed.

The switch initially attempts to authenticate a username using the ***Location_1*** server group. If a server within that group is available, authentication proceeds through it. If not, the switch continues checking subsequent server groups until it finds an available one, or it resorts to option 5 (None), permitting access without authentication.

9.1.1.6.1.2 *Configuring Service Lists*

Service lists specify the services the switch uses to authenticate usernames and the enable password, and they are incorporated into the following **`aaa authentication`** commands:

- **aaa authentication login** specifies services the switch uses to authenticate usernames.
- **aaa authentication enable** specifies services the switch uses to authenticate the enable password.

Examples

- This command configures the switch to authenticate usernames through the ***TAC-1*** server group. The local database is the backup method if ***TAC-1*** servers are unavailable.

```
switch(config)# aaa authentication login default group TAC-1 local
```

- This command configures the switch to authenticate usernames through all ***TACACS+*** servers and, if the ***TACACS+*** servers are not available, all RADIUS servers. If the RADIUS servers are unavailable, the switch does not authenticate any login attempts.

```
switch(config)# aaa authentication login default group tacacs+ group radius none
```

- This command configures the switch to authenticate the enable password through all ***TACACS+*** servers and, if the ***TACACS+*** servers are unavailable, through the local database.

```
switch(config)# aaa authentication enable default group TACACS+ local
```

9.1.1.6.2 AAA Time-based Lockout

AAA time-based lockout enables managing remote user unsuccessful login attempts for a specified period.

- The **aaa authentication policy lockout failure** command locks out remote user access for a specified period after several specific consecutive unsuccessful login attempts within a lockout period. In the following example, a user is allowed 4 attempts to log in within 1 day (the default window). After four consecutive unsuccessful logins, the system locks out their user account for 360 seconds.

```
switch(config)# aaa authentication policy lockout failure 4 duration 360
```

- The **show aaa authentication lockout** command displays the status of locked-out users.

```
switch# show aaa authentication lockout
```

- The **clear aaa authentication lockout** command clears a user's locked status, thus restoring access within a lockout period.

```
switch# clear aaa authentication lockout
```

9.1.1.6.3 Authorization

Authorization commands control EOS shell access, CLI command access, and configuration access through the console port. The switch also supports role-based authorization, which allows access to specified CLI commands by assigning command profiles (or roles) to usernames. See Role-Based Authorization for details.

During the exec authorization process, TACACS+ server responses may include attribute-value (AV) pairs. The switch recognizes the mandatory AV pair named ***priv-lvl=x*** (where **x** is between ***0*** and ***15***).

A TACACS+ server that sends any other mandatory AV pair is denied access to the switch by default. The switch's receipt of optional AV pairs does not affect decisions to permit or deny access to the TACACS+ server. The **tacacs-server policy** command programs the switch to allow access to TACACS+ servers that send unrecognized mandatory AV pairs.

The following **aaa authorization** commands configure authorization to switch services:

- To specify the method of authorizing the opening of an EOS shell, enter **aaa authorization exec**.
- To specify the method of authorizing CLI commands, enter **aaa authorization commands**.

Examples

- This command specifies that TACACS+ servers authorize users attempting to open a CLI shell.

```
switch(config)# aaa authorization exec default group tacacs+
```

- This command programs the switch to authorize configuration commands (privilege level ***15***) through the local file and to deny command access to users not listed in the local file.

```
switch(config)# aaa authorization commands all default local
```

- This command programs the switch to permit all commands entered on the CLI.

```
switch(config)# aaa authorization commands all default none
```

- This command configures the switch to permit access to TACACS+ servers that send unrecognized mandatory AV pairs.

```
switch(config)# tacacs-server policy unknown-mandatory-attribute ignore
```

All commands are typically authorized through **aaa authorization commands**. However, the **no aaa authorization config-commands** command disables the authorization of configuration commands. In this state, authorization to execute configuration commands can be managed by controlling access to global configuration commands. The default setting authorizes configuration commands through the policy specified for all other commands.

- Use the **aaa authorization config-commands** command to enable the authorization of configuration commands with the policy specified for all other commands.
- To require authorization of commands entered on the console, enter **aaa authorization serial-console**.

By default, EOS does not verify the authorization of commands entered on the console port.

Examples

- This command disables the authorization of configuration commands.

```
switch(config)# no aaa authorization config-commands
```

- This command enables the authorization of configuration commands.

```
switch(config)# aaa authorization config-commands
```

- This command configures the switch to authorize commands entered on the console using the method specified through a previously executed **aaa authorization** command.

```
switch(config)# aaa authorization serial-console
```

9.1.1.6.4 Accounting

The accounting service collects information for billing, auditing, and reporting. The switch supports TACACS + and RADIUS accounting by reporting user activity to either the TACACS+ server or the RADIUS server as accounting records.

The switch supports two types of accounting:

- **EXEC**: Provides information about user CLI sessions.
- **Commands**: Command authorization for all commands, including configuration commands associated with a privilege level.

The accounting mode determines when accounting notices are sent. Mode options include:

- **start-stop**: a **start** notice is sent when a process begins; a **stop** notice is sent when it ends.
- **stop-only**: a **stop** accounting record is generated upon the successful completion of a process.

The **aaa accounting** command enables accounting.

Examples

- This command configures the switch to maintain start-stop accounting records for all commands executed by switch users and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting commands all default start-stop group tacacs+
```

- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting exec console stop group tacacs+
```

9.1.1.7 TACACS+ Configuration Examples

These sections describe two sample TACACS+ host configurations.

9.1.1.7.1 Single Host Configuration

The example single host configuration consists of a TACACS+ server with these attributes:

- IP address: ***10.1.1.10***.
- encryption key: ***example_1***.
- port number: ***49*** (global default).
- timeout: ***5*** seconds (global default).

The switch authenticates the username and enable command against all TACACS+ servers which, in this case, is one host. If the TACACS+ server is unavailable, the switch authenticates with the local file.

1. This step configures TACACS+ server settings; port number and timeout are global defaults.

```
switch(config)# tacacs-server host 10.1.1.10 key example_1
```

2. This step configures the login authentication service.

```
switch(config)# aaa authentication login default group tacacs+ local
```

3. This step configures the **enable** command password authentication service.

```
switch(config)# aaa authentication enable default group tacacs+ local
```

9.1.1.7.2 Multiple Host Configuration

The example multiple host configuration consists of three TACACS+ servers at these locations:

- IP address ***10.1.1.2*** - port ***49***.
- IP address ***172.16.4.12*** - port ***4900***.
- IP address ***192.168.2.10*** - port ***49***.

The configuration combines the servers into these server groups:

- ***Bldg_1*** group consists of the servers at ***10.1.1.2*** and ***172.16.4.12***.
- ***Bldg_2*** group consists of the servers at ***192.168.2.10***.

All servers use these global TACACS+ defaults:

- encryption key - ***example_2***.
- timeout - ***10 seconds***.

The switch authenticates these access methods:

- username access against ***Bldg_1*** group then, if they are not available, against the local file.
- enable command against ***Bldg_2*** group, then ***Bldg_1*** group, then against the local file.

1. TACACS+ Host Commands:

   These commands configure the IP address and ports for the three TACACS+ servers. The port for the first and third server is default ***49***.

```
switch(config)# tacacs-server host 10.1.1.12
switch(config)# tacacs-server host 172.16.4.12 port 4900
switch(config)# tacacs-server host 192.168.2.10
```

2. Global Configuration Commands:

   These commands configure the global encryption key and timeout values.

```
switch(config)# tacacs-server key example_2
switch(config)# tacacs-server timeout 10
```

3. Group Server Commands:

   The **`aaa group server`** commands create the server groups and place the CLI in server group configuration mode, during which the servers are placed in the group. The port number must be included if it is not the default port, as in the line that adds ***192.168.1.1***.

```
switch(config)# aaa group server tacacs+ Bldg_1
switch(config-sg-tacacs+-Bldg_1)# server 10.1.1.2
switch(config-sg-tacacs+-Bldg_1)# server 192.168.1.1 port 4900
switch(config-sg-tacacs+-Bldg_1)# exit
switch(config)# aaa group server tacacs+ Bldg_2
switch(config-sg-tacacs+-Bldg_2)# server 192.168.2.2
switch(config-sg-tacacs+-Bldg_2)# exit
switch(config)#
```

4. Login and enable configuration authentication responsibility commands.

   These commands configure the username and enable command password authentication services.

```
switch(config)# aaa authentication login default group Bldg_1 local
switch(config)# aaa authentication enable default group Bldg_1 group Bldg_2 local
```

9.1.1.7.3 TACACS+ over TLS

Traditional **TACACS+ (Terminal Access Controller Access-Control System Plus)** relies on raw TCP (Port 49) for transport. While it encrypts the body of the packets, the packet headers, including sensitive fields such as usernames, authorization states, and accounting command logs, remain visible in plaintext. Additionally, the cryptographic model depends on a legacy pre-shared MD5 key, leaving it vulnerable to session hijacking, packet manipulation, and offline brute-force attacks in modern untrusted networks.

TACACS+ over TLS encapsulates all AAA traffic inside a secure **TLS 1.3** tunnel. This implementation provides the following features:

- **Full Session Encryption** - Protects the entire packet payload, including headers, from interception.
- **Mutual Authentication (mTLS)** - Validates the identity of the switch and the identity engine which may be a server using digital certificates.
- **Modern Cryptographic Hardening** - Replaces vulnerable MD5 hashing with the state-of-the-art cipher suites and provides Perfect Forward Secrecy (PFS).
- **Compliance Alignment** - Meets rigid regulatory guidelines, such as NIST-800, FIPS 140-3, and PCI DSS, that strictly forbid legacy, unauthorized transport keys.

Configuring TACACS+ over TLS

To implement TACACS+ over TLS, create a target host with a predefined local SSL client profile. For example, configure a profile on TACACS+ server with the IPv4 address, `10.21.22.23`, and the profile name, `tacacs_server1`:

```
switch(config) tacacs-server host 10.21.22 tls ssl-profile tacacs_server1
switch(config)#
```

To revert the configuration, use the **no** version of the command.

```
switch(config) no tacacs-server host tls
               switch(config)#
```

Creating the Client SSL Profile

To create the SSL profile, define the cryptographic rules, provide the local identity certificate for the TLS server, and configure the trust root Certificate Root Authority that signed the AAA server certificate. Use the following commands to configure the SSL profile, `TACACS-TLS-CLIENT`, and add the certificates:

```
switch(config)# management security
switch(config-mgmt-security)# ssl TACACS-TLS-CLIENT
switch(config-mgmt-sec-ssl-profile-TACACS-TLS-CLIENT)# certificate switch-identity.crt key switch-
identity.key
switch(config-mgmt-sec-ssl-profile-TACACS-TLS-CLIENT)# trust certficate enterprise-root-ca.crt
switch(config-mgmt-sec-ssl-profile-TACACS-TLS-CLIENT)# tls versions 1.3
switch(config-mgmt-sec-ssl-profile-TACACS-TLS-CLIENT)#
```

Provisioning the Secure TACACS+ Host Entry

Configure the switch to access the AAA infrastructure node and activate the TLS option mapped to the `TACACS-TLS-CLIENT` profile:

```
switch(config)# tacacs-server host 192.168.10.20 tls ssl-profile TACACS-TLS-CLIENT
switch(config)#
```

Mapping the Secure Host to the AAA Engine

Construct a TACACS+ server group containing the secure host, and assign it to control terminal access and privilege elevation behavior.

```
switch(config)# aaa group server tacacs+ SECURE-AAA-GROUP
switch(config-aaa-vessel-SECURE-AAA-GROUP)# server 192.168.10.50
switch(config-aaa-vessel-SECURE-AAA-GROUP)# exit
!
switch(config)# aaa authentication login default group SECURE-AAA-GROUP local
switch(config)# aaa authorization exec default group SECURE-AAA-GROUP local
switch(config)# aaa accounting commands 15 default start-stop group SECURE-AAA-GROUP
switch(config)#
```

Displaying TACACS+ over TLS

Use the **`show management security`** to display the TACACS+ configuration:

```
switch# show management security ssl profile TACACS-TLS-CLIENT
Profile: TACACS-TLS-CLIENT
  Type: Client
  State: Operational
  TLS Versions: 1.3
  Certificate: switch-identity.crt
  Trust Anchor: enterprise-root-ca.crt
  Active Connections: 1
```

9.1.1.8 AAA Accounting for OpenConfig Remote Procedure Call (RPC) Messages Overview

OpenConfig allows network engineers to collaboratively develop programming interfaces and tools to manage networks dynamically and in a vendor-neutral manner.

EOS supports AAA Accounting for gRPC Network Management Interface (gNMI), gRPC Network Operations (gNOI) Interface, and gRPC Network Security Interface (gNSI) RPCs by logging the accounting records to a TACACS+ server, RADIUS server, or to a syslog server.

9.1.1.9 AAA Commands

Local Security File Commands

- aaa root
- enable password
- show privilege

- show users
- show users accounts
- username
- username ssh-key

Accounting, Authentication, and Authorization Commands

- aaa accounting
- aaa accounting dot1x
- aaa accounting system
- aaa authentication dot1x
- aaa authentication enable
- aaa authentication login
- aaa authentication policy local allow-nopassword-remote-login
- aaa authentication policy lockout failure
- aaa authentication policy log
- aaa authorization commands
- aaa authorization config-commands
- aaa authorization exec
- aaa authorization policy local default-role
- aaa authorization serial-console
- clear aaa authentication lockout
- clear aaa counters
- clear aaa counters radius
- clear aaa counters tacacs+
- clear radius proxy counters client group
- show aaa
- show aaa authentication lockout
- show aaa counters
- show aaa methods
- show management ldap
- show users detail

Automatic X.509 Certificate Management Commands

- auto-certificate protocol connection
- auto-certificate protocol credentials
- auto-certificate protocol disabled
- auto-certificate protocol server
- auto-certificate profile
- auto-certificate profile
- auto-certificate profile parameters
- show management security auto-certificate profile
- show management security auto-certificate protocol est

Server (RADIUS and TACACS+) Configuration Commands

- ip radius source-interface
- ip tacacs source-interface
- radius proxy
- radius proxy client group client
- radius proxy client group server
- radius proxy client key
- radius proxy client session
- radius proxy dynamic-authorization
- radius-server deadtime
- radius-server host
- radius-server key
- radius-server retransmit
- radius-server timeout
- show radius
- show radius proxy client group
- show radius proxy server group
- show tacacs
- tacacs-server host
- tacacs-server key
- tacacs-server policy

- tacacs-server timeout

Server Group Configuration Commands

- aaa group server radius
- aaa group server tacacs+
- server (server-group-RADIUS configuration mode)
- server (server-group-TACACS+ configuration mode)

Role-Based Authorization Configuration Commands

- deny (Role)
- no <sequence number> (Role)
- permit (Role)
- resequence (Role)
- role
- show users roles

9.1.1.9.1 aaa accounting dot1x

The **`aaa accounting dot1x`** command enables the accounting of requested 802.1X services for network access.

The **`no aaa accounting dot1x`** and **`default aaa accounting dot1x`** commands disable the specified method list by removing the corresponding **`aaa accounting dot1x`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa accounting dot1x default` [**METHOD_1**][**METHOD_2**][**METHOD_N**]

`no aaa accounting dot1x default`

`default aaa accounting dot1x default`

Parameters

- **MODE** - The accounting mode that defines when to send accounting notices. Options include the following:
  - **start-stop** - Send a *start* notice when a process begins, and a *stop* notice when it ends.
- **METHOD_X** - The server groups (methods) that receives accounting records from the switch. The switch sends the method list to the first available listed group.
- No parameter specified if **MODE** is set to **none**. If **MODE** not set to **none**, the command must provide at least one method. Each method consists of one of the following:
- ***group name*** the server group identified by *name*.
  - ***group radius*** server group that includes all defined RADIUS hosts.
  - ***logging*** server group that includes all defined TACACS+ hosts.

Examples

- This example configures ***IEEE 802.1X*** accounting on the switch.

```
switch(config)# aaa accounting dot1x default start-stop group radius
switch(config)#
```

- This example disables ***IEEE 802.1X*** accounting on the switch.

```
switch(config)# no aaa accounting dot1x default
switch(config)#
```

9.1.1.9.2 aaa accounting system

The **aaa accounting system** command performs accounting for all system-level events.

The **no aaa accounting system** and **default aaa accounting system** commands clear the specified method list by removing the corresponding **aaa accounting system** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa accounting system default` [**METHOD_1**][**METHOD_2**] ... [**METHOD_N**]

`no aaa accounting system default`

`default aaa accounting system default`

Parameters

- **MODE** The accounting mode that defines when to send accounting notices. Options include the following:
  - **none** - Do not send notices.
  - **start-stop** - Send a *start* notice when a process begins, and send a *stop* notice when it ends.
  - **stop-only** - Generate a *stop* accounting record after a process successfully completes.
- **METHOD_X** - The server groups (methods) that receives accounting records from the switch. The switch sends the method list to the first available listed group.
- No parameter specified if **MODE** is set to **none**. If **MODE** not set to **none**, the command must provide at least one method. Each method consists of one of the following:
  - **group *name*** - The server group identified by the *name.*
    - **group radius** - The server group that includes all defined RADIUS hosts.
    - **group tacacs+** - The server group that includes all defined TACACS+ hosts.
    - **logging** Log all accounting messages to Syslog..

Examples

- This command configures AAA accounting to not use any accounting methods for system events.

```
switch(config)# aaa accounting system default none
switch(config)#
```

- This command configures the switch to maintain stop accounting records for system events to all defined RADIUS hosts.

```
switch(config)# aaa accounting system default stop-only group radius
switch(config)#
```

9.1.1.9.3 aaa accounting

The **`aaa accounting`** command configures accounting method lists for a specified authorization type. Each list consists of a prioritized list of methods. The accounting module uses the first available listed method for the authorization type.

The **`no aaa accounting`** and **`default aaa accounting`** commands clear the specified method list by removing the corresponding **`aaa accounting`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa accounting` **TYPE CONNECTION MODE** [**METHOD_1**][**METHOD_2**] ... [**METHOD_N**]

`no aaa accounting` **TYPE CONNECTION**

`default aaa accounting` **TYPE CONNECTION**

Parameters

- **TYPE** -Authorization type for which the command specifies a method list. Options include:
  - **EXEC** - Records user authentication events.
  - **COMMANDS ALL** - Records all entered commands.
  - **COMMANDS** *level* - Records entered commands of the specified *level* (ranges from ***0*** to ***15***).
- **CONNECTION** - The connection type of sessions that report method lists. Options include the following:
  - **console** - Console connection.
  - **default** - All connections not covered by other command options.
- **MODE** - The accounting mode that defines when to send accounting notices. Options include the following:
  - **none** - No notices sent.
  - **start-stop** a *start* - Send a notice when a process begins, and send a *stop* notice when it ends.
  - **stop-only** a *stop* - Generate an accounting record after a process successfully completes.
- **METHOD_X** server groups (methods) to receive accounting records. The switch sends the method list to the first available listed group.

- If you set the **MODE** to **none**, no parameter value is specified. If you do not set the **MODE** to **none**, the command must provide at least one method. Each method consists of one of the following:
  - ***group name*** - The server group identified by *name*.
  - ***group radius*** - The server group that includes all defined RADIUS hosts.
  - ***group tacacs+*** - The server group that includes all defined TACACS+ hosts.
  - ***logging*** - Log all accounting messages to Syslog.

Examples

- This command configures the switch to maintain start-stop accounting records for all commands executed by switch users and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting commands all default start-stop group tacacs+
switch(config)#
```

- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting exec console stop group tacacs+
switch(config)#
```

- This command configures the switch to maintain start-stop accounting records for all commands executed by switch users and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting commands all default start-stop group tacacs+
switch(config)#
```

- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.

```
switch(config)# aaa accounting exec console stop group tacacs+
switch(config)#
```

9.1.1.9.4 aaa authentication dot1x

The **aaa authentication dot1x** command configures the default authentication list of requested 802.1X services for network access.

The **no aaa authentication dot1x** and **default aaa authentication dot1x** commands remove the default authentication list for IEEE 802.1X.

Command Mode

Global Configuration

Command Syntax

`aaa authentication dot1x default` group {*group_name* | *radius*}

`no aaa authentication dot1x default`

`default aaa authentication dot1x`

Parameters

- **default** configures the default authentication list of requested 802.1X services for network access.
- **group** configures server group.
- ***group_name*** server group name; multiple group names can be entered in a single command.
- **radius** list of all defined RADIUS hosts.

Example

This command configures the switch in the **auth1** group for IEEE 802.1X authentication.

```
switch(config)# aaa authentication dot1x default group auth1
switch(config)#
```

9.1.1.9.5 aaa authentication enable

The **`aaa authentication enable`** command configures the service list that the switch references to authorize access to Privileged EXEC command mode.

The list consists of a prioritized list of service options. Available service options include the following:

- A named server group
- All defined TACACS+ hosts
- All defined RADIUS hosts
- Local authentication
- No authentication

The switch authorizes access by using the first listed service option available. When the local file is a service list element, attempts to locally authenticate a username not in the local file results in the switch continuing to the next service list element.

EOS supports a **console list** for authorizing usernames through the console and a default list for authorizing usernames through all other connections.

- If no console list exists, the console connection uses the **default** list.
- If no default list exists, the list sets to **local**.

The **`no aaa authentication enable`** and **`default aaa authentication enable`** commands revert the list configuration to the *default* by removing the corresponding **`aaa authentication enable`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa authentication enable` [console | default] **METHOD_1** [**METHOD_2**] ... [**METHOD_N**]

`no aaa authentication enable` [console | default]

`default aaa authentication enable` [console | default]

Parameters

console - Uses the console authentication list.

default - Uses the default authentication list.

METHOD_X authentication service method list. The command must provide at least one method. Each method consists of one of the following:

- **group *name*** the server group identified by *name*.
- **group radius** a server group that consists of all defined RADIUS hosts.
- **group tacacs+** a server group that consists of all defined TACACS+ hosts.
- **local** local authentication.
- **none** users are not authenticated; all access attempts succeed.

Example

This command configures the switch to authenticate the enable password through all configured TACACS+ servers. Local authentication is the backup if TACACS+ servers are unavailable.

```
switch(config)# aaa authentication default enable group TACACS+ local
switch(config)#
```

9.1.1.9.6 aaa authentication login

The **aaa authentication login** command configures service lists the switch references to authenticate usernames. Service lists consist of service options ordered by usage priority. The switch authenticates usernames through the first available service option. Supported service options include the following:

- A named server group
- All defined TACACS+ hosts
- All defined RADIUS hosts
- Local authentication
- No authentication.

When the local file contains a service list element, attempts to locally authenticate a username not in the local file results in the switch continuing to the next service list element.

The switch supports a **console** list for authenticating usernames through the console and a default list for authenticating usernames through all other connections.

- When the **console** list is not configured, the console connection uses the **default** list.
- When the **default** list is not configured, it is set to *local*.

The **no aaa authentication login** and **default aaa authentication login** commands revert the specified list configuration to its default by removing the corresponding **aaa authentication** login command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa authentication login` **CONNECTION SERVICE_1** [**SERVICE_2**] ... [**SERVICE_N**]

`no aaa authentication login` **CONNECTION**

`default aaa authentication login` **CONNECTION**

Parameters

- **CONNECTION** connection type of sessions for which authentication list is used.

  - **default** the default authentication list.
  - **console** the authentication list for console logins.
- **SERVICE_X** an authentication service. Settings include:
  - **group *name*** identifies a previously defined server group.
  - **group radius** a server group that consists of all defined RADIUS hosts.
  - **group tacacs+** a server group that consists of all defined TACACS+ hosts.
  - **local** local authentication.
  - **none** The switch does not perform authentication. All access attempts succeed.

Examples

- This command configures the switch to authenticate usernames through the ***TAC-1*** server group. The local database is the backup method if ***TAC-1*** servers are unavailable.

```
switch(config)# aaa authentication login default group TAC-1 local
switch(config)#
```

- This command configures the switch to authenticate usernames through all TACACS+ servers, then all RADIUS servers if the TACACS+ servers are not available. If the RADIUS servers are also unavailable, the switch allows access to all login attempts without authentication.

```
switch(config)# aaa authentication login default group tacacs+ group radius none
switch(config)#
```

9.1.1.9.7 aaa authentication policy local allow-nopassword-remote-login

The **aaa authentication policy local allow-nopassword-remote-login** command permits usernames without passwords to log in from any port. The default switch setting only allows unprotected usernames to log in from the console.

The **no aaa authentication policy local allow-nopassword-remote-login** and **default aaa authentication policy local allow-nopassword-remote-login** commands return the switch to the default setting of allowing unprotected usernames to log in only from the console.

Command Mode

Global Configuration

Command Syntax

```
aaa authentication policy local allow-nopassword-remote-login

no aaa authentication policy local allow-nopassword-remote-login

default aaa authentication policy local allow-nopassword-remote-login
```

Examples

- This command configures the switch to allow unprotected usernames to log in from any port.

```
switch(config)# aaa authentication policy local allow-nopassword-remote-login
switch(config)#
```

- This command configures the switch to allow unprotected usernames to log in only from the console port.

```
switch(config)# no aaa authentication policy local allow-nopassword-remote-login
switch(config)#
```

9.1.1.9.8 aaa authentication policy lockout failure

The **aaa authentication policy lockout failure** command configures the switch to block the remote user from access after a specified number of unsuccessful login attempts within a lockout period.

The **no aaa authentication policy lockout failure** and the **default aaa authentication policy lockout failure** commands disable the lockout period configuration.

Command Mode

Global Configuration

Command Syntax

`aaa authentication policy lockout failure` *failure_count* duration *duration_time* {window *window_time*}

`no aaa authentication policy lockout failure`

`default aaa authentication policy lockout failure`

Parameters

- ***failure_count*** - The number of failed logins allowed during access. Specify a valid number between 1 and 255.
- **duration *duration_time*** - The time in seconds to block a user account from login. Specify a value between ***1*** and ***4294967295*** seconds.
- **window *window_time*** the time in seconds to track failed logins within this duration. The value is between ***1*** and ***4294967295*** seconds while the default is 1 day.

Examples

- This command configures the system to allow four attempts to log in within a duration of 1 day by default. If the user has 4 unsuccessful consecutive logins, EOS locks the person out of the account for 360 seconds.

```
switch(config)# aaa authentication policy lockout failure 4 duration 360
```

- This command configures the system to allow five attempts to log in within a duration of 1 day by default. If the user has 5 unsuccessful consecutive logins, EOS locks the person out of the account for 60 seconds.

```
switch(config)# aaa authentication policy lockout failure 5 window 10 duration 60
```

9.1.1.9.9 aaa authentication policy log

The **aaa authentication policy log** command configures the switch to generate syslog messages for login authentication success or failure events.

The **no aaa authentication policy log** and the **default aaa authentication policy log** commands restore the default behavior of not generating syslog messages for these events.

Command Mode

Global Configuration

Command Syntax

`aaa authentication policy` {on-failure | on-success} `log`

`no aaa authentication policy` {on-failure | on-success} `log`

`default aaa authentication policy` {on-failure | on-success} `log`

Parameters

- **on-failure** - Generates syslog messages for failed login events.
- **on-success** - Generates syslog messages for successful login events.

Example

This command configures the switch to log successful and failed login attempts.

```
switch(config)# aaa authentication policy on-success log
switch(config)# aaa authentication policy on-failure log
```

9.1.1.9.10 aaa authorization commands

The **`aaa authorization commands`** command configures the service list that authorizes CLI command access. All switch commands are assigned a privilege level that corresponds to the lowest level command mode from which it can be executed:

- **Level 1**: Commands accessible from ***EXEC*** mode.
- **Level 15**: Commands accessible from any mode except ***EXEC***.

Command usage is authorized for each privilege level specified in the command.

The list consists of a prioritized list of service options. The switch authorizes access by using the first listed service option available. The available service options include the following:

- A named server group.
- All defined TACACS+ hosts.
- All defined RADIUS hosts.
- Local authorization.
- No authorization.

The list is set to **none** for all unconfigured privilege levels, allowing all CLI access attempts to succeed.

The **`no aaa authorization commands`** and **`default aaa authorization commands`** commands revert the list contents to **none** for the specified privilege levels.

Command Mode

Global Configuration

Command Syntax

`aaa authorization commands` **PRIV default SERVICE_1[SERVICE_2] ... [SERVICE_N]**

`no aaa authorization commands` **PRIV default**

`default aaa authorization commands` **PRIV default**

Parameters

- **PRIV** Privilege levels of the commands. Options include the following:
  - **level** - Numbers between ***0*** and ***15***. Number, range, and comma-delimited list of numbers and ranges.

- **all** - Commands of all levels.

- **SERVICE_X** Authorization service. Command must list at least one service. Options includethe following:
  - **group *name*** - The server group identified by name.
  - **group tacacs+** - A server group that consists of all defined TACACS+ hosts.
  - **local** - Local authorization.
  - **none** - The switch does not perform authorization. All access attempts succeed.

Examples

- This command authorizes configuration commands (privilege level ***15***) through the local file. The switch denies command access to users not listed in the local file.

```
switch(config)# aaa authorization commands all default local
switch(config)#
```

- This command authorizes all commands entered on the CLI.

```
switch(config)# aaa authorization commands all default none
switch(config)#
```

9.1.1.9.11 aaa authorization config-commands

The **aaa authorization config-commands** command enables authorization of commands in any configuration mode, such as Global Configuration and all interface configuration modes. The policy specified by the aaa authorization commands setting authorizes the commands. EOS enables authorization by default, so issuing this command has no effect unless ***running-config*** contains the **no aaa authorization config-commands** command.

The **no aaa authorization config-commands** command disables configuration command authorization. When disabled, ***running-config*** contains the **no aaa authorization config-commands** command. The **default aaa authorization config-commands** command restores the default setting by removing the **no aaa authorization config-commands** from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
aaa authorization config-commands

no aaa authorization config-commands

default aaa authorization config-commands
```

Examples

- This command enables the authorization of configuration commands.

```
switch(config)# aaa authorization config-commands
switch(config)#
```

- This command disables the authorization of configuration commands.

```
switch(config)# no aaa authorization config-commands
switch(config)#
```

9.1.1.9.12 aaa authorization exec

The **aaa authorization exec** command configures the service list that the switch references to authorize access to open an EOS CLI shell.

The list consists of a prioritized list of service options. The switch authorizes access by using the first listed service option to which the switch can connect. When the switch cannot communicate with an entity that provides a specified service option, it attempts to use the next option in the list.

The available service options include the following:

- A named server group.
- All defined TACACS+ hosts.
- All defined RADIUS hosts.
- Local authentication.
- No authentication.

EOS supports a **console** list to authorize access to a CLI shell through the console and a **default** list to authorize access for all other connections.

- If no console list exists, the console connection uses the **default** list and you enable **aaa authorization serial-console**. Otherwise, uses **none**.
- If no default list exists, the list sets to **local**.

The **no aaa authorization exec** and **default aaa authorization exec** commands set the list contents to **none**.

Command Mode

Global Configuration

Command Syntax

`aaa authorization exec default` **METHOD_1** [**METHOD_2**] ... [**METHOD_N**]

`no aaa authorization exec default`

`default aaa authorization exec default`

Parameters

- **METHOD_X** authorization service (method). The switch uses the first listed available method.

  The command must provide at least one method. Each method is composed of one of the following:

- **group *name*** - The server group identified by name.
- **group radius** - A server group that consists of all defined RADIUS hosts.
- **group tacacs+** - A server group that consists of all defined TACACS+ hosts.
- **local** - Local authentication.
- **none** - The switch does not perform authorization. All access attempts succeed.

Guidelines

During the EXEC authorization process, the TACACS+ server response may include attribute-value (AV) pairs. The switch recognizes **priv-lvl=x** (where **x** is an integer between ***0*** and ***15***), which is a mandatory AV pair. A TACACS+ server that sends any other mandatory AV pair cannot access the switch. The receipt of optional AV pairs by the switch has no effect on decisions to permit or deny access to the TACACS+ server.

Example

This command specifies that the TACACS+ servers authorize users attempting to open an EOS CLI shell.

```
switch(config)# aaa authorization exec default group tacacs+
switch(config)#
```

9.1.1.9.13 aaa authorization policy local default-role

The **aaa authorization policy local** command specifies the name of the default role. A role provides a data structure that supports local command authorization through assignment to user accounts. Roles consist of permit and deny rules that define authorization levels for specified commands. Applying a role to a username authorizes the user to execute commands specified by the role.

The default role is assigned to the following users:

- Local or remote users assigned to an unconfigured role.
- Local users without an assigned role.

If you do not specify the default-role for a user, EOS assigns **network-operator** to qualified users as the default role. The network-operator role authorizes assigned users access to all CLI commands in EXEC and Privileged EXEC modes.

The **no aaa authentication policy local default-role** and **default aaa authentication policy local default-role** commands remove the **authentication policy local default-role** statement from ***running-config***. Removing this statement restores **network-operator** as the default role.

Command Mode

Global Configuration

Command Syntax

```
aaa authorization policy local default-role  role_name

no aaa authorization policy local default-role

default aaa authorization policy local default-role
```

Parameter

role_name - Specify the name of the default role.

Related Command

The role command places the switch in ***role*** configuration mode for creating and editing roles.

Examples

- This command configures the sysuser as the default role.

```
switch(config)# aaa authorization policy local default-role sysuser
switch(config)#
```

- This command restores **network-operator** as the default role.

```
switch(config)# no aaa authorization policy local default-role
switch(config)#
```

- This command displays the contents of the **network-operator** role.

```
switch# show users roles network-operator
The default role is network-operator
role: network-operator
        10 deny mode exec command bash|\|
        20 permit mode exec command .*
switch#
```

9.1.1.9.14 aaa authorization serial-console

The **aaa authorization serial-console** command configures the switch to authorize commands entered through the console. By default, commands entered through the console do not require authorization.

The **no aaa authorization serial-console** and **default aaa authorization serial-console** commands restore the default setting.

Command Mode

Global Configuration

Command Syntax

```
aaa authorization serial-console

no aaa authorization serial-console

default aaa authorization serial-console
```

Example

This command configures the switch to authorize commands entered on the console, using the method specified through a previously executed aaa authorization commands command.

```
switch(config)# aaa authorization serial-console
switch(config)#
```

9.1.1.9.15 aaa group server radius

The **`aaa group server radius`** command enters the Server-group-RADIUS Configuration Mode for the specified group name. The command creates the specified group if not previously created.

A server group consists of a collection of servers associated with a single label. Subsequent authorization and authentication commands access all servers in a group by invoking the group name. Server group members must be previously configured with a radius-server host command.

The **`no aaa group server radius`** and **`default aaa group server radius`** commands delete the specified server group from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa group server radius` *group_name*

`no aaa group server radius` *group_name*

`default aaa group server radius` *group_name*

Parameters

group_name - Specify a name, as a text string, to assign to the group. Cannot be identical to a name already assigned to a TACACS+ server group.

Commands Available in Server-group-RADIUS Configuration Mode

server (server-group-RADIUS configuration mode).

Related Command

aaa group server tacacs+.

Example

This command creates the RADIUS server group named ***RAD-SV1*** and enters ***Server-group-RADIUS*** configuration mode for the new group.

```
switch(config)# aaa group server radius RAD-SV1
switch(config-sg-radius-RAD-SV1)#
```

9.1.1.9.16 aaa group server tacacs+

The **aaa group server tacacs+** command enters Server-group-TACACS+ Configuration Mode for the specified group name. The command creates the specified group if not previously created.

A server group consists of a collection of servers associated with a single label. Subsequent authorization and authentication commands access all servers in a group by invoking the group name. Server group members must be previously configured with a tacacs-server host command.

The **no aaa group server tacacs+** and **default aaa group server tacacs+** commands delete the specified server group from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`aaa group server tacacs+` *group_name*

`no aaa group server tacacs+` *group_name*

`default aaa group server tacacs+` *group_name*

Parameters

group_name - Specify a name, as a text string, to assign to the group. Cannot be identical to a name already assigned to a RADIUS server group.

Commands Available in Server-group-TACACS+ Configuration Mode

server (server-group-TACACS+ configuration mode)

Related Command

aaa group server radius

Example

This command creates the TACACS+ server group named TAC-GR and enters the Server-group-TACAS+ Configuration Mode for the new group.

```
switch(config)# aaa group server tacacs+ TAC-GR
switch(config-sg-tacacs+-TAC-GR)#
```

9.1.1.9.17 aaa root

The **aaa root** command specifies the password security level for the root account and can assign a password to the account.

The **no aaa root** and **default aaa root** commands disable the root account by removing the **aaa root** command from ***running-config***. The root account is disabled by default.

Command Mode

Global Configuration

Command Syntax

`aaa root` **SECURITY_LEVEL** [**ENCRYPT_TYPE**] [*password*]

`no aaa root`

`default aaa root`

Parameters

- **SECURITY_LEVEL** - Specify the password assignment level. Settings include the following:
  - **secret** Assigns the password to the root account.
  - **nopassword** - Does not assign a password to the root account.
- **ENCRYPT_TYPE** encryption level of the ***password*** parameter. This parameter is present only when **SECURITY_LEVEL** is **secret**. Settings include:
  - **no parameter** the password is entered as clear text.
  - **0** the password is entered as clear text. Equivalent to **no parameter**.
  - **5** the password is entered as an MD5-encrypted string.
  - **sha512** the password is entered as an SHA-512-encrypted string.
- ***password*** text that authenticates the username. The command includes this parameter only if **SECURITY_LEVEL** is **secret**.
  - ***password*** must be in clear text if **ENCRYPT_TYPE** specifies clear text.
  - ***password*** must be an appropriately encrypted string if **ENCRYPT_TYPE** specifies encryption.

Encrypted strings entered through this parameter are generated elsewhere.

Examples

- These equivalent commands assign ***f4980*** as the root account password.

```
switch(config)# aaa root secret f4980
switch(config)# aaa root secret 0 f4980
```

- This command assigns the text (***ab234***) that corresponds to the encrypted string of ***1HW05LEY8$QEVw6JqjD9VqDfh.O8r.b.*** as the root password.

```
switch(config)# aaa root secret 5 $1$HW05LEY8$QEVw6JqjD9VqDfh.O8r.b
switch(config)#
```

- This command removes the password from the root account.

```
switch(config)# aaa root nopassword
switch(config)#
```

- This command disables the root login.

```
switch(config)# no aaa root
switch(config)#
```

9.1.1.9.18 auto-certificate protocol connection

The **auto-certificate protocol connection** command configures parameters for Enrollment over Secure Transport (EST) profiles used for Automatic Certificate Management.

Command Mode

Management Security Configuration

EST Protocol Profile Configuration

Command Syntax

auto-certificate protocol est ***profile_name*** **connection retry [count** ***retries*** **| interval** ***seconds***

Parameters

- **est** ***profile_name*** - Configure a name for the EST profile.
- **connection** - Configure the options for connecting to the EST server.
  - **retry** - Configure the retry behavior.

- **`count`** ***retries*** - Configure the number of attempted retries before giving up on the connection. If unconfigured, the connection attempts an infinite number of retries. Configure the number of retries between 0 and 4294967295.
- **`interval`** ***seconds*** - Configure the time interval, in seconds, between retries. Use a value between 1 and 4294967295 seconds.

Example

Use the following commands to configure the number of retries to *100* with an interval of *2* seconds, on the EST profile, *EST_1*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# connection retry count 100
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# connection retry interval 2 seconds
```

9.1.1.9.19 auto-certificate protocol credentials

The **auto-certificate protocol credentials** command configures the enrollment and re-enrollment usernames and pairs or JSON Web Tokens (JWTs). The EST profile only uses the credentials for HTTP authentication requests to the server.

The **no | default** versions of the command disables the credentials configuration on the switch.

Command Mode

Management Security Configuration

EST Protocol Profile Configuration

Command Syntax

auto-certificate protocol est ***profile_name*** **credentials [enroll | re-enroll] [secret | token | username] [0 | 7 | 8a]** ***line*****]**

Parameters

- **protocol est** ***profile_name*** - Configure an EST protocol profile name.
- **credentials** - Configure credentials for EST authentication.
- **[enroll | re-enroll]** - Configure credentials for initial enrollment and re-enrollment.
  - **secret** - Configure a password for HTTP basic authentication.
  - **token** - Configure a token for HTTP basic authentication.
  - **username** - Configure a username for HTTP basic authentication.
    - **0** - Indicates an unencrypted key string follows.
    - **7** - Specifies a hidden key follows.
    - **8a** - Specifies an AES-256-GCM encrypted key follows.
    - ***line*** - Configure a clear text key string.

Example

Use the following commands to create enrollment credentials for EST protocol profile, *EST_1*, with an unencrypted secret, *password1234*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# credentials enroll secret 0 password1234
```

```
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)#
```

9.1.1.9.20 auto-certificate protocol disabled

The **auto-certificate protocol disabled** command temporarily pauses retrieving certificates from the server by disabling the profile and prevents sending unnecessary requests to the server. This may be helpful when troubleshooting server connections and does not require reconfiguration of the EST protocol profile. The **no** version of the command re-enables the profile.

Command Mode

Management Security

EST Protocol Profile Configuration

Command Syntax

auto-certificate protocol est ***profile_name*** **disabled**

Parameters

- **disabled** - Temporarily disable sending EST requests to the server.

Examples

Use the following commands to disable EST protocol profile, *EST_1*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# disabled
```

To re-enable the profile, use the following commands:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# no disabled
```

9.1.1.9.21 auto-certificate protocol server

The **auto-certificate protocol server** command configures EST server behavior and options such as SSL profiles, server URLs, and VRFs.

The **no | default** versions of the command removes the configuration from the EST Protocol Profile.

Command Mode

Management Security

EST Protocol Profile Configuration

Command Syntax

auto-certificate protocol est ***profile_name*** **server [ssl** ***ssl_profile*****] [url** ***server_url*****] [vrf** ***vrf*****]**

Parameters

- **protocol est** ***profile_name*** - Configure a name for the EST protocol profile.
- **server** - Configure EST server options:
  - **ssl** ***ssl_profile*** - Specify an SSL profile name to add to the configuration.
  - **url** ***server_url*** - Specify an EST server URL to retrieve certificates. The URL must start with **https://**.
  - **vrf** ***vrf*** - Specify the VRF to perform EST requests.

Example

Use the following commands to add a URL, *https://myestserver.mycompany.com*, to the EST protocol profile, *EST_1*

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate protocol est EST_1
switch(config-mgmt-sec-auto-cert-proto-est-EST_1)# server url https://myestserver.mycompany.com
```

9.1.1.9.22 auto-certificate profile

The **auto-certificate profile** command allows configuration of Automatic Certificate Management and profiles for X.509 certificates. X.509 automatic certificate management provides support for retrieving signed X.509v3 certificates from a server using the Enrollment over Secure Transport (EST) protocol. EOS only supports EST as the client protocol.

The **no | default** versions of the command remove the configuration from the ***running-config***.

Command Mode

Management Security Configuration

Certificate Profile Configuration

Command Syntax

auto-certificate profile ***profile_name*** **[digest [sha256 | sha384 | sha512]] [key** ***key_name*****] [protocol instance** ***protocol_instance_name*****] [renewal** ***expire_seconds*** **seconds]**

Parameters

- **profile** ***profile_name*** - Specify a name for the auto-certificate profile.
- **digest [sha256 | sha384 | sha512** - Specify a digest algorithm to sign Certificate Signing Requests.
  - **sha256** - Use a 256 bit SHA digest algorithm, the default value.
  - **sha384** - Use a 384 bit SHA digest algorithm.
  - **sha512** - Use a 512 bit SHA digest algorithm.
- **key** ***key_name*** - Configure a key for the certificate.
- **protocol instance** ***protocol_instance_name*** - Configure automatic certificate management for the certificate.
- **renewal** ***expire_seconds*** - Configure a renewal time for the certificate in seconds with a range of 1 to 4294967295, with a default value of 7200.

Example

Use the following commands to add a digest algorithm, *sha512*, to the certificate profile, *CertACM*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertACM
```

```
switch(config-mgmt-sec-auto-cert-prof-CertACM) digest sha512
```

9.1.1.9.23 auto-certificate profile parameters

The **auto-certificate profile parameters** command configures the certificate attributes including distinguished name and subject alternative name. By default, all fields do not have values until configured. Use quotation marks (" ") for attributes with multiple words, such as *"Switch 1"*. Repeating the commands with different values replaces the existing values. For the configuration to be valid, you must configure at least one parameter.

The **no | default** versions of the command clears the field values from the ***running-config***.

Command Mode

Management Security Configuration

Certificate Profile Configuration

Command Syntax

auto-certificate profile ***profile_name*** **parameters [distinguished-name [common-name** ***common_name*****] [country** ***country_code*****] [email** ***email_address*** **] [locality** ***locality_name*** **] [organization** ***name*** **] [organization-unit** ***unit_name*** **] [state** ***state_name*****]]**

auto-certificate profile ***profile_name*** **parameters [subject-alternative-name [dns** ***dns_name*****] [email** ***email_address*****] [ip** ***ip_address*****] [uri** ***uri*****]]**

Parameters

- **profile** ***profile_name*** - Specify the name of the certificate profile.
- **parameters** - Configure the parameters for the certificate.
  - **distinguished-name** - Configure the distinguished name for the certificate.
  - **common-name** ***common_name*** - Specify the common name used in the subject of the certificate.
  - **country** ***country_code*** - Specify the two-letter country code used in the subject of the certificate.
  - **email** ***email_address*** - Specify the email address.
  - **locality** ***locality_name*** - Specify the locality.
  - **organization** ***name*** - Specify the organization name.
  - **organization-unit** ***organization-unit*** - Specify the organization-unit name.
  - **serial-number** ***single_double_quote*** **system**- Specify a single or double quoted line or use the system serial number.
  - **state** ***state_name*** - Specify the state name.

- **`profile`** ***profile_name*** - Specify the name of the certificate profile.
- **`parameters subject-alternative-name`** - Configure the subject alternative name extensions.
  - **`dns`** ***dns_name*** - Specify the DNS name to use in the configuration.
  - **`email`** ***email_address*** - Specify the email address.
  - **`ip`** ***ip_address*** - Specify the IP address as an IPv4 or IPv6 address.
  - **`uri`** ***uri*** - Specify the URI to use in the configuration.

Example

Use the following commands to add the IPv4 address, *192.168.1.1*, the IPv6 address, *3FF.FFFF::1*, the email address, *mail@yourcompany.com*, and the URI, *http://example.com/path/etc* to the certificate profile, *CertAlpha*:

```
switch(config)# management security
switch(config-mgmt-security)# auto-certificate profile CertAlpha
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name ip 192.0.2.1
 192.0.2.2 3FFF:FFFF::1"
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name email
 mail@example.com
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)# parameters subject-alternative-name uri https://
example.com/path/one
switch(config-mgmt-sec-auto-cert-prof-CertAlpha)#
```

9.1.1.9.24 clear aaa authentication lockout

The **`clear aaa authentication lockout`** command clears the locked status of a user and allows access within a lockout period. If no user specified, the command clears the locked status of all users.

Command Mode

Privileged EXEC

Command Syntax

`clear aaa authentication lockout` **[user *user_name*]**

Parameter

user *user_name* - Specify the name of the user.

Example

- This command clears the locked status of the user ***Alice***.

```
switch# clear aaa authentication lockout user Alice
```

9.1.1.9.25 clear aaa counters radius

The **clear aaa counters radius** command resets the counters tracking the statistics for the RADIUS servers that the switch accesses. The show radius command displays the counters reset by the **clear aaa counters radius** command.

Command Mode

Privileged EXEC

Command Syntax

clear aaa counters radius

Example

These commands display the effect of the **clear aaa counters radius** command on the RADIUS counters.

```
switch# show radius
RADIUS server            : radius/10
          Connection opens:        204
         Connection closes:          0
    Connection disconnects:        199
       Connection failures:         10
       Connection timeouts:          2
             Messages sent:       1490
         Messages received:       1490
            Receive errors:          0
           Receive timeouts:          0
              Send timeouts:          0

Last time counters were cleared: never
switch# clear aaa counters radius
switch# show radius
RADIUS server            : radius/10
          Connection opens:          0
         Connection closes:          0
    Connection disconnects:          0
       Connection failures:          0
       Connection timeouts:          0
             Messages sent:          0
         Messages received:          0
            Receive errors:          0
           Receive timeouts:          0
              Send timeouts:          0

Last time counters were cleared: 0:00:03 ago
```

9.1.1.9.26 clear aaa counters tacacs+

The **clear aaa counters tacacs+** command resets the counters tracking the statistics for the TACACS+ servers that the switch accesses. The show tacacs command displays the counters reset by the **clear aaa counters tacacs+** command.

Command Mode

Privileged EXEC

Command Syntax

clear aaa counters tacacs+

Example

These commands display the effect of the **clear aaa counters tacacs+** command on the tacacs+ counters.

```
switch# show tacacs
TACACS+ server            : tacacs/49
          Connection opens:      15942
         Connection closes:          7
    Connection disconnects:       1362
       Connection failures:          0
       Connection timeouts:          0
             Messages sent:      34395
         Messages received:      34392
            Receive errors:          0
          Receive timeouts:          2
             Send timeouts:          0

Last time counters were cleared: never

TACACS+ source-interface: Enabled
  TACACS+ outgoing packets will be sourced with an IP address associated with the
Loopback0 interface
switch# clear aaa counters tacacs+
switch# show tacacs
TACACS+ server            : tacacs/49
          Connection opens:          0
         Connection closes:          0
    Connection disconnects:          0
       Connection failures:          0
       Connection timeouts:          0
             Messages sent:          0
         Messages received:          0
            Receive errors:          0
          Receive timeouts:          0
             Send timeouts:          0

Last time counters were cleared: 0:00:03 ago
switch#

TACACS+ source-interface: Enabled
  TACACS+ outgoing packets will be sourced with an IP address associated with the
Loopback0 interface
```

9.1.1.9.27 clear aaa counters

The **clear aaa counters** command resets the counters tracking the number of service transactions performed by the switch since the last reset of the counters. The show aaa counters command displays the counters reset by the **`clear aaa counters`** command.

Command Mode

Privileged EXEC

Command Syntax

`clear aaa counters` **[SERVICE_TYPE]**

Example

These commands display the effect of the **`clear aaa counters`** command on the AAA counters.

```
switch# clear aaa counters
switch# show aaa counters
Authentication
          Successful:          0
              Failed:          0
 Service unavailable:          0

Authorization
             Allowed:          1
              Denied:          0
 Service unavailable:          0

Accounting
          Successful:          0
               Error:          0
             Pending:          0

Last time counters were cleared: 0:00:44 ago
```

9.1.1.9.28 clear radius proxy counters client group

The **clear radius proxy client group** command clears RADIUS proxy client packet counters.

Command Mode

Privileged EXEC

Command Syntax

clear radius proxy client group ***group_name***

Parameters

- *group_name* - Clear all RADIUS proxy client group packet counters or specify a group name to clear counters for a specific group.

Example

Use the following command to clear RADIUS proxy client packet counters:

```
switch# clear radius proxy client group
```

9.1.1.9.29 deny (Role)

The **deny** command adds a deny rule to the configuration mode role. Deny rules prohibit access of specified commands from usernames with the applied role. Sequence numbers determine rule placement in the role. Commands are compared sequentially to rules within a role until it matches a rule. A commands authorization is determined by the first rule it matches. Sequence numbers for commands without numbers are derived by adding 10 to the number of the roles last rule.

Deny rules use regular expressions to denote commands. A **mode** parameter specifies command modes with restricted commands. Modes use either by predefined keywords, a command modes short key, or a regular expression that specifies the long key of one or more command modes.

The **no deny** and **default deny** commands remove the specified rule from the configuration mode role. The no <sequence number> (Role) command also removes the specified rule from the role.

Command Mode

Role Configuration

Command Syntax

[**SEQ_NUM**] `deny` [**MODE_NAME**] command *command_name*

`no deny` [**MODE_NAME**] command *command_name*

`default deny` [**MODE_NAME**] command *command_name*

Parameters

- **SEQ_NUM** - A sequence number assigned to the rule. Options include:
  - **no parameter** - The number derived by adding 10 to the number of the roles last rule.
  - ***1 - 256*** - A number assigned to an entry.
- **MODE_NAME** - The command mode that prohibits command access. Values include:
  - **no parameter** All command modes.
  - **mode *short_name*** - Specify an exact match of a modes short key name.
  - **mode *long_name*** - A regular expression matching long key name of one or more modes.
  - **mode config** - The ***Global*** configuration mode.
  - **mode config-all** - All configuration modes, including ***global*** configuration mode.
  - **mode exec** - ***EXEC*** and ***Privileged EXEC*** modes.
- ***command_name*** Regular expression that denotes the name of one or more commands.

Guidelines

These CLI prompt format commands program the prompt to display the following mode keys:

- **%p** Short mode key.
- **%P** Long mode key.

Deny statements save to the ***running-config*** only when exiting the **Role** configuration mode.

Related Command

The role command places the switch in **Role** configuration mode.

Example

These commands append a **deny** rule at the end of the ***sysuser*** role that restricts access to the **reload** command from ***EXEC*** and ***Privileged EXEC*** mode.

```
switch(config)# role sysuser
switch(config-mode-sysuser)# deny mode exec command reload
switch(config-mode-sysuser)#
```

9.1.1.9.30 enable password

The **enable password** command creates a new enable password or changes an existing password.

The **no enable password** and **default enable password** commands delete the **enable password** by removing the **enable password** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`enable password` [**ENCRYPT_TYPE**] *password*

`no enable password`

`default enable password`

Parameters

- **ENCRYPT_TYPE** encryption level of the ***password*** parameter. Settings include:
  - **no parameter** the password is entered as clear text.
  - ***0*** the password is entered as clear text. Equivalent to <no parameter>.
  - ***5*** the password is entered as an MD5 encrypted string.
  - ***sha512*** the password is entered as an SHA-512-encrypted string.
- ***password*** text that authenticates the username.
  - ***password*** must be in clear text if **ENCRYPT_TYPE** specifies clear text.
  - ***password*** must be an appropriately encrypted string if **ENCRYPT_TYPE** specifies encryption.

Encrypted strings entered through this parameter are generated elsewhere.

Examples

- These equivalent commands assign ***xyrt1*** as the enable password.

```
switch(config)# enable password xyrt1
switch(config)# enable password 0 xyrt1
```

- This command assigns the enable password to the clear text (***12345***) that corresponds to the encrypted string ***$1$8bPBrJnd$Z8wbKLHpJEd7d4tc5Z/6h/***. The string was generated by an MD5-encryption program using ***12345*** as the seed.

```
switch(config)# enable password 5 $1$8bPBrJnd$Z8wbKLHpJEd7d4tc5Z/6h/
switch(config)#
```

- This command deletes the enable password.

```
switch(config)# no enable password
switch(config)#
```

9.1.1.9.31 ip radius source-interface

The **ip radius source-interface** command specifies the interface from which the IPv4 or IPv6 address is derived for use as the source for outbound RADIUS packets. If the interface has an IP address but the address becomes unavailable, AAA falls back to the next configured authentication method.

The **no ip radius source-interface** and **default ip radius source-interface** commands remove the **ip radius source-interface** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ip radius` [*vrf_inst*] `source-interface` *slot_number*

`no ip radius` [*vrf_inst*] `source-interface`

`default ip radius` [*vrf_inst*] `source-interface`

Parameters

- ***vrf_inst*** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf *vrf_name*** switch communicates with the server using the specified user-defined VRF.
- **int_name** Interface type and number. Options include:
  - **Ethernet *e_num*** - Ethernet interface specified by ***slot_number***.
  - **Loopback *slot_number*** - Loopback interface specified by ***slot_number***.
  - **Management *slot_number*** - Management interface specified by ***slot_number***.
  - **Port-channel *slot_number*** - Port-channel interface specified by ***slot_number***.
  - **Tunnel *tunnel_number*** -
  - **Vlan *v_num*** VLAN interface specified by ***v_num***.

Example

This command configures the source address for outbound RADIUS packets as the IPv4 address assigned to the loopback interface.

```
switch(config)# ip radius source-interface loopback 0
switch(config)#
```

9.1.1.9.32 ip tacacs source-interface

The **ip tacacs source-interface** command specifies the interface from which the IPv4 or IPv6 address is derived for use as the source for outbound TACACS+ packets. If the interface has an IP address but the address becomes unavailable, AAA falls back to the next configured authentication method.

The **no ip tacacs source-interface** and **default ip tacacs source-interface** commands remove the **ip tacacs source-interface** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`ip tacacs` [**VRF_INST**] `source-interface` **INT_NAME**

`no ip tacacs` [**VRF_INST**] `source-interface`

`default ip tacacs` [**VRF_INST**] `source-interface`

Parameters

- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf *vrf_name*** switch communicates with the server using the specified user-defined VRF.
- **INT_NAME** Interface type and number. Options include:
  - **interface ethernet *e_num*** Ethernet interface specified by ***e_num***.
  - **interface loopback *l_num*** Loopback interface specified by ***l_num***.
  - **interface management *m_num*** Management interface specified by ***m_num***.
  - **interface port-channel *p_num*** Port-channel interface specified by ***p_num***.
  - **interface vlan *v_num*** VLAN interface specified by ***v_num***.

Example

This command configures the source address for outbound TACACS+ packets as the IPv4 address assigned to the loopback interface.

```
switch(config)# ip tacacs source-interface loopback 0
switch(config)#
```

9.1.1.9.33 no <sequence number> (Role)

The **no <sequence number>** command removes the rule with the specified sequence number from the configuration-mode role. The **default <sequence number>** command also removes the specified rule.

Command Mode

Role Configuration

Command Syntax

no *sequence_num*

default *sequence_num*

Parameters

sequence_num sequence number of rule to be deleted. Values range from ***1*** to ***256***.

Guidelines

Role statement changes are saved to ***running-config*** only upon exiting ***Role*** configuration mode.

Related Command

The role command places the switch in ***Role*** configuration mode.

Example

These commands display the rules in the ***sysuser*** role, remove rule ***30*** from the role, then display the edited role.

```
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        20 deny mode config command (no |default )?router
        30 deny mode config command (no |default )?(ip|mac) access-list
        40 deny mode if command (no |default )?(ip|mac) access-group
        50 deny mode config-all command lacp|spanning-tree
        60 permit command .*
switch(config)# role sysuser
switch(config-role-sysuser)# no 30
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator
```

```
role: sysuser
        10 deny mode exec command reload
        20 deny mode config command (no |default )?router
        40 deny mode if command (no |default )?(ip|mac) access-group
        50 deny mode config-all command lacp|spanning-tree
        60 permit command .*
switch(config)#
```

9.1.1.9.34 monitor server radius

The **monitor server radius** command enters the Monitor Server RADIUS Configuration Mode and allows the configuration of RADIUS server monitoring on the switch.

The **no** version of the command removes the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

monitor server radius

no monitor server radius

Parameters

- **monitor server radius** - Enter the RADIUS Server Monitor Configuration mode.

Example

Use the following command to enter the RADIUS server monitoring configuration mode:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)#
```

9.1.1.9.35 probe interval

The **probe interval** command in the Monitor Server RADIUS Configuration Mode configures EOS to send probes to the RADIUS server at specific time intervals to ensure the availability of the server.

The **no probe interval** command disables the configuration and removes it from the ***running-config***.

Command Mode

Monitor Server RADIUS Configuration

Command Syntax

probe interval ***period*** **seconds**

no probe interval

Parameters

- **interval** ***period*** **seconds**. - Specify the probe interval for RADIUS servers with a value between 1 and 1000 seconds with a default value of 300 seconds.

Example

Use the following commands to configure a probe interval of 600 seconds:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)# probe interval 600 seconds
switch(config-monitor-server-radius)#
```

9.1.1.9.36 probe method

The **probe method** command in the Monitor Server RADIUS Configuration Mode determines the type of probe sent to the RADIUS server. Some RADIUS servers do not respond to `RADIUS Status-Server` packets, but respond to the `RADIUS Access-Request` packets. This applies to RADIUS servers configured for IEEE 802.1X authentication.

The **no** version of the command disables the configuration and removes it from the ***running-config***.

Command Mode

Monitor Server RADIUS Configuration

Command Syntax

probe method [[access-request username ***username*** **password** ***password*** **] | [status-server]]**

no probe method

Parameters

- **access-request** - Specify sending access-request probes and configure a username and password on the switch and RADIUS server.
  - **username** ***username*** - Configure the username used in the RADIUS Access-Request packets.
  - **password** ***password*** - Configure the password used in the RADIUS Access-Request packets.
- **status-server** - Specify sending RADIUS Status-Server packets as probes to RADIUS servers. Used by default.

Example

Use the following commands to configure using **access-request** with a username, *ServerAdmin*, and password, *Sup3rS3cr3t*:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)# probe method access-request username ServerAdmin password
 Sup3rS3cr3t
switch(config-monitor-server-radius)#
```

9.1.1.9.37 probe threshold

The **probe threshold** command in the Monitor Server RADIUS Configuration Mode configures sets the number of consecutive failed probes before determining a RADIUS server has become nonresponsive. By default, the threshold as a value of 1.

The **no** version of the command disables the configuration and removes it from the ***running-config***.

Command Mode

Monitor Server RADIUS Configuration

Command Syntax

probe threshold failure ***number***

no probe threshold failure

Parameters

- **threshold** - Specify a threshold before determining the RADIUS server becomes unresponsive.
- **failure** ***number*** - Specify the consecutive number of failures before determining the RADIUS server status as unresponsive. Use a value between 1 and 255 with a default value of 1.

Example

Use the following commands to configure a threshold failure of *60* probes:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)# probe threshold failure 60
switch(config-monitor-server-radius)#
```

9.1.1.9.38 radius proxy

The **radius proxy** command enters the RADIUS Proxy Configuration Mode on a switch.

Command Mode

RADIUS Proxy Configuration Mode

Command Syntax

radius proxy

Parameters

None

Example

Use the following command to enter the RADIUS proxy configuration mode on a switch.

```
switch(config)# radius proxy
switch(config-radius-proxy)#
```

9.1.1.9.39 radius proxy client group client

The **radius proxy client group client** command configures RADIUS Proxy client groups on the switch.

Command Mode

RADIUS Proxy Configuration Mode

Command Syntax

radius proxy client group ***group_name*** **client [host** ***host_name*****] | [ipv4** ***ipv4_addr*****] | [ipv6** ***ipv6_addr*****]**

Parameters

- **group** ***group_name*** - Specify a name for the client group.
- **client** - Specify the following client parameters:
  - ***host_name*** - Specify the hostname of the client hostname configuration.
  - **ipv4 [** ***ipv4_addr*** **|** ***ipv4_prefix*****]** - Specify an IPv4 address or IPv4 prefix.
  - **[ipv6 [***ipv6_addr* **|** ***ipv6_prefix*****]** - Specify an IPv6 address or IPv6 prefix.

Example

Use the following command to enter the RADIUS Proxy configuration mode on a switch and add the IPv4 address, *192.168.1.25* as the client.

```
switch(config)# radius proxy
switch(config-radius-proxy)# client group MyGroup
switch(config-rp-cg-MyGroup)# client ipv4 192.168.1.25
```

9.1.1.9.40 radius proxy client group server

The **radius proxy client group server** command configures RADIUS Proxy server groups on the switch.

Command Mode

RADIUS Proxy configuration mode

Command Syntax

radius proxy client group ***group_name*** **server** ***group_name***

Parameters

- **group** ***group_name*** - Specify a name for the client group.
- **server** ***group_name*** - Specify the server group name.

Example

Use the following command to enter the RADIUS Proxy configuration mode on a switch and add the server group, *RADIUS_SG1* as the RADIUS server group.

```
switch(config)# radius proxy
switch(config-radius-proxy)# client group MyGroup
switch(config-rp-cg-MyGroup)# server group RADIUS_SG1
```

9.1.1.9.41 radius proxy client key

The **radius proxy client key** command enters the RADIUS Proxy Configuration Mode on a switch and allows the configuration of a global client key.

Command Mode

RADIUS Proxy configuration mode

Command Syntax

`radius proxy client key` [0 | 7 | 8a] line

Parameters

- **0** - Specify if the key string is unencrypted.
- **7** - Specify if a hidden key follows.
- **8a** - Specifies that an AES-256-GCM encrypted key follows.
- **line** - Specifies that the key text is unobfuscated.

Example

Use the following command to enter the RADIUS Proxy configuration mode on a switch and add a key of 0 with the key text, *SuperSecretKey*:

```
switch(config)# radius proxy
switch(config-radius-proxy)# client key 0 SuperSecretKey
```

9.1.1.9.42 radius proxy client session

The **radius proxy client session** command enters the RADIUS proxy configuration mode on a switch and allows the configuration of a client session idle-timeout parameter.

Command Mode

RADIUS proxy configuration mode

Command Syntax

radius proxy client session **idle-timeout *seconds***

Parameters

- **idle-timeout *seconds*** - Configure the minimum time to wait before clearing the client session.

Example

Use the following command to enter the RADIUS proxy configuration mode on a switch and add a session idle-timeout of *300* seconds:

```
switch(config)# radius proxy
                switch(config-radius-proxy)# client session idle-timeout 300 seconds
```

9.1.1.9.43 radius proxy dynamic-authorization

The **radius proxy client key** command enters the RADIUS proxy configuration mode on a switch and enables dynamic authorization for RADIUS proxy server groups.

Command Mode

RADIUS proxy configuration mode

Command Syntax

radius proxy dynamic-authorization

Example

Use the following command to enter the RADIUS Proxy Configuration Mode on a switch and enable dynamic authorization:

```
switch(config)# radius proxy
switch(config-radius-proxy)# dynamic-authorization
```

9.1.1.9.44 radius-server deadtime

The **radius-server deadtime** command defines global deadtime period, when the switch ignores a non-responsive RADIUS server. A non-responsive server is one that fails to answer any attempt to retransmit after a timeout expiry. Deadtime is disabled if a value is not configured.

The **no radius-server deadtime** and **default radius-server deadtime** commands restore the default global deadtime period of three minutes by removing the **radius-server deadtime** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`radius-server deadtime` *dead_interval*

`no radius-server deadtime`

`default radius-server deadtime`

Parameter

dead_interval period that the switch ignores non-responsive servers (minutes). Values range from ***1*** to ***1000***. Default is ***3***.

Example

This command programs the switch to ignore a server for two hours if it fails to respond to a request during the period defined by timeout and retransmit parameters.

```
switch(config)# radius-server deadtime 120
switch(config)#
```

9.1.1.9.45 radius-server host

The **`radius-server host`** command sets parameters for communicating with a specific RADIUS server. These values override global settings when the switch communicates with the specified server.

A RADIUS server is defined by its server address, authorization port, and accounting port. Servers with different address-authorization port-accounting port combinations have separate configurations.

The **`no radius-server host`** and **`default radius-server`** commands remove settings for the RADIUS server configuration at the specified address-authorization port-accounting port location by deleting the corresponding **`radius-server host`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`radius-server host` **ADDR** [**VRF_INST**][**AUTH**][**ACCT**][**TIMEOUT**][**DEAD**][**RETRAN**][**ENCRYPT**]

`no radius-server host` [**ADDR**][**VRF_INST**][**AUTH**][**ACCT**]

`default radius-server host` [**ADDR**][**VRF_INST**][**AUTH**][**ACCT**]

Parameters

- **ADDR** RADIUS server location. Options include:
  - ***ipv4_addr*** server's IPv4 address.
  - ***host_name*** server's DNS host name (FQDN).
- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf *vrf_name*** switch communicates with the server using the specified user-defined VRF.
- **AUTH** Authorization port number.
  - **no parameter** default port of ***1812***.
  - **auth-port *number*** number ranges from ***1*** to ***65535***.
- **ACCT** Accounting port number.
  - **no parameter** default port of ***1813***.
  - **acct-port *number*** numbers range from ***1*** to ***65535***.

- **TIMEOUT** timeout period (seconds). Ranges from ***1*** to ***1000***.
  - **no parameter** assigns global timeout value (see radius-server timeout).
  - **timeout *number*** assigns number as the timeout period. Ranges from ***1*** to ***1000***.
- **DEAD** period (minutes) when the switch ignores a non-responsive RADIUS server.
  - **no parameter** assigns global deadtime value (see radius-server deadtime).
  - **deadtime *number*** specifies deadtime, where number ranges from ***1*** to ***1000***.
- **RETRAN** attempts to access RADIUS server after the first timeout expiry.
  - **no parameter** assigns global retransmit value (see radius-server retransmit).
  - **retransmit *number*** specifies number of attempts, where number ranges from ***1*** to ***100***.
- **ENCRYPT** encryption key that switch and server use to communicate.
  - **no parameter** assigns global encryption key (see radius-server key).
  - **key *key_text*** where ***key_text*** is in clear text.
  - **key 5 *key_text*** where ***key_text*** is in clear text.
  - **key 7 *key_text*** where ***key_text*** is provide in an encrypted string.

Examples

- This command configures the switch to communicate with the RADIUS server located at ***10.1.1.5***. The switch uses the global timeout, deadtime, retransmit, and key settings to communicate with this server, and communicates through port ***1812*** for authorization and ***1813*** for accounting.

```
switch(config)# radius-server host 10.1.1.5
switch(config)#
```

- This command configures the switch to communicate with the RADIUS server assigned the host name ***RAD-1***. Communication for authorization is through port ***1850***; communication for accounting is through port ***1813*** (the default).

```
switch(config)# radius-server host RAD-1 auth-port 1850
switch(config)#
```

9.1.1.9.46 radius-server key

The **`radius-server key`** command defines the global encryption key the switch uses when communicating with any RADIUS server for which a key is not defined.

The **`no radius-server key`** and **`default radius-server key`** commands remove the global key from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`radius-server key` [**ENCRYPT_TYPE**] *encrypt_key*

`no radius-server key`

`default radius-server key`

Parameters

- **ENCRYPT_TYPE** encryption level of *encrypt_key*.
  - **no parameter** encryption key is entered as clear text.
  - **0** encryption key is entered as clear text. Equivalent to **no parameter**.
  - **7 *encrypt_key*** is an encrypted string.
- ***encrypt_key*** shared key that authenticates the username. The ***encrypt_key*** must be in clear text if **ENCRYPT_TYPE** specifies clear text.
  - ***encrypt_key*** must be an encrypted string if **ENCRYPT_TYPE** specifies an encrypted string.

Encrypted strings entered through this parameter are generated elsewhere.

Related Command

radius-server host

Examples

- This command configures ***cv90jr1*** as the global encryption key.

```
switch(config)# radius-server key 0 cv90jr1
```

```
switch(config)#
```

- This command assigns ***cv90jr1*** as the key by specifying the corresponding encrypted string.

```
switch(config)# radius-server key 7 020512025B0C1D70
switch(config)#
```

9.1.1.9.47 radius-server retransmit

The **`radius-server retransmit`** command defines the global retransmit count, which specifies the number of times the switch attempts to access the RADIUS server after the first timeout expiry.

The **`no radius-server retransmit`** and **`default radius-server retransmit`** commands restore the global retransmit count to its default value of three by deleting the **`radius-server retransmit`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`radius-server retransmit` *count*

`no radius-server retransmit`

`default radius-server retransmit`

Parameters

count retransmit attempts after first timeout expiry. Values range from ***1*** to ***100***. Default is ***3***.

Related Command

radius-server host

Example

This command configures the switch to attempt five RADIUS server contacts after the initial timeout. If the timeout parameter is set to ***50*** seconds, then the total period that the switch waits for a response is ((5+1)*50) = ***300*** seconds.

```
switch(config)# radius-server retransmit 5
switch(config)#
```

9.1.1.9.48 radius-server timeout

The **`radius-server timeout`** command defines the global timeout the switch uses when communicating with any RADIUS server for which a timeout is not defined.

The **`no radius-server timeout`** and **`default radius-server timeout`** commands restore the global timeout default period of five seconds by removing the **`radius-server timeout`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`radius-server timeout` *time_period*

`no radius-server timeout`

`default radius-server timeout`

Parameters

time_period timeout period (seconds). Values range from ***1*** to ***1000***. Default is ***5***.

Related Commands

- radius-server host
- radius-server key
- radius-server deadtime
- radius-server retransmit

Example

This command configures the switch to wait ***50*** seconds for a RADIUS server response before issuing an error.

```
switch(config)# radius-server timeout 50
switch(config)#
```

9.1.1.9.49 resequence (Role)

The **resequence** command assigns sequence numbers to rules in the configuration mode role. Command parameters specify the number of the first rule and the numeric interval between consecutive rules.

The maximum sequence number is 256.

Command Mode

Role Configuration

Command Syntax

`resequence` *start_num inc_num*

Parameters

- ***start_num*** sequence number assigned to the first rule. Value ranges from ***1*** to ***256***. Default is ***10***.
- ***inc_num*** numeric interval between consecutive rules. Value ranges from ***1*** to ***256***. Default is ***10***.

Guidelines

Role statement changes are saved to ***running-config*** only upon exiting ***Role*** configuration mode.

Related Command

The role command places the switch in ***Role*** configuration mode.

Example

The **resequence** command renumbers the rules in the ***sysuser*** role, starting the first rule at ***15*** and incrementing subsequent lines by ***5***.

```
switch(config)# show users roles sysuser
The default role is network-operator

role: sysuser
        10 deny mode exec command reload
        20 deny mode config command (no |default )?router
        40 deny mode if command (no |default )?(ip|mac) access-group
        50 deny mode config-all command lacp|spanning-tree
        60 permit command .*
switch(config)# role sysuser
switch(config-role-sysuser)# resequence 15 5
switch(config-role-sysuser)# exit
switch(config)# show users roles sysuser
The default role is network-operator
```

```
role: sysuser
        15 deny mode exec command reload
        20 deny mode config command (no |default )?router
        25 deny mode if command (no |default )?(ip|mac) access-group
        30 deny mode config-all command lacp|spanning-tree
        35 permit command .*
switch(config)#
```

9.1.1.9.50 permit (Role)

The **permit** command adds a permit rule to the configuration mode role. Permit rules authorize access to specified commands for usernames to which the role is applied. Sequence numbers determine rule placement in the role. Commands compare sequentially to rules within a role until it matches a rule. The first matching rule determines a command's authorization. EOS derives sequence numbers for commands without numbers by adding 10 to the number of the role's last rule.

Permit rules use regular expression to denote commands. A **mode** parameter specifies the command modes for authorized commands. EOS denotes modes either by predefined keywords, a command modes short key, or a regular expression that specifies the long key of one or more command modes.

The **no deny** and **default deny** commands remove the specified rule from the configuration mode role. The no <sequence number> (Role) command also removes the specified rule from the role.

Command Mode

Role Configuration

Command Syntax

[**SEQ_NUM**] `permit` [**MODE_NAME**] command *command_name*

`no permit` [**MODE_NAME**] command `]` *command_name*

`default permit` [**MODE_NAME**] command *command_name*

Parameters

- **SEQ_NUM** - The sequence number assigned to the rule. Options include the following:
  - **no parameter** - A number derived by adding 10 to the number of the roles last rule.
  - ***<1 - 256>*** - A number assigned to the entry.
- **MODE_NAME** - The command mode that authorizes command access. Values include the following:
  - **no parameter** - All command modes.
  - **mode *short_name*** - The exact match of a modes short-key name.
  - **mode *long_name*** - A regular expression matching long-key name of one or more modes.
  - **mode config** - The ***Global*** configuration mode.
  - **mode config-all** All configuration modes, including ***global*** configuration mode.
  - **mode exec** EXEC and Privileged EXEC modes.
- ***command_name*** Regular expression that denotes the name of one or more commands.

Guidelines

These CLI prompt format commands program the prompt to display the following mode keys:

- **%p** Short-mode key.
- **%P** Long-mode key.

`Permit` statements save to the ***running-config*** only when exiting **Role** configuration mode.

Related Commands

The role command places the switch in the **Role** Configuration Mode.

Example

These commands append a **`permit`** rule at the end of the sysuser role that authorizes all commands from ***VLAN 1*** or ***VLAN 2*** interface configuration modes.

```
switch(config)# role sysuser
switch(config-mode-sysuser)# permit mode if-Vl(1|2) command .*
switch(config-mode-sysuser)#
```

9.1.1.9.51 role

The **role** command places the switch in Role Configuration Mode, which is a group-change mode that modifies a role. A role is a data structure that supports local command authorization through its assignment to user accounts. Roles consist of permit and deny rules that define authorization levels for specified commands. Applying a role to a username authorizes the user to execute commands specified by the role.

The **role** command specifies the name of the role that subsequent commands modify and creates a role if it references a nonexistent role. All changes in a group change mode edit session are pending until the session ends:

- The **exit** command saves pending changes to ***running-config*** and returns the switch to Global Configuration Mode. Changes are also saved by entering a different configuration mode.
- The **abort** command discards pending changes, returning the switch to Global Configuration Mode.

The **no role** and **default role** commands delete the specified role by removing the role and its statements from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`role` *role_name*

`no role` *role_name*

`default role` *role_name*

Parameter

role_name Name of role.

Commands Available in Role Configuration Mode:

- deny (Role)
- permit (Role)
- no <sequence number> (Role)
- resequence (Role)

Related Commands

show users roles

Examples

- This command places the switch in ***Role*** configuration mode to modify the speaker role.

```
switch(config)# role speaker
switch(config-role-speaker)#
```

- This command saves changes to **speaker** role, then returns the switch to ***Global*** configuration mode.

```
switch(config-role-speaker)# exit
switch(config)#
```

- This command discards changes to **speaker**, then returns the switch to ***Global*** configuration mode.

```
switch(config-role-speaker)# abort
switch(config)#
```

9.1.1.9.52 server (server-group-RADIUS configuration mode)

The **`server (server-group-RADIUS configuration mode)`** command adds the specified RADIUS server to the configuration-mode group. Servers must be configured with the radius-server host command before adding them to the server group.

A RADIUS server is defined by its server address, authorization port, and accounting port. A group can contain multiple servers with the same IP address that have different authorization or accounting ports.

The **`no server`** and **`default server`** commands remove the specified server from the group.

Command Mode

Server-Group-RADIUS Configuration

Command Syntax

`server` **LOCATION** [**VRF_INST**][**AUTH**][**ACCT**]

`no server` **LOCATION** [**VRF_INST**][**AUTH**][**ACCT**]

`default server` **LOCATION** [**VRF_INST**][**AUTH**][**ACCT**]

Parameters

- **LOCATION** RADIUS server location. Options include:
  - ***ipv4_addr*** server's IPv4 address.
  - **host_name** server's DNS host name (FQDN).
- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf *vrf_name*** switch communicates with the server using the specified user-defined VRF.
- **AUTH** Authorization port number.
  - **no parameter** default port of ***1812***.
  - **auth-port *number*** *number* ranges from ***1*** to ***65535***.
- **ACCT** Accounting port number.
  - **no parameter** default port of ***1813***.
  - **acct-port *number*** *number* ranges from ***1*** to ***65535***.

Related Commands

The aaa group server radius command places the switch in ***Server-group-RADIUS*** configuration mode.

Example

These commands add two servers to the ***RAD-SV1*** server group.

```
switch(config)# aaa group server radius RAD-SV1
switch(config-sg-radius-RAD-SV1)# server RAC-1
switch(config-sg-radius-RAD-SV1)# server 10.1.5.14 acct-port 1851
switch(config-sg-radius-RAD-SV1)#
```

9.1.1.9.53 server (server-group-TACACS+ configuration mode)

The **`server (server-group-TACACS+ configuration mode)`** command adds the specified TACACS+ server to the configuration-mode group. Servers must be configured with the tacacs-server host command before adding them to the server group.

A TACACS+ server is defined by its server address and port number. Servers with different address-port combinations have separate statements in ***running-config***.

The **`no server`** and **`default server`** commands remove the specified server from the group.

Command Mode

Server-group-TACACS+ Configuration

Command Syntax

`server` **LOCATION** [**VRF_INST**][**PORT**]

`no server` **LOCATION** [**VRF_INST**][**PORT**]

`default server` **LOCATION** [**VRF_INST**][**PORT**]

Parameters

- **LOCATION** TACACS+ server location. Options include:
  - ***ipv4_addr*** server's IPv4 address.
  - ***ipv6_addr*** server's IPv6 address.
  - ***host_name*** server's DNS host name (FQDN).
- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf *vrf_name*** switch communicates with the server using the specified user-defined VRF.
- **PORT** TCP connection port number.
  - **no parameter** default port of ***49***.
  - **port *number***. ***number*** ranges from ***1*** to ***65535***.

Related Command

The aaa group server tacacs+ command places the switch in ***Server-group-TACACS+*** configuration mode.

Example

These commands add two servers to the TAC-GR server group with default port number ***49***.

```
switch(config)# aaa group server tacacs+ TAC-GR
switch(config-sg-tacacs+-TAC-GR)# server TAC-1
switch(config-sg-tacacs+-TAC-GR)# server 10.1.4.14
switch(config-sg-tacacs+-TAC-GR)#
```

9.1.1.9.54 service dot1x

The **service dot1x** command in the Monitor Server RADIUS Configuration Mode applies monitoring globally to the RADIUS servers used for 802.1X authentication.

The **no service dot1x** command disables monitoring and removes the configuration from the ***running-config***.

Command Mode

Monitor Server RADIUS Configuration

Command Syntax

service dot1x

no service dot1x

Parameters

- **service dot1x** - Specify to apply monitoring globally to all RADIUS servers used for 802.1X authentication.

Example

Use the following commands to apply monitoring globally to RADIUS servers used for 802.1X authentication:

```
switch(config)# monitor server radius
switch(config-monitor-server-radius)# service dot1x
switch(config-monitor-server-radius)#
```

9.1.1.9.55 show aaa

The **show aaa** command displays the user database. The command displays the encrypted enable password first, followed by a table of usernames and their corresponding encrypted password.

The command does not display unencrypted passwords.

Command Mode

Privileged EXEC

Command Syntax

```
show aaa
```

Example

This command displays the local user database.

```
switch# show aaa
Enable password (encrypted): $1$UL4gDWy6$3KqCPYPGRvxDxUq3qA/Hs/
Username  Encrypted passwd
--------  ----------------------------------
admin
janis     $1$VVnDH/Ea$iwsfnrGNO8nbDsf0tazp9/
thomas    $1$/MmXTUil$.fJxLfcumzppNSEDVDWq9.
switch#
```

9.1.1.9.56 show aaa authentication lockout

The **show aaa authentication lockout** command displays the status of locked-out users who could not log within the specified time and number of login attempts.

Command Mode

Privileged EXEC

Command Syntax

```
show aaa authentication lockout
```

Example

This command displays the status of Alice, who is the locked out user. Alice's last failed login was at 17:50:06, and her lockout will be cleared at 17:51:06, in 58 seconds. When the duration of 58 seconds elapses, Alice’s name will no longer be displayed.

```
switch# show aaa authentication lockout
 User     Start Time                End Time                  Expires In
--------- ------------------------- ------------------------- ----------
 alice    Fri Jul 12 17:50:06 2020  Fri Jul 12 17:51:06 2020  0:00:58
```

9.1.1.9.57 show aaa counters

The **`show aaa counters`** command displays the number of service transactions performed by the switch since the last time the counters were reset.

Command Mode

Privileged EXEC

Command Syntax

```
show aaa counters
```

Example

This command displays the number of AAA transactions.

```
switch# show aaa counters
Authentication
          Successful:         30
              Failed:          0
 Service unavailable:          0

Authorization
             Allowed:        188
              Denied:          0
 Service unavailable:          0

Accounting
          Successful:          0
               Error:          0
             Pending:          0

Last time counters were cleared: never
```

9.1.1.9.58 show aaa methods

The **show aaa methods** command displays all the named method lists defined in the specified Authentication, Authorization, and Accounting (AAA) service.

Command Mode

Privileged EXEC

Command Syntax

show aaa methods [**SERVICE_TYPE** [accounting | authentication | authorization | all]]

Parameters

SERVICE_TYPE the service type of the method lists that the command displays.

- **accounting** accounting services.
- **authentication** authentication services.
- **authorization** authorization services.
- **all** accounting, authentication, and authorization services.

Example

This command configures the named method lists for all AAA services.

```
switch# show aaa methods all
Authentication method lists for LOGIN:
  name=default methods=group tacacs+, local
Authentication method list for ENABLE:
  name=default methods=local
Authorization method lists for COMMANDS:
  name=privilege0-15 methods=group tacacs+, local
Authentication method list for EXEC:
  name=exec methods=group tacacs+, local
Accounting method lists for COMMANDS:
  name=privilege0-15 default-action=none
Accounting method list for EXEC:
  name=exec default-action=none switch#
```

9.1.1.9.59 show management ldap

The **show management ldap** command displays information about the LDAP configuration.

Command Mode

EXEC

Command Syntax

```
show management ldap
```

Examples

- The following command shows general information for LDAP.

```
switch# show management ldap
LDAP server: prod-dc-hq1.aristanetworks.com/389
   Binds requested: 6
   Binds successful: 6
   Binds failed: 0
   Binds timed out: 0
   FIPS is ON

Last time counters were cleared: 1:16:41 ago
```

- The authentication action in LDAP is the ***bind***, which is equivalent to attempting a log-in. There will be two binds per login attempt, one for the admin account and one for the user account.

```
switch# show management security ssl profile
   Profile          State
----------------- -----------
   testProfile      valid

To verify a user accounts authorization being performed by ldap, use "show users detail":
switch# show users detail
Session  Username  Roles         TTY  State Duration  Auth       Remote Host
-------- --------- ------------- ---- ----- --------- ---------- ----------------------------------------
1006     erahn     network-admin vty3 E     0:00:05   group ldap fd7a:629f:52a4:dc25:b08d:feff:feed:2ce7
```

- The FIPS mode is controlled by the SSL profile in AAA. To validate an SSL profile use the following:
  - To validate the role for a current session the **vty** information in the TTY column must be matched against the Line column in the following command. The row with a "*" character at the start is the current session where the command was run:

```
switch# show users
   Line      User            Host(s)  Idle       Location
   1 con 0   admin           idle     01:19:00   -
   2 vty 10  srv-sw-ldaptest idle     01:19:00   172.16.124.151
*  3 vty 3   erahn           idle     00:00:04   fd7a:629f:52a4:dc25:b08d:feff:feed:2ce7
```

9.1.1.9.60 show management security auto-certificate profile

The **`show management security auto-certificate profile`** displays information about auto-certificate profiles configured on the switch. Add the **`detail`** parameter to displayed detailed information about the profiles.

Command Mode

EXEC

Command Syntax

show management security auto-certificate profile ***profile_name*** **detail**

Parameters

- ***profile_name*** - Specify a specific profile name to display certificate profile information.
- **detail** - Display detailed information about certificate profiles.

Examples

Use the following command to display certificate profile information:

```
switch# show management security auto-certificate profile CertAlpha
            Auto certificate profile CertAlpha:
            Key:        clientkey.pem
            State:      Valid
            Next request in 89 days, 21:59:47 at: 2025-02-05 01:45:51
```

Use the following command to display detailed certificate profile information:

```
switch# show management security auto-certificate profile CertAlpha detail
            Auto certificate profile CertAlpha:
            Key:        clientkey.pem
            State:      Valid
            Next request in 89 days, 21:59:37 at: 2025-02-05 01:45:51
            Initial enrollment statistics:
            Number of successes: 1
            Number of failures:  0
            Renewal statistics:
            Number of successes: 0
```

9.1.1.9.61 show management security auto-certificate protocol est

The **show management security auto-certificate protocol est** command displays information about all Enrollment over Secure Transport (EST) protocol profiles configured on the switch.

Command Mode

EXEC

Command Syntax

show management security auto-certificate protocol est [*profile_name*] [detail]

Parameters

- ***profile_name*** - Specify a profile to display EST protocol information.
- **detail** - Displays detailed information about all or a single EST protocol.

Examples

Use the following command to display EST protocol information:

```
switch# show management security auto-certificate protocol est EST_2
Automatic Certificate Management policy EST_2:
State:      Invalid
Last error:
Message: Invalid SSL profile
Time:    2025-05-07 06:28:20
```

Use the following command to display detailed EST protocol information:

```
switch# show management security auto-certificate protocol est EST_2 detail
Automatic Certificate Management policy EST_2:
State:      Invalid
Last error:
Message: Invalid SSL profile
Time:    2025-05-07 06:28:20
Managed certificate profile:
certProfileBravo:
Certificate state:   Needs enrolling
```

9.1.1.9.62 show monitor server radius

The **show monitor server radius** command in EXEC mode displays information about RADIUS server monitoring on the switch. Use the output to determine the status of the RADIUS servers.

Command Mode

EXEC

Command Syntax

show monitor server radius [detail]

Parameters

The output displays the following parameters:

- **Probe method**
- **RADIUS Server** - Displays the IP address of the RADIUS server.
- **Messages Sent** - Displays the total number of probes sent to the RADIUS servers.
- **Messages Accepted** - Displays the total number of successful responses received from the server.
- **Messages Dropped** - Displays the total number responses received but failed packet validation.
- **Status** - Displays the status of the RADIUS server.

Examples

Use the following command to display RADIUS Server information:

```
switch(config)# show monitor server radius

   Probe method: Status-Server packet
   RADIUS Server            Messages Sent            Messages Accepted             Messages
 Dropped               Status
   -------------            -------------            -----------------             -------------
---              ---------
   10.0.0.101                    48                       35                            1
                 alive
   10.0.0.102                    48                       29                            1
                 not alive
```

Add the **detail** parameter to display additional information:

```
switch(config)# show monitor server radius detail
```

```
Probe method: Status-Server packet

RADIUS server: 10.0.0.101, Authentication port: 33922, Accounting port: 34685
Status: alive, Last changed: 0:02:32 ago
Last probed: 0:00:02 ago
Last successful probe: 0:00:02 ago, Failed probes since then: 0
Messages sent: 47
Messages accepted: 34
Messages dropped: 1
Last time counters were cleared: never

RADIUS server: 10.0.0.102 Authentication port: 34406, Accounting port: 47258
Status: not alive, Last changed: 0:00:12 ago
Last probed: 0:00:02 ago
Last successful probe: 0:00:27 ago, Failed probes since then: 4
Messages sent: 47
Messages accepted: 29
Messages dropped: 1
Last time counters were cleared: never
```

9.1.1.9.63 show privilege

The **show privilege** command displays the current privilege level for the CLI session.

Command Mode

EXEC

Command Syntax

show privilege

Example

This command displays the current privilege level.

```
switch> show privilege
Current privilege level is 15 switch>
```

9.1.1.9.64 show radius

The **`show radius`** command displays statistics for the RADIUS servers that the switch accesses.

Command Mode

EXEC

Command Syntax

```
show radius
```

Example

This command displays statistics for connected RADIUS servers.

```
switch# show radius
RADIUS server            : radius/10
          Connection opens:        204
         Connection closes:          0
    Connection disconnects:        199
       Connection failures:         10
       Connection timeouts:          2
             Messages sent:       1490
         Messages received:       1490
            Receive errors:          0
          Receive timeouts:          0
             Send timeouts:          0

Last time counters were cleared: never switch#
```

9.1.1.9.65 show radius proxy client group

The **`show radius proxy client group`** command displays information about RADIUS proxy configurations.

Command Mode

Privileged EXEC

Command Syntax

`show radius proxy client group` *group_name*

Parameters

- ***group_name*** - Display all RADIUS proxy client groups or specify a group name to see details about a specific group.

Example

Use the following command to display details about RADIUS proxy clients:

```
switch# show radius proxy client group
                Radius Client Group                : MyClientGroup
                Last time counters were cleared    : never

                Client                           : 192.168.1.25, authentication port 1812,
 accounting port 1813, vrf default
                Resolved IP address              : 192.168.1.25/32
                Messages received:          0
                    Messages sent:          0
               Accept response sent:        0
               Reject response sent:        0
            Counting start received:        0
           Interim updates received:        0
           Accounting stop received:        0
                     Bad requests:          0
                CoA requests sent:          0
                 DM requests sent:          0
                CoA ACKs received:          0
                 DM ACKs received:          0
                CoA NAKs received:          0
                 DM NAKs received:          0
                    Bad responses:          0
                Connection errors:          0
```

9.1.1.9.66 show radius proxy server group

The **`show radius proxy server group`** command displays information about RADIUS proxy server group configurations.

Command Mode

Privileged EXEC

Command Syntax

`show radius proxy server group` *group_name*

Parameters

group_name - Display all RADIUS proxy server groups or specify a group name to see details about a specific group.

Example

Use the following command to display details about RADIUS proxy clients:

```
switch# show radius proxy server group
                Radius Server Group: MyServerGroup
                    Radius Server 1: RADIUS
                Resolved IP address: 192.168.25.33
                             Status: active
```

9.1.1.9.67 show tacacs

The **`show tacacs`** command displays statistics for the TACACS+ servers that the switch accesses.

Command Mode

EXEC

Command Syntax

```
show tacacs
```

Example

This command displays statistics for connected TACACS+ servers.

```
switch# show tacacs
TACACS+ server            : tacacs/49
          Connection opens:      15942
         Connection closes:          7
    Connection disconnects:       1362
       Connection failures:          0
       Connection timeouts:          0
             Messages sent:      34395
         Messages received:      34392
            Receive errors:          0
          Receive timeouts:          2
             Send timeouts:          0

Last time counters were cleared: never

TACACS+ source-interface: Enabled
  TACACS+ outgoing packets will be sourced with an IP address associated with the
Loopback0 interface
```

9.1.1.9.68 show users accounts

The **`show users accounts`** command displays the names, roles, and privilege levels of users that are listed in ***running-config***. The SSH public key is also listed for names for which an SSH key is configured.

Command Mode

Privileged EXEC

Command Syntax

```
show users accounts
```

Example

This command displays the usernames that are configured on the switch.

```
switch# show users accounts
user: FRED
       role: <unknown>
       privilege level: 1
       ssh public key: ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQDjUg2VDiBX7In0q
HtN5PyHOWtYvIoeZsxF5YmesQ/rh++mbpT504dL7So+Bpr9T/0qIj+zilat8fX/JlO42+3pjfkHY/+l

F2S7/EOU13pY42RztDSs42nMNNrutPT0q5Z17aAKvhpd0dDlc+qIwrCrXbeIChHem7+0N8/zA3alBK4
eKSFSZBd3Pb admin@switch
switch#
user: JANE
       role: sysuser2
       privilege level: 1
user: admin
       role: network-admin
       privilege level: 1
```

9.1.1.9.69 show users detail

The **`show users detail`** command displays information about active AAA login sessions. Information includes username, roles, TTY, state of the session (pending or established), duration, authentication method, and if available, remote host and remote username.

Command Mode

Privileged EXEC

Command Syntax

```
show users detail
```

Example

This command displays information about the active AAA login sessions.

```
switch# show users detail
Session  Username Roles           TTY    State Duration  Auth          Remote Host
-------   ---------- ------------ ------ ----- --------  ------------- ------------
2      admin     network-admin    ttyS0  E     0:01:21  local
4      joe       sysadmin         telnet E     0:02:01  local        sf.example.com
6      alice     sysadmin         ssh    E     0:00:52  group radius ny.example.com
7      bob       sysadmin         ssh    E     0:00:48  group radius la.example.com
8      kim       network-admin1   ssh    E     0:00:55  group radius de.example.com
9      admin     network-admin    ssh    E     0:00:07  local        bj.example.com
10     max       network-admin    telnet E     0:00:07  local        sf.example.com
```

9.1.1.9.70 show users roles

The **`show users roles`** command displays the name of the default role and the contents of the specified roles. Commands that do not specify a role display the rules in all built-in and configured roles.

Command Mode

Privileged EXEC

Command Syntax

`show users roles` [**ROLE_LIST**]

Parameters

ROLE_LIST Roles that the command displays. Options include:

- **no parameter** Command displays all roles.
- ***role_name*** Name of role displayed by command.

Related Command

The role command places the switch in ***Role*** configuration mode, which is used to create new roles or modify existing roles.

Example

This command displays the contents of all user-defined and built-in roles.

```
switch# show users roles
The default role is network-operator

role: network-admin
        10 permit command .*
role: network-operator
        10 deny mode exec command bash|\|
        20 permit mode exec command .*
role: sysuser
        15 deny mode exec command reload
        20 deny mode config command (no |default )?router
        25 deny mode if command (no |default )?(ip|mac) access-group
        30 deny mode config-all command lacp|spanning-tree
        35 permit command .*
        40 deny mode exec command .*
        50 permit mode exec command show|clear (counters|platform)|configure
```

9.1.1.9.71 show users

The **`show users`** command displays the usernames that are currently logged into the switch.

Command Mode

Privileged EXEC

Command Syntax

```
show users
```

Example

This command displays the users that are logged into the switch.

```
switch# show users
    Line       User       Host(s)              Idle       Location
   1 vty 2     john       idle                      1d  10.22.6.113
   2 vty 4     jane       idle                21:33:00  10.22.26.26
*  3 vty 6     ted        idle                00:00:01  10.17.18.71
```

9.1.1.9.72 tacacs-server host

The **`tacacs-server host`** command sets communication parameters for communicating with a specific TACACS+ server. These values override global settings when the switch communicates with the specified server.

A TACACS+ server is defined by its server address and port number. Servers with different combinations of address-port-VRF-multiplex settings have separate statements in ***running-config***.

The **`no tacacs-server host`** and **`default tacacs-server host`** commands remove settings for the TACACS+ server configuration at the specified address-port-VRF combination by deleting the corresponding **`tacacs-server host`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`tacacs-server host` **SERVER_ADDR** [**MULTIPLEX**][**VRF_INST**][**PORT**][**TIMEOUT**][**ENCRYPT**]

`no tacacs-server host` [**SERVER_ADDR**][**MULTIPLEX**][**VRF_INST**][**PORT**]

`default tacacs-server host` [**SERVER_ADDR**][**MULTIPLEX**][**VRF_INST**][**PORT**]

Parameters

- **SERVER_ADDR** TACACS+ server location. Options include:
  - ***ipv4_addr*** server's IPv4 address.
  - ***ipv6_addr*** server's IPv6 address.
  - ***host_name*** server's DNS host name (FQDN).
- **MULTIPLEX** TACACS+ server support of multiplex sessions on a TCP connection.
  - **no parameter** server does not support multiplexing.
  - **single-connection** server supports session multiplexing.
- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
  - **no parameter** switch communicates with the server using the default VRF.
  - **vrf** *vrf_name* switch communicates with the server using the specified user-defined VRF.
- **PORT** port number of the TCP connection.
  - **no parameter** default port of ***49***.
  - **port *number*** port number ranges from ***1*** to ***65535***.

- **TIMEOUT** timeout period (seconds).
  - **no parameter** assigns the globally configured timeout value (see tacacs-server timeout).
  - **timeout *number*** timeout period (seconds). Number ranges from ***1*** to ***1000***.
- **ENCRYPT** encryption key the switch and server use to communicate. Settings include:
  - **no parameter** assigns the globally configured encryption key (see tacacs-server key).
  - **key *key_text*** where ***key_text*** is in clear text.
  - **key 5 *key_text*** where ***key_text*** is in clear text.
  - **key 7 *key_text*** where ***key_text*** is an encrypted string.

Examples

- This command configures the switch to communicate with the TACACS+ server located at ***10.1.1.5***. The switch uses the global timeout, encryption key, and port settings.

```
switch(config)# tacacs-server host 10.1.1.5
switch(config)#
```

- This command configures the switch to communicate with the TACACS+ server assigned the host name ***TAC_1***. The switch defines the timeout period as ***20*** seconds and the encryption key as ***rp31E2v***.

```
switch(config)# tacacs-server host TAC_1 timeout 20 key rp31E2v
switch(config)#
```

- This command configures the switch to communicate with the TACACS+ server located at ***10.12.7.9***, indicates that the server supports multiplexing sessions on the same TCP connection, and that access is through port ***54***.

```
switch(config)# tacacs-server host 10.12.7.9 single-connection port 54
switch(config)#
```

9.1.1.9.73 tacacs-server key

The **tacacs-server key** command defines the global encryption key the switch uses when communicating with any TACACS+ server for which a key is not defined.

The **no tacacs-server key** and **default tacacs-server key** commands remove the global key from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`tacacs-server key` [**ENCRYPT_TYPE**] *encrypt_key*

`no tacacs-server key`

`default tacacs-server key`

Parameters

- **ENCRYPT_TYPE** encryption level of *encrypt_key*.
  - **no parameter** encryption key is entered as clear text.
  - **0** encryption key is entered as clear text. Equivalent to **no parameter**.
  - **7** ***encrypt_key*** is an encrypted string.
- ***encrypt_key*** shared key that authenticates the username.
  - ***encrypt_key*** must be in clear text if **ENCRYPT_TYPE** specifies clear text.
  - ***encrypt_key*** must be an encrypted string if **ENCRYPT_TYPE** specifies an encrypted string.

  Encrypted strings entered through this parameter are generated elsewhere.

Related Command

tacacs-server host

Examples

- This command configures ***cv90jr1*** as the encryption key.

```
switch(config)# tacacs-server key 0 cv90jr1
```

```
switch(config)#
```

- This command assigns ***cv90jr1*** as the key by specifying the corresponding encrypted string.

```
switch(config)# tacacs-server key 7 020512025B0C1D70
switch(config)#
```

9.1.1.9.74 tacacs-server policy

The **tacacs-server policy** command programs the switch to permit access to TACACS+ servers that send mandatory attribute-value (AV) pairs that the switch does not recognize. By default, the switch denies access to TACACS+ servers when it receives unrecognized AV pairs from the server.

The switch recognizes the following mandatory AV pairs:

priv-lvl=x where x is an integer between ***0*** and ***15***.

The **no tacacs-server policy** and **default tacacs-server policy** commands restore the switch default of denying access to servers from which it receives unrecognized mandatory AV pair by deleting the **tacacs-server policy** statement from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`tacacs-server policy` unknown-mandatory-attribute ignore

`no tacacs-server policy` unknown-mandatory-attribute ignore

`default tacacs-server policy` unknown-mandatory-attribute ignore

Parameters

Example

This command configures the switch to permit access to TACACS+ servers that send unrecognized mandatory AV pairs.

```
switch(config)# tacacs-server policy unknown-mandatory-attribute ignore
switch(config)#
```

9.1.1.9.75 tacacs-server timeout

The **`tacacs-server timeout`** command defines the global timeout the switch uses when communicating with any TACACS+ server for which a timeout is not defined.

The **`no tacacs-server timeout`** and **`default tacacs-server timeout`** commands restore the global timeout default period of five seconds by removing the **`tacacs-server timeout`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`tacacs-server timeout` *time_period*

`no tacacs-server timeout`

`default tacacs-server timeout`

Parameters

time_period timeout period (seconds). Values range from ***1*** to ***1000***. Default is ***5***.

Related Command

tacacs-server host

Example

This command configures the switch to wait ***20*** seconds for a TACACS+ server response before issuing an error.

```
switch(config)# tacacs-server timeout 20
switch(config)#
```

9.1.1.9.76 username ssh-key

The **`username ssh-key`** command configures an SSH key for the specified username. Command options allow the key to be entered directly into the CLI or referenced from a file.

The specified username must be previously configured through a username command.

The **`no username ssh-key`** and **`default username ssh-key`** commands delete the SSH key for the specified username by removing the corresponding **`username ssh-key`** command from ***running-config***.

The **`no username ssh-key role`** and **`default username ssh-key role`** commands perform the following:

- delete the SSH key for the specified username by removing the corresponding **username ssh-key** command from ***running-config***.
- delete the role assignment from the specified username by editing the corresponding username statement in ***running-config***.

Command Mode

Global Configuration

Command Syntax

`username` *name* `sshkey` **KEY**

`no username` *name* `sshkey` [role]

`default username` *name* `sshkey` [role]

Parameters

- ***name*** username text that the user enters at the login prompt to access the CLI.

  Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:

  @ # $ % ^ & * - _ = + ; < > , . ~ |

- **KEY** SSH key. Options include:
  - ***key_text*** username is associated with ssh key specified by ***key_text*** string.
  - **file *key_file*** username is associated with SSH key in the specified file.

Example

These commands create the username ***john***, assign it the password ***x245***, then associate it to the SSH key listed in the file named ***john-ssh***.

```
switch(config)# username john secret x245
switch(config)# username john sshkey file john-ssh
switch(config)#
```

9.1.1.9.77 username

The **username** command adds a username to the local file and optionally assigns a password to the username. If the command specifies an existing username, the command replaces the password in the local file. The command can also define a username without a password or remove the password from a username.

The **no username** command deletes the specified username by removing the corresponding **username** statement from ***running-config***. The **default username** command removes user-specified usernames, but restores the **admin** username to its default parameters.

The **no username role** command assigns the default role assignment to the specified **username** statement by editing the corresponding **username** statement in ***running-config***. The **default username role** command reverts the specified username to its default role by editing the corresponding **username** statement in ***running-config***. For the **admin** username, this restores **network-admin** as its role, even if the **admin** username has been deleted and then created again.

Command Mode

Global Configuration

Command Syntax

`username` *name* [**PRIVILEGE_LEVEL**] **SECURITY** [**ROLE_USER**]

`no username` *name* [role]

`default username` *name* [role]

All parameters except ***name*** can be placed in any order.

Parameters

- ***name*** username text that the user enters at the login prompt to access the CLI.

  Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:

  @ # $ % ^ & * - _ = + ; < > , . ~ |

- **PRIVILEGE_LEVEL** user's initial session privilege level. This parameter is used when an authorization command includes the local option.
  - **no parameter** the privilege level is set to ***1***.
  - **privilege *rank*** where rank is an integer between ***0*** and ***15***.
- **SECURITY** password assignment option.

- **nopassword** *name* is not password protected.
- **secret** ***password name*** is protected by specified password (clear-text string).
- **secret 0** ***password name*** is protected by specified password (clear-text string).
- **secret 5** ***password name*** is protected by specified password. (MD5-encrypted string).
- **secret sha5** ***password name*** is protected by specified password (SHA-512-encrypted string).

- **ROLE_USER** specifies the role for performing command authorization. Options include:
  - **no parameter** user is assigned default role aaa authorization policy local default-role.
  - **role** ***role_name*** specifies role assigned to the user.

Guidelines

Encrypted strings entered through this parameter are generated elsewhere. The secret 5 option (**SECURITY**) is typically used to enter a list of username-passwords from a script.

The **SECURITY** parameter is mandatory for unconfigured usernames. For previously configured users, the command can specify a **PRIVILEGE_LEVEL** or **ROLE** without a **SECURITY** setting.

The **admin** username is provided by the initial configuration, but it can be deleted, and its parameters are editable. The initial **admin** configuration is:

```
username admin privilege 1 role network-admin nopassword
```

Note: when deleting the **admin** username, it is advisable to create at least one other username on the switch before saving the configuration.

Examples

- These equivalent commands create the username ***john*** and assign it the password ***x245***. The password is entered in clear text because the **ENCRYPTION** parameter is either omitted or zero.

```
switch(config)# username john secret x245
switch(config)# username john secret 0 x245
```

- This command creates the username ***john*** and assigns it to the text password that corresponds to the encrypted string ***1sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1***. The string was generated by an MD5-encryption program using ***x245*** as the seed.

```
switch(config)# username john secret 5 $1$sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1
switch(config)#
```

A user authenticates the username ***john*** by entering ***x245*** when the CLI prompts for a password.

- This command creates the username ***jane*** without securing it with a password or removes a password if the ***jane*** username exists.

```
switch(config)# username jane nopassword
switch(config)#
```

- This command removes the username ***william*** from the local file.

```
switch(config)# no username william
switch(config)#
```

9.2 Control Plane Security

This section contains the following topics:

- Transport Layer Security
- 802.1X Port Security

9.2.1 Transport Layer Security

Transport Layer Security (TLS), the successor to Secure Sockets Layer (SSL), is a security protocol used to communicate between client and server. It establishes an encrypted communication channel to secure data.

By default, EOS uses a self-signed certificate for client and server connections. However, some browsers or TLS libraries may refuse connections to the default self-signed certificates on EOS, and in such cases, Arista recommends installing the TLS server certificates that meet the following criteria:

- RSA key sizes must be greater than or equal to ***2048*** bits.
- There must be less than ***825*** days to expiry.
- The certificate must use the ***SHA-2*** family of hashing functions.

Note: Although Arista switches use TLS, the terms TLS and SSL are used interchangeably in this document.

The following are the two main components used by TLS for the authentication of identity before any communication starts.

- Certificate
- Key

An SSL certificate is required to establish a secure connection between the client and server. The certificate includes all of the details necessary for authentication. Cryptographic keys are used to provide a secure channel of communication. TLS uses two cryptographic keys: a private key known only to the server and a public key embedded in the certificate. The keys are used to validate the certificate.

This chapter contains the following sections.

- Overview
- Configuration
- Rotating Certificate and Key Pair
- Resetting Diffie-Hellman Parameters

- Configuring the TLS Handshake Settings
- Syslog with TLS Support
- Displaying Certificate and Key Information
- TLS Commands

9.2.1.1 Overview

We can manage and configure SSL certificates, keys, and profiles with the SSL certificate, key, and profile management framework. SSL is an application-layer protocol that transfers the data securely between the client and server using a combination of authentication, encryption, and data integrity. SSL uses certificates and private-public key pairs to provide this security. A user can configure an SSL profile, which includes a certificate, key, and trusted CA certificates used in SSL communication. A user can manage certificates, keys, and also multiple SSL profiles. An SSL profile can be configured and attached to any other EOS configuration which supports SSL communication. The individual EOS configuration using this framework includes details of using the SSL profile in their configuration.

The only private keys supported are those using the RSA algorithm. Encode both the certificate and keys in the Privacy Enhanced Mail (PEM) format.

Example

This is a code sample of a PEM encoded certificate.

```
$cat server.crt

-----BEGIN CERTIFICATE-----

9.2.1.2 Configuration

- Configuring Certificates
- Configuring Keys
- Configuring a certificate with a RSA key in SSL Profile

9.2.1.2.1 Configuring Certificates

Copying a Certificate to the Switch

The **`copy file: certificate:`** command copies the certificate to the *certificate:* file system from any supported source URLs of the copy command. The source file may contain multiple PEM-encoded certificates but must not contain other entities such as keys.

Example

This command copies a server.crt certificate to the *certificate:* file system.

```
switch(config)# copy file:/tmp/ssl/server.crt certificate:
Copy completed successfully.
switch(config)#
```

Errors while Copying the Certificates

Examples

- The PEM-encoded entities in the source file must all be certificates. If the source file contains different types of entities (e.g., a certificate and a key), the copy fails and displays an error message.

```
switch(config)# copy file:tmp/ssl/mixed.crt certificate:
% Error copying file:tmp/ssl/mixed.crt to certificate: (Multiple types of entities in
certificate file not supported)
switch(config)#
```

- The source file must contain valid PEM-encoded certificates. If the file contains invalid certificates, the copy fails and displays an error message.

```
switch(config)# copy file:tmp/ssl/bad.crt certificate:
% Error copying file:tmp/ssl/bad.crt to certificate: (Invalid certificate)
switch(config)#
```

- Only certificates with RSA public keys are supported. The copy fails if the certificate does not have an RSA public key and displays an error message.

```
switch(config)# copy file:tmp/ssl/dsa.crt certificate:
% Error copying file:tmp/ssl/dsa.crt to certificate: (Certificate does not have RSA key)
switch(config)#
```

Deleting a Certificate

The **delete certificate** command deletes a certificate configuration from the *certificate:* file system on the switch.

Example

This command deletes the *server.crt* certificate from the switch.

```
switch(config)#delete certificate:server.crt
switch(config)#
```

Generating Certificates

The following commands help the user to generate a self-signed certificate or Certificate Signing Request (CSR).

Examples

- This command creates either a self-signed certificate or a Certificate Signing Request (CSR). The following example demonstrates using the existing private key ***test.key*** for certificate generation. During this process, the system prompts you to provide details like the common name, two-letter country code, etc. A common-name entry is mandatory. While you can view the generated CSR directly on the CLI, a self-signed certificate gets saved to the designated certificate: file system location.

```
switch# security pki certificate generate self-signed test.crt key test.key
Common Name for use in subject: test
[...]
certificate:test.crt generated switch#
```

- This command specifies the digest and the certificate's validity (in days). The validity applies only to self-signed certificates.

```
switch# security pki certificate generate signing-request key test.key digest sha256 validity
 365
Common Name for use in subject: test
[...]
```

```
certificate:test.crt generated switch#
```

- This command adds the certificate parameters such as common-name, country, email, and others.

```
switch# security pki certificate generate signing-request key test.key parameters common-name
 Test [country US ...]
certificate:test.crt generated switch#
```

9.2.1.2.2 Configuring Keys

Copying a Key to the Switch

The **copy** command copies an RSA key to the sslkey: file system. The key can be copied from any supported source URLs of the copy command. The source file must contain only one key. Password-protected keys are not supported.

Example

This command copies a server.key RSA key to the sslkey: file system.

```
switch# copy file:/tmp/ssl/server.key sslkey:
Copy completed successfully.
switch#
```

Errors While Copying the Keys

Examples

- Only one PEM-encoded key per file is supported. The copy fails and displays an error message if the source file contains multiple PEM-encoded keys.

```
switch# copy file:tmp/ssl/multi.key sslkey:
% Error copying file:tmp/ssl/multi.key to sslkey: (Multiple PEM entities in
single file not supported)
```

- The source file must contain a valid PEM-encoded RSA key. If the file contains an invalid RSA key, the copy fails and displays an error message.

```
switch# copy file:tmp/ssl/bad.key sslkey:
% Error copying file:tmp/ssl/bad.key to sslkey: (Invalid RSA key)
```

- Password-protected keys are not supported. If the source file contains a password-protected key, the copy fails and displays an error message.

```
switch# copy file:/tmp/ssl/pass.key sslkey:
% Error copying file:tmp/ssl/pass.key to sslkey: (Password protected keys are not supported)
```

Deleting a Key

The **delete** command deletes the key configuration from the switch.

Example

This command deletes the server.key key from the switch.

```
switch# delete sslkey:server.key
```

Generating Keys

The following commands generate the RSA keys.

Examples

- This command generates a 2048-bit RSA private key and saves it to sslkey:test.key.

```
switch# security pki key generate rsa 2048 test.key
```

- This command generates a 4096-bit self-signed certificate RSA key and a 2048-bit certificate signing request RSA key.

```
switch# security pki certificate generate self-signed test.crt key test.key generate rsa 4096
switch# security pki certificate generate signing-request key test.key generate rsa 2048
```

9.2.1.2.3 Configuring a certificate with a RSA key in SSL Profile

An SSL profile is configured with a certificate and its corresponding RSA key. The public key information in the certificate must match the RSA key. This certificate and RSA key pair are used to authenticate to the peer during SSL negotiation. The individual EOS features that use SSL profile configuration will decide whether the certificate and key configuration is optional or mandatory.

Examples

-

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# certificate server.crt key server.key
```

- In this case, if the RSA key configured in the SSL profile does not match with the configured certificate, the SSL profile state becomes invalid, and an error message is displayed.

```
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# certificate server.crt key client.key
switch(config-mgmt-sec-ssl-profile-server)# show management security ssl profile
   Profile       State      Error
------------- ------------- ----------------------------------------
   server        invalid    Certificate 'server.crt' does not match
   with key
```

9.2.1.2.3.1 *Configuring SSL Profile with a Certificate Authority (CA)*

During SSL negotiation with mutual authentication, the peer (or client) certificate is verified by checking if it is signed by one of these trusted certificates. The full bundle of certificates leading to the trusted certificates must be included for peer certificates that do not have a chain to a trusted certificate. The individual EOS features that use SSL profile configuration will decide whether the trusted certificate configuration is optional or mandatory.

Example

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# trust certificate ca1.crt
switch(config-mgmt-sec-ssl-profile-server)# trust certificate ca2.crt
```

9.2.1.2.3.2 *Configuring Certificate Chains*

Certificate chains establish a chain of trust for the SSL Profile server certificate, ensuring its authenticity to a remote party. Several chain certificate commands can be issued to build a certificate chain with many intermediate CAs, regardless of the order. Use the **chain certificate** command to configure the certificate chain for an SSL profile. The **no** form of the command deletes the certificate configuration.

Examples

Assume that *server.crt* is issued by an intermediate CA ***intermediate.crt*** and ***intermediate.crt*** itself is issued by the root CA ***ca.crt***, as shown in the following figure.

Figure 9-1: Certificate Chain Example

- These commands configure the certificate chain shown schematically in the preceding figure.

```
switch#(config)# management security
switch#(config-mgmt-security)# ssl profile server
switch#(config-mgmt-sec-ssl-profile-server)# certificate server.crt key server.key
switch#(config-mgmt-sec-ssl-profile-server)# chain certificate intermediate.crt
switch#(config-mgmt-sec-ssl-profile-server)# exit
switch(config)#
```

- Configure the other peer to trust ***ca.crt*** to verify the certificate chain during the TLS handshake, as shown below.

```
switch# config
switch#(config)# management security
```

```
switch(config-mgmt-security)# ssl profile client
switch(config-mgmt-sec-ssl-profile-client)# certificate client.crt key client.key
switch(config-mgmt-sec-ssl-profile-client)# trust certificate ca.crt
```

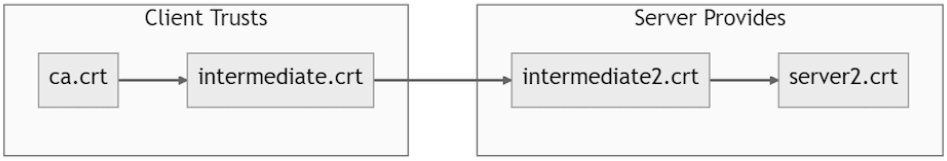
- To check the revocation status of the server certificate chain, the client can add the Certificate Revocation List (CRLs) to its SSL profile configuration. One CRL needs to be specified for every CA in the chain, even if it's not revoking any certificate.

```
switch# config
switch#(config)# management security
switch(config-mgmt-security)# ssl profile client
switch(config-mgmt-sec-ssl-profile-client)# crl intermediate.crl
switch(config-mgmt-sec-ssl-profile-client)# crl ca.crl
```

Note: Both the chain certificate and **`crl`** commands look into the *certificate:* file system to find the right PEM file.

Several **`chain certificate`** commands can be used to build a certificate chain with multiple intermediate CAs, regardless of the order. The following diagram shows an example certificate chain.

Figure 9-2: Certificate Chain Example 2



Configure this SSL profile in the following way. Note that the order of intermediate CAs does not matter.

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile server2
switch(config-mgmt-sec-ssl-profile-server2)# certificate server2.crt key server2.key
switch(config-mgmt-sec-ssl-profile-server2)# chain certificate intermediate2.crt
switch(config-mgmt-sec-ssl-profile-server2)# chain certificate intermediate.crt
switch(config-mgmt-sec-ssl-profile-server2)# exit
switch(config-mgmt-security)# exit
switch(config)#
```

You can divide a certificate chain into two segments, each configured on a separate peer. As long as this division occurs somewhere between the client and the server, they can collaborate to assemble a complete chain. The provided example illustrates precisely this scenario, demonstrating how to configure server and client SSL profiles with a split certificate chain.

Server side:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile server2
switch(config-mgmt-sec-ssl-profile-server2)# certificate server2.crt key server2.key
switch(config-mgmt-sec-ssl-profile-server2)# chain certificate intermediate2.crt
```

```
switch(config-mgmt-sec-ssl-profile-server2)# exit
switch(config-mgmt-security)# exit
switch(config)#
```

Client side:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile client
switch(config-mgmt-sec-ssl-profile-client)# certificate client.crt key client.key
switch(config-mgmt-sec-ssl-profile-client)# trust certificate ca.crt
switch(config-mgmt-sec-ssl-profile-client)# trust certificate intermediate.crt
switch(config-mgmt-sec-ssl-profile-client)# exit
switch(config-mgmt-security)# exit
switch(config)#
```

Incorrect Configuration Example

The following configuration will not work, as it results in invalid SSL profiles.

Server:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile server2
switch(config-mgmt-sec-ssl-profile-server2)# certificate server2.crt key server2.key
switch(config-mgmt-sec-ssl-profile-server2)# chain certificate intermediate.crt
switch(config-mgmt-sec-ssl-profile-server2)# show management security ssl profile
   Profile                      State      Additional Info
---------------------------- ------------ ----------------------------------------
   server3                      invalid    Profile has invalid certificate chain
switch(config-mgmt-sec-ssl-profile-server3)# exit
switch(config-mgmt-security)# exit
switch(config)#
```

Client:

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile client3
switch(config-mgmt-sec-ssl-profile-client3)# certificate client3.crt key client3.key
switch(config-mgmt-sec-ssl-profile-client3)# trust certificate intermediate.crt
switch(config-mgmt-sec-ssl-profile-client3)# show management security ssl profile
   Profile                      State      Additional Info
---------------------------- ------------ ----------------------------------------
   client3                      invalid    Profile has invalid trusted certificate
                                           chain
switch(config-mgmt-sec-ssl-profile-client3)# exit
switch(config-mgmt-security)# exit
switch(config)#
```

9.2.1.2.3.3 Local Certificate Checks

EOS conducts various checks on the certificates in an SSL profile before allowing its use. You can modify, add to, or relax these checks locally. Here are some checks EOS performs before communicating with the peer:

Examples

- Check whether the certificate has an extended key usage attribute:

```
switch(config-mgmt-sec-ssl-profile-client)# certificate requirement extended-key-usage
```

- Check whether all the trusted certificates or certificates in the chain have CA basic constraints set to true.

```
switch(config-mgmt-sec-ssl-profile-client)# trust certificate requirement basic-constraints ca
 true
switch(config-mgmt-sec-ssl-profile-client)# chain certificate requirement basic-constraints ca
 true
```

- Do not mark an expired certificate as invalid.

```
switch(config-mgmt-sec-ssl-profile-client)# certificate policy expiry-date ignore
```

9.2.1.2.3.4 *Displaying SSL profile status and SSL profile errors*

The **show management security ssl profile** command displays the SSL profile status information. To view a specific SSL profile status, use the name of the SSL profile. Otherwise, all SSL profile statuses are displayed.

Example

This command displays the status of the SSL profile server.

```
switch# show management security ssl profile server
 Profile      State
------------- -----------
 server       valid
```

If the SSL profile contains errors, an **invalid** state is displayed, and the errors are listed in the third column. After fixing the error, the SSL profile becomes **valid**.

Examples

- When the certificate ***server.crt*** does not match with the key, EOS displays the following error message.

```
switch# show management security ssl profile server
 Profile        State       Error
------------- ------------- ----------------------------------------
 server         invalid     Certificate 'server.crt' does not match
                            with key
```

- EOS displays the following error message when a trusted certificate ***ca2.crt*** does not exist.

```
switch# show management security ssl profile server
 Profile        State       Error
------------- ------------- -------------------------------------
 server         invalid     Certificate 'ca2.crt' does not exist
```

- EOS displays the following error message when a trusted certificate ***foo.crt*** is not a self-signed root certificate.

```
switch# show management security ssl profile server
 Profile        State       Error
------------- ------------- ----------------------------------------
server         invalid     Certificate 'foo.crt' is trusted and not
                           a root certificate
```

- When the certificate ***server.crt*** is expired, EOS displays the following error message.

```
switch# show management security ssl profile server
 Profile        State       Error
------------- ------------- -------------------------------------
 server         invalid     Certificate 'server.crt' has expired
```

- EOS displays the following error message when the certificate chain is missing an intermediate certificate.

```
switch# show management security ssl profile server
    Profile        State     Error
------------- ------------- ----------------------------------------------
    server        invalid    Profile has invalid certificate chain
                             Certificate 'intermediate.crt' does not exist
```

9.2.1.3 Rotating Certificate and Key Pair

The SSL profile uses a certificate and key pair. Rotation commands can rotate the certificate and key pair. For example, to rotate ***cert.pem*** and ***key.pem*** in the SSL profile ***profile01***, use the following commands.

```
switch01# show running-config section ssl
management security
ssl profile profile01
certificate cert.pem key key.pem
```

Using the command **`security pki certificate generate signing-request rotation ssl profile`**, generate a new key and signing request for SSL profile ***profile01***. The command also generates a unique rotation ID for later certificate import.

```
switch01# security pki certificate generate signing-request rotation ssl profile profile01 key
 generate rsa 2048 parameters common-name switch01
Rotation ID: 2ad7771e8cbc11ebbba37483ef8d9c4b
Certificate Signing Request:
-----BEGIN CERTIFICATE REQUEST-----

-----END CERTIFICATE REQUEST-----
```

The following example illustrates the command's complete syntax. The **import-timeout** argument specifies the timeout period for the rotation ID. If the system does not import a certificate within this period, the rotation ID expires and the system deletes it.

```
switch# security pki certificate generate signing-request rotation ssl profile <profile-name>
key generate rsa <2048|3072|4096>
[ import-timeout <minutes> ] (default: 60 mins)
[ digest <sha256|sha384|sha512> ]  (default: sha256) parameters common-name <common-name>
[ country <country-code> ]
[ state <state-name> ]
[ locality <locality-name> ]
[ organization <org-name> ]
[ organization-unit <org-unit-name> ]
[ email <email> ]
[ subject-alternative-name [ ip <ip1 ip2 …> ]
[ dns  <nm1 nm2 …> ] [ dns  <nm1 nm2 …> ]
```

Use the **`show security pki certificate rotation`** command to view the status of rotation IDs.

Example

```
switch# show security pki certificate rotation
Rotation ID                       Profile Name State           Expiry
--------------------------------- ------------ --------------- -------------------
2ad7771e8cbc11ebbba37483ef8d9c4b  profile01    Import Pending  2021-03-24 10:15:37
```

Copy the Certificate Signing Request (CSR) and submit the CSR to a trusted Certificate Authority (CA) for signing. Import the signed certificate using the **`security pki certificate rotation import <rotation-id>`** command. Use the previously generated rotation ID with the signing request.

```
switch# security pki certificate rotation import 2ad7771e8cbc11ebbba37483ef8d9c4b
Enter TEXT certificate. Type 'EOF' on its own line to end.

-----END CERTIFICATE-----
EOF
Success
```

Commit the rotation ID using the **`security pki certificate rotation commit <rotation-id>`** command. This command will rotate ***cert.pem*** and ***key.pem*** of SSL profile ***profile01*** with new certificate and key.

```
switch# security pki certificate rotation commit 2ad7771e8cbc11ebbba37483ef8d9c4b
                                    Success
```

Note: For keys generated outside of EOS, use the following command to rotate the certificate and key pairs in place of the earlier workflow:

```
switch# security pki certificate rotation commit ssl profile profile01
Enter TEXT private key. Type 'EOF' on its own line to end.

EOF
Success
```

After rotating the certificate and key pair, use the **show management security ssl certificate cert.pem** and **show management security ssl key key.pem** commands to display the new contents.

9.2.1.4 Resetting Diffie-Hellman Parameters

The Diffie-Hellman parameters file facilitates the exchange of symmetric keys during SSL negotiations. When the system is booted, it auto-generates a Diffie-Hellman parameters file if one does not exist. Use the reset command to reset the auto-generated Diffie-Hellman parameters file. The individual features that use SSL profile configuration will decide whether they also use the Diffie-Hellman parameters file. The switch uses 2048-bit Diffie-Hellman parameters with no options to select the size.

Note: Not all features that use SSL profile configuration will use the Diffie-Hellman parameters file.

Example

This command resets the Diffie-Hellman parameters file.

```
switch# reset ssl diffie-hellman parameters
```

9.2.1.4.1 Displaying the Diffie-Hellman parameters

The **`show management security ssl diffie-hellman`** command displays the Diffie-Hellman parameters.

Example

This command displays the Diffie-Hellman parameters.

```
switch# show management security ssl diffie-hellman
Last successful reset on Apr 10 16:18:08 2015
Diffie-Hellman Parameters 1024 bits
 Generator: 2
 Prime:     dc47b5edc0d2b41451432f79f45efab452bba7b1ab118c194d671d6752ed1c550
            664ed8f052ad0fdad623c1d54ae5aee5e728d2bd7a6221636b787a4c08d1fef8c
            6dcd10759d38f8b70b47d1c7972d69b0b295a2ee6ab44cfc7352cb133e85197c8
            9f1fc27aac7e8e02afb4fb01ca1cb05558a7bef505b73a8d06cdfe403576b
```

9.2.1.5 Configuring the TLS Handshake Settings

During a TLS handshake, both peers send each other a list of the TLS versions they support to agree on and use the highest common version. The following allowable versions can be configured in an SSL profile using the **`tls versions`** command. By default, ***TLSv1***, ***TLSv1.1***, and ***TLSv1.2*** are enabled.

Examples

- This command forces the use of ***TLSv1.2***. If the other peer does not support this version, the TLS handshake fails.

```
switch# config
switch#(config)# management security
switch(config-mgmt-security)# ssl profile client
switch(config-mgmt-sec-ssl-profile-client)#
switch(config-mgmt-sec-ssl-profile-client)# tls versions 1.2
```

- These commands add support for ***TLSv1.1*** on top of the already configured ***TLSv1.2***.

```
switch(config-mgmt-sec-ssl-profile-client)# tls versions add 1.1
switch(config-mgmt-sec-ssl-profile-client)# tls versions 1.1 1.2
```

The TLS handshake establishes a secure communication channel by negotiating the cipher suite and the TLS version. The client initiates this process by providing the server a list of supported cipher suites. Based on the client's list and capabilities, the server selects a mutually supported cipher suite. This selection ensures both parties utilize the same cryptographic algorithms for secure data exchange.

The default **`cipher-list`** setting employs an OpenSSL cipher string **(HIGH:!eNULL:!aNULL:!MD5)**. This configuration permits only key lengths longer than 128 bits and excludes cipher suites using MD5.

To view the complete list of cipher suites included in this setting, execute the following shell command: **openssl ciphers HIGH:!eNULL:!aNULL:!MD5**.

Example

This command builds a cipher suite list.

```
switch(config-mgmt-sec-ssl-profile-client)# cipher-list AESGCM
switch(config-mgmt-sec-ssl-profile-client)# cipher-list SHA256:SHA384
switch(config-mgmt-sec-ssl-profile-client)# cipher-list ECDHE-ECDSA-AES256-GCM-SHA384
```

9.2.1.5.1 Configuring TLSv1.3 Key Establishment Groups

Use TLSv1.3 Key Establishment Groups to ensure cryptographic security and Perfect Forward Secrecy (PFS) during the TLS handshake. Key Establishment Groups provide specific mathematical structures to perform the Diffie-Hellman key exchange which creates a shared secret key between the client and the server.

Unlike previous versions of Transport Layer Security (TLS) that used a static RSA key exchange, TLSv1.3 mandates the use of an Ephemeral Diffie-Hellman key exchange for all initial handshakes. Ephemerol denotes the use of a temporary key generated uniquely for each session and provides PFS.

- Diffie-Hellman (DH) - Uses mathematical properties of finite fields.
- Elliptic Curve Diffie-Hellman Ephemoral (ECHDE) - Uses smaller and faster elliptic curve cryptography for the same key exchange goal.

Defining the Role of the Group

The group defines the mathematical parameters, the curve or infinite field, used by the DH and ECDHE computations. A strong group ensures that the shared secret key cannot be compromised even if you record the session.

- Client Role - In the `ClientHello` message, the client lists the supported name groups and sends the public key share for the preferred group in the `key_share` extension.
- Server Role - The server selects a mutually supported group and uses the client public key to generate the same session secret.

EOS supports the following TLSv1.3 Key Establishment Groups:

- Finite-field Diffie-Hellman
  - ffdhe2048
  - fdhe3072
  - ffdhe4096
  - ffdhe6144
  - ffdhe8192
- NIST Elliptic Curves
  - secp256r1
  - secp384r1
  - secp521r1
- Other Elliptic Curves
  - ecdh_x25519
  - ecdh_x448
- Pure Post-Quantum Cryptography (PQC) Key Encapsulation Mechanisms (KEM)
  - MLKEM512
  - MLKEM768
  - MLKEM1024
- PQC-Classical Hybrid Mechanisms
  - SecP256r1MLKEM768
  - X25519MLKEM768
  - SecP384r1MLKEM1024

Configuring Groups on the SSL Profile

Configure the specific list of enabled key establishment groups on an SSL profile with the most preferred specified first. Enable TLSv1.3 for the profile, *mytls_key*:

```
switch(config)# management security
```

```
switch(config-mgmt-security)# ssl profile mytls_key
switch(config-mgmt-sec-ssl-profile-mytls_key)# tls versions 1.3
switch(config-mgmt-sec-ssl-profile-mytls_key)#
```

Next, configure the Key Establishment Group for the profile:

```
switch(config-mgmt-sec-ssl-profile-mytls_key)# key-establishment-group X25519MLKEM768:ecdh_x25519
:secp256r1
```

The configuration lists `X25519MLKEM768`, a PQC-classical hybrid mechanism, as the most preferred key, and then two classical ECC groups as the next preferred keys. Separate the keys using colons. By default, the SSL profile uses the following list of Key Establishment Groups:

```
ecdh_x25519:secp256r1:ecdh_x448:secp521r1:secp384r1:ffdhe2048:ffdhe3072:ffdhe4096:ffdhe6144
:ffdhe8192
```

Displaying Key Establishment Groups Information

Use the **`show management security ssl profile`** command to display Key Establishment Groups:

```
switch# show management security ssl profile mytls_key key-establishment-group
Profile: server
        - X25519MLKEM768
        - ecdh_x25519
        - secp256r1
```

9.2.1.5.2 Enabling the Federal Information Processing Standards (FIPS) Mode

Federal Information Processing Standards (FIPS) is a cryptographic standard that restricts the cryptographic functions and protocol versions used by OpenSSL.

Example

This command enables the FIPS mode for a SSL profile.

```
switch(config-mgmt-sec-ssl-profile-client)# fips restrictions
```

9.2.1.6 Syslog with TLS Support

Collecting syslog information on a remote syslog server requires defining an SSL profile. This profile ensures the secure transmission of syslog data to the server over a TLS connection.

Configuring Syslog with TLS Support

The following command configures a remote syslog server with an SSL profile. It configures a syslog server with the hostname ***test.example.com*** using the SSL profile (***test-profile***) for communications over port ***1234***.

```
switch(config)# logging host test.example.com 1234 protocol tls ssl-profile test-profile
```

SSL Profile Example (Minimal)

The following commands set up a minimal profile to support remote logging over TLS. Ensure the proper configuration of the remote server to enable TLS communication.

```
switch(config-mgmt-security)# ssl profile test-profile
switch(config-mgmt-sec-ssl-profile-test-profile)# certificate clientCert key clientKey
switch(config-mgmt-sec-ssl-profile-test-profile)# trust certificate serverCA
```

9.2.1.7 Displaying Certificate and Key Information

- Displaying Certificate Information
- Displaying Key Information

9.2.1.7.1 Displaying Certificate Information

Displaying the Directory Information

The **dir** command displays the directory output of certificate file systems.

Example

This command displays the directory output of certificate: file-system.

```
switch# dir certificate:
Directory of certificate:/
   -rw- 3319 Apr 10 11:50 server.crt
No space information available
```

Displaying the certificate information

The **show management security ssl certificate** command displays the certificate information. To display a specific certificate, specify the certificate name. Omitting a name displays all available certificates.

Example

This command displays the ***server.crt*** certificate information.

```
switch# show management security ssl certificate server.crt
Certificate server.crt:
 Version:                    1
 Serial Number:              9
 Issuer:
    Common name:             ca
    Email address:           ca@foo.com
    Organizational unit:     Foo Org
    Organization:            Foo
    Locality:                SC
    State:                   CA
    Country:                 US
 Validity:
    Not before:             Aug 11 21:44:17 2014 GMT
    Not After:              May 14 21:44:17 2069 GMT
 Subject:
```

```
    Common name:            server
    Email address:          server@arista.com
    Organizational unit:    Foo Org
    Organization:           Foo
    Locality:               SC
    State:                  CA
    Country:                US
 Subject public key info:
    Encryption Algorithm:   RSA
    Size:                   2048 bits
    Public exponent:        65537
    Modulus:                e04e3ff8e1c64dbcb141fe96133f998e90a322c671b9f28307bf873
                            2239f69804a77fbb8f146841eb6253b7bb50bf6c66bbf3097ec695b
                            0d7985cfdd939c9913b4ba4f6cb8655b208ed0254a269ecab574987
                            ea5ee80085f5216d303cf704372b2fa1aae62756c3762441fcc1c04
                            635a831d5ec96d841
```

Displaying Certificate Revocation List (CRL) Information

The **show management security ssl crl** command displays the installed Certificate Revocation List (CRL) information. To view a specific CRL, use its name. Omitting a name displays all the CRLs.

Example

This command displays the ***intermediate.crl*** information.

```
switch# show management security ssl crl intermediate.crl
CRL intermediate.crl:
   CRL Number: 11
   Issuer:
      Common name: intermediate
      Email address: intermediate@foo.com
      Organizational unit: Foo Org
      Organization: Foo
      State: CA
      Country: US
   Validity:
      Last Update: Jul 19 19:27:34 2016 GMT
      Next Update: Dec 05 19:27:34 2043 GMT
```

9.2.1.7.2 Displaying Key Information

Displaying the Directory Information

The **dir** command displays the directory output of SSL key file systems.

Example

This command displays the directory output of sslkey: file-system.

```
switch# dir sslkey:
Directory of sslkey:/
   -rw- 1675 Apr 10 12:55 server.key
No space information available
```

Displaying the RSA Key Information

The **show management security ssl key** command displays the RSA key information. To view a specific RSA key, use the name of the key; otherwise, all the keys are displayed. For security reasons, only the public part of the key is displayed.

Example

This command displays the server.key key information.

```
switch# show management security ssl key server.key
Key server.key:
 Encryption Algorithm: RSA
 Size:                 2048 bits
 Public exponent:      65537
 Modulus:              e04e3ff8e1c64dbcb141fe96133f998e90a322c671b9f28307bf873
                       2239f69804a77fbb8f146841eb6253b7bb50bf6c66bbf3097ec695b
                       0d7985cfdd939c9913b4ba4f6cb8655b208ed0254a269ecab574987
                       b502f8c3f541fa3bae59743cced6e6ca04f6ca6c9268744add79c3a
                       f8178d12dd744ddf5db100b33c46b40e53f0a1c7d49f83488976c5d
```

9.2.1.8 TLS Commands

Configuration Commands

- copy file: certificate:
- copy file: sslkey:
- delete certificate:
- delete sslkey:
- dir certificate:
- dir sslkey:
- reset ssl diffie-hellman parameters
- security pki certificate generate
- security pki key generate
- ssl profile

Show Commands

- show management security ssl certificate
- show management security ssl crl
- show management security ssl diffie-hellman
- show management security ssl key
- show management security ssl profile

9.2.1.8.1 copy file: certificate:

The **copy file: certificate:** command copies the certificate to the **certificate: file** system. The certificate can be copied from any supported source URL of the **copy** command.

Command Mode

Global Configuration

Command Syntax

`copy file:` *file_name* `certificate:`

Parameter

file_name location or the path of the file or the directory to save the certificate.

Guidelines

The following requirements apply to copying certificates:

- A single source file can contain multiple PEM encoded entities, but they must all be certificates. If including other types such as SSL keys, the copy fails and displays an error message.

```
switch(config)# copy file:tmp/ssl/mixed.crt certificate:
% Error copying file:tmp/ssl/mixed.crt to certificate: (Multiple types of entities in
 certificate file not supported)
switch(config)#
```

- The source file must contain valid PEM encoded certificates. If the file contains invalid certificates, the copy fails and displays an error message.

```
switch(config)# copy file:tmp/ssl/bad.crt certificate:
% Error copying file:tmp/ssl/bad.crt to certificate: (Invalid certificate)
switch(config)#
```

- EOS only supports certificates with RSA public keys. If the certificate does not have an RSA public key, the copy fails and displays an error message.

```
switch(config)# copy file:tmp/ssl/dsa.crt certificate:
% Error copying file:tmp/ssl/dsa.crt to certificate: (Certificate does not have RSA key)
switch(config)#
```

- This command copies a server.crt certificate to the **certificate: file** system.

```
switch(config)# copy file:/tmp/ssl/server.crt certificate:
Copy completed successfully.
```

9.2.1.8.2 copy file: sslkey:

The **copy file: sslkey:** command copies the SSL key to the **sslkey: file** system. The key can be copied from any supported source URL of the **copy** command.

Command Mode

Global Configuration

Command Syntax

`copy file:` *file_name* `sslkey:`

Parameter

file_name location or the path of the file or the directory to save the key.

Guidelines

The following requirements apply to copying SSL keys:

- EOS only supports one PEM encoded key per file. If the source file contains multiple PEM encoded keys, the copy fails and displays an error message.

```
switch# copy file:tmp/ssl/multi.key sslkey:
% Error copying file:tmp/ssl/multi.key to sslkey: (Multiple PEM entities in single file not
 supported)
```

- The source file must contain a valid PEM encoded RSA key. If the file contains an invalid RSA key, the copy fails and displays an error message.

```
switch# copy file:tmp/ssl/bad.key sslkey:
% Error copying file:tmp/ssl/bad.key to sslkey: (Invalid RSA key)
```

- EOS does not support password protected keys. If the source file contains a password protected key, the copy fails and displays an error message.

```
switch# copy file:/tmp/ssl/pass.key sslkey:
% Error copying file:tmp/ssl/pass.key to sslkey: (Password protected keys are not supported)
```

Example

This command copies an SSL key in the file *server.key* to the **sslkey: file** system.

```
switch(config)# copy file:/tmp/ssl/server.key sslkey:
Copy completed successfully.
switch(config)#
```

9.2.1.8.3 delete certificate:

The **`delete certificate:`** command deletes a specified certificate from the **certificate: file** system on the switch.

Command Mode

Global Configuration

Command Syntax

`delete certificate:` *certificate_name*

Parameter

certificate_name name of the certificate to delete.

Example

This command deletes the ***server.crt*** certificate from the switch.

```
switch(config)# delete certificate:server.crt
```

9.2.1.8.4 delete sslkey:

The **`delete sslkey:`** command deletes a SSL key from the **sslkey: file** system on a switch.

Command Mode

Global Configuration

Command Syntax

`delete sslkey:` *key_name*

Parameter

key_name name of the key.

Example

This command deletes the ***server.key*** SSL key on the switch.

```
switch(config)# delete sslkey:server.key
```

9.2.1.8.5 dir certificate:

The **`dir certificate:`** command displays the directory output of the **certificate: file** system on the switch.

Command Mode

Global Configuration

Command Syntax

```
dir certificate:
```

Example

This command shows the directory output of **certificate: file** system on the switch.

```
switch(config)# dir certificate:
Directory of certificate:/
   -rw- 3319 Apr 10 11:50 server.crt
No space information available
```

9.2.1.8.6 dir sslkey:

The **`dir sslkey:`** command displays the directory output of **sslkey: file** system on the switch.

Command Mode

Global Configuration

Command Syntax

```
dir sslkey:
```

Example

This command shows the directory output of **sslkey: file** system on the switch.

```
switch(config)# dir sslkey:
Directory of sslkey:/
   -rw- 1675 Apr 10 12:55 server.key
No space information available
```

9.2.1.8.7 reset ssl diffie-hellman parameters

The **`reset ssl diffie-hellman parameters`** command resets the Diffie-Hellman parameters file after a system reboot.

Command Mode

Global Configuration

Command Syntax

```
reset ssl diffie-hellman parameters
```

Example

This command resets the Diffie-Hellman parameters file.

```
switch(config)# reset ssl diffie-hellman parameters
switch(config)#
```

9.2.1.8.8 security pki certificate generate

The **`security pki certificate generate`** command generates a self-signed certificate or a Certificate Signing Request (CSR) certificate. The CLI displays the generated CSR, and a self-signed certificate saves to the **certificate: file** system.

Many other parameters can be entered and applied to the certificate as shown in the following examples.

Command Mode

Global Configuration

Command Syntax

`security pki certificate generate` {self-signed |signing-request} *certificate_name* Key *key_name*

Parameters

- ***certificate_name*** - name of the certificate to generate. Options include the following:
  - Self-signed request to generate self-signed certificate.
  - Signing-request request to generate signing-request.
  - **digest** - Signs the certificate or key with the following cryptographic hash algorithm (***sha256***, ***sha384***, ***sha512***).
  - ***key_name*** - Name of the key to modify.
- **parameters** - Signing request parameters for a certificate. Option include the following:
  - ***common-name*** - Common name to use in the subject.
  - ***country*** - Two-letter country code to use in the subject.
  - ***email*** - Email address to use in the subject.
  - ***locality*** - Locality name to use in the subject.
  - ***organization*** - Organization name to use in the subject.
  - ***organization-unit*** - Organization Unit Name for use in the subject.
  - ***state*** - State to use in the subject.
  - ***subject-alternative-name*** - Subject alternative name extension.
  - ***rotation*** - Generate a unique rotation ID.
- ***validity*** - Validity of the certificate in days. Value ranges from ***1*** to ***30000***.

Examples

- This command generates a self-signed certificate or CSR certificate. This example uses an existing private key (***test.key***) to generate the certificates.

```
switch(config)# security pki certificate generate self-signed test.crt key test.key
```

- This command specifies the digest and the validity, in days, of the certificate or key.

```
switch(config)# security pki certificate generate signing-request key test.key digest sha256
 validity 365
```

- This command adds the certificate parameters such as common-name, country, email, and others.

```
switch(config)# security pki certificate generate signing-request key test.key parameters
 common-name Test [country US ...]
```

9.2.1.8.9 security pki key generate

The **`security pki key generate`** command generates a RSA key used to validate a specific certificate.

The key generated can be modified and saved by entering the value of the length in the **`generate rsa`** ***length*** parameter.

Command Mode

Global Configuration

Command Syntax

`security pki key generate` [rsa [2048 | 3072 | 4096] *key_name*

Parameters

- **rsa** - Use the Rivest-Shamir-Adleman (RSA) algorithm. Options include the following.
  - **2048** - Use 2048-bit keys.
  - **3072** - Use 3072-bit keys.
  - **4096** - Use 4096-bit keys.
- ***key_name*** - The name of the key to generate.

Examples

- This command generates a a 2048-bit long RSA private key,***test.key***, and saves it to **sslkey:test.key**.

```
switch(config)# security pki key generate rsa 2048 test.key
```

- This command modifies the generated RSA key length value.

```
switch(config)# security pki certificate generate self-signed test.crt key
test.key generate rsa 4096
switch(config)# security pki certificate generate signing-request key test.key
generate rsa 2048
```

9.2.1.8.10 show management security ssl certificate

The **show management security ssl certificate** command displays information about the certificate. Provide the name of the certificate to view more information about the certificate. If you do not provide a name, this command displays information about all of the certificates.

Command Mode

EXEC

Command Syntax

`show management security ssl certificate` [*certificate_name*]

Parameter

certificate_name - The name of the certificate (optional).

Example

This command displays the **server.crt** certificate information.

```
switch# show management security ssl certificate server.crt
Certificate server.crt:
 Version:                    1
 Serial Number:              9
 Issuer:
    Common name:             ca
    Email address:           ca@myorg.com
    Organizational unit:     Myorg Org
    Organization:            Myorg
    Locality:                SC
    State:                   CA
    Country:                 US
 Validity:
    Not before:             Aug 11 21:44:17 2014 GMT
    Not After:              May 14 21:44:17 2069 GMT
 Subject:
    Common name:            server
    Email address:          server@arista.com
    Organizational unit:    Org Org
    Organization:           ORg
    Locality:               SC
    State:                  CA
    Country:                US
 Subject public key info:
    Encryption Algorithm:   RSA
    Size:                   2048 bits
    Public exponent:        65537
    Modulus:                e04e3ff8e1c64dbcb141fe96133f998e90a322c671b9f28307bf873
                            2239f69804a77fbb8f146841eb6253b7bb50bf6c66bbf3097ec695b
                            0d7985cfdd939c9913b4ba4f6cb8655b208ed0254a269ecab574987
                            9f54c8c7f0b3a57a7ab826870119083222ad5ee76d40f3fae49d36e
                            b502f8c3f541fa3bae59743cced6e6ca04f6ca6c9268744add79c3a
                            c08af6b451455b4a61071f4c0b3ec3553585312783e9381f65bb0e2
                            ea5ee80085f5216d303cf704372b2fa1aae62756c3762441fcc1c04
                            97ee6190586ed28c0e376f48e53f05a40c7e1f3a65e3c6165bae5df
                            f8178d12dd744ddf5db100b33c46b40e53f0a1c7d49f83488976c5d
                            635a831d5ec96d841
```

9.2.1.8.11 show management security ssl crl

The **show management security ssl crl** command displays the basic information about the installed Certificate Revocation List (CRLs). To view information of a specific CRL provide the name of the CRL. If you do not provide a name, this command displays information about all of the CRLs.

Note: The command only displays basic information and does not display any information on the revocation status of certificates.

Command Mode

EXEC

Command Syntax

```
show management security ssl crl
```

Example

This command displays the basic information of the **intermediate.crl** CRL.

```
switch# show management security ssl crl intermediate.crl
CRL intermediate.crl:
   CRL Number: 11
   Issuer:
      Common name: intermediate
      Email address: intermediate@mycompany.com
      Organizational unit: mycompany Org
      Organization: mycompany
      State: CA
      Country: US
   Validity:
      Last Update: Jul 19 19:27:34 2016 GMT
      Next Update: Dec 05 19:27:34 2043 GMT
```

9.2.1.8.12 show management security ssl diffie-hellman

The **show management security ssl diffie-hellman** command displays the Diffie-Hellman parameter information.

Command Mode

EXEC

Command Syntax

```
show management security ssl diffie-hellman
```

Example

This command displays the Diffie-Hellman parameter information.

```
switch# show management security ssl diffie-hellman
Last successful reset on Apr 10 16:18:08 2015
Diffie-Hellman Parameters 1024 bits
 Generator: 2
 Prime:     dc47b5edc0d2b41451432f79f45efab452bba7b1ab118c194d671d6752ed1c550
            664ed8f052ad0fdad623c1d54ae5aee5e728d2bd7a6221636b787a4c08d1fef8c
            6dcd10759d38f8b70b47d1c7972d69b0b295a2ee6ab44cfc7352cb133e85197c8
            9f1fc27aac7e8e02afb4fb01ca1cb05558a7bef505b73a8d06cdfe403576b
```

9.2.1.8.13 show management security ssl key

The **show management security ssl key** command displays the RSA key information. To view information of a specific key, provide the name of the key in the command. If you do not provide a name, this command displays information about all of the keys.

Note: For security reasons, the output displays only the public part of the key.

Command Mode

EXEC

Command Syntax

`show management security ssl key` [*key_name*]

Parameter

key_name name of the key (optional).

Example

This command displays the **server.key** key information.

```
switch# show management security ssl key server.key
Key server.key:
Encryption Algorithm: RSA
Size:                 2048 bits
Public exponent:      65537
Modulus:              e04e3ff8e1c64dbcb141fe96133f998e90a322c671b9f28307bf873
                      2239f69804a77fbb8f146841eb6253b7bb50bf6c66bbf3097ec695b
                      0d7985cfdd939c9913b4ba4f6cb8655b208ed0254a269ecab574987
                      9f54c8c7f0b3a57a7ab826870119083222ad5ee76d40f3fae49d36e
                      b502f8c3f541fa3bae59743cced6e6ca04f6ca6c9268744add79c3a
                      c08af6b451455b4a61071f4c0b3ec3553585312783e9381f65bb0e2
                      ea5ee80085f5216d303cf704372b2fa1aae62756c3762441fcc1c04
                      97ee6190586ed28c0e376f48e53f05a40c7e1f3a65e3c6165bae5df
                      f8178d12dd744ddf5db100b33c46b40e53f0a1c7d49f83488976c5d
                      635a831d5ec96d841
```

9.2.1.8.14 show management security ssl profile

The **`show management security ssl profile`** command displays the SSL profile status information. To display information about a specific SSL profile, provide the name of the profile. If you do not provide a name, this command displays profile status of all the SSL profiles.

If the SSL profile contains errors, the state displays as invalid and lists the errors are listed in the third column.

Command Mode

EXEC

Command Syntax

`show management security ssl profile` [*profile_name*]

Parameter

profile_name - Name of the SSL profile (optional).

Examples

- This command displays the SSL profile status of profile server.

```
switch# show management security ssl profile server
 Profile      State
------------- -----------
 server       valid
```

- If the certificate ***server.crt*** does not match with the key, the following error displays.

```
switch# show management security ssl profile server
Profile       State         Error
------------- ------------- ----------------------------------------
server        invalid       Certificate 'server.crt' does not match
                            with key
```

- If a trusted certificate ***ca2.crt*** does not exist ,the following error displays.

```
switch# show management security ssl profile server
Profile       State         Error
------------- ------------- ----------------------------------------
server        invalid       Certificate 'ca2.crt' does not exist
```

- If a trusted certificate ***mycert.crt*** is not a self-signed root certificate, the following error displays.

```
switch# show management security ssl profile server
Profile       State         Error
------------- ------------- ----------------------------------------
```

```
server          invalid      Certificate 'mycert.crt' is trusted and not
                             a root certificate
```

- If the certificate ***server.crt*** expired, the following error displays.

```
switch# show management security ssl profile server
Profile       State         Error
------------- ------------- ----------------------------------------
 server       invalid       Certificate 'server.crt' has expired
```

- If the certificate chain is missing an intermediate certificate, the following error occurs.

```
switch# show management security ssl profile server
Profile        State         Error
-------------- ------------- ------------------------------------------
server          invalid       Profile has invalid certificate chain
                              Certificate 'intermediate.crt' does not exist
```

9.2.1.8.15 ssl profile

The **ssl profile** command places the switch in the SSL profile configuration mode. Various SSL profile management configurations are allowed in this mode. For example, this mode allows to configure a SSL profile with a certificate and its corresponding RSA key.

Similarly, other configurations such as trust certificate, chain certificate, crl, tls, cipher-list can be configured to a SSL profile in this mode.

The **no** form of the command deletes the SSL profile management configuration from ***running-config***.

Command Mode

Management Security Mode

SSL Profile Mode

Command Syntax

`ssl profile` *profile_name*

Parameter

profile_name name of the profile.

Examples

- These commands place the switch in SSL profile mode.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)#
```

- These commands configure SSL profile server with a certificate and its corresponding RSA key. The **no** command deletes the certificate configuration.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# certificate server.crt key server.key
switch(config-mgmt-sec-ssl-profile-server)# no certificate server.crt key server.key
```

- These commands configure the trust certificate ca1.crt to an SSL profile. The **no** command deletes a trusted certificate configuration.

```
switch# config
switch(config)# management security
```

```
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# trust certificate ca1.crt
switch(config-mgmt-sec-ssl-profile-server)# no trust certificate ca1.crt
```

- These commands configure the intermediate.crt chain certificate to an SSL profile. The **no** command deletes a chain certificate configuration.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# certificate server.crt key server.key
switch(config-mgmt-sec-ssl-profile-server)# chain certificate intermediate.crt
switch(config-mgmt-sec-ssl-profile-server)# no chain certificate intermediate.crt
```

- These commands provides Certificate Revocation List (CRL) to a SSL profile to check the revocation status of the certificate chain. The **no** command deletes the CRL configuration.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# crl intermediate.crl
switch(config-mgmt-sec-ssl-profile-server)# crl ca.crl
switch(config-mgmt-sec-ssl-profile-server)# no crl ca.crl
```

- These commands configure ***TLSv1.2*** to be used in the SSL profile.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# tls versions 1.2
```

- These commands build a cipher suite list.

```
switch# config
switch(config)# management security
switch(config-mgmt-security)# ssl profile server
switch(config-mgmt-sec-ssl-profile-server)# cipher-list AESGCM
switch(config-mgmt-sec-ssl-profile-server)# cipher-list SHA256:SHA38
switch(config-mgmt-sec-ssl-profile-server)# cipher-list ECDHE-ECDSA-AES256-GCM-SHA384
```

- This command check that the certificate has an extended key usage attribute.

```
switch(config-mgmt-sec-ssl-profile-client)# certificate requirement extended-key-usage
```

- These commands check that all the trusted certificates or certificates in the chain have a CA basic constraints set to true.

```
switch(config-mgmt-sec-ssl-profile-client)# trust certificate requirement basic-constraints ca
 true
switch(config-mgmt-sec-ssl-profile-client)# chain certificate requirement basic-constraints ca
 true
```

- This command enables the Federal Information Processing Standards (FIPS) mode for a SSL profile.

```
switch(config-mgmt-sec-ssl-profile-client)# fips restrictions
```

9.2.2 802.1X Port Security

This section explains the basic concepts behind 802.1X port security, including switch roles, how the switches communicate, and the procedure used for authenticating clients.

- 802.1X Port Security Introduction
- 802.1X Port Security Description
- Configuring 802.1X Port Security
- 802.1X AAA Unresponsive VLAN
- 802.1X Web Authentication
- Displaying 802.1X Information
- 802.1X Port Security Commands

9.2.2.1 802.1X Port Security Introduction

802.1X is an IEEE standard protocol that prevents unauthorized devices from accessing the network.

802.1X defines three device roles,

- Supplicant (client).
- Authenticator (switch).
- Authentication server (RADIUS).

Before authentication can succeed, the switch port is in unauthorized mode and blocks all traffic, but after authentication has succeeded, normal data can flow through the switch port.

Port security controls who can send or receive traffic from an individual switch port. An end node cannot send or receive traffic through a port until a RADIUS server authenticates the node.

This security prevents unauthorized individuals from connecting to a switch port to access the network. Only designated valid users on a RADIUS server can use the switch to access the network.

9.2.2.2 Overview of 802.1X Port Security

802.1X port security controls can send traffic through and receive traffic from the individual switch ports. A supplicant must authenticate using EAPOL packets with the switch before obtaining full access to the port. Arista switches act as an authenticator, passing the messages from 802.1X supplicants through to the RADIUS server and vice versa. 802.1X can operate in three different modes:

- **Single Host Mode** - Once the 802.1X supplicant authenticates on the port, the port only allows the traffic from the supplicant's MAC address.
- **Multi-Host Mode**: Once the 802.1X supplicant authenticates on the port, the port allows any traffic from any source MAC.

- **Multi-Host Authenticated Mode** - Allows multiple 802.1X supplicants and allows the incoming traffic from all authenticated supplicants MAC addresses through the port.

The Single Host and the Multi-Host modes allow only one 802.1X supplicant to authenticate for one port. After successfully authenticating, no other 802.1X supplicant can authenticate unless the current one logs off. However, the Multi-Host Authenticated Mode allows multiple 802.1X supplicants to authenticate and provide access to the network.

In addition to 802.1X authentication, EOS supports MAC-Based Authentication (MBA) and allows devices without 802.1X to access the network. The authenticator uses the MAC address of such devices as username/password in its RADIUS request packets. Depending on the MAC-Based Authentication configuration on the RADIUS server, the server permits or denies authentication to the supplicant. Unlike 802.1X supplicants, a single port allows multiple MBA supplicants. The MBA configuration does not require the 802.1X host modes. MBA supplicants permit or reject unauthenticated traffic based on the host mode.

EOS also supports Dynamic VLAN assignment, which permits the RADIUS server to assign the desired VLAN for the supplicant, using the tunnel attributes with the Access-Accept message. The RADIUS server assigns VLANs to the 802.1X and MBA supplicants. EOS supports only one VLAN per port. When the first host authenticates, the authenticator port assigns the respective VLAN through dynamic VLAN assignment, and subsequently, all other hosts must belong to that VLAN as well.

802.1X features support 802.1Q trunk ports that permit the user to use Port-Based Network Access Control (PNAC) on a port. With this feature, traffic arriving at an 802.1X-enabled port with a VLAN tag authenticates the 802.1X and MBA supplicants.

By default, traffic from any unauthenticated device on an 802.1X-enabled port drops. However, by configuring the Authentication Failure VLAN on the authenticator switch, the 802.1X or MBA supplicant traffic can be put into a specific VLAN, if the supplicant fails to authenticate via the RADIUS server.

Note: EOS supports one configurable VLAN for failure events such as failure due to server timeout, server unreachable, server AUTH-FAIL, or Quarantine.

9.2.2.2.1 Switch Roles for 802.1X Configurations

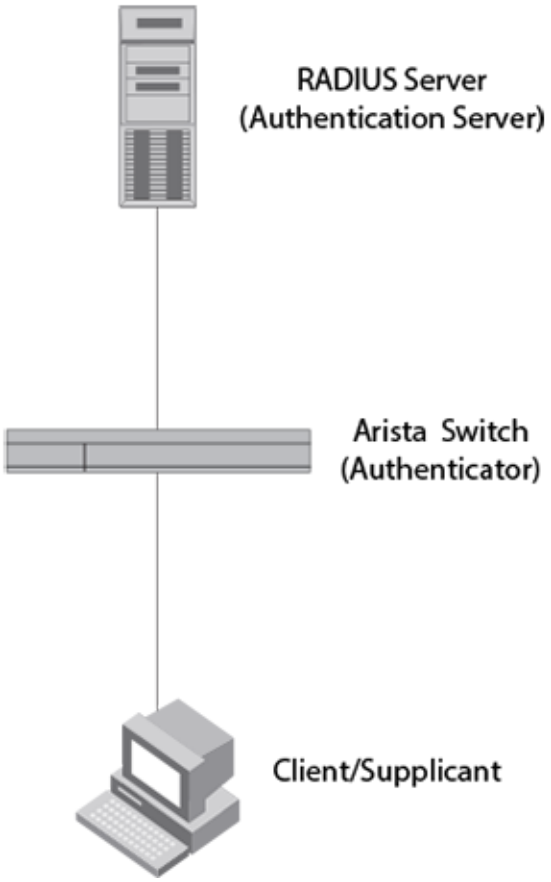
The 802.1X standard specifies the roles of **Supplicant (client)**, **Authenticator**, and **Authentication Server** in a network. Switch Roles for 802.1X Configurations illustrates these roles.

Authentication Server - The switch that validates the client and specifies if the client may access services on the switch. The switch supports Authentication Servers running RADIUS.

Authenticator - The switch that controls access to the network. In an 802.1X configuration, the switch serves as the Authenticator. As the Authenticator, it moves messages between the client and the Authentication Server. The Authenticator either grants or does not grant network access to the client based on the identity data provided by the client, and the authentication data provided by the Authentication Server.

Supplicant/Client - The client provides a username or password data to the Authenticator. The Authenticator sends this data to the Authentication Server. Based on the supplicants information, the Authentication Server determines whether the supplicant can use services given by the Authenticator. The Authentication Server sends this data to the Authenticator, which then provides services to the client, based on the authentication result.

Figure 9-3: Authenticator, Supplicant, and Authentication Server in an 802.1X configuration



9.2.2.2.2 Authentication Process

The authentication that occurs between a supplicant, authenticator, and authentication server include the following processes.

- Either the authenticator (a switch port) or the supplicant starts an authentication message exchange. The switch starts an exchange when it detects a change in the status of a port, or if it gets a packet on the port with a source MAC address that is not included in the MAC address table.
- An authenticator starts the negotiation by sending an EAP-Request/Identity packet. A supplicant starts the negotiation with an EAPOL-Start packet, to which the authenticator answers with a EAP-Request/ Identity packet.
- The supplicant answers with an EAP-Response/Identity packet to the authentication server via the authenticator.
- The authentication server responds with an EAP-Request packet to the supplicant via the authenticator.

- The supplicant responds with an EAP-Response.
- The authentication server transmits either an EAP-Success packet or EAP-Reject packet to the supplicant.
- If an EAP-Reject is received, the supplicant will receive an EAP-Reject message and their traffic will not be forwarded.

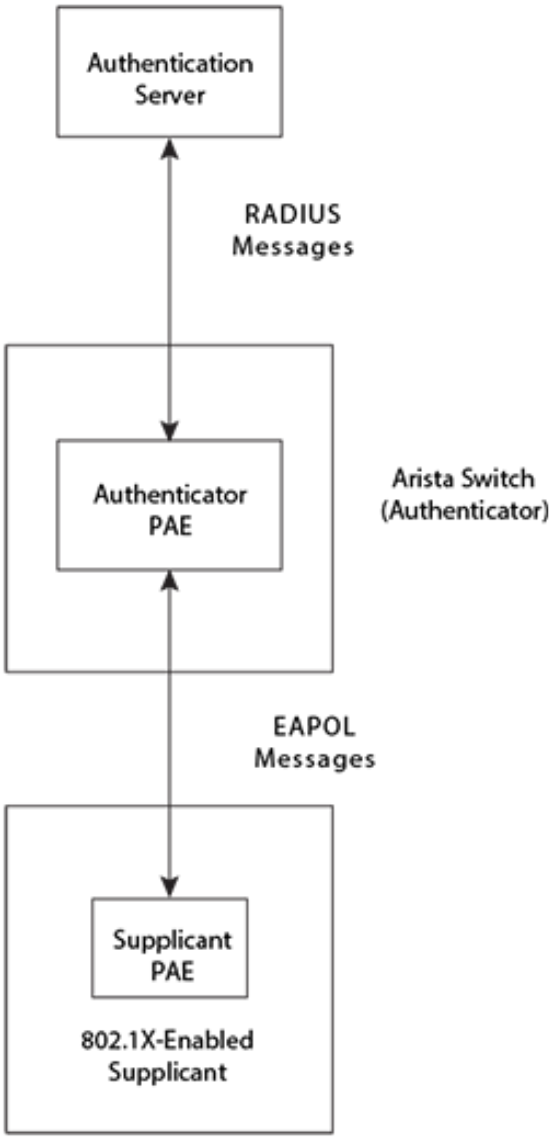
9.2.2.2.3 Communication Between the Switches

802.1X port security uses the Extensible Authentication Protocol (EAP), defined in ***RFC 2284*** and the RADIUS authentication protocol For communication between the switches.

The 802.1X standard defines a method for encapsulating and sending EAP messages over a LAN. This type of encapsulated EAP is known as EAP over LAN (EAPOL). The standard also specifies a method for transferring the EAPOL information between the client or Supplicant, Authenticator, and Authentication Server.

Supplicants and Authenticators pass the EAPOL messages between the Port Access Entity (PAE). The following figure displays the relationship between the Authenticator PAE and the Supplicant PAE.

Figure 9-4: Authenticator PAE and Supplicant PAE



Authenticator PAE - The Authenticator PAE communicates with the Supplicant PAE to receive the Supplicants identifying information. Behaving as a RADIUS client, the Authenticator PAE passes the Supplicants information to the Authentication Server, which decides whether to grant the Supplicant access. If the Supplicant passes authentication, the Authenticator PAE allows it access to the port.

Supplicant PAE - The Supplicant PAE provides information about the client to the Authenticator PAE and replies to requests from the Authenticator PAE. The Supplicant PAE may initiate the authentication procedure with the Authenticator PAE, as well as send logoff messages.

The 802.1X supplicant also supports unicast EAPOL by allowing EAPOL packets to the physical MAC address of the port and retains the Ethertype as 0x888e. Use the following command on the device with the EAPOL supplicant configuration to direct EAPOL packets with physical addresses to the CPU:

```
switch(config)# eapol mac destination rx physical
switch(config)#
```

9.2.2.2.4 Dot1x Dropped Counters

The Dot1x Dropped Counters count the packets dropped by dot1x interfaces. The dropped counter will not represent all the dropped packets in case of high volume dropping, and the CPU queue drop counter will reflect the rest of the dropped packet counter. This is due to the fact that EOS limits the bandwidth for the packets that get sent to the CPU.

The following counters are supported and increment depending on the ***dot1x interface*** configuration mode:

- EAPOL unauthorized port (indicates the dropped packet number due to the unauthorized EAPOL port when Mac Base Authorization is disabled).
- EAPOL unauthorized host (indicates the dropped packet number due to the unauthorized EAPOL host).
- MBA unauthorized host (counts the dropped packet due to the unauthorized host when Mac Base Authorization is enabled.)

9.2.2.2.5 Enabling 802.1X Port Control

To enable 802.1X port authentication on the switch, use the following command:

```
switch(config)# dot1x system-auth-control
```

Port mode can be set to access or trunk port and 802.1X port access entity set to authenticator:

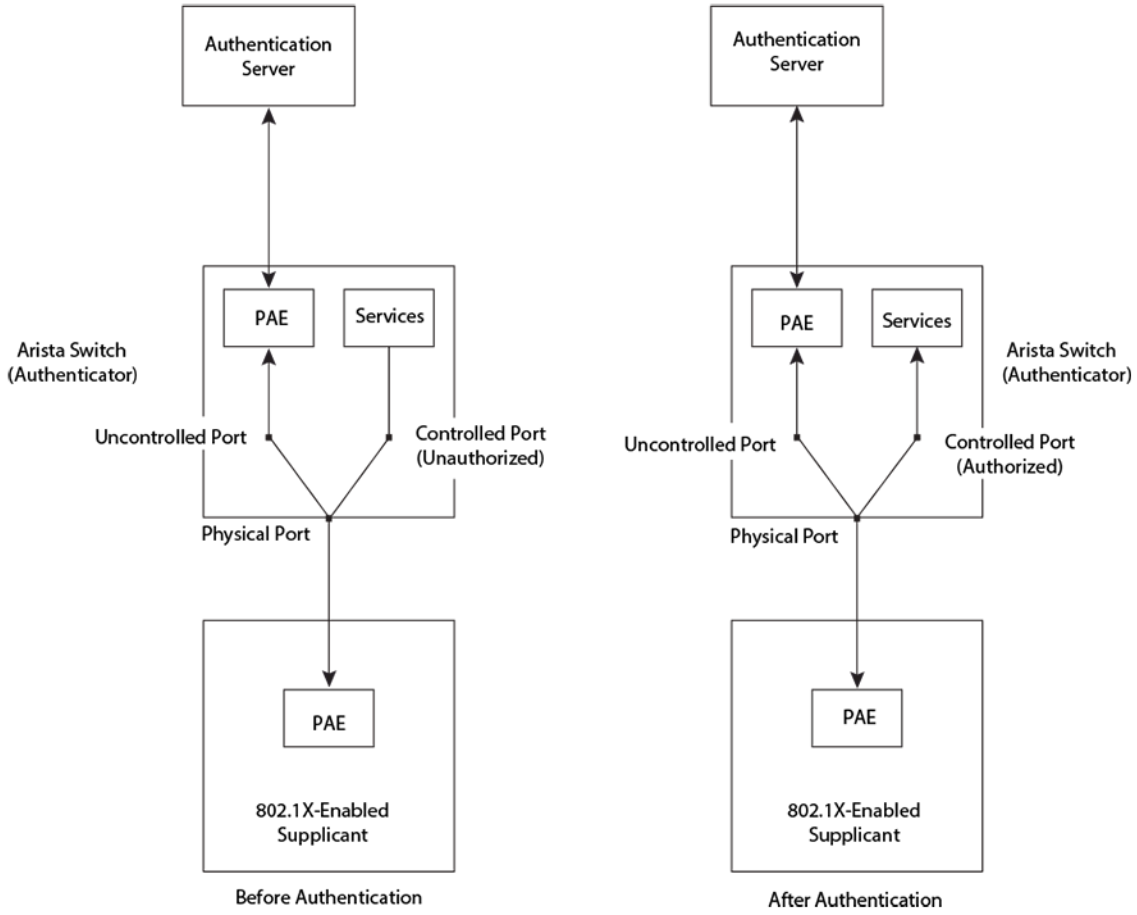
```
switch(config-if-Et1)# switchport mode access
switch(config-if-Et1)# dot1x pae authenticator
```

9.2.2.2.6 Controlled and Uncontrolled Ports

A physical port on the switch used with 802.1X has two virtual access points that include a controlled port and an uncontrolled port. The controlled port grants full access to the network. The uncontrolled port only gives

access for EAPOL traffic between the client and the Authentication Server. When a client is authenticated successfully, the controlled port is opened to the client.

Figure 9-5: Ports Before and After Client Authentication



9.2.2.2.6.1 Control Port State

Before authenticating the port, the port is unauthorized. In this state, the 802.1X agent only processes EAPOL packets and drops all other packets. After the port successfully authenticates, the port becomes authorized and allows all packets to pass. The authentication exchange controls the state transition between the supplicant and the authentication server. However, you can control the state by using any one of the following commands:

`dot1x port-control` force-authorized

force-authorized - disables 802.1X authentication and directly put the port to the authorized state. This is the default setting.

`dot1x port-control` force-unauthorized

force-unauthorized - also disables 802.1X authentication and directly put the port to unauthorized state, ignoring all attempts by the client to authenticate.

`dot1x port-control` auto

auto - enables 802.1X authentication and put the port to unauthorized state first. The port state remains in an unauthorized state or transit to authorized state according to authentication result and configuration.

9.2.2.2.6.2 Uncontrolled Port State

The Authenticator only opens one uncontrolled port before authenticating a client. The client and the Authentication Server swap EAPOL frames through the uncontrolled port. No other traffic passes through the controlled port in the unauthorized state.

During authentication, the Supplicant PAE and the Authenticator PAE exchange EAPOL messages, and the Authenticator PAE and the Authentication Server exchange RADIUS messages. If the client successfully authenticates, the controlled port becomes authorized, and traffic from the client can flow through the port normally.

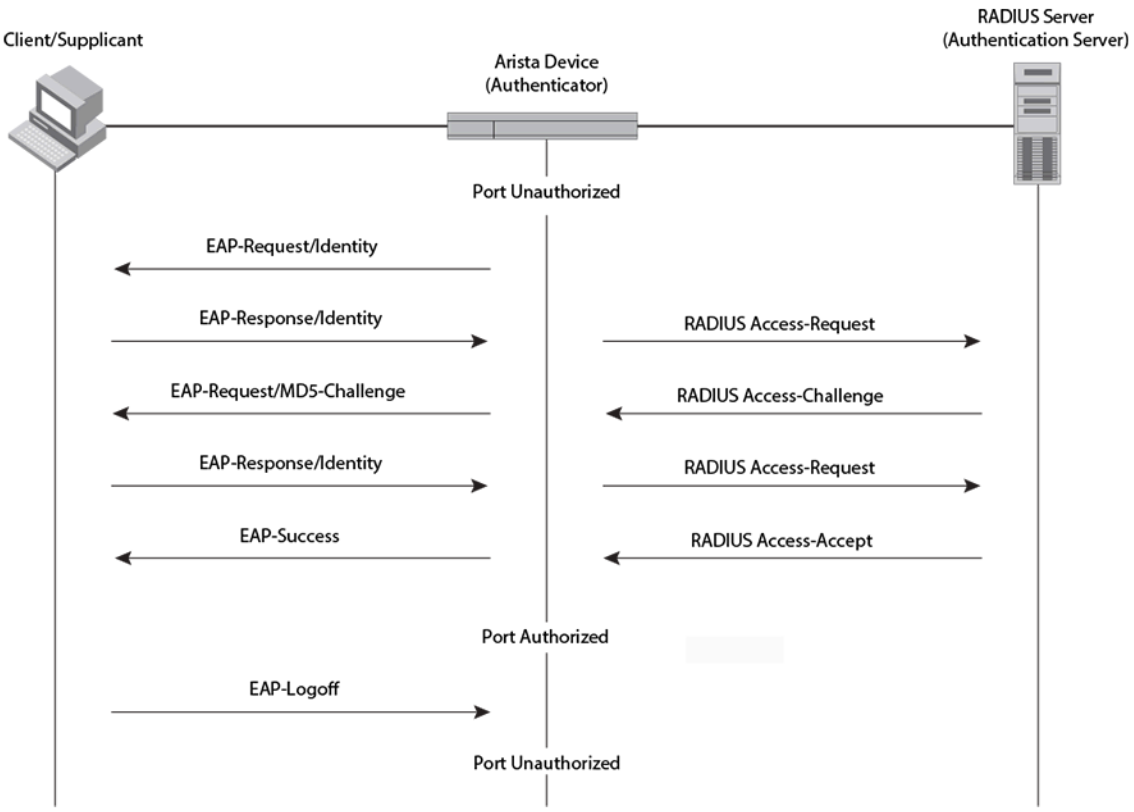
By default, all controlled ports on the switch become authorized and allow all traffic. When initially authenticating, the controlled port on the interface initially sets to the unauthorized state. If a client connected to the port authenticates successfully, the controlled port sets in the authorized state.

9.2.2.2.7 Message Exchange During Authentication

The following figure illustrates an exchange of messages between an 802.1X-enabled client, an Authenticator switch, and a RADIUS server operating as an Authentication Server.

Arista switches support MD5-challenge TLS and other EAP-encapsulated authentication types in EAP Request or Response messages. In other words, the switches are transparent to the authentication scheme used.

Figure 9-6: Message Exchange During Authentication



9.2.2.2.8 Authenticating Multiple Clients Connected to the Same Port

Arista switches support 802.1X authentication for ports with more than one client connected to them. Figure 9-7: Multiple clients connected to a 802.1X-enabled port illustrates a sample configuration where multiple clients are connected to a single 802.1X port. 802.1X authentication may use multi-host mode, or, on selected switches, single-host mode. In both modes, the port authenticates the packets received from any one client, and drops the packets received from other clients, until authentication of the connected client by the RADIUS server.

9.2.2.2.8.1 Single-host Mode

In single-host mode, the 802.1X client has authenticated on the RADIUS server and does not require further authentication. However, the port accepts packets only from the MAC address of the authenticated client.

9.2.2.2.8.2 Multi-Host Mode

In multi-host mode, once the 802.1X client authenticates with the RADIUS server, the port accepts all packets from any connected client, and these packets do not require any authentication.

9.2.2.2.9 Configuring 802.1X Round Robin Authentication

Adding Round Robin Authentication enables sending authentication requests across all live servers within a RADIUS server group and selects a group based on Round Robin Authentication. The dead timer or server probe determines the liveliness or reachability of the RADIUS server group. Fallback to the next RADIUS server group only happens if none of the servers can be reached in the current RADIUS server group.

Use the following commands to enable round robin authentication for 802.1X:

```
switch(config)# dot1x
switch(config-dot1x)# aaa authentication load-balance round-robin
```

9.2.2.2.10 802.1X MAC-based Authentication

802.1X MAC-based authentication allows programming a set of MAC addresses into the RADIUS server. These MAC addresses (MAC-based authentication supplicants) do not connect to 802.1X profiles but are still allowed access to the network. The authenticator identifies devices that do not support 802.1X and uses the MAC address of these devices as username and password in its RADIUS request packets.

In MAC-based authentication, every supplicant attempting to access the authenticator port individually authenticates, as opposed to authenticating just one supplicant on a given VLAN or port with 802.1X. Different behavior occurs for MAC-based authentication supplicants when an 802.1X supplicant authenticates in single-host and multi-host 802.1X modes.

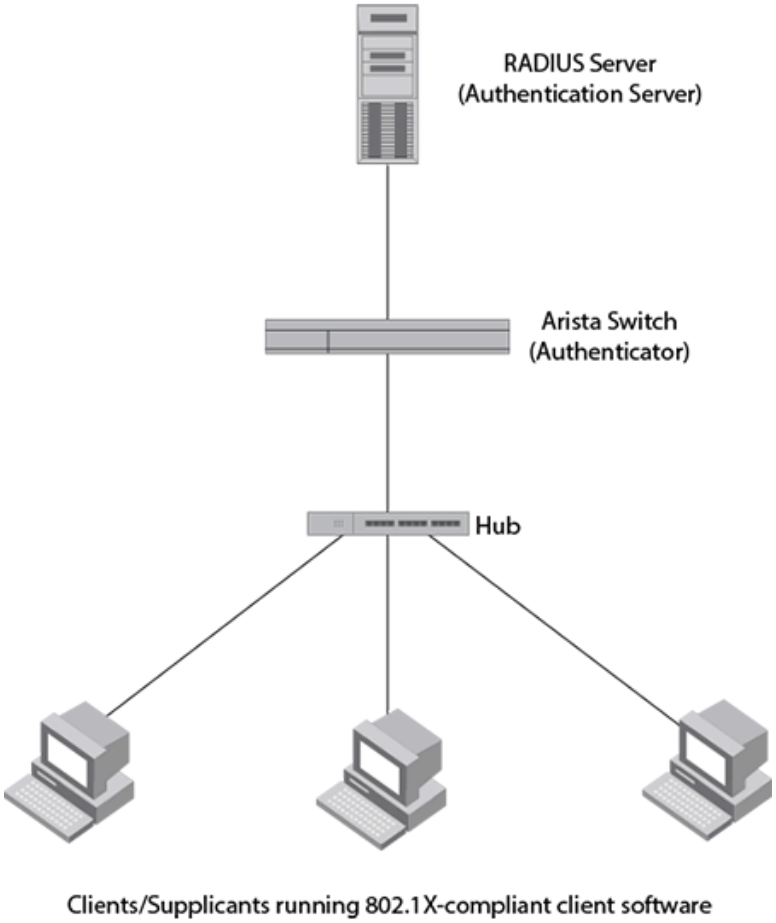
To enable Mac-based authentication, use the following command:

```
switch(config)#dot1x mac based authentication
```

Note: By adding this command to the existing 802.1X configuration on the port, a typical 802.1X interface configuration with MAC-Based Authentication enabled may look something like this:

```
switch(config-if-Et1/1)# show active
speed forced 1000full
dot1x pae authenticator
dot1x port-control auto
dot1x mac based authentication
```

Figure 9-7: Multiple clients connected to a 802.1X-enabled port



Mac-Based Authentication Delay

Use the **`mac based authentication delay`** command to configure a MAC-based Authentication delay. By default, the delay triggers after ***5*** seconds.

Command Syntax

`mac based authentication` delay *0-300* seconds

Mac-based Authentication Hold-Period

When an AAA server rejects a MAC-based Authentication, a default hold period of ***60*** seconds occurs before the MAC-based Authentication retries again even if the host continues to send traffic. However, the hold-period can be configured manually using the **`mac based authentication hold period`** command.

Command Syntax

`mac based authentication` hold period *0-300* seconds

> **Note:** Configuring a low value for the hold-period can significantly increase the load on a AAA server when MAC-based Authentication is not enabled for a host.

9.2.2.2.11 Dot1x Web Authentication FQDN Allowlist

When using dot1x captive portal authentication, supplicants receive the WEB-AUTH-START page to begin redirecting the HTTPS requests to a captive portal as a second step in the authentication process. The Dot1x Web Authentication Fully Qualified Domain Name (FQDN) Allowlist provides a list of FQDN masks that bypass the redirection and allows the supplicant to access URLs on these hosts before completing the second step of the authentication process.

The Dot1x Web Authentication captures the IP address that the supplicant attempts to access and performs a reverse DNS resolution to check if the FQDN matches an entry on the configured Allowlist.

9.2.2.3 802.1X AAA Unresponsive VLAN

Overview

Devices connected to 802.1X controlled ports must perform authentication before their generic traffic is allowed into the network. During this process, the switch contacts a configured AAA server that determines if the device's access to the network is accepted or denied. When the AAA server is unresponsive, the default behavior is to deny all authentication attempts. The AAA Unresponsive VLAN feature allows the user to specify different behavior for this case, accepting authentication attempts and assigning devices to the native VLAN or a specified VLAN. As in other failure scenarios, the switch tries to authenticate the supplicant after the quiet period has passed.

9.2.2.3.1 Configuring 802.1X AAA Unresponsive VLAN

Configure the aaa unresponsive action traffic allow vlan command to enable the dot1x AAA unresponsive VLAN feature on the switch. When configured, the switch changes the action taken with authentication attempts when the AAA server becomes unresponsive. Unresponsiveness occurs when the AAA communication times out.

Example

These commands places the switch in the dot1x configuration mode and enables the dot1x AAA unresponsive VLAN feature on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# aaa unresponsive action traffic allow vlan
```

9.2.2.3.2 Limitations

- AAA unresponsive VLAN does not act on devices that tried to authenticate using VLAN-tagged frames.
- When AAA unresponsive VLAN is enabled without a VLAN, devices get assigned to the native VLAN – even phones that would otherwise be assigned to the phone VLAN. If phones should be assigned to the phone VLAN when AAA is unavailable, the knob aaa unresponsive phone vlan action allow should be additionally used.

9.2.2.4 802.1X Web Authentication

The 802.1X Web authentication feature provides authentication for a supplicant through a Web page, referred to as a captive portal. Redirection to a captive portal provides support for guest devices or supplicants where 802.1X is not sufficient and an additional Web based authentication is required.

9.2.2.4.1 Configuring 802.1X Web Authentication

Use the following global command under the 802.1X node to enable the 802.1X Web authentication:

`captive portal` url ***URL***][ssl profile ***profile***]

Enabling the 802.1X Web authentication starts the redirection agent (Dot1xWeb) and the internal HTTP redirector. Then, 802.1X acts on the RADIUS web-auth-start VSAs. If specifying a URL, the URL redirects the authentication when AAA does not provide a specific URL. If providing a valid SSL profile, the 802.1X Web internal HTTPS redirector uses the configured certificate and key.

For ACL based Web Authentication, an additional parameter provides more functionality:

```
switch(config-dot1x)# captive portal access-list ipv4 test-ACL
```

An ACL can be defined locally on the switch and be configured to use for Web Authentication, for cases, when AAA is not able to send ACL with web auth = start.

Table 11: RADIUS VSAs

AttributeName	Attribute ID	Type	Value
Arista-WebAuth	6	integer	start = 1 complete = 2
Arista-Captive-Portal	10	string	any valid url

Show Commands

The **`show`** commands that display the state of a host includes the new values for WebAuth stage as well.

Example

```
switch(config)# show dot1x hosts
Interface: Ethernet36
Supplicant MAC     Auth Method     State               VLAN Id
--------------     -----------     -----               -------
00:1c:73:73:f9:38  MAC-BASED-AUTH  WEB-AUTH-START
00:1c:73:73:f9:39  MAC-BASED-AUTH  WEB-AUTH-FAILED
```

9.2.2.4.2 Limitations

The following limitations apply to the 802.1X feature.

- Only one device per port is supported (MAC ACLs are not supported), connected in wired fashion.
- HTTPS redirection is only attempted when the connection is to the default TCP port ***443***.
- Limitations present in versions lower than **RIO RELEASE**.
  - HTTPS is not supported.
- Limitations present in versions EOS Release *4.25.0* and *4.25.1*:
  - There is no downloadable ACL support - only implicit ACL support is available. This might not suffice if there is a need to allow multiple intranet websites.
  - There is only support of one Captive portal at a time.
- Limitations in version EOS Release *4.25.0*:
  - IPv4 Management IP needs to be configured on the management interface. If the management ip address is changed, then captive portal configuration needs to be reconfigured.
  - SVI needs to be configured for the VLAN where the host is going to be after the first phase of authentication - be it EAPOL or MBA.

9.2.2.5 Configuring 802.1X Port Security

Basic steps to implementing 802.1X Port-based Network Access Control and RADIUS accounting on the switch:

1. A RADIUS server is required on one or more of your network servers or management stations. 802.1X is not supported with the TACACS+ authentication protocol.
2. You must create supplicant accounts on the RADIUS server:
   - The account for a supplicant connected to an authenticator port must have a username and password combination when set to the 802.1X authentication mode.
     - An account for the supplicant connected to an authenticator port and placed in the MAC address-based authentication mode needs use the MAC address of the node as both the username and password.
     - Connected clients to an 802.1X authenticator port will require 802.1X client software.

3. The RADIUS client must be configured by entering the IP addresses and encryption keys of the authentication servers on your network.
4. The port access control settings must be configured on the switch. This includes the following:
   - Specifying the port roles.
     - Configuring 802.1X port parameters.
       - Enabling 802.1X Port-based Network Access Control.

Guidelines

- Do not set a port that is connected to a RADIUS authentication server to the authenticator role as an authentication server cannot authenticate itself.
- A supplicant connected to an authenticator port set to the 802.1X username and password authentication method must have 802.1X client software.
- To prevent unauthorized individuals from accessing the network through unattended network workstations, end users of 802.1X port-based network access control should always log off when they are finished with a work session.
- The RADIUS client should be configured on the switch before activating port-based access control.

9.2.2.5.1 Configuring 802.1X Authentication Methods

Configure external client authentication methods for IEEE 802.1X port security. Arista currently supports RADIUS authentication. Use the aaa authentication dot1x command to configure the switch to use a RADIUS server for client authentication.

Example

This command configures the switch to use RADIUS authentication.

```
switch(config)# aaa authentication dot1x default group radius
switch(config)#
```

9.2.2.5.2 Configuring Dot1x Dropped Counters

Use the **`statistics packets dropped`** command to configure the dot1x dropped counters on the switch in the ***dot1x*** configuration mode. By default, EOS turns off the dot1x dropped counters. The **no** form of the command disables them from the running configuration.

Example

These commands places the switch in the ***dot1x*** mode and enables the dot1x dropped counters.

```
switch(config-dot1x)# statistics packets dropped
```

9.2.2.5.3 Globally Enabling IEEE 802.1X

To enable IEEE 802.1X port authentication globally on the switch, use the `dot1x system-auth-control` command.

Example

This command enables IEEE 802.1X globally on the switch.

```
switch(config)# dot1x system-auth-control
switch(config)#
```

9.2.2.5.4 Designating Authenticator Ports

To set the port access entity (PAE) type of an Ethernet or management interface to the **authenticator**, use the **`dot1x pae authenticator`** command.

Example

These commands configure the PAE type to **authenticator** on the Ethernet interface ***1*** to enable IEEE 802.1X on the port.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x pae authenticator
switch(config-if-Et1)#
```

Example

For ports to act as authenticator ports to connected supplicants, those ports must be designated using the **`dot1x port_control`** command.

The **auto** option of the **`dot1x port_control`** command designates an authenticator port for immediate use, blocking all traffic that is not authenticated by the AAA server.

Example

This command configures Ethernet ***1*** to immediately begin functioning as an authenticator port.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x port-control auto
switch(config-if-Et1)#
```

The **force-authorized** option of the **dot1x port_control** command sets the state of the port to **authorized** without authentication, allowing traffic to continue uninterrupted.

Example

These commands designate Ethernet ***1*** as an authenticator port that forwards packets without authentication.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x port-controlforce-authorized
switch(config-if-Et1)#
```

To designate a port as an authenticator but prevent it from authorizing any traffic, use the **force-unauthorized** option of the **dot1x port_control** command.

Example

The **force-unauthorized** option of the **dot1x port_control** command places the specified port in the unauthorized state, which will deny any access requests from users of the ports.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x port-control force-unauthorized
switch(config-if-Et1)#
```

9.2.2.5.5 Specifying the Authentication Mode for Multiple Clients

By default, Arista switches authenticate in multi-host mode, allowing packets from any source MAC address once 802.1X authentication has taken place. To configure the switch for single-host mode (allowing traffic only from the authenticated clients MAC address), use the `dot1x host-mode` command.

Example

These commands configure Ethernet interface ***1*** to use single-host mode for 802.1X authentication.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x host-mode single-host
switch(config-if-Et1)#
```

9.2.2.5.6 Configuring Re-authentication

The **dot1x reauthentication** command enables the authenticator ports to re-authenticate with the default values..

The **dot1x timeout reauth-period** command allows the customization of the re-authentication period of authenticator ports.

Examples

- These commands configure the configuration mode interface to require re-authentication from clients at regular intervals.

```
switch(config)# interface Ethernet 1
switch(config-if-Eth)# dot1x reauthentication
```

- These commands configure the Ethernet interface ***1*** authenticator to require re-authentication from clients every ***6*** hours (***21600*** seconds).

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x reauthentication
switch(config-if-Et1)# dot1x timeout reauth-period 21600
switch(config-if-Et1)#
```

- These commands deactivate re-authentication on the Ethernet interface ***1***.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# no dot1x reauthentication
switch(config-if-Et1)#
```

9.2.2.5.7 Setting the EAP Request Maximum

The `dot1x reauthorization request limit` command configures the number of times the switch retransmits an 802.1X Extensible Authentication Protocol (EAP) request packet before ending the conversation and restarting authentication.

Example

These commands set the number of times the authenticator sends an EAP request packet to the client before restarting authentication.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x reauthorization request limit 4
switch(config-if-Et1)#
```

The default value is ***2***.

9.2.2.5.8 Disabling Authentication on a Port

To disable authentication on an authenticator port, use the **no** form of the dot1x port-control command.

Example

These commands disable authentication on Ethernet interface ***1***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# no dot1x port-control
switch(config-if-Et1)#
```

9.2.2.5.9 Setting the Quiet Period

If the switch fails to immediately authenticate the client, the `dot1x timeout quiet-period` command specifies the time the switch waits before trying again. This timer also indicates how long a client that failed authentication is blocked.

Example

These commands set the 802.1X quiet period for Ethernet interface ***1*** to ***30*** seconds.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x timeout quiet-period 30
```

The default value is ***60*** seconds.

9.2.2.5.10 Setting the Dot1x Timeout Reauth-period

The **`dot1x timeout reauth-period`** command specifies the time period in seconds that the configuration mode interface waits before requiring re-authentication from clients.

Example

These commands configure the timeout reauth-period to ***21600*** seconds.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x reauthentication
switch(config-if-Et1)# dot1x timeout reauth-period 21600
```

The default value is ***3600*** seconds.

9.2.2.5.11 Setting the Transmission Timeout

The authenticator sends an Extensible Authentication Protocol (EAP) request to the supplicant, and the supplicant sends a response that the authenticator forwards to an authentication server. If the authenticator doesn't receive a reply to the EAP request, it waits a specified time before retransmitting the request. To configure the wait time, use the dot1x timeout tx-period command.

Example

These commands configure Ethernet interface ***1*** to wait ***30*** seconds before retransmitting EAP requests to the supplicant.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x timeout tx-period 30
switch(config-if-Et1)#
```

The default value is ***5*** seconds.

9.2.2.5.12 Enabling Authentication Failure VLAN

Configure Authentication Failure VLAN on a dot1x-enabled port using the **`dot1x authentication failure action traffic allow`**CLI command under the ***interface-config*** mode. Set ***VLAN10*** as authentication failure VLAN:

```
switch(config-if-Et1/1)# dot1x authentication failure action traffic allow vlan 10
```

When configuring a VLAN with **no authentication failure** VLAN on a dot1x-enabled port, the default action drops any unauthorized traffic on the port. This behavior can also be specified using the following command:

Example

```
switch(config-if-Et1/1)# dot1x authentication failure action traffic drop
```

9.2.2.5.13 802.1X Guest VLANs

802.1X provides a guest VLAN that allows access to hosts unable to communicate over EAPoL and then perform actions to become EAPoL capable. Then, the host can move out of the guest VLAN. A typical use case includes situations where hosts perform PXE booting and become capable of responding to EAPoL requests.

Note: You cannot configure Guest VLANs and MBA on the same network.

Example

To configure a guest VLAN on Ethernet6/1 and VLAN 25, use the following commands:

```
switch(config)# interface Ethernet6/1
switch(config-if-Et6/1)# dot1x
switch(config-dot1x)# eapol unresponsive action traffic allow vlan 25
```

Disable the feature on an interface and override the global configuration:

```
switch(config-dot1x)# eapol unresponsive action traffic disable
```

9.2.2.5.14 Clearing 802.1X Statistics

The `clear dot1x statistics` command resets the 802.1X counters.

Examples

- This command clears the 802.1X counters on all interfaces.

```
switch# clear dot1x statistics all
switch#
```

- This command clears the 802.1X counters on Ethernet interface ***1***.

```
switch# clear dot1x statistics interface ethernet 1
switch#
```

9.2.2.5.15 Configuring Dot1x Web Authentication FQDN Allowlist

Use the following command to add a hostname to the captive portal redirection bypass list:

```
switch(config)# dot1x
switch(config-dot1x)# captive-portal bypass fqdn_wildcard
```

Repeat the configuration statement to add more FQDNs to the list. The wildcard * can be used once at the start of the FQDN and must be followed by a *dot*, for example **.myfqdn.com*.

Example

Use the following commands to add the FQDN, **.mycompany.com* to the FQDN Allowlist:

```
switch(config)#dot1x
switch(config-dot1x)#captive-portal bypass *.mycompany.com
```

Clearing Dot1x Captive Portal Resolutions

Use the **`clear dot1x captive-portal resolutions`** command to clear all reverse DNS entries and active bypass and redirect decisions.

```
switch# clear dot1x captive portal resolutions
```

Displaying Dot1x Web Authentication FQDN Allowlist Information

Use the **show captive-portal bypass** command to display the active bypass entries:

```
switch# show captive-portal bypass
Captive portal bypass:
*.eng.mycompany.com matched by 10.0.1.3, 1.0.2.4
web5.it.mycompany.com matched by 10.0.5.7
```

Use the **show captive-portal resolutions** command to display all reverse DNS resolution entries in use by the captive portal, including redirected IP addresses.

```
switch# show dot1x captive-portal resolutions
  Address         Hostnames                 Expiration
--------------- ------------------------ -------------------
 1.0.2.4         www1.eng.mycompany.com    2033-05-17 20:33:20
 10.0.5.7        web4.it.mycompany.com     2033-05-17 20:33:23
                 web5.it.mycompany.com
 10.10.1.3       -                      2033-05-17 20:33:26
 10.20.1.3       (pending)
 80.0.6.3        www1.eng.mycompany.com    2033-05-17 20:33:21
```

9.2.2.6 Displaying 802.1X Information

You can display information about 802.1X on the switch and on individual ports.

9.2.2.6.1 Displaying 802.1X statistics

Use the **show dot1x statistics** command to display 802.1X statistics for the specified port or ports.

Example

- This command displays IEEE 802.1X statistics for Ethernet interface ***5***.

```
switch# show dot1x interface ethernet 5 statistics
Dot1X Authenticator Port Statistics for Ethernet5
-------------------------------------------------
RxStart = 0      RxLogoff = 0    RxRespId = 0
RxResp = 0       RxInvalid = 0   RxTotal = 0
TxReqId = 0      TxReq = 0       TxTotal = 0
RxVersion = 0    LastRxSrcMAC = 0000.0000.0000 switch#
```

- This command displays the dot1x dropped counters for all the dot1x interfaces.

```
switch# show dot1x all statistics
Dot1X Authenticator Port Statistics for Ethernet51/1
----------------------------------------------
RX start = 1     RX logoff = 0   RX response ID = 1
RX response = 10         RX invalid = 0  RX total = 12
TX request ID = 2        TX request = 11         TX total = 13
RX version = 2   Last RX src MAC = ded6.404b.ec94
Data packet drop counters:
EAPOL unauthorized port = 2
EAPOL unauthorized host = 1
MBA unauthorized host = 0
```

```
Dot1X Authenticator Port Statistics for Ethernet49
-------------------------------------------------
RX start = 1     RX logoff = 0   RX response ID = 1
RX response = 10         RX invalid = 0  RX total = 12
TX request ID = 2        TX request = 11         TX total = 13
RX version = 2   Last RX src MAC = ded6.404b.ec94
Data packet drop counters:
EAPOL unauthorized port = 2
EAPOL unauthorized host = 1
MBA unauthorized host = 0
```

9.2.2.6.2 Displaying 802.1X supplicant information

Use the **show dot1x hosts** command to display information for all the supplicants.

Example

This command displays 802.1X supplicant information.

```
switch# show dot1x hosts
    Interface: Ethernet1/1
    Supplicant MAC       Auth Method      State     VLAN Id
    --------------       -----------      -----     -------
    e2:29:cb:11:2f:4a    EAPOL            SUCCESS   300
    e2:29:cb:11:2f:4b    MAC-BASED-AUTH   SUCCESS   300
```

9.2.2.6.3 Displaying MAC Address Tables

Use the show mac address-table command to display the MAC address of the supplicants allowed to pass the traffic through the port.

Example

```
switch# show mac address-table
    Mac Address Table
    ------------------------------------------------------------------

    Vlan    Mac Address       Type        Ports      Moves   Last Move
    ----    -----------       ----        -----      -----   ---------
    300     e229.cb11.2f4a    STATIC      Et1/1
    300     e229.cb11.2f4b    STATIC      Et1/1
    Total Mac Addresses for this criterion: 2
```

9.2.2.6.4 Displaying Port Security Configuration Information

The **show dot1x** command shows information about the 802.1X configuration on the specified port or ports.

Example

This commands displays IEEE 802.1X configuration information for Ethernet interface ***5***.

```
switch# show dot1x interface ethernet 5
Dot1X Information for Ethernet5
-------------------------------------------
PortControl             : auto
QuietPeriod             : 60 seconds
TxPeriod                : 5 seconds
ReauthPeriod            : 3600 seconds
MaxReauthReq            : 2 switch#
```

9.2.2.6.5 Displaying the Status of the 802.1X Attributes for each Port

Use the **`show dot1x interface`** ***interface-id*** command to display the status of the 802.1X attributes for each port.

Example

```
switch(config-if-Et1/1)# show dot1x interface ethernet1/1
       Dot1X Information for Ethernet1
       -------------------------------------------
       PortControl             : force-authorized
       HostMode                : multi-host
       QuietPeriod             : 60 seconds
       TxPeriod                : 5 seconds
       ReauthPeriod            : 0 seconds
       MaxReauthReq            : 2
       ReauthTimeoutIgnore     : No
       AuthFailVlan            : 10
```

9.2.2.6.6 Displaying 802.1X Information for all Ports

Use the show dot1x all brief command to display IEEE 802.1X status for all ports.

Example

The following commands display a summary of IEEE 802.1X status.

```
switch# show dot1x all brief
Interface   Client   Status
----------  -------- -------------
Ethernet5   None     Unauthorized switch#
```

9.2.2.6.7 Displaying VLANS

Use the **`show vlan`** command to display dynamically assigned VLANs on the port.

Example

```
switch# show vlan
    VLAN  Name          Status    Ports
    ----- ------------- --------- ---------------------------------
    1     default        active
    2     VLAN0002       active    Et7, Et17, Et18, Et41
    300*  VLAN0300       active    Et1/1, Et6, Et19, Et20, Et29
                                   Et30, Et31, Et32, Et42, Et43, Et44

* indicates a Dynamic VLAN
```

9.2.2.6.8 Displaying EAPOL Fallback to MBA Authentication and MBA Timeout Information

Use the **`show dot1x interface`** ***interface ID*** **`details`** command to display information about the EAPOL fallback to MBA authentication and MBA timeout details.

Example

```
switch(config-if-Et1)# show dot1x interface Ethernet1 details
Dot1X Information for Ethernet1
-------------------------------------------
Port control: auto
Host mode: multi-host authenticated
Quiet period: 60 seconds
TX period: 5 seconds
Maximum reauth requests: 2
Ignore reauth timeout: No
Auth failure VLAN: 101
Unauthorized access VLAN egress: Yes
Unauthorized native VLAN egress: Yes
EAPOL: enabled
MAC-based authentication: disabled
EAPOL authentication failure fallback: MBA, timeout 200 seconds

Dot1X Authenticator Client

Port status: Authorized
Supplicant MAC  Reauth Period (in seconds)
--------------  --------------------------
0022.0100.0001  120
```

9.2.2.7 802.1X Port Security Commands

Global Configuration Commands

- dot1x system-auth-control

Dot1x Configuration Commands

- aaa unresponsive action traffic allow vlan
- captive portal
- dot1x eapol
- dot1x mac based authentication delay

- dot1x mac based authentication hold period

Interface Configuration Commands Ethernet Interface

- dot1x host-mode
- dot1x mac based authentication
- dot1x pae authenticator
- dot1x port-control
- dot1x reauthentication
- dot1x reauthorization request limit
- dot1x timeout quiet-period
- dot1x timeout reauth-period
- dot1x timeout tx-period
- statistics packets dropped

Privileged EXEC Commands

- clear dot1x statistics
- show dot1x
- show dot1x all brief
- show dot1x captive-portal bypass
- show dot1x captive-portal resolutions
- show dot1x hosts
- show dot1x statistics

9.2.2.7.1 aaa unresponsive action traffic allow vlan

The **aaa unresponsive action traffic allow vlan** enables the the dot1x AAA unresponsive VLAN feature on the switch.

The **no aaa unresponsive action traffic allow vlan** command disbales the dot1x AAA unresponsive VLAN feature from the ***running-config***.

Command Mode

Dot1x Configuration Mode

Command Syntax

`aaa unresponsive action traffic allow vlan` *VLAN-ID*

`no unresponsive action traffic allow vlan`

Parameters

- **unresponsive** Configure AAA timeout options.
- **action** Set action for supplicant when AAA times out.
- **traffic** Set action for supplicant traffic when AAA times out.
- **allow** Allow traffic when AAA times out.
- **vlan** Allow traffic in VLAN when AAA times out.
- ***VLAN-ID*** Identifier for a Virtual LAN. Value ranges from ***1*** to ***4094***.

Example

These commands places the switch in the dot1x configuration mode and enables the dot1x AAA unresponsive VLAN feature on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# aaa unresponsive action traffic allow vlan 50
```

9.2.2.7.2 aaa authentication load-balance round-robin

The **aaa authentication load-balance round-robin** command in the Dot1X Configuration Mode enables round robin authentication for RADIUS Server Groups.

The **no** version of the command disables the feature and removes it from the ***running-config***.

Command Mode

Dot1X Configuration

Command Syntax

aaa authentication load-balance round-robin

no aaa authentication load-balance round-robin

Parameters

- **aaa** - Configure AAA parameters.
- **authentication** - Specify authentication parameters.
- **load-balance** - Configure load balancing on an AAA server.
- **round-robin** - Configure round-robin based load-balancing on a RADIUS server group.

Example

Use the following commands to configure round robin authentication for 802.1X:

```
switch(config)# dot1x
switch(config-dot1x)# aaa authentication load-balance round-robin
switch(config-dot1x)#
```

9.2.2.7.3 captive portal

The **captive portal** command enables the 802.1X Web Authentication on the switch.

The **no captive portal** command removes the 802.1X Web Authentication configuration from the ***running-config***.

Command Mode

Dot1x Configuration Mode

Command Syntax

captive portal url ***URL*** **ssl profile profile access-list ipv4** ***ACL name*** **bypass** ***fqdn_wildcard*** **request timeout** ***seconds***

no captive portal url ***URL*** **ssl profile** ***profile*** **access-list ipv4** ***ACL name*** **bypass** ***fqdn_wildcard*** **request timeout** ***seconds***

Parameters

- **url** - Configure captive portal URL.
- **ssl** - Configure SSL related option.
- **access-list** - Configure access control list.
- **bypass** - Configure Fully Qualified Domain Names (FQDN) for the redirection bypass list.
- **request timeout** ***seconds*** - Configure the request timeout from 1 to 120 seconds. By default, the configuration uses 60 seconds. Specifies the time that the agent waits for an HTTP/HTTPS GET request.

Examples

- This command enables 802.1X Web Authentication on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# captive portal ssl profile test-ssl_profile
```

- This command enables the ACL based Web authentication.

```
switch(config)# dot1x
switch(config-dot1x)# captive portal access-list ipv4 test-ACL
```

- This command enables captive portal bypass redirection with the FQDN, *www.mycompany.com*.

```
switch(config)# dot1x
switch(config-dot1x)# captive portal bypass www.mycompany.com
```

9.2.2.7.4 clear dot1x statistics

The **`clear dot1x statistics`** command resets the 802.1X counters on the specified interface or all interfaces.

Command Mode

Privileged EXEC

Command Syntax

`clear dot1x statistics` **INTERFACE_NAME**

Parameters

INTERFACE_NAME Interface type and number. Options include:

- **all** Display information for all interfaces.
- **interface ethernet *e_num*** Ethernet interface specified by ***e_num***.
- **interface loopback *l_num*** Loopback interface specified by***l_num***.
- **interface management *m_num*** Management interface specified by ***m_num***.
- **interface port-channel *p_num*** Port-Channel Interface specified by ***p_num***.
- **interface vlan *v_num*** VLAN interface specified by ***v_num***.

Example

This command resets the 802.1X counters on all interfaces.

```
switch# clear dot1x statistics all
switch#
```

9.2.2.7.5 dot1x eapol

The **dot1x eapol** command places the switch into 802.1X Configuration Mode and configures the EAPoL actions for Guest VLAN access. The **[no | default]** options reverts the configuration to match the global configuration.

Command Mode

Dot1x Configuration Mode

Command Syntax

`dot1x eapol` unresponsive action traffic allow [vlan *vlan_id*]

Parameters

- **eapol** - Configure Dot1x EAPOL attributes.
- **unresponsive** - Configure unresponsive hosts.
- **action** - Configure the action in case of EAPOL unresponsive hosts.
- **traffic** - Configure the traffic action in case of EAPOL unresponsive hosts.
- **allow** - Allow traffic in case of EAPOL unresponsive hosts.
- **vlan *vlan_id*** - Specify the VLAN to allow traffic in case of EAPOL unresponsive hosts.

Example

To configure a guest VLAN on Ethernet6/1 and VLAN 25, use the following commands:

```
switch(config)#interface Ethernet6/1
switch(config-if-Et6/1)#dot1x
switch(config-dot1x)#eapol unresponsive action traffic allow vlan 25
```

9.2.2.7.6 dot1x mac based authentication

The **dot1x mac based authentication** command enables MAC-based authentication on the existing 802.1X authenticator port.

The **no dot1x mac based authentication** and the **default dot1x mac based authentication** commands restore the switch default by disabling the corresponding dot1x mac based authentication command for the specific 802.1X authenticator port.

Command Mode

Interface-Ethernet Configuration

Command Syntax

```
dot1x mac based authentication

no dot1x mac based authentication

default dot1x mac based authentication
```

Related Command

`show dot1x hosts`

Example

These commands configure MAC-based authentication on ***Ethernet interface 1***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x mac based authentication
switch(config-if-Et1)#
```

9.2.2.7.7 dot1x mac based authentication delay

The **dot1x mac based authentication delay** command enables MAC-based authentication delay. By default, the delay is triggered after ***5*** seconds.

The **no dot1x mac based authentication delay** and the **default dot1x mac based authentication delay** commands restore the switch default by disabling the corresponding dot1x mac based authentication delay command.

Command Mode

Dot1x Configuration

Command Syntax

`dot1x mac based authentication delay` *delay-time* seconds

`no dot1x mac based authentication delay`

`default dot1x mac based authentication delay`

Parameters

- ***delay-time*** Delay in seconds. The value is from ***0*** to ***300***.
- **seconds** Unit in seconds.

Example

These commands configure a MAC-based authentication delay of ***30*** seconds on a switch.

```
switch(config)# dot1x
switch(config-dot1x)# mac based authentication delay 30 seconds
```

9.2.2.7.8 dot1x mac based authentication hold period

The **dot1x mac based authentication hold period** command enables MAC-based authentication hold period. By default, the hold period is ***60*** seconds.

The **no dot1x mac based authentication hold period** and the **default dot1x mac based authentication hold period** commands restore the switch default by disabling the corresponding dot1x mac based authentication hold period command.

Command Mode

Dot1x Configuration

Command Syntax

`dot1x mac based authentication hold period` *hold period-time* seconds

`no dot1x mac based authentication hold period`

`default dot1x mac based authentication hold period`

Parameters

- ***hold period-time*** Hold period in seconds. The value is from ***1*** to ***300*** in seconds.
- **seconds** Unit in seconds.

Example

These commands configure a MAC-based authentication hold period of ***100*** seconds on a switch.

```
switch(config)# dot1x
switch(config-dot1x)# mac based authentication hold period 100 seconds
```

9.2.2.7.9 dot1x mac based authentication request-identity

The **dot1x mac based authentication request-identity** command in the Global Configuration Mode sends identity requests at 60 second intervals until successfully authenticating the EAPOL supplicant. The **[no | default]** versions of the command remove the configuration from the ***running-config***.

Command Mode

Global Configuration Mode

Command Syntax

dot1x mac based authentication request-identity common

no dot1x mac based authentication request-identity common

default dot1x mac based authentication request-identity common

Parameters

- **dot1x mac based authentication** - Specify to configure MAC-based 802.1X authentication.
- **request-identity** - Specify to send EAP identity request packets.
- **common** - Specify sending the identity requests for both MBA-enabled and MBA disabled configurations.

Example

Use the following commands to specify sending the request identity packets for both MBA-enabled and MBA disabled configurations:

```
switch(config)# doct1x
switch(config-dot1x)# mac based authentication request-identity common
switch(config-dot1x)#
```

9.2.2.7.10 dot1x pae authenticator

The **dot1x pae authenticator** command sets the port access entity (PAE) type of the configuration mode interface to **authenticator**, which enables IEEE 802.1X on the port. EOS disables IEEE 802.1X on all ports by default.

The **no dot1x pae authenticator** and **default dot1x pae authenticator** commands restore the switch default by deleting the corresponding **dot1x pae authenticator** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

```
dot1x pae authenticator

no dot1x pae authenticator

default dot1x pae authenticator
```

Examples

- These commands configure ***interface ethernet 2*** as a port access entity (PAE) authenticator, enabling IEEE 802.1X on the port.

```
switch(config-if-Et1)# interface ethernet 2
switch(config-if-Et1)# dot1x pae authenticator
switch(config-if-Et1)#
```

- These commands disable IEEE 802.1X authentication on ***interface ethernet 2***.

```
switch(config-if-Et1)# interface ethernet 2
switch(config-if-Et1)# no dot1x pae authenticator
switch(config-if-Et1)#
```

9.2.2.7.11 dot1x protocol bpdu

The **dot1x protocol bpdu** command enables bypassing BPDU guard on unauthenticated hosts and does not require configuration of the Wake on LAN feature.

The **no dot1x system-auth-control** command disables bypassing BPDU guard by removing the **dot1x system-auth-control** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

dot1x protocol bpdu bypass

no dot1x dot1x protocol bpdu bypass

Examples

This command bypasses BPDU guard for 802.1X on the switch.

```
switch(config)# dot1x system-auth-control
switch(config)#
```

9.2.2.7.12 dot1x reauthentication

The **dot1x reauthentication** command configures the configuration mode interface to require re-authentication from clients at regular intervals. Use the **dot1x timeout reauth-period** command to set the interval.

The **no dot1x reauthentication** and **default dot1x reauthentication** commands restore the default setting by deleting the corresponding **dot1x reauthentication** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

```
dot1x reauthentication

no dot1x reauthentication

default dot1x reauthentication
```

Example

These commands configure the ***interface Ethernet 1*** authenticator to require periodic re-authentication from clients.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x reauthentication
switch(config-if-Et1)#
```

9.2.2.7.13 dot1x reauthorization request limit

The **dot1x reauthorization request limit** command configures how often the switch retransmits an 802.1X Extensible Authentication Protocol (EAP) request packet before ending the conversation and restarting authentication.

The **no dot1x reauthorization request limit** and **default dot1x reauthorization request limit** commands restore the default value of 2 by deleting the corresponding **dot1x reauthorization request limit** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

`dot1x reauthorization request limit` attempts

`no dot1x reauthorization request limit`

`default dot1x reauthorization request limit`

Parameter

attempts Maximum number of attempts. Values range from ***1*** to ***10***; default value is ***2***.

Examples

- This command sets the 802.1X EAP-request retransmit limit to ***6***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x reauthorization request limit 6
switch(config-if-Et1)#
```

- This command restores the default request repetition value of ***2***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# no dot1x reauthorization request limit
switch(config-if-Et1)#
```

9.2.2.7.14 dot1x system-auth-control

The **dot1x system-auth-control** command enables 802.1X authentication on the switch.

The **no dot1x system-auth-control** and **default dot1x system-auth-control** commands disables 802.1X authentication by removing the **dot1x system-auth-control** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
dot1x system-auth-control

no dot1x system-auth-control

default dot1x system-auth-control
```

Examples

- This command enables 802.1X authentication on the switch.

```
switch(config)# dot1x system-auth-control
switch(config)#
```

- This command disables 802.1X authentication on the switch.

```
switch(config)# no dot1x system-auth-control
switch(config)#
```

9.2.2.7.15 dot1x timeout quiet-period

If the switch fails to immediately authenticate the client, the switch waits a specified time configured with the **dot1x timeout quiet-period** command. This timer also indicates the blocked time for a client with failed authentication.

The **no dot1x timeout quiet-period** and **default dot1x timeout quiet-period** commands restore the default quiet period of ***60*** seconds by removing the corresponding **dot1x timeout quiet-period** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

`dot1x timeout quiet-period` *quiet_time*

`no dot1x timeout quiet-period`

`default dot1x timeout quiet-period`

Parameter

quiet_time Interval in seconds. Values range from ***1*** to ***65535***. Default value is ***60***.

Example

These commands set the 802.1X quiet period for Ethernet interface ***1*** to ***30*** seconds.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x timeout quiet-period 30
switch(config-if-Et1)#
```

9.2.2.7.16 dot1x timeout reauth-period

The **dot1x timeout reauth-period** command specifies the time period that the configuration mode interface waits before requiring re-authentication from clients.

The **no dot1x timeout reauth-period** and **default dot1x timeout reauth-period** commands restore the default period of ***60*** minutes by removing the corresponding **dot1x timeout reauth-period** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

`dot1x timeout reauth-period` *reauth_time*

`no dot1x timeout reauth-period`

`default dot1x timeout reauth-period`

Parameter

reauth_time The number of seconds the interface passes traffic before requiring re-authentication. Values range from *1* to *65535*. Default value is *3600*.

Example

These commands configure the interface Ethernet ***1*** authenticator to require re-authentication from clients every ***6*** hours (***21600*** seconds).

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x reauthentication
switch(config-if-Et1)# dot1x timeout reauth-period 21600
switch(config-if-Et1)#
```

9.2.2.7.17 dot1x timeout tx-period

The authenticator establishes authentication and re-authentication by sending Extensible Authentication Protocol (EAP) requests to the supplicant, and the supplicant sends a reply which the authenticator forwards to an authentication server. If the authenticator does not receive a reply to the EAP request, it waits a specified time before retransmitting the request. The **dot1x timeout tx-period** command configures the wait time.

The **no dot1x timeout tx-period** and **default dot1x timeout tx-period** commands restore the default wait time by removing the corresponding **dot1x timeout tx-period** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

`dot1x timeout tx-period` *tx_time*

`no dot1x timeout tx-period`

`default dot1x timeout tx-period`

Parameter

tx_time Values range from ***1*** to ***65535***. Default value is ***5***.

Example

These commands configure interface Ethernet ***1*** to wait ***30*** seconds before retransmitting EAP requests to the supplicant.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x timeout tx-period 30
switch(config-if-Et1)#
```

9.2.2.7.18 dot1x host-mode

When multiple clients are connected to an Ethernet interface providing 802.1X authentication, the port can accept packets from all MAC addresses once the supplicant has been authenticated (multi-host mode), or it can accept only those packets originating from the MAC address of the authenticated client (single-host mode) or ultiple authenticated clients (multi-host authenticated mode) . The **dot1x host-mode** command specifies the host mode for authentication of multiple clients on the configuration mode interface.

The **no dot1x host-mode** and **default dot1x host-mode** commands restore the switch default (multi-host mode) by removing the corresponding dot1x host-mode command for the configuration mode interface.

Command Mode

Interface-Ethernet Configuration

Command Syntax

`dot1x host-mode` [multi-host | single-host | multi-host authenticated]

`no dot1x host-mode`

`default dot1x host-mode`

Parameters

- **multi-host** Configures the interface to use multi-host mode (the default).
- **single-host** Configures the interface to use single-host mode.
- **multi-host authenticated** Configures the interface to use multi-host authenticated mode.

Example

These commands configure ***interface Ethernet 1*** to use single-host mode for 802.1X authentication.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# dot1x host-mode single-host
switch(config-if-Et1)#
```

9.2.2.7.19 dot1x port-control

The **dot1x port-control** command configures the configuration mode interface as an authenticator port and specifies whether it will authenticate traffic.

The **no dot1x port-control** and **default dot1x port-control** commands configure the port to pass traffic without authorization by removing the corresponding **dot1x port-control** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Management Configuration

Command Syntax

dot1x port-control **STATE**

no dot1x port-control

default dot1x port-control

Parameters

STATE Specifies whether the interface will authenticate traffic. The default value is **force-authorized**. Options include:

- **auto** Configures the port to authenticate traffic using Extensible Authentication Protocol messages.
- **force-authorized** Configures the port to pass traffic without authentication.
- **force-unauthorized** Configures the port to block all traffic regardless of authentication.

Examples

- These commands configure ***interface Ethernet 1*** to pass traffic without authentication. This is the default setting.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x port-control force-authorized
switch(config-if-Et1)#
```

- These commands configure ***interface Ethernet 1*** to block all traffic.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x port-control force-unauthorized
switch(config-if-Et1)#
```

- These commands configure ***interface Ethernet 1*** to authenticate traffic using EAP messages.

```
switch(config)# interface Ethernet 1
switch(config-if-Et1)# dot1x port-control auto
switch(config-if-Et1)#
```

9.2.2.7.20 neighbor classification

The **neighbor classification** command in the Global Configuration Mode centralizes how the switch responds when it identifies a device, such as a VoIP phone, and moves between different classes such as moving from a generic host to a phone.

When a device authenticates using dot1x or MBA,the switch monitors the device classification. If the classification changes, for instance, a RADIUS VSA suddenly identifies a generic MAC address as a phone, the switch automatically flaps the port to force the device to restart the DHCP process in the correct Voice VLAN.

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

neighbor classification post-auth action port-flap

no neighbor classification post-auth action port-flap

default neighbor classification post-auth action port-flap

Parameters

- **neighbor** - Configure neighbor details.
- **classification** - Set the neighbor classification.
- **post-auth** - Targets the state of the device after a successful authentication event.
- **action** - Specify the behavior if a status change occurs on the device.
- **port-flap** - Specify bringing down the interface momentarily and return to an up status.

Example

Use the following command to configure the response to device identification on the switch:

```
switch(config)# neighbor classification post-auth action port-flap
        switch(config)#
```

9.2.2.7.21 neighbor resolution

The **neighbor resolution** command in the Global Configuration Mode enters the Neighbor Resolution Configuration Mode. Then configure the switch to actively discover the IP addresses of authenticated devices, using ARP or Neighbor Discovery, so that it can correctly apply classification rules, such as identifying a device as a phone, based on IP-specific attributes.

The **no** version of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Neighbor Resolution Configuration

Neighbor Resolution Interface Configuration

Command Syntax

neighbor resolution interface ***interface*** **[neighbor** ***ipv4*** **|** ***ipv6*****]] [mac-address** ***mac_address*****]**

no neighbor resolution

Parameters

- **interface** - Configure neighbor resolution parameters on an interface.
- ***interface*** - Specify one of the following types of interfaces:
  - **Ethernet** - Ethernet interface
  - **Loopback** - Hardware interface used for looping packets.
  - **Management** - Management interface
  - **Port-Channel** - Port-Channel sub-interface
  - **Recirc-Channel** - Recirc-Channel Interface
  - **Tunnel** - Tunnel interface
  - **Vlan** - Logical interface into a VLAN
- **neighbor** - Configure a static neighbor entry.
- **[*ipv4* | *ipv6*]** - Specify an IPv4 or IPv6 address for the interface.
- **mac-address** ***mac_address*** - Specify a MAC address for the interface.

Example

Use the following commands to enable neighbor resolution on the *Ethernet* interface with an IPv4 address, *172.16.21.101*, and MAC address, *fcbd.670f.49fa*:

```
switch(config)# neighbor resolution
switch(config-nbr-res)# interface Ethernet1/1
switch(config-nbr-res-if-Et1/1)# neighbor 172.16.21.101 mac-address fcbd.670f.49fa
switch(config-nbr-res-if-Et1/1)#
```

9.2.2.7.22 radius mtu

The **radius mtu** command in the Dot1X Configuration Mode configures the size of the RADIUS Access-Request Maximum Transmission Unit (MTU) for an 802.1X payload to prevent fragmentation of the packet on the RADIUS server.

The **no** of the command removes the configuration from the switch ***running-config***.

Command Mode

Dot1X Configuration

Command Syntax

radius mtu ***bytes***

no radius mtu

Parameters

- **radius mtu** - Specifies the MTU of the RADIUS Access-Request packets.
- ***bytes*** - Configure a size in bytes from 68 to 65535.

Example

Use the following commands to configure an MTU size of 1500 bytes for the RADIUS Access-Request packet:

```
switch(config)# dot1x
switch(config-dot1x)# radius mtu 1500
switch(config-dot1x)#
```

9.2.2.7.23 show dot1x all brief

The **`show dot1x all brief`** command displays the IEEE 802.1X status for all ports.

Command Mode

EXEC

Command Syntax

```
show dot1x all brief
```

Example

This command displays the IEEE 802.1X status.

```
switch# show dot1x all brief
Interface           Client          Status
-------------------------------------------------
Ethernet5           None            Unauthorized switch#
```

9.2.2.7.24 show dot1x hosts

The **`show dot1x hosts`** command displays 802.1X information for all the supplicants.

Command Mode

EXEC

Command Syntax

`show dot1x hosts` [*ethernet*]

Parameter

ethernet e_num Ethernet interface specified by ***e_num***.

Related Command

`dot1x mac based authentication`

Examples

- This command displays 802.1X information for all the supplicants.

```
switch# show dot1x hosts
Legend:
* - Statically configured VLAN

Port      Supplicant MAC Username           Auth  State         Fallback       VLAN   VLAN
 Name
--------- -------------- ------------------ ----- ------------- -------------- ------ ---------
Et1/4     36d4.b67b.67c6 user101            EAPOL SUCCESS       NONE            123   DATA
Et2/4     36d4.b67b.67c7 user102            EAPOL SUCCESS       NONE            124   VLAN0124
Et1/4     36d4.b67b.68e3 36:d4:b6:7b:68:e3  MBA   SUCCESS       NONE            1*    default
```

- Use the following command to display 802.1X details for an interface:

```
switch# show dot1x hosts interface Ethernet2/4 detail

Supplicant: user1 (36d4.b67b.67c8)
Operational:
Supplicant MAC: 36d4.b67b.67c8

Session-Timeout: 28800 seconds
Idle-Timeout: 200 seconds
```

9.2.2.7.25 show dot1x statistics

The **`show dot1x statistics`** command displays 802.1X statistics for the specified port or ports.

Command Mode

EXEC

Command Syntax

`show dot1x` **INTERFACE_NAME** `statistics`

Parameters

- **INTERFACE_NAME** Interface type and number. Options include:
  - **all** Display information for all interfaces.
  - **ethernet *e_num*** Ethernet interface specified by ***e_num***.
  - **loopback *l_num*** Loopback interface specified by ***l_num***.
  - **management *m_num*** Management interface specified by ***m_num***.
  - **port-channel *p_num*** Port-Channel Interface specified by ***p_num***.
  - **vlan *v_num*** VLAN interface specified by ***v_num***.
  -
- **Output Fields**
  - **`RxStartNumber`** of EAPOL-Start frames received on the port.
  - **`TxReqIdNumber`** of EAP-Request/Identity frames transmitted on the port.
  - **`RxVersionVersion`** number of the last EAPOL frame received on the port.
  - **`RxLogoffNumber`** of EAPOL-Logoff frames received on the port.
  - **`RxInvalidNumber`** of invalid EAPOL frames received on the port.
  - **`TxReqNumber`** of transmitted EAP-Request frames that were not EAP-Request/Identity.
  - **`LastRxSrcMAC`** The source MAC address in the last EAPOL frame received on the port.
  - **`RxRespId`** The number of EAP-Response/Identity frames received on the port.
  - **`RxTotal`** The total number of EAPOL frames transmitted on the port.
  - **`TxTotal`** The total number of EAPOL frames transmitted on the port.

Example

This command displays the 802.1X statistics for ***interface ethernet 5***.

```
switch# show dot1x interface ethernet 5 statistics
Dot1X Authenticator Port Statistics for Ethernet5
-------------------------------------------------
RxStart = 0      RxLogoff = 0    RxRespId = 0
RxStart= 0       RxInvalid = 0   RxTotal = 0
TxReqId = 0      TxReq = 0       TxTotal = 0
RxVersion = 0    LastRxSrcMAC = 0000.0000.0000 switch#
```

9.2.2.7.26 show dot1x

The **`show dot1x`** command displays 802.1X information for the specified interface.

Command Mode

EXEC

Command Syntax

`show dot1x` **INTERFACE_NAME INFO**

Parameters

- **INTERFACE_NAME** Interface type and number. Options include:
  - **all** Display information for all interfaces.
  - **ethernet *e_num*** Ethernet interface specified by ***e_num***.
  - **loopback *l_num*** Loopback interface specified by ***l_num***.
  - **management *m_num*** Management interface specified by ***m_num***.
  - **port-channel *p_num*** Port-Channel Interface specified by ***p_num***.
  - **vlan *v_num*** VLAN interface specified by ***v_num***.
- **INFO** Type of information the command displays. Values include:
  - **no parameter** displays summary of the specified interface.
  - **detail** displays all 802.1X information for the specified interface.

Examples

- This command displays 802.1X summary information for ***interface ethernet 5***.

```
switch# show dot1x interface ethernet 5
Dot1X Information for Ethernet5
-------------------------------------------
PortControl             : auto
QuietPeriod             : 60 seconds
TxPeriod                : 5 seconds
ReauthPeriod            : 3600 seconds
MaxReauthReq            : 2 switch#
```

- This command displays detailed 802.1X information for ***interface ethernet 5***.

```
switch# show dot1x interface ethernet 5 detail
Dot1X Information for Ethernet5
-------------------------------------------
PortControl             : auto
QuietPeriod             : 60 seconds
TxPeriod                : 5 seconds
ReauthPeriod            : 3600 seconds
MaxReauthReq            : 2
```

```
Dot1X Authenticator Client

Port Status             : Unauthorized switch#
```

9.2.2.7.27 show dot1x captive-portal bypass

The **`show dot1x captive-portal bypass`** command displays information about dot1x captive portal bypass configurations.

Command Mode

EXEC

Command Syntax

`show dot1x captive-portal bypass` address [ipv4 | ipv6]

Parameters

- **[ipv4 | ipv6]** - Display dot1x captive portal bypass information for a specific IP address.

Use the following command to display information about dot1x captive portal bypass entries:

```
switch# show captive-portal bypass
Captive portal bypass:
*.eng.mycompany.com matched by 10.0.1.3, 1.0.2.4
web5.it.mycompany.com matched by 10.0.5.7
```

9.2.2.7.28 show dot1x captive-portal resolutions

The **show dot1x captive-portal resolutions** command displays information for all reverse DNS resolution entries in use by the captive portal.

Command Mode

EXEC

Command Syntax

show dot1x captive-portal resolutions address [ipv4 | ipv6]

Parameters

- **[ipv4 | ipv6]** - Display dot1x captive portal resolutions information for a specific IP address.

The table displays the following information:

- **Address** - Displays the IP address the supplicant attempted to access and used to find the hostname through reverse DNS.
- **Hostnames** - Displays the hostnames reported by the DNS server. The entry displays *pending* if the resolution has not completed, and - if the resolution completed but no hostname found or if the resolution timed out.
- **Expiration** - The DNS server provided a valid resolution and provided a time-to-live (TTL) before updating the resolution.

Use the following command to display information about dot1x captive portal resolution entries:

```
switch#show dot1x captive-portal resolutions
   Address         Hostnames                       Expiration
--------------- ------------------------ -------------------
   1.0.2.4         www1.eng.arista.com    2033-05-17 20:33:20
   10.0.5.7        web4.it.arista.com     2033-05-17 20:33:23
   web5.it.mycompany.com
   10.10.1.3       -                      2033-05-17 20:33:26
   10.20.1.3       (pending)
   80.0.6.3        www1.eng.mycompany.com 2033-05-17 20:33:21
```

9.2.2.7.29 statistics packets dropped

The **statistics packets dropped**command to configure the dot1x dropped counters on the switch in the ***dot1x*** configuration mode. By default, EOS disable the dot1x dropped counters. The **no** form of the command disables the dot1x dropped counters from the running configuration.

The **no statistics packets dropped** command disables the dot1x dropped counters from the running configuration.

Command Mode

Dot1x Configuration

Command Syntax

```
statistics packets dropped

no statistics packets dropped
```

Example

These commands places the switch in the ***dot1x*** mode and enables the dot1x dropped counters.

```
switch(config-dot1x)# statistics packets dropped
```

9.3 Data Plane Security

This section contains the following topics:

- IP NAT
- Media Access Control Security
- Internet Protocol Security (IPsec)
- Macro-Segmentation Service (CVX)

9.3.1 IP NAT

Network Address Translation (NAT) is a router process that modifies the address information of IP packets in transit. NAT is typically used to correlate address spaces between a local network and a remote, often public, network. Static NAT defines a one-to-one map between local and remote IP addresses. Static maps are configured manually through CLI commands. An interface can support multiple NAT commands, but each command must specify a unique local IP address-port location.

NAT is configured on routers with interfaces connecting to the local networks and interfaces connecting to a remote network.

Inside and Outside Addresses

NAT configurations categorize IP addresses into one of two categories: inside or outside. Inside refers to IP addresses used within the organizational network, while outside refers to addresses on an external network outside the organizational network.

9.3.1.1 Static IP NAT

Static NAT configurations create a one-to-one mapping and translate a particular address to another address. This type of configuration creates a permanent entry in the NAT table as long as the configuration is present, enabling both inside and outside hosts to initiate a connection.

Static NAT options include source NAT, destination NAT, and Twice Network Address Translation (Twice NAT).

- Source NAT modifies the source address in the IP header of a packet exiting the interface and can optionally change the source port referenced in the TCP/UDP headers.
- Destination NAT modifies the destination address in the IP header of a packet entering the interface and can optionally change the destination port referenced in the TCP/UDP headers.
- Twice NAT modifies both the source and destination IP addresses of packets traversing the interface. The process optionally changes L4 port information within TCP/UDP headers. Implement Twice NAT to prevent conflicts when inside network addresses overlap with outside network addresses. When a packet exits the interface, local source and destination addresses are translated to global source and destination

addresses. When a packet enters the interface, global source and destination addresses are translated to local source and destination addresses.

9.3.1.1.1 Configuring Static NAT

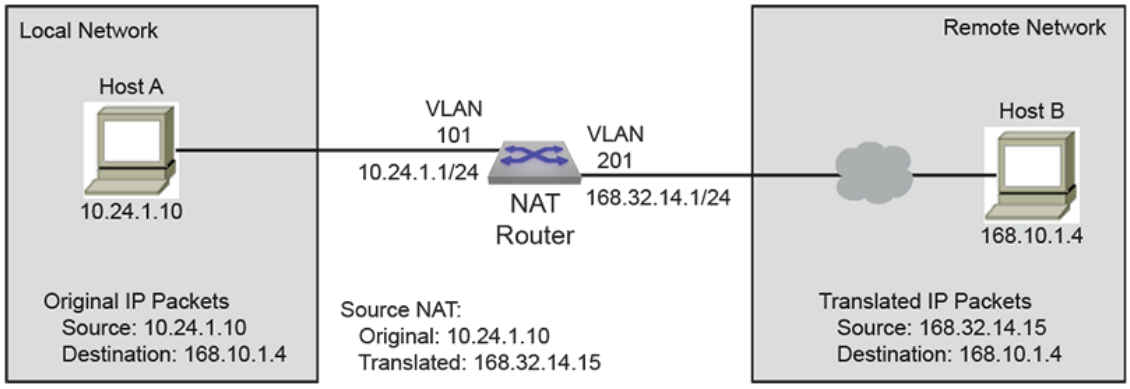
Configuring Source NAT

Enable the NAT of a source address (source NAT) using the ip nat source static command for the configuration mode interface. Applying source NAT to interfaces that connect to local hosts shields the hosts' IP address when sending IP packets to remote destinations.

This command installs hardware translation entries for forward and reverse unicast traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. The command may include an access control list to filter packets for translation.

Note: The switch uses a common NAT table for the entire switch, not a per interface. For example, if a customer has the same inside local address translated to different inside global addresses depending on which interface it exits. It might be translated to exit interface B's inside global address even though it exits through interface A. The way to avoid this is to use an access list that differentiates based on the destination IP address.

Figure 9-8: Source NAT Example



Example

These commands configure ***VLAN 201*** to translate source address ***10.24.1.10*** to ***168.32.14.15***.

```
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip nat source static 10.24.1.10 168.32.14.15
switch(config-if-Vl201)#
```

The **`ip nat source static`** command may include an ACL to limit packet translation. Only packets whose source IP address matches the ACL are cleared. ACLs configured for source NAT must specify a source IP address of **any**. Source port or protocol matching is not permitted. The destination may be an IP

subnet. Commands referencing nonexistent ACLs are accepted by the CLI but only installed in hardware once the ACL is created. Modifying a referenced ACL causes the corresponding hardware entries to be replaced by entries that match the new command.

Example

These commands configure ***VLAN 101*** to translate the source address ***10.24.1.10*** to ***168.32.14.15*** for all packets with IP destination addresses in the ***168.10.1.1/24*** subnet.

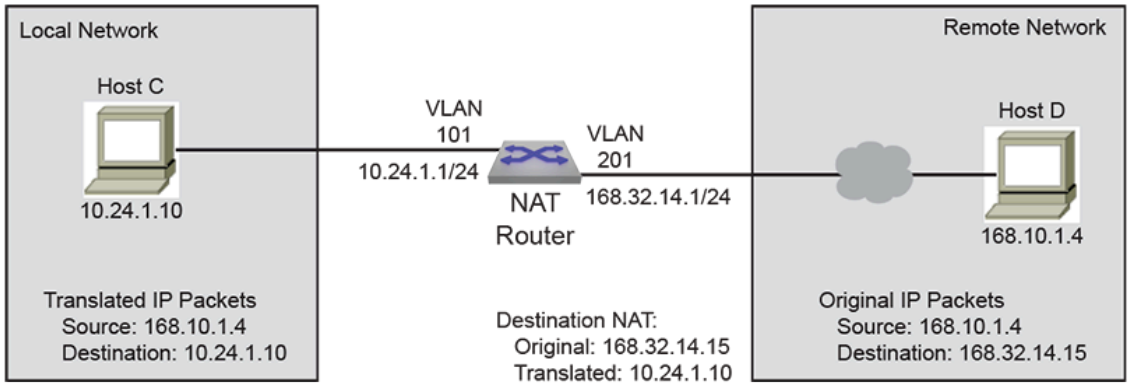
```
switch(config)# ip access-list ACL1
switch(config-acl-ACL1)# permit ip any 168.10.1.0/24
switch(config-acl-ACL1)# exit
switch(config)# interface vlan 101
switch(config-if-Vl101)# ip nat source static 10.24.1.10 access-list ACL1 168.32.14.15
switch(config-if-Vl101)#
```

Configuring Destination NAT

Enable the NAT of a destination address (destination NAT) using the ip nat destination static command for the configuration mode interface. Applying destination NAT to interfaces that connect to remote hosts shields the IP address of the recipient host when receiving IP packets from remote destinations.

This command installs hardware translation entries for forward and reverse unicast traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. The command may include an access control list to filter packets for translation.

Figure 9-9: Destination NAT Example



Example

These commands configure ***VLAN 201*** to translate destination address ***168.32.14.15*** to ***10.24.1.10***.

```
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip nat destination static 168.32.14.15 10.24.1.10
switch(config-if-Vl201)#
```

The ip nat destination static command may include an ACL to limit packet translation. Only packets whose source IP address matches the ACL are cleared. ACLs configured for destination NAT must specify a destination IP address of **any**. Destination port or protocol matching is not permitted. The source may be an IP subnet. Commands referencing nonexistent ACLs are accepted by the CLI but not installed in hardware until the ACL is created. Modifying a referenced ACL causes the corresponding hardware entries to be replaced by entries that match the new command.

Example

These commands configure ***VLAN 201*** to translate the destination address ***168.32.14.15*** to ***10.24.1.10*** for all packets with the source of host ***168.10.1.4***.

```
switch(config)# ip access-list ACL2
switch(config-acl-ACL2)# permit ip 168.10.1.4/32 any
switch(config-acl-ACL2)# exit
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip nat destination static 168.32.14.15 access-list ACL2 10.24.1.10
switch(config-if-Vl201)#
```

Configuring Twice NAT

Network address translation of both source and destination addresses on the same interface (twice NAT) is enabled by creating one source NAT rule and one destination NAT rule on the same interface and associating them through a NAT group using the ip nat source static and ip nat destination static commands.

The **`ip nat source static`** command translates the actual local source address to a source address, which can be used outside the local network to reference the source. The **`ip nat destination static`** command translates an internally used destination address to the actual IP address that is the packet's destination.

The source and destination NAT rules must reference the same NAT group, and both should either specify only IP addresses or specify both IP addresses and L4 port information. An error message will be displayed if L4 port information is configured in one rule but not in the other.

Each NAT rule installs hardware translation entries for forward and reverse unicast traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. Twice NAT does not support using access control lists to filter packets for translation.

Example

These commands configure ***interface ethernet 2*** to translate the local source address ***10.24.1.10*** to the global source address ***168.32.14.15***, and to translate the local destination address ***10.68.104.3*** to the global destination address ***168.25.10.7*** for all packets moving through the interface. The use of NAT ***group 3*** is arbitrary, but must be the same in both rules.

```
switch(config)# interface ethernet 2
switch(config-if-Et2)# ip nat source static 10.24.1.10 168.32.14.15 group 3
switch(config-if-Et2)# ip nat destination static 10.68.104.3 168.25.10.7 group 3
```

9.3.1.1.2 Static NAT Configuration Considerations

Egress VLAN Filter for Static NAT

When a static source NAT is configured on an interface, the source IP translation happens only for those packets going 'out' of this interface. If a packet is egressing on an interface that does not have NAT configured, then the source IP is not translated.

When static SNAT is configured on two interfaces, the translation specified for one interface can be applied to a packet going out on the other interface.

Examples

- In this example, the packets with source IP ***20.1.1.1*** going out of ***E1*** will still have the source IP translated to ***172.1.1.1*** even though the rule is configured in ***E2*** and not on ***E1***.

```
switch(config)# interface ethernet 1
switch(config-if-Et1)# ip nat source static 10.1.1.1 171.1.1.1
switch(config)# interface ethernet 2
switch(config-if-Et2)# ip nat source static 20.1.1.1 172.1.1.1
```

- To prevent this, use an ACL to filter the traffic that needs NAT on the interfaces.

```
switch(config)# ip access-list acl1
switch(config-acl-acl1)# permit ip any 171.1.1.0/24
switch(config)# ip access-list acl2
switch(config-acl-acl2)# permit ip any 172.1.1.0/24
switch(config)# interface ethernet 1
switch(config-if-Et1)# ip nat source static 10.1.1.1 access-list acl1 171.1.1.1
switch(config)# interface ethernet 2
switch(config-if-Et2)# ip nat source static 20.1.1.1 access-list acl2 172.1.1.1
```

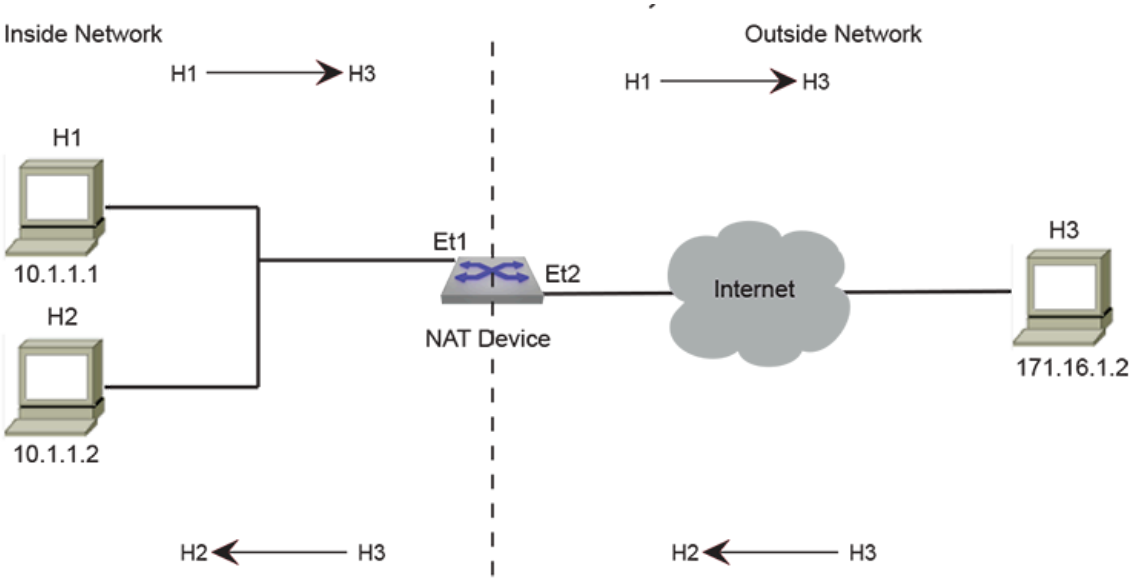
- ACL filtering is not supported when using twice NAT.

9.3.1.2 Dynamic NAT

Dynamic NAT offers a solution when fewer outside addresses are available than the number of internal hosts requiring external access. The process creates a dynamic entry in the NAT table when a host initiates an outbound connection. This entry establishes a one-to-one mapping between the internal private address and the available outside address. The specific outside address assigned to a host can vary and depends on the addresses available in the pool at the time of the connection request. Dynamic NAT sessions initiate only from inside networks. NAT should be configured on a Layer 3 interface, either a routed port or a Switch Virtual

Interface (SVI). Dynamic NAT entries are removed from the translation table if the host doesn't communicate for a specific period. The address returns to the pool for use by another host.

Figure 9-10: Dynamic NAT Scenario



Dynamic NAT options:

- Many-to-Many NAT

  Many-to-Many NAT maps local addresses to a global address selected from a pool of global addresses. After the pool is configured, the first available address from the pool is picked dynamically on receiving the first packet.

- Many-to-One NAT (PAT)

  PAT is a form of dynamic NAT where multiple local addresses are mapped to a single global address (many-to-one) using different source ports. This method is also called NAT Overloading, Network Address Port Translation (NAPT), and Masquerade. The global address can be the IP address configured on the outside interface.

  Hardware entries that translate packets are created when the CLI command is processed. Entries for forward and reverse traffic are created for unicast traffic. The hardware entry for reverse traffic is not created for multicast traffic.

  Commands may include ACLs to filter packets that are cleared. Source NAT uses ACLs to filter packets based on the destination IP address, while destination NAT uses ACLs to filter packets based on the source IP address. When using NAT, inside usually refers to a private network, while outside usually refers to a public network.

  A switch with NAT configured translates forwarded traffic between inside and outside interfaces and the flow that matches the criteria specified for translation.

  The same IP address can't be used for the NAT static configuration and in the pool for dynamic NAT configurations. Public IP addresses must be unique. The global addresses used in static translations aren't excluded from dynamic pools containing the same global addresses.

Commands may include ACLs to filter packets that are cleared. Source NAT uses ACLs to filter packets based on destination IP address. Destination NAT uses ACLs to filter packets based on source IP address. When using NAT, inside usually refers to a private network, while outside usually refers to a public network.

A switch with NAT configured translates forwarded traffic between inside and outside interfaces and the flow that matches the criteria specified for translation.

Note: The same IP address can't be used for the NAT static configuration and in the pool for dynamic NAT configurations. Public IP addresses must be unique. The global addresses used in static translations aren't excluded from dynamic pools containing the same global addresses.

Note: Dynamic NAT with ACL destination port is not supported on the 7050SX3 switch.

9.3.1.2.1 Configuring Dynamic NAT

Prerequisites

- Configure an ACL to specify IP addresses for translation.
- Determine if you should use an IP address as the translated source address.
- Decide on a public IP address pool for address translation.

Configure the Address Pool

The addresses used for translation are configured by issuing the ip nat pool command in global configuration mode.

Example

This command configures the pool of addresses using start address, and end address.

```
switch(config)# ip nat pool p1 10.15.15.15 10.15.15.25
switch(config)#
```

Set the IP Address

The ip address command configures ***VLAN 201*** with an IP address.

Examples

- This command configures an IPv4 address for ***VLAN 201***.

```
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip address 10.0.0.1/24
switch(config-if-Vl201)#
```

- This command configures the dynamic NAT source address and sets the NAT overload for pool ***P2***.

```
switch(config-if-Vl201)# ip nat source dynamic access-list ACL2 pool p2
switch(config-if-Vl201)#
```

Configuring Dynamic NAT Priority

For each Dynamic NAT configuration, you can specify the priority from lowest to highest in an interface mode. Theip nat source dynamic command allows you to configure dynamic NAT priority from the source IP address. Multiple dynamic NAT configurations have the same priority irrespective of the order. If a priority is not specified in NAT rule, by default, the priority is ***0*** (lowest priority).

Service FTP dynamic NAT rules with a single IP in the pool are considered to be of the highest priority.

Note: Priorities in address-only and non-address-only NAT rules are independent of each other.

Example

This command configures the dynamic NAT priority of the access-list in the pool with the order ***a5 > a4 > a3 > a2 > a1 > a0***.

```
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip address 10.0.0.1/24
switch(config-if-Vl201)# ip nat source dynamic access-list a0 pool p0
switch(config-if-Vl201)# ip nat source dynamic access-list a1 pool p1 priority 1
switch(config-if-Vl201)# ip nat source dynamic access-list a2 pool p2 priority 2
switch(config-if-Vl201)# ip nat source dynamic access-list a3 pool p3 priority 3
switch(config-if-Vl201)# ip nat source dynamic access-list a4 pool p4 priority 4
switch(config-if-Vl201)# ip nat source dynamic access-list a5 pool p5 priority 5
switch(config-if-Vl201)#
```

Configuring Dynamic NAT with Overload

The following configures a dynamic NAT profile with overload.

Example

This command configures the dynamic NAT for overload.

```
ip nat profile patName
   ip nat source dynamic access-list accessList1 overload
!
```

```
ip access-list accessList1
20 permit ip host 1.1.1.2 any log
```

Define the NAT Source Address for Translation

The ip nat source dynamic command specifies a dynamic translation from the source IP address to the pool and to overload the pool address (or addresses).

Example

This command configures the dynamic NAT source address and sets the pool ***P2*** NAT overload.

```
switch(config)# interface ethernet 3/1
switch(config-if-Et3/1)# ip nat source dynamic access-list ACL2 pool p2
switch(config-if-Et3/1)#
```

Specify the Timeout Values

The ip nat translation tcp-timeout or ip nat translation udp-timeout commands alter the translation timeout period for NAT translation table entries.

Examples

- This command globally sets the timeout for TCP to **600** seconds.

```
switch(config)# ip nat translation tcp-timeout 600
switch(config)#
```

- This command globally sets the timeout for UDP to **800** seconds.

```
switch(config)# ip nat translation udp-timeout 800
switch(config)#
```

9.3.1.2.2 Verify the NAT Configuration

Display the Address Pools

The show ip nat pool command displays the configuration of the address pool.

Example

This command displays all the address pools configured on the switch.

```
switch# show ip nat pool
```

```
Pool      StartIp          EndIp           Prefix
p1        10.15.15.15      10.15.15.25     24
p2        10.10.15.15      10.10.15.25     22
p3        10.12.15.15      10.12.15.25     12 switch#
```

9.3.1.2.3 Clearing IP NAT Table Entries

Use the clear ip nat flow translation command to remove all or the specified NAT table entries.

Example

This command clears all dynamic entries from the NAT table.

```
switch# clear ip nat flow translation
switch#
```

9.3.1.2.4 Dynamic NAT Configuration Considerations

Configuring Dynamic NAT Using Pools in a L2 Adjacent Network

When configuring many-to-one dynamic NAT using a NAT pool, and the next hop router for the NAT device is on the same network (L2 adjacent), you must configure the IP addresses in the NAT pool as a secondary address on the interface.

Example:

The IP addresses in the NAT pool are configured as the secondary address on the interface.

```
switch(config)# ip nat pool p1 10.1.1.1 10.1.1.4 prefix-length 24
switch(config)# interface ethernet 1
switch(config-if-Et1)# ip nat source dynamic access-list a1 pool p1
switch(config-if-Et1)# ip address 10.1.1.1/24 secondary
switch(config-if-Et1)# ip address 10.1.1.2/24 secondary
switch(config-if-Et1)# ip address 10.1.1.3/24 secondary
switch(config-if-Et1)# ip address 10.1.1.4/24 secondary
```

Configuring Dynamic NAT Using Pool in a L3 Network

If the next hop of the NAT device is on a different subnet, configure a static Null route for the IP addresses in the NAT pool. Redistribute the static route using BGP/OSPF.

Examples

- Outside Interface

```
switch(config)# interface port-channel 319
switch(config-if-Po319)# ip nat source dynamic access-list dynamic-nat-m2m pool natpl-dynamic-
nat-m2m
switch(config)# ip access-list dynamic-nat-m2m
```

```
switch(config-acl-dynamic-nat-m2m)# 10 permit ip 192.168.93.0/24 any
switch(config)# ip nat pool natpl-dynamic-nat-m2m prefix-length 24
switch(config-natpool-p1)# range 11.3.3.2 11.3.3.10
```

- Static Null Route for Virtual IP

```
switch(config)# ip route 11.0.0.0/8 Null0
switch(config)# router ospf 1
switch(config-router-ospf)# redistribute static
```

Configuring Dynamic NAT Using Overload with ECMP Routes

Do not configure Dynamic many-to-one NAT using overload (PAT) on interfaces that form an ECMP group. When one interface in the group goes down, the return packet for established connections will continue to go to the IP address of the interface that went down and will not be forwarded to the inside host. For this type of scenario, use Dynamic NAT with pool configurations.

9.3.1.2.5 Dynamic NAT Peer State Synchronization

The NAT peer state synchronization provides redundancy and resiliency for dynamic NAT across a pair of devices to avoid a single NAT device failure. Both devices in redundant pair are active and they track new sessions and create or delete NAT entries dynamically. Essentially, an active NAT entry is maintained on both devices, irrespective of who created the NAT entry.

Configuring Dynamic NAT Peer State Synchronization

Ensure the following prerequisites are in place before configuring NAT peer state synchronization on devices in a redundant pair.

- Both devices in redundant pairs must be reachable across an IP address within the same subnet.
- NAT version on both devices in redundant pair must be compatible.
- Dynamic NAT configuration must be identical across both devices in redundant pairs.

The following configuration output indicates a valid running configuration of the NAT peer state synchronization on one device.

```
ip nat pool POOL61 prefix-length 24
  range 170.24.0.2 170.24.0.200

ip access-list NatACL61
  10 permit ip 61.0.0.0/16 any

interface Port-Channel5
  mtu 9214
  no switchport
  ip address 10.0.0.1/31
  ip nat source dynamic access-list NatACL61 pool POOL61

ip nat synchronization
  peer-address 11.11.11.1
  local-interface Vlan1111
  port-range 1024 2048
```

The following limitations are applicable during NAT peer state synchronization.

- To prevent virtual IP address conflicts during dynamic NAT peer state synchronization, ensure the configured port ranges for each switch are disjoint, meaning they do not overlap.
- NAT peer state synchronization does not support asymmetrical TCP setup (SYN—SYNACK—ACK should always be hashed to the same peer).
- Peer state synchronization for NAT only occurs for connections in the TCP-established state.

The following command specifies the description of the device itself.

```
switch(config)# ip nat synchronization
switch(config-nat-synchronization)# description <description>
```

The following command specifies the time the switch waits before timing out existing connections.

```
switch(config)# ip nat synchronization
switch(config-nat-synchronization)# expiry-interval 6
```

The following command specifies the IP address of the peer device from where the synchronization is coming.

```
switch(config)# ip nat synchronization
switch(config-nat-synchronization)# peer address 202.1.1.2
```

This command displays details of the connections of advertised translations to peer devices.

```
switch(config)# show ip nat synchronization advertised-translations
Source IP        Destination IP Translated IP    TGT  Type Interface/Profile
-------------------------------------------------------------------------------------------
10.1.3.10:21800  191.1.1.10:80  139.1.1.1:21800  SRC  DYN  Port-Channel100
10.1.2.10:13750  191.1.1.10:80  139.1.1.1:13750  SRC  DYN  Port-Channel100
10.1.2.10:33757  191.1.1.10:80  139.1.1.1:5951   SRC  DYN  Port-Channel100
10.1.5.10:37111  191.1.1.10:80  139.1.1.1:7561   SRC  DYN  Port-Channel100
```

The following command displays the details of discovered translations advertised by the peer devices.

```
switch(config)# show ip nat synchronization discovered-translations
Source IP        Destination IP Translated IP    TGT  Type Interface/Profile
-------------------------------------------------------------------------------------------
10.1.3.10:28606  191.1.1.10:80  139.1.1.1:28606  SRC  DYN  Port-Channel100
10.1.6.10:39697  191.1.1.10:80  139.1.1.1:39697  SRC  DYN  Port-Channel100
10.1.6.10:20583  191.1.1.10:80  139.1.1.1:31683  SRC  DYN  Port-Channel100
10.1.6.10:28419  191.1.1.10:80  139.1.1.1:28419  SRC  DYN  Port-Channel100
```

9.3.1.3 Applying NAT profile on a Tunnel Interface

The following commands apply the configured NAT profile on a tunnel interface.

Example

This command applies the NAT configuration profile ***natNameProfile*** to the tunnel ***Tunnel0***.

```
interface Tunnel0
   ip address 10.1.1.1/24
   tunnel source 2.1.1.1
   tunnel destination 2.1.1.2
   ip nat service-profile natNameProfile
```

9.3.1.4 IP NAT Commands

IP NAT Commands

- clear ip nat flow translation
- ip address
- ip nat destination static
- ip nat pool
- ip nat source dynamic
- ip nat source static
- ip nat translation counters
- ip nat translation low-mark
- ip nat translation max-entries
- ip nat translation tcp-timeout
- ip nat translation udp-timeout
- show ip nat access-list interface
- show ip nat pool
- show ip nat synchronization advertised-translations
- show ip nat synchronization discovered-translations
- show ip nat synchronization peer
- show ip nat translation

9.3.1.4.1 clear ip nat flow translation

The **clear ip nat flow translation** command clears all or the specified NAT table entries.

Command Mode

Privileged EXEC

Command Syntax

clear ip nat flow translation [**HOST_ADDR** [**DEST_ADDR**]][**INTF**][**PROT_TYPE**]

Parameters

DEST_ADDR must immediately follow **HOST_ADDR**. All other parameters, including **HOST_ADDR** may be placed in any order.

- **HOST_ADDR** Host address to be modified. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - **address *local_ipv4*** IPv4 address.
  - **address *local_ipv4* *local_port*** IPv4 address and port (port value ranges from **1** to **65535**).
- **DEST_ADDR** Destination address of translated packet. Destination address can be entered only when the **HOST_ADDR** is specified. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - ***global_ipv4*** IPv4 address.
  - ***global_ipv4 global_port*** IPv4 address and port (port value ranges from **1** to **65535**).
- **INTF** Route source. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - **interface ethernet *e_num*** Ethernet interface specified by ***e_num***.
  - **interface loopback *l_num*** Loopback interface specified by ***l_num***.
  - **interface management *m_num*** Management interface specified by ***m_num***.
  - **interface port-channel *p_num*** Port-channel interface specified by ***p_num***.
  - **interface vlan *v_num*** VLAN interface specified by ***v_num***.

- **PROT_TYPE** Filters packets based on protocol type. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - **tcp** TCP packets with specified destination address are cleared.
  - **udp** UDP packets with specified destination address are cleared.

Examples

- This command clears all dynamic entries from the NAT translation table.

```
switch# clear ip nat flow translation
switch#
```

- This command clears a specific NAT IP address ***172.22.30.52***.

```
switch# clear ip nat flow translation address 172.22.30.52
switch#
```

- This command clears the inside entry that maps the private address ***10.10.10.3*** to Internet address ***172.22.30.52***.

```
switch# clear ip nat flow translation address 172.22.30.52 10.10.10.3
switch#
```

9.3.1.4.2 ip address

The **ip address** command configures the IPv4 address and connected subnet on the configuration mode interface. Each interface can have one primary address and multiple secondary addresses.

The **no ip address** and **default ip address** commands remove the IPv4 address assignment from the configuration mode interface. Entering the command without specifying an address removes the primary and all secondary addresses from the interface. The primary address cannot be deleted until all secondary addresses are removed from the interface.

Removing all IPv4 address assignments from an interface disables IPv4 processing on that port.

Command Mode

Interface-Ethernet Configuration

Interface-Loopback Configuration

Interface-Management Configuration

Interface-Port-channel Configuration

Interface-VLAN Configuration

Command Syntax

`ip address` [*ipv4_subnet*][**PRIORITY**]

`no ip address` [*ipv4_subnet*][**PRIORITY**]

`default ip address` [*ipv4_subnet*][**PRIORITY**]

Parameters

- ***ipv4_subnet*** IPv4 and subnet address (CIDR or address-mask notation). ***Running-config*** stores value in CIDR notation.
- **PRIORITY** interface priority. Options include:
  - **no parameter** The address is the primary IPv4 address for the interface.
  - **secondary** The address is the secondary IPv4 address for the interface.

Guidelines

The **ip address** command is supported on routable interfaces.

Example

This command configures an IPv4 address for ***VLAN 200***.

```
switch(config)# interface vlan 200
switch(config-if-Vl200)# ip address 10.0.0.1/24
switch(config-if-Vl200)#
```

9.3.1.4.3 ip nat destination static

The **ip nat destination static** command enables NAT of a specified destination address for the configuration mode interface. This command installs hardware translation entries for forward and reverse unicast traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. The command may include an access control list to filter packets for translation.

When configuring twice NAT, an arbitrary NAT group number is used to associate the source NAT and destination NAT rules. This number must be the same in both rules.

The **no ip nat destination static** and **default ip nat destination static** commands disables NAT translation of the specified destination address by removing the corresponding **ip nat destination static** command from ***running_config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-channel Configuration

Interface-VLAN Configuration

Command Syntax

`ip nat destination static` **ORIGINAL** [**FILTER**] **TRANSLATED** [*PROT_TYPE*][group *group_number*]

`no ip nat destination static` **ORIGINAL** [**FILTER**] **TRANSLATED** [*PROT_TYPE*] [group *group_number*]

`default ip nat destination static` **ORIGINAL** [**FILTER**] **TRANSLATED** [*PROT_TYPE*][group *group_number*]

Parameters

- **ORIGINAL** Destination address to be modified. Options include:
  - ***local_ipv4*** IPv4 address.
  - ***local_ipv4 local_port*** IPv4 address and port (port value ranges from **1** to **65535**)
- **FILTER** Access control list that filters packets. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - **access-list *list_name*** List that specifies the packets that are cleared. Not supported when configuring twice NAT.
- **TRANSLATED** Destination address of translated packet. Options include:

- ***global_ipv4*** IPv4 address.
- ***global_ipv4 global_port*** IPv4 address and port (port value ranges from `1` to `65535`). When configuring twice NAT, source and destination NAT rules must either both specify a port translation or both not specify a port translation.

- **PROT_TYPE** Filters packets based on protocol type. Options include:
  - **no parameter** All packets with specified destination address are cleared.
  - **protocol tcp** TCP packets with specified destination address are cleared.
  - **protocol udp** UDP packets with specified destination address are cleared.

- **group*group_number*** Used only when configuring twice NAT, the NAT group number associates a source NAT rule with a destination NAT rule on the same interface. The group number (values range from `1` to `255`) is arbitrary, but must be the same in both rules.

Examples

- These commands configure ***VLAN 201*** to translate destination address ***10.24.1.10*** to ***168.32.14.15***.

```
switch(config)# interface vlan 201
switch(config-if-Vl201)# ip nat destination static 10.24.1.10 168.32.14.15
switch(config-if-Vl201)#
```

- These commands configure ***VLAN 201*** to translate the source address ***10.24.1.10*** to ***168.32.14.15*** for all packets with IP destination addresses in the ***168.10.1.1/32*** subnet.

```
switch(config)# ip access-list ACL2
switch(config-acl-ACL2)# permit ip 168.10.1.1/32 any
switch(config-acl-ACL2)# exit
switch(config)# interface vlan 201
switch(config-if-Vl201)#
switch(config-if-Vl201)#
```

- These commands configure ***interface Ethernet 2*** to translate the local source address ***10.24.1.10*** to the global source address ***168.32.14.15***, and to translate the local destination address ***10.68.104.3*** to the global destination address ***168.25.10.7*** for all packets moving through the interface. The use of NAT ***group 3*** is arbitrary, but must be the same in both rules.

```
switch(config)# interface ethernet 2
switch(config-if-Et2)# ip nat source static 10.24.1.10 168.32.14.15 group 3
switch(config-if-Et2)# ip nat destination static 10.68.104.3 168.25.10.7 group 3
```

9.3.1.4.4 ip nat pool

The **ip nat pool** command identifies a pool of addresses using start address, end address, and either netmask or prefix length. If its starting IP address and ending IP address are the same, there is only one address in the address pool.

The **no ip nat pool** removes the **ip nat pool**command from ***running_config***.

Command Mode

Global Configuration

Command Syntax

`ip nat pool` *pool_name* [*ADDRESS_SPAN*] *SUBNET_SIZE*

`no ip nat pool` *pool_name*

`default ip nat pool` *pool_name*

Parameters

- ***pool_name*** Name of the IP address pool.
- ***ADDRESS_SPAN*** Options include:
  - ***start_addr*** The first IP address in the address pool (IPv4 addresses in dotted decimal notation).
  - ***end_addr*** The last IP address in the address pool. (IPv4 addresses in dotted decimal notation).
- ***SUBNET_SIZE*** This functions as a sanity check to ensure it is not a network or broadcast network. Options include:
  - **netmask *ipv4_addr*** The netmask of the address pool's network (dotted decimal notation).
  - **prefix-length** **0** to **32** The number of bits of the netmask (of the address pool's network) that are ones (how many bits of the address indicate network).

Examples

- This command configures the pool of addresses using start address, end address, and prefix length of **24**.

```
switch(config)# ip nat pool poo1 10.15.15.15 10.15.15.25 prefix-length 24
switch(config)
```

- This command removes the pool of addresses.

```
switch(config)# no ip nat pool poo1 10.15.15.15 10.15.15.25 prefix-length 24
 switch(config)
```

9.3.1.4.5 ip nat source dynamic

The **ip nat source dynamic** command enables NAT of a specified source address for packets sent and received on the configuration mode interface. This command installs hardware translation entries for forward and reverse traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. The command may include an access control list to filter packets for translation.

The **no ip nat source dynamic** and **default ip nat source dynamic** commands disables NAT translation of the specified destination address by removing the corresponding **ip nat source dynamic** command from ***running_config*** .

Note: Ethernet and Port-channel interfaces should be configured as routed ports.

Command Mode

Interface-Ethernet Configuration

Interface-Port-channel Configuration

Interface-VLAN Configuration

Command Syntax

`ip nat source dynamic access-list` *acl_name* **POOL_TYPE**

`no ip nat source dynamic access-list` *acl_name*

`default ip nat source dynamic access-list` *acl_name*

Parameters

- ***acl_name*** Access control list that controls the internal network addresses eligible for NAT.
- **POOL_TYPE** Options include:
  - **overload** Translates multiple local addresses to a single global address. When overloading is enabled, conversations using the same IP address are distinguished by their TCP or UDP port number.
  - **pool *pool_name*** The name of the IP address pool. The pool is defined using the ip nat pool command.

    The pool option is required even if the pool has just one address. NAT uses that one address for all of the translations.
- ***pool_fullcone*** Enables full cone NAT where all requests from the same internal IP address and port are mapped to the same external IP address and port.

Examples

- This command configures the dynamic NAT source address and sets the NAT overload for pool ***P2***.

```
switch(config)# interface ethernet 3/1
```

```
switch(config-if-Et3/1)# ip nat source dynamic access-list ACL2 pool p2
switch(config-if-Et3/1)#
```

- This command disables the NAT source translation on interface Ethernet ***3/1***.

```
switch(config)# interface ethernet 3/1
switch(config-if-Et3/1)# no ip nat source dynamic access-list ACL2
switch(config-if-Et3/1)#
```

9.3.1.4.6 ip nat source static

The **ip nat source static** command enables NAT of a specified source address for the configuration mode interface. This command installs hardware translation entries for forward and reverse unicast traffic. When the rule specifies a multicast group, the command does not install the reverse path in hardware. The command may include an access control list to filter packets for translation.

When configuring twice NAT, an arbitrary NAT group number is used to associate the source NAT and destination NAT rules. This number must be the same in both rules.

The **no ip nat source static** and **default ip nat source static** commands disables NAT translation of the specified source address by removing the corresponding **ip nat source** command from ***running_config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-channel Configuration

Interface-VLAN Configuration

Command Syntax

`ip nat source static` **ORIGINAL** [**FILTER**] **TRANSLATED** [**PROT_TYPE**] [group *group_number*]

`no ip nat source static` **ORIGINAL** [**FILTER**] **TRANSLATED** [**PROT_TYPE**] [group *group_number*]

`default ip nat source static` **ORIGINAL** [**FILTER**] **TRANSLATED** [**PROT_TYPE**] [group *group_number*]

Parameters

- **ORIGINAL** Source address to be modified. Options include:
  - ***original_ipv4*** IPv4 address.
  - ***original_ipv4*** ***original_port*** IPv4 address and port (port value ranges from **1** to **65535**).
- **FILTER** Access control list that filters packets. Options include:
  - **no parameter** All packets with specified source address are cleared.
  - **access-list *list_name*** List that specifies the packets that are cleared. Not supported when configuring twice NAT.
- **TRANSLATED** Source address of translated packet. Options include:
  - ***translated_ipv4*** IPv4 address.

    - ***translated_ipv4 translated_port*** IPv4 address and port (port value ranges from `1` to `65535`). When configuring twice NAT, source and destination NAT rules must either both specify a port translation or both not specify a port translation.

- **PROT_TYPE** Filters packets based on protocol type. Options include:
    - **no parameter** All packets with specified source address are cleared.
    - **protocol tcp** TCP packets with specified source address are cleared.
    - ***protocol udp*** UDP packets with specified source address are cleared.

- **group *group_number*** Used only when configuring twice NAT, the NAT group number associates a source NAT rule with a destination NAT rule on the same interface. The group number (values range from `1` to `255`) is arbitrary, but must be the same in both rules.

Restrictions

- If **ORIGINAL** includes a port, **TRANSLATED** must also include a port.
- If **ORIGINAL** does not include a port, **TRANSLATED** cannot include a port.

Examples

- These commands configure ***VLAN 101*** to translate source address ***10.24.1.10*** to ***168.32.14.15***.

```
switch(config)# interface vlan 101
switch(config-if-Vl101)# ip nat source static 10.24.1.10 168.32.14.15
switch(config-if-Vl101)#
```

- These commands configure ***VLAN 101*** to translate the source address ***10.24.1.10*** to access-list ACL1 ***168.32.14.15*** for all packets with IP destination addresses in the ***168.10.1.1/32*** subnet.

```
switch(config)# ip access-list ACL1
switch(config-acl-ACL1)# permit ip any 168.10.1.1/24
switch(config-acl-ACL1)# exit
switch(config)# interface vlan 101
switch(config-if-Vl101)# ip nat source static 10.24.1.10 access-list ACL1
168.32.14.15
switch(config-if-Vl101)#
```

- These commands configure Ethernet interface ***2*** to translate the local source address ***10.24.1.10*** to the global source address ***168.32.14.15***, and to translate the local destination address ***10.68.104.3*** to the global destination address ***168.25.10.7*** for all packets moving through the interface. The use of NAT ***group 3*** is arbitrary, but must be the same in both rules.

```
switch(config)# interface ethernet 2
switch(config-if-Et2)# ip nat source static 10.24.1.10 168.32.14.15 group 3
switch(config-if-Et2)# ip nat destination static 10.68.104.3 168.25.10.7 group 3
```

9.3.1.4.7 ip nat synchronization

The **ip nat synchronization** command places the switch into the NAT Synchronization Configuration Mode and configures NAT Synchronization to provide redundancy and resiliency for dynamic NAT across a pair of switches. This mitigates the risk of a single NAT failure.

To disable the feature, use the parameter **shutdown** in NAT Synchronization Mode.

Command Mode

IP NAT Synchronization Configuration

Command Syntax

ip nat synchronization [description ***description*****] [expiry-interval** ***seconds*****] [local-interface** ***interface_type port_number*****] [peer-address** ***ip_address*****] [port-range [***port_range***] [split [***port_range*** | disabled]] [shutdown]**

Parameters

- **ip nat synchronization** - Enter the IP NAT Synchronization Configuration Mode.
- **description** ***description*** - Enter a description for the NAT configuration.
- **expiry-interval** ***seconds*** - Configure an interval to time out existing connections when a peer goes offline or other event. Use a range from 60 to 360 seconds.
- **local-interface** ***interface_type port_number*** - Specify a local interface and port. EOS supports the following interfaces:
  - **Backplane-Channel**
  - **Ethernet**
  - **Fabric**
  - **Loopback**
  - **Management**
  - **Port-Channel**
  - **Recirc-Channel**
  - **Tunnel**
  - **Vlan**
  - **Vxlan**
- **peer-address** ***ip_address*** Specify an IPv4 address as a peer address.

- **port-range*port_range port_range*** - Specify a discontiguous port range from 0 to 160 for the first port range and 161 to 2000 for the second port range.
  - `split` *port_range* - Specify to split the port range automatically.
  - **disabled** - Specify to manually set the port range.
- **shutdown** - Use this parameter to disable NAT Peer State Synchronization.

Example

Use the following commands to configure IP NAT Synchronization:

```
switch(config)#ip nat synchronization
switch(config-nat-synchronization)#  expiry-interval 3600
switch(config-nat-synchronization)#  peer-address 202.1.1.2
switch(config-nat-synchronization)#  local-interface Vlan2022
switch(config-nat-synchronization)#  port-range 1024 24000
```

9.3.1.4.8 ip nat translation counters

The **ip nat translation counters** command enables the feature to count packets that are translated by static and twice NAT rules in hardware. Once this feature is enabled, all current rules in hardware and new rules that are configured after running this command receive policers for counting packets.

The **no ip nat translation counters** and **default ip nat translation counters** commands disable the packet counter feature for static and twice NAT connections.

Command Mode

Global Configuration

Command Syntax

```
ip nat translation counters

no ip nat translation counters

default ip nat translation counters
```

Guidelines

The **ip nat translation counters** command is supported on the DCS-7150 series switches only. This command is solely intended to debug static and twice NAT translation failures in hardware. Disable this feature after completing troubleshooting. If this feature remains enabled even when the count of static connections exceed ***275***, it can cause unpredictable behavior including restart of FocalPointV2 agent. The restart of FocalPointV2 agent results in traffic disruption.

Example

The **ip nat translation counters** command enables the packet counter feature for static and twice NAT connections. Using the **show ip nat translation hardware detail** and the **show ip nat translation twice hardware detail** commands, you can verify the packet count.

```
switch(config)# ip nat translation counters
switch(config)# show ip nat translation hardware detail

Source IP        Destination IP  Translated IP  TGT Type Intf   Proto  Packets  Packets Reply
---------------------------------------------------------------------------------------------
192.168.10.2:0    -              20.1.10.2:0    SRC STAT Vl2640 -      2         1
192.168.110.2:0   -              20.1.110.2:0   SRC STAT Vl2640 -      2         1

switch(config)# show ip nat translation twice hardware detail

19.16.150.2:0  10.1.150.2:0    20.1.150.2:0   10.1.160.2:0  Vl2922 12 -    2
```

9.3.1.4.9 ip nat translation low-mark

The **ip nat translation low-mark** command configures the minimum threshold that triggers the resumption of programming new NAT translation connections.

The ip nat translation max-entries command specifies the maximum number of NAT translation connections that can be stored. When this limit is reached, new connections are dropped instead of being programmed in hardware or software. At this point no new connections will be programmed until the number of stored entries drop below the configured low-mark, expressed as a percentage of the max-entries value. The default low mark value is 90%.

The **no ip nat translation low-mark** and **default ip nat translation low-mark** commands restores the default low-mark value by removing the **ip nat translation low-mark** command from ***running_config***.

Command Mode

Global Configuration

Command Syntax

`ip nat translation low-mark` *threshold*

`no ip nat translation low-mark`

`default ip nat translation low-mark`

Parameter

threshold Percentage of maximum connection entries. Value ranges from **1** to **99**. Default is **90**.

Example

This command globally sets the translation low mark of ***93%***.

```
switch(config)# ip nat translation low-mark 93
switch(config)#
```

9.3.1.4.10 ip nat translation max-entries

The **ip nat translation max-entries** command specifies maximum number of NAT translation connections. After this threshold is reached, new connections are dropped until the number of programmed connections is reduced below the level specified by the ip nat translation low-mark command.

The **no ip nat translation max-entries** and **default ip nat translation max-entries** commands removes the maximum connection limit and resets the parameter value to zero by removing the **ip nat translation max-entries** command from ***running_config***.

Command Mode

Global Configuration

Command Syntax

`ip nat translation max-entries` *connections*

`no ip nat translation max-entries`

`default ip nat translation max-entries`

Parameters

connections The maximum number of NAT translation connections. Value ranges from **0** to **4294967295**. Default value is **0**, which removes the connection limit.

Example

This command limits the number of NAT translation connections the switch can store to ***3000***.

```
switch(config)# ip nat translation max-entries 3000
switch(config)#
```

9.3.1.4.11 ip nat translation tcp-timeout

The **ip nat translation tcp-timeout** command specifies the translation timeout period for translation table entries. The timeout period specifies the interval during which the switch will attempt to reuse an existing TCP translation for devices specified by table entries.

The **no ip nat translation tcp-timeout** and **default ip nat translation tcp-timeout** commands reset the timeout to its default by removing the corresponding **ip nat translation tcp-timeout** command from ***running_config***.

Command Mode

Global Configuration

Command Syntax

`ip nat translation tcp-timeout` *period*

`no ip nat translation tcp-timeout`

`default ip nat translation tcp-timeout`

Parameter

period Time-out period in seconds for port translations. Value ranges from **0** to **4294967295**. Default value is **86400** (24 hours).

Examples

- This command sets the TCP timeout for translations to ***600*** seconds.

```
switch(config)# ip nat translation tcp-timeout 600
switch(config)#
```

- This command removes the TCP translation timeout.

```
switch(config)# no ip nat translation tcp-timeout
switch(config)#
```

9.3.1.4.12 ip nat translation udp-timeout

The **ip nat translation udp-timeout** command specifies the translation timeout period for translation table entries. The timeout period specifies the interval the switch attempts to establish a UDP connection with devices specified by table entries.

The **no ip nat translation udp-timeout** and **default ip nat translation udp-timeout** commands disables NAT translation of the specified destination address by removing the corresponding **ip nat translation udp-timeout** command from ***running_config***.

Command Mode

Global Configuration

Command Syntax

`ip nat translation udp-timeout` *period*

`no ip nat translation udp-timeout`

`default ip nat translation udp-timeout`

Parameter

period Value ranges from **0** to **4294967295**. Default value is **300** (5 minutes).

Examples

- This command globally sets the timeout for UDP to ***800*** seconds.

```
switch(config)# ip nat translation udp-timeout 800
```

- This command removes the timeout for UDP.

```
switch(config)# no ip nat translation udp-timeout
```

9.3.1.4.13 show ip nat access-list interface

The **show ip nat acl interface** command displays the access control lists (ACLs) that are configured as source NAT or destination NAT filters. The display indicates ACL rules that do not comply with these NAT requirements:

- Source IP address is any.
- Destination IP address may use any mask size.
- Source port matching is not allowed.
- Protocol matching is not allowed.

Command Mode

EXEC

Command Syntax

`show ip nat access-list interface` [**INTF**][**LISTS**]

Parameters

- **INTF** Filters NAT statements by interface. Options include:
  - **no parameter** Includes all statements on all interfaces.
  - **interface ethernet *e_num*** Statements on specified Ethernet interface.
  - **interface loopback *l_num*** Statements on specified Loopback interface.
  - **interface management *m_num*** Statements on specified Management interface.
  - **interface port-channel *p_num*** Statements on specified Port-Channel Interface.
  - **interface vlan *v_num*** Statements on specified VLAN interface.
  - **interface VXLAN *vx_num*** Statements on specified VXLAN interface.
- **LISTS** ACLs displayed by command. Options include:
  - **no parameter** All ACLs.
  - ***acl_name*** Specifies individual ACL.

Example

These commands display the NAT command usage of the ACL1 and ACL2 access control lists.

```
switch> show ip nat acl ACL1
```

```
acl ACL1
        (0.0.0.0/0, 168.10.1.1/32)
Interfaces using this ACL for Nat:
        Vlan100

switch> show ip nat acl ACL2
acl ACL2
        (168.10.1.1/32, 0.0.0.0/0)
Interfaces using this ACL for Nat:
        Vlan201 switch>
```

9.3.1.4.14 show ip nat pool

The **`show ip nat pool`** command displays the configuration of the address pool.

Command Mode

EXEC

Command Syntax

`show ip nat pool` **POOL_SET**

Parameters

- ***pool_name*** The name of the pool.
- **POOL_SET** Options include:
  - **no parameter** All configured port channels.
  - ***pool_name*** The name of the pool.

Examples

- This command displays all the address pools configured on the switch.

```
switch# show ip nat pool
Pool                 StartIp              EndIp                Prefix
p1                   10.15.15.15          10.15.15.25          24
p2                   10.10.15.15          10.10.15.25          22
p3                   10.12.15.15          10.12.15.25          12 switch#
```

- These commands display specific information for the address pools configured on the switch.

```
switch# show ip nat pool p1
Pool                 StartIp              EndIp                Prefix
p1                   4.1.1.1              4.1.1.2              24
                     1.1.1.1              1.1.1.2              24
                     3.1.1.1              3.1.1.2              24
switch# show ip nat pool p2
Pool                 StartIp              EndIp                Prefix
p2                   10.1.1.1             10.1.1.2             16 switch#
```

9.3.1.4.15 show ip nat synchronization advertised-translations

The **`show ip nat synchronization advertised-translations`** command displays the detailed status of devices that are advertised to a peer device.

Command Mode

EXEC

Command Syntax

```
show ip nat synchronization advertised-translations
```

Example

This command displays details of devices that are advertised to a peer device.

```
switch# show ip nat synchronization advertised-translations

Source IP         Destination IP   Translated IP          TGT  Type Intf
-------------------------------------------------------------------------
61.0.0.15:6661    100.0.0.2:80     192.170.230.171:6661    SRC  DYN  Et5
61.0.0.41:2245    100.0.0.2:80     192.170.230.170:2245    SRC  DYN  Et5
61.0.0.48:22626   100.0.0.2:80     192.170.230.169:22626   SRC  DYN  Et5
61.0.0.41:22601   100.0.0.2:80     192.170.230.170:22601   SRC  DYN  Et5
61.0.0.41:16798   100.0.0.2:80     192.170.230.170:16798   SRC  DYN  Et5
61.0.0.18:22605   100.0.0.2:80     192.170.230.177:22605   SRC  DYN  Et5
61.0.0.16:2256    100.0.0.2:80     192.170.230.166:2256    SRC  DYN  Et5
```

9.3.1.4.16 show ip nat synchronization discovered-translations

The **show ip nat synchronization discovered-translations** command displays details of what has been advertised from a peer device.

Command Mode

EXEC

Command Syntax

```
show ip nat synchronization discovered-translations
```

Example

This command displays details of devices that are advertised to a peer device.

```
switch# show ip nat synchronization discovered-translations

Source IP         Destination IP    Translated IP          TGT  Type Intf
-------------------------------------------------------------------------
61.0.2.229:63     100.0.0.2:63     170.24.86.180:63        SRC  DYN  Et5
61.0.15.51:63     100.0.0.2:63     170.24.73.90:63         SRC  DYN  Et5
61.0.6.68:63      100.0.0.2:63     170.24.110.128:63       SRC  DYN  Et5
61.0.7.163:63     100.0.0.2:63     170.24.104.35:63        SRC  DYN  Et5
```

9.3.1.4.17 show ip nat synchronization peer

The **`show ip nat synchronization peer`** command displays the detailed status of a peer device.

Command Mode

EXEC

Command Syntax

```
show ip nat synchronization peer
```

Example

This command displays details of a peer device with an IP address of ***11.11.11.0*** and interface ***VLAN 1111*** that is used to connect to the peer device.

```
switch# show ip nat synchronization peer
Description : Value
Peer : 11.11.11.0
Connection Port : 4532
Connection Source : 0.0.0.0
Kernel Interface : vlan1111
Local Interface : Vlan1111
Established Time : 1969-12-31 16:00:00
Connection Attempts : 0
Oldest Supported Version : 1
Newest Supported Version : 1
Version Compatible : True
Connection State : connected
Shutdown State : False
Status Mount State : mountMounted
Version Mount State : mountMounted
Recover Mount State : mountMounted
Reboot Mount State : mountMounted
```

9.3.1.4.18 show ip nat translation

The **`show ip nat translation`** command displays configured NAT statements in the switch hardware.

Command Mode

EXEC

Command Syntax

`show ip nat translation` [address | address-only | destination | detail | dynamic | hardware | interface | kernel | max-entries | source | static | summary | twice]

The command position of all parameters are interchangeable.

Parameters

- **no parameter** Displays all NAT connections installed in software.
- **address *ipv4_addr*** Displays NAT connections of the specified IPv4 host address.
- **address-only *ipv4_addr*** Displays address-only NAT connections of the specified IPv4 host address.
- **destination** Displays destination NAT connections installed in software.
- **detail** Displays detailed output of all NAT connections.
- **dynamic** Displays dynamic NAT connections.
- **hardware** Displays NAT connections installed in hardware.
- **interface** Filters NAT connections by interface. Options include:
  - **interface ethernet *e_num*** Displays NAT connections of the specified ethernet interface.
  - **interface port-channel *p_num*** Displays NAT connections of the specified port-channel interface.
  - **interface vlan *v_num*** Displays NAT connections of the specified VLAN interface.
- **kernel** Displays NAT connections installed in kernel.
- **max-entries** Displays the configured NAT connection limits of a hardware.
- **source** Displays source NAT connections installed in software.
- **static** Displays static NAT connections.
- **summary** Displays summary of all NAT connections.
- **twice** Displays twice NAT connections.

Examples

- This command displays all configured NAT translations.

```
switch> show ip nat translation

Source IP          Destination IP   Translated IP         TGT Type Intf
-------------------------------------------------------------------------------
192.168.1.10:62822 172.22.22.40:53  172.17.254.161:62822  SRC DYN  Vl3925
192.152.1.10:20342 172.22.22.40:80  172.17.254.161:22222  SRC STAT Vl3945 switch#
```

- This command displays NAT connections of the specified ethernet interface.

```
switch> show ip nat translation dynamic interface Ethernet 26

Source IP          Destination IP    Translated IP       TGT Type Intf
-------------------------------------------------------------------------
192.168.1.2:8080   10.1.1.5:600      20.1.1.5:8080       SRC DYN  Et26
```

- This command displays the configured NAT connection limits of a hardware.

```
switch> show ip nat translation max-entries

Global connection limit                          100
Global connection limit low mark                 90(90%)
Hosts connection limit                           20
Hosts connection limit low mark                  18(90%)
Total number of connections                       1

Host           Max-Entries           Low-Mark              Connections
-------------------------------------------------------------------
10.1.1.1       10                    9(90%)                0
```

9.3.2 Media Access Control Security

This section explains the basic concepts of Media Access Control Security (MACsec) including overview, configuration, and the different MACsec commands used.

- MACsec Overview
- Configuring MACsec
- Displaying MACsec Information
- MACsec Key Retirement Immediate
- MACsec EAP-FAST Support
- MACsec Proxy For VXLAN
- MACsec Fallback to Unprotected Traffic
- MACsec Commands

9.3.2.1 MACsec Overview

Media Access Control Security (MACsec) is an industry-standard encryption mechanism that protects all traffic flowing on Ethernet links. MACsec is based on IEEE 802.1X and IEEE 802.1AE standards.

The major benefits of MACsec include the following:

- MACsec supports packet authentication by providing integrity checking so that packet data cannot be altered during a packet flow.
- MACsec provides secure encryption at the Layer 2 level by ensuring complete data confidentiality.
- Integrating a high-density MACsec solution for Cloud Data Centers using the 7500R switch for the highest density and performance in a modular platform.
- Optimizing the cost and performance of the Data Center Interconnect to transport massive traffic volumes through metro or long haul networks.
- Securing data transport over distance with MACsec encryption, eliminating additional intermediate devices.

9.3.2.1.1 MACsec Terminology

MACsec Key Agreement Protocol (MKA) - provides the key agreement protocol for discovering MACsec peers and negotiating keys between MACsec peers (IEEE 802.1X-REV).

Connectivity Association (CA) - allows a security relationship between MACsec-capable devices (endpoints). Endpoints in the same CA share a Connectivity Association Key (CAK). The Arista implementation supports 2 endpoints.

Connectivity Association Key (CAK) - contains a master key used to generate all other keys that are used for MACsec. Endpoints in the same secure Connectivity Association (CA) share a CAK. This key can either be a static pre-shared key or dynamically derived using 802.1X authentication.

Primary Key - contains the CAK for the MKA session in progress. The Primary key consists of a combination of the key name and the actual key. For example, when a configuration uses ***0abcd1 0 1234abcd*** as a primary key, ***0abcd1*** is the hex key name, while ***1234abcd*** is the actual key.

Note: A key name must be in hex format. The operator ***0*** means the entered key is unencrypted (or unhashed), versus ***7*** meaning the hashed version of the entered key in cases where the configuration replays on the switch.

Fallback Key- When the configured primary key does not establish a connection, the fallback key establishes the session to ensure no traffic loss.

Secure Association Key (SAK) - Derived from the CAK and used by the network device ports to encrypt traffic for a given session.

Key Server - One of the MACsec peers in the CA becomes the Key Server. The Key Server creates and distributes SAKs and uses them for data encryption.

Static Secure Association Key (SAK) - A SAK configured directly on a switch and used with unidirectional links when the MKA protocol is not feasible. Static SAKs require using eXtended Packet Numbering (XPN) cipher suites.

Secure Channel Identifier (SCI) - Uniquely identifies a Secure Channel (SC) consisting of a unidirectional connection for transmitting protected MACsec frames from one MACsec entity (SecY) to one or more others.

The SCI allows a receiving device to determine which secure channel and subsequently, which Secure Association Key (SAK), should be used to decrypt and authenticate the incoming frame.

9.3.2.1.2 MACsec Limitations

The following are the limitations of MACsec:

- EOS supports MACsec only on point-to-point links unless static SAK is enabled.
- When enabling MACsec on an interface for the first time, interface flapping occurs until MACsec takes effect.

- A port configured with MACsec and without a statically configured SAK will remain blocked, preventing data forwarding until the MKA protocol successfully negotiates encryption keys.

9.3.2.1.3 MACsec Licensing

MACsec encryption is an EOS-licensed feature that requires a valid MACsec license on a switch. MACsec licenses are based on a switch's serial number and the licensee. Every switch running MACsec requires a separate license.

Use one of the following methods to configure a MACsec license:

1. Use the command **`license`** ***licensee_name license_value*** in MACsec mode. The license value is an 8-digit hexadecimal number. This method of license configuration supports backward compatibility.

2. Use the command **`license`** ***import license_file_path*** in Global configuration mode. All new licenses generated on the license portal are JSON-based.

Contact your system engineer to acquire the required license codes before attempting to configure MACsec.

9.3.2.1.4 MACsec in FIPS mode

Federal Information Processing Standards (FIPS) are a set of standards defined by the United States federal government related to data processing in computer systems by non-military government agencies and government contractors. These standards define specific requirements for various purposes, such as ensuring computer security and interoperability within and across the computer networking industry.

Arista devices are compliant with FIPS 140. The FIPS 140 enforces the use of a "FIPS Crypto Module." This implementation ensures that the algorithms are correct and restricts the set of allowed algorithms to those approved by the FIPS standard. These are the FIPS-supported algorithms AES-128/256, SHA-256/512, RSA with 2048 bit keys, a subset of Elliptic Curve Digital Signature Algorithm (ECDSA). MACsec has both the AES-128-GCM and AES-256-GCM algorithms certified for the data plane. The FIPS mode is enabled using the **`fips restrictions`** command, which, when enabled, filters out any unapproved algorithms and warns you if you try to set them.

9.3.2.1.5 VLAN Tagged MACsec

Media Access Control Security (MACsec) is configured on subinterfaces using the **`mac security profile`** command. Since subinterfaces are logical interfaces that send and receive VLAN tagged traffic, encryption/decryption is applied per VLAN tag.

9.3.2.1.6 MACsec Using Static Secure Association Key

MAC security uses the MACsec Key Agreement (MKA) protocol to negotiate between peers using keys (CAKs and CKNs) which are either pre-shared or derived from an 802.1X session and derives a Secure Association Key (SAK) based on the MKA negotiation. This SAK is then programmed in hardware and used for encrypting and decrypting data traffic. In cases where MKA negotiation is not feasible but encryption and decryption of traffic is required (such as unidirectional links), MACsec can instead be configured to use static Secure Association Keys (SAK) configured separately on transmitting and receiving peers. Each peer can have up to four receiving secure keys and one transmitting key.

9.3.2.2 Configuring MACsec

These sections describe basic MACsec configuration steps:

- Enabling MACsec
- Configuring MACsec for MKA
- Configuring the FIPS mode
- Configuring the Layer 2 Protocol Processing Mode
- Configuring MACsec Profile on a Subinterface
- Configuring MACsec Using Static SAK
- Configuring MACsec Proxy For VXLAN
- Configuring MAC Security Dynamic Key Derivation
- Configuring MACsec Fallback to Unprotected Traffic

9.3.2.2.1 Enabling MACsec

Use the **`mac security`** command to enable MACsec and enter the MAC Security Configuration Mode, followed by the **`profile`** command to create a profile and enter the MAC Security Profile Configuration Mode.

The following commands are available for detailed configuration:

- cipher
- key (MACsec)
- l2-protocol
- mka key-server
- mka session
- replay
- sci
- traffic unprotected allow

Example

These commands enable MACsec and enter MAC Security Configuration Mode, then create a profile named "MACsec_test" and enter MAC Security Profile Configuration Mode.

```
switch(config)# mac security
switch(config-mac-security)# profile MACsec_test
switch(config-mac-security-profile-MACsec_test)#
```

9.3.2.2.2 Configuring MACsec for MKA

By default, MAC security (MACsec) uses the MACsec Key Agreement (MKA) protocol to negotiate and exchange encryption keys among peers. To complete a typical MACsec configuration:

1. Use the cipher command to select a valid encryption standard.
2. Use the key (MACsec) command to enter a Connectivity Association Key (CAK).
3. Use the **fallback** option to add a fallback CAK if the primary CAK fails.

The key server is responsible for generating and distributing encryption keys. Run the **mka key-server priority** command on a peer to change its priority. The peer with the lowest priority is elected as the key server. If multiple peers have the same priority, the system chooses the peer with the lowest MAC address. Priority values range from 0 to 255; the default priority is 16.

Configure the refresh period for the Secure Association Key (SAK) using the **mka session rekey-period** command. MACsec uses an SAK to encrypt data traffic and derives this SAK from the CAK. The rekey-period values range from ***30*** to ***100000*** seconds. The system does not enforce a session rekey period by default and does not refresh the SAK periodically.

To improve the randomness of the numbers used to generate MACsec's cryptographic keys, add a source of entropy with the **entropy source** command in the Management Security Configuration Mode.

Examples

These commands configure MACsec to use the AES256-GCM-XPN cipher and add a key and a fallback key. For MKA with a pre-shared key configuration, keys of any length are allowed to work. However, for a 256-bit cipher, use keys with 64 hexadecimal digits in length.

```
switch(config-mac-security-profile-test)# cipher aes256-gcm-xpn
switch(config-mac-security-profile-test)# key 0abc12340def56780abc12340def5678 7 06070E234E4D0
A48544540585F507E
switch(config-mac-security-profile-test)# key 0def56780abc12340def56780abc1234 7 09484A0C1C031
1475E5A527D7C7C70 fallback
```

These commands give the switch a key-server priority of 10, and an MKA session rekey period of 600 seconds.

```
switch(config-mac-security-profile-test)# mka key-server priority 10
switch(config-mac-security-profile-test)# mka session rekey-period 600
```

These commands add an entropy source for more random cryptographic keys.

```
switch(config-mac-security-profile-test)# management security
switch(config-mgmt-security)# entropy source hardware
```

These commands apply the "test" profile to Ethernet interface 5/3/1.

```
switch(config-mgmt-security)# interface ethernet 5/3/1
switch(config-if-Et5/3/1)# mac security profile test
switch(config-if-Et5/3/1)#
```

9.3.2.2.3 Configuring the FIPS mode

To configure the FIPS mode on the MACsec protocol, use the **FIPS** command.

Example

This command configures the FIPS mode on the MACsec protocol.

```
switch(config)# mac security
switch(config-mac-security) fips restrictions
```

9.3.2.2.4 Configuring the Layer 2 Protocol Processing Mode

To configure the Layer 2 (L2) Protocol Processing mode on the MACsec protocol, use the `l2-protocol` command.

Example

Use this command to configure the L2 Protocol Processing mode to bypass encryption and send traffic without protection.

```
switch(config)# mac security
switch(config-mac-security) l2-protocol ethernet-flow-control bypass
```

9.3.2.2.5 Configuring MACsec Profile on a Subinterface

Use the following commands to configure a MACsec profile on a subinterface.

Example

- The following example enables MAC security on a subinterface with a predefined MACsec profile **test-profile**.

```
switch(config)# interface ethernet1
switch(config-if-Et1)# no switchport
switch(config-if-Et1)# interface ethernet1.10
switch(config-if-Et1.10)# encapsulation dot1q vlan 20
switch(config-if-Et1.10)# mac security profile test-profile
```

9.3.2.2.6 Configuring MACsec Using Static SAK

Static SAK is configured separately for receive (Rx) and transmit (Tx) directions. In the Rx direction, multiple SAKs can be configured. For the Tx direction, only one SAK is allowed at a time. An SAK configured for Rx on the local peer should match the SAK configured for Tx on the connected peer and vice versa. Configure the Rx direction first on all the MACsec peers, then configure the Tx direction. Use the **cipher** command to select a cipher suite. You must choose an eXtended Packet Number (XPN) cipher suite, such as AES128-GCM-XPN or AES256-GCM-XPN. Static SAK will not work with a non-XPN cipher.

Examples

- These commands select the AES256-GCM-XPN cipher suite for the MACsec profile ***rx_test*** on the receiving peer (Rx).

```
switch(config)# mac security
switch(config-mac-security)# profile rx_test
switch(config-mac-security-profile-rx_test)# cipher aes128gcm-xpn
switch(config-mac-security-profile-rx_test)#
```

- This command configures the key source as static SAK.

```
switch(config-mac-security-profile-rx_test)# key source sak static
switch(config-mac-security-profile-rx_test-sak-static)#
```

- These commands configure a secure channel identifier (SCI) on the receiving peer. The SCI is a MAC address with six hexadecimal octets and a decimal port number.

```
switch(config-mac-security-profile-rx_test-sak-static)# secure channel rx
switch(config-mac-security-profile-rx_test-sak-static-rx)# identifier 01:02:03:04:05:06::1234
switch(config-mac-security-profile-rx_test-sak-static-rx)#
```

- This command configures an SAK and assigns it an association number (AN) of ***0***.

```
switch(config-mac-security-profile-rx_test-sak-static-rx)# an 0 key 0 1111222233334
4445555666677778888
switch(config-mac-security-profile-rx_test-sak-static-rx)#
```

- This command configures another SAK and its association number. Up to four associations can be configured.

```
switch(config-mac-security-profile-rx_test-sak-static-rx)# an 1 key 0 9999aaaabbbbc
ccddddeeeeffff0000
switch(config-mac-security-profile-rx_test-sak-static-rx)#
```

- These commands configure the secure channel on a transmitting peer using the profile ***tx_test***. Only one SAK can be configured per transmitting peer. This will encrypt traffic in the Tx direction, so the receiving peer must be configured with a matching SAK to decrypt this traffic.

```
switch(config-mac-security-profile-tx_test-sak-static)# secure channel tx
switch(config-mac-security-profile-tx_test-sak-static-tx)# identifier 01:02:03:04:05:07::1235
switch(config-mac-security-profile-tx_test-sak-static-tx)# an 0 key 0 2222333344445
5556666777788889999
switch(config-mac-security-profile-tx_test-sak-static-tx)#
```

9.3.2.2.7 Configuring MACsec Proxy For VXLAN

The switch platforms that use this feature are:

- 7280SRAM-48C6
- 7280CR2M-30
- 7500R2M-36CQ-LC

The mandatory steps to configure a MACsec proxy sub-interface on an Arista switch are:

1. Configure the parent interface to be a routed port.
2. Create a L3 sub-interface on the parent interface. This is the MACsec proxy sub-interface.
3. Create a L2 sub-interface on the parent interface. This is the MACsec patch sub-interface.
4. Configure and enable the MACsec proxy port on a sub-interface.
5. Configure the VXLAN tunnel.
6. Assign the forwarding VLAN ID for the MACsec patch sub-interface and VXLAN tunnel.

   Example Configurations

   a. Configure a ***100g*** MACsec interface as a routed port.

   ```
   switch(config)# interface et49/1
   switch(config-if-Et49/1)# no switchport
   ```

   b. Create a new L3 sub-interface - ***et49/1.1*****.**

   ```
   switch(config-if-Et49/1)# interface et49/1.1
   ```

   c. Create a new L2 sub-interface - ***et49/1.2***.

   ```
   switch(config-if-Et49/1)# interface et49/1.2
   ```

   d. Configure the MACsec proxy port, and enable MACsec on the proxy port.

   ```
   switch(config)# interface et49/1.1
   switch(config-if-Et49/1.1)# mac security proxy patch Ethernet49/1.2
   switch(config-if-Et49/1.1)# mac security profile test1
   switch(config-if-Et49/1.1)# ip address 2.2.2.1/24
   ```

   e. Configure the VXLAN tunnel. The remote VTEP is provided as the flood VTEP.

   ```
   switch(config)# interface VXLAN 1
   switch(config-if-Vx1)# VXLAN source-interface Loopback0
   switch(config-if-Vx1)# VXLAN udp-port 4789
   ```

```
switch(config-if-Vx1)# VXLAN vlan 20 vni 20
switch(config-if-Vx1)# VXLAN vlan 20 flood vtep 100.100.100.2
```

f. Configure the L2 MACsec patch interface to be in the same VLAN as VXLAN.

```
switch(config)# interface et49/1.2
switch(config-if-Et49/1.2)# vlan id 20
```

9.3.2.2.8 Configuring MAC Security Dynamic Key Derivation

9.3.2.2.8.1 802.1X Authenticator Configuration

A new option is added to the 802.1X authenticator configuration to make the authenticator stronger for unreliable authentication servers. By default, when an authentication server is unreachable, the authenticator blocks all traffic on the port and keeps the port as Unauthorized until it gets replies from the authentication server. The following option changes the behavior and maintains the port in its current state if the authentication server is not reachable:

Example

```
switch(config-if-Et1)# dot1x timeout reauth-timeout-ignore always
```

9.3.2.2.8.2 802.1X Supplicant Configuration

Configure 802.1X supplicant using MACsec profiles. The MACsec profile contains all the credentials necessary for 802.1X authentication to succeed. EAP-PWD provides an EAP method that uses a shared password for authentication and allows EOS devices to interoperate with systems that rely on EAP-PWD for deriving MACsec CAK/CKN from the EAP Master Session Key (MSK) and EAP Session ID.

Perform the following steps to configure an 802.1X supplicant profile:

1. Use **dot1x** command to enter the dot1x mode to configure a supplicant profile.

```
switch(config)# dot1x
switch(config-dot1x)#
```

2. Use **supplicant profile** command to configure a 802.1X supplicant profile.

```
switch(config)# supplicant profile <profileName>
```

3. The following mandatory commands must be configured for a supplicant profile to be operational:
   a. Configure the Extensible Authentication Protocol (EAP) method for the profile. EOS supports Fast and Password methods for 802.1X authentication.

```
switch(config-dot1x-supp-profile-test)# eap-method fast
```

b. Configure EAP Identity which is used to authenticate the supplicant with the Radius server:

```
switch(config-dot1x-supp-profile-test)# identity user-identity
```

c. Configure EAP pass-phrase used to authenticate the supplicant with the Radius server:

```
switch(config-dot1x-supp-profile-test)# passphrase options
```

d. Configure the EAP password-based authentication using a shared password:

```
switch(config-dot1x-supp-profile-test)# eap-method pwd
```

Example

This is an sample 802.1X supplicant profile:

```
switch(config-dot1x-supp-profile-test)# show active
dot1x
   supplicant profile test
      identity arista
      passphrase 7 070E334D5D1D0B04
```

This is an sample 802.1X supplicant profile with EAP password enabled:

```
switch(config-dot1x-supp-profile-test)# show active
dot1x
supplicant profile test
identity arista
eap-method pwd
```

Apply the supplicant profile by enabling it on the Mac Security interface:

```
switch(config-if-Et6/1)# dot1x pae supplicant test
```

Mac Security

Mac Security configuration remains the same as described in the configuration guide, but there is one important difference. Instead of configuring manual keys, configure the Mac security profile to use dynamic keys:

```
switch(config-mac-security-profile-test)# key source dot1x
```

9.3.2.2.8.3 Displaying 802.1X Supplicant Status

The **`show dot1x supplicant`** command displays the 802.1X supplicant status.

```
switch #show dot1x supplicant
Interface: Ethernet6/1
```

```
    Identity: arastra
    EAP method: fast
    Status: success
    Supplicant MAC: 44:4c:a8:34:bf:20
    Authenticator MAC: 00:1c:73:e0:d3:76
```

About the Output

- **`Interface`**: The port on which the supplicant is running.
- **`Identity`**: Configured supplicant identity.
- **`EAP method`**: Configured EAP method (Currently just EAP-FAST).
- **`Status`**: Supplicant Status. Can be one of the following:
  - Success Authentication has been successful.
  - Down Authentication sequence has not begun.
  - Failed Authentication has failed.
  - Connecting Authentication is in progress.
  - Unused Supplicant is uninitialized.
- **`Supplicant MAC`**: MAC address of the supplicant.
- **`Authenticator MAC`**: MAC address of the authenticator (peer).
- **`Existing Mac Security`**: Show commands can be used to look at Mac Security status.

9.3.2.2.9 Configuring MACsec Fallback to Unprotected Traffic

EOS supports this feature on all MACsec capable cards except the 7500E-6CFPX-LC.

The MACsec Fallback to Unprotected Traffic feature is configured under MACsec profile mode using the **`traffic unprotected allow`** command. The **no** form of the command removes the configuration from the switch. This configuration must be present in both the peers for the unprotected traffic to flow between them successfully.

Example

```
switch(config-mac-security-profile-sampleProfile)# no traffic unprotected allow
```

9.3.2.2.10 Configuring a Secure Channel Identifier for MACsec

Configure the Secure Channel Identifier (SCI) as part of a MACsec profile using the **`sci`** command. The **`no`** form of the command removes the configuration from the switch.

The **sci** command adds a Secure Channel Identifier (SCI) in data packets for MACsec on the switch. Each MACsec device has a Secure Channel (SC) used to send traffic to other device. Each channel has an 8-byte Secure Channel Identifier (SCI). The first 6 bytes match the MAC address of the device transmitting through that channel. The remaining 2 bytes are a Port Identifier used to distinguish between multiple channels from the same device.

Use the following commands to add an SCI to the MACsec profile *Macsec_office*:

```
switch(config)# mac security
switch(config-mac-security)# profile Macsec_office
switch(config-mac-security-profile-Macsec_office)# sci
switch(config-mac-security-profile-Macsec_office)#
```

9.3.2.3 Displaying MACsec Information

The following sections provide information about MACsec on a switch.

This section contains the following topics:

- Displaying MACsec Information
- Displaying MACsec Detailed Information
- Displaying MACsec Participants
- Displaying MACsec Participants Detailed Information
- Displaying MACsec MKA Counters
- Displaying MACsec Security Counters Detailed Information
- Displaying MACsec Security Counters
- Displaying MACsec MKA Counters Detailed Information
- Displaying MACsec FIPS Status
- Displaying Information for MACsec Using Static Secure Association Key

9.3.2.3.1 Displaying MACsec Information

The **show mac security interface** command shows information about the MACsec on the interface.

Example

```
switch# show mac security interface
Interface SCI Controlled Port Key in Use
Ethernet4/1/1 28:99:3a:82:6f:82::605 True 9d5bc0d3076ea4a08b99b9d9:1
Ethernet4/3/1 28:99:3a:82:6f:85::613 True 9d5bc0d3076ea4a08b99b9d9:1
```

9.3.2.3.2 Displaying MACsec Detailed Information

Use the **`show mac security interface detail`** command to display detailed information about MACsec.

Example

```
switch# show mac security interface detail
Interface: Ethernet4/1/1
    SCI: 28:99:3a:82:6f:82::605
    SSCI: 00000002
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Protected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)

Interface: Ethernet4/3/1
    SCI: 28:99:3a:82:6f:85::613
    SSCI: 00000001
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Protected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)
```

About the Output:

- **`Interface`**: Name of the interface.
- **`Secure Channel Identifier (SCI)`**: Combination of MAC address and port number. Used to uniquely identify a Mac Security port.
- **`Controlled Port`**: Indicates if Mac Security is enabled on the port. A value of True indicates that encryption is enabled on the port.
- **`Key In Use`**: The SAK identifier currently in use. Combination of Key Servers message identifier (see below) and key number.
- **`Key Server Priority`**: Configured key server priority.
- **`Session Rekey Period`**: Configured session rekey period.
- **`Latest Key`**: Latest SAK being negotiated by Mac Security Key Agreement Protocol (MKA)
- **`Old Key`**: The last SAK negotiated by Mac Security Key Agreement Protocol (MKA)

Note: Latest and Old key are MKA protocol specific terminology and are used to refer to the last two keys in use. For all practical purposes, Key In Use field is used to identify the current key.

9.3.2.3.3 Displaying MACsec Participants

Use the **show mac security participants** command to display information about the MACsec participants.

Example

```
switch# show mac security participants
Interface: Ethernet4/1/1
    CKN: abcd
      Message ID: 9d5bc0d3076ea4a08b99b9d9
      Elected self: True
      Success: True
      Principal: True
      Default: False

    CKN: dead
      Message ID: 4ef4cf009161bd551b5e7434
      Elected self: True
      Success: True
      Principal: False
      Default: True

Interface: Ethernet4/3/1
    CKN: abcd
      Message ID: c79ad8882c2dd3a8e838a691
      Elected self: False
      Success: True
      Principal: True
      Default: False

    CKN: dead
      Message ID: 3dfd4486b5f68a81014a37ec
      Elected self: False
      Success: True
      Principal: False
      Default: True
```

9.3.2.3.4 Displaying MACsec Participants Detailed Information

Use the **show mac security participants detail** command to display detailed information about the MACsec participants.

Example

```
switch# show mac security participants detail
Interface: Ethernet4/1/1
    CKN: abcd
      Message ID: 9d5bc0d3076ea4a08b99b9d9
      Elected self: True
      Success: True
      Principal: True
      Default: False
      KeyServer SCI: 28:99:3a:82:6f:82::605
      SAK transmit: True
```

```
      LLPN exhaustion: 0
      Distributed key identifier: 9d5bc0d3076ea4a08b99b9d9:1
      Live peer list: ['c79ad8882c2dd3a8e838a691']
      Potential peer list: []

    CKN: dead
      Message ID: 4ef4cf009161bd551b5e7434
      Elected self: True
      Success: True
      Principal: False
      Default: True
      KeyServer SCI: 28:99:3a:82:6f:82::605
      SAK transmit: False
      LLPN exhaustion: 0
      Distributed key identifier: None
      Live peer list: ['3dfd4486b5f68a81014a37ec']
      Potential peer list: []

Interface: Ethernet4/3/1
    CKN: abcd
      Message ID: c79ad8882c2dd3a8e838a691
      Elected self: False
      Success: True
      Principal: True
      Default: False
      KeyServer SCI: 28:99:3a:82:6f:82::605
      SAK transmit: True
      LLPN exhaustion: 0
      Distributed key identifier: 9d5bc0d3076ea4a08b99b9d9:1
      Live peer list: ['9d5bc0d3076ea4a08b99b9d9']
      Potential peer list: []

    CKN: dead
      Message ID: 3dfd4486b5f68a81014a37ec
      Elected self: False
      Success: True
      Principal: False
      Default: True
      KeyServer SCI: 28:99:3a:82:6f:82::605
      SAK transmit: False
      LLPN exhaustion: 0
      Distributed key identifier: None
      Live peer list: ['4ef4cf009161bd551b5e7434']
      Potential peer list:
```

About the Output

- **`Connectivity Association Key Name (CKN)`**: Configured name of the key in use.
- **`Message ID`**: A random 92 bit string used as an identifier for an MKA participant.
- **`Elected Self`**: True if this participant is the elected key server.
- **`Success`**: True if this participant is live and has at least one live peer.
- **`Principal`**: True if this participant is the principal participant elected to distribute SAKs or if participant receives SAKs from key server.
- **`Default`**: True if this participant is a fallback/backup participant (spawned when a fallback key is configured in a Mac Security profile).
- **`Key Server SCI`**: The SCI of the key server.
- **`SAK Transmit`**: True if the participant is ready to use the negotiated key for transmit.

- **`LLPN Exhaustion`**: Increments if the number of data packets sent using the current key exceeds a certain threshold.
- **`Distributed Key Identifier`**: Message ID + key number of the most recently generated SAK.
- **`Live Peer List`**: Message IDs of all the live peers of the participant.
- **`Potential Peer List`**: Message IDs of all the potential peers of the participant. These are peers which have not yet established mutual liveness but have sent out at least one control packet.

9.3.2.3.5 Displaying MACsec MKA Counters

Use the **`show mac security mka counters`** command to display information about the MACsec MKA counters.

Example

```
switch# show mac security mka counters
Interface       Rx Success      Rx Failure      Tx Success      Tx Failure
Ethernet4/1/1   287             0               288             0
Ethernet4/3/1   288             0               287             0
```

9.3.2.3.6 Displaying MACsec Security Counters Detailed Information

Use the **`show mac security counters detail`** command to display detailed information about the MACsec security counters.

Example

```
switch# show mac security counters detail
Ethernet4/1/1     Counter Name        Count
-------------------------------------------------------
                  outPktsEncrypted    112
                  outOctetsEncrypted  11984
                  outPktsUntagged     0
                  outPktsTooLong      0
                  outPktCtrl          224
                  inPktsDecrypted     2
                  inOctetsDecrypted   214
                  inPktsUnchecked     0
                  inPktsOK            2
                  inPktsNotValid      0
                  inPktsNotUsingSA    0
                  inPktsCtrl          223
                  inPktsNoTag         8

                    inPktsNoSCI         0
                    inPktsLate          0
```

9.3.2.3.7 Displaying MACsec Security Counters

Use the **`show mac security counters`** command to display information about the MACsec security counters.

Example

```
switch# show mac security counters
Port     InPktsDecrypted  InOctetsDecrypted  OutPktsEncrypted OutOctetsEncrypted
Et4/1/1                2                214               109              11663
Et4/3/1              109              11663                 2                214
```

9.3.2.3.8 Displaying MACsec MKA Counters Detailed Information

Use the **`show mac security mka counters detail`** command to display detailed information about the MACsec MKA counters.

Example

```
switch# show mac security mka counters detail
Interface: Ethernet4/1/1
    Tx packet success: 290
    Tx packet failure: 0
        Tx invalid: 0
    Rx packet success: 289
    Rx packet failure: 0
        Rx invalid: 0
        Rx eapol error: 0
        Rx basic parameter set error: 0
        Rx unrecognized CKN error: 0
        Rx ICV validation error: 0
        Rx live peer list error: 0
        Rx potential peer list error: 0
        Rx SAK use set error: 0
        Rx distributed SAK set error: 0
        Rx distributed CAK set error: 0
        Rx ICV Indicator error: 0
        Rx unrecognized parameter set error: 0

Interface: Ethernet4/3/1
    Tx packet success: 289
    Tx packet failure: 0
```

```
        Tx invalid: 0
    Rx packet success: 290
    Rx packet failure: 0
        Rx invalid: 0
        Rx eapol error: 0
        Rx basic parameter set error: 0
        Rx unrecognized CKN error: 0
        Rx ICV validation error: 0
        Rx live peer list error: 0
        Rx potential peer list error: 0
        Rx SAK use set error: 0
        Rx distributed SAK set error: 0
        Rx distributed CAK set error: 0
        Rx ICV Indicator error: 0
        Rx unrecognized parameter set error: 0
```

9.3.2.3.9 Displaying MACsec FIPS Status

Use the **show mac sec status** command to display information about the MACsec FIPS status.

Example

```
switch(config)# mac security
switch(config-mac-security)# show mac sec status
Active Profiles:          1
FIPS Mode:                Yes
Secured Interfaces:       2
```

9.3.2.3.10 Displaying Information for MACsec Using Static Secure Association Key

If MACsec is configured to use static SAKs, these commands will show additional information related to static SAKs:

- **show active**

  In MAC Security configuration mode, the **show active** command displays the MAC security key source. If one or more static SAKs are configured, this key source will be shown as "key source sak static."

- **show mac security interface**

  With a static SAK configured, the **show mac security interface** command shows the association numbers for SAKs which are programmed for Rx and Tx. **Show** commands never display actual SAK values.

  If a unidirectional link is configured with a static SAK, the Rx side will show the SCI as "00:00:00:00:00:00::0," and only the Rx AN will be shown. On the Tx side, the configured SCI and Tx AN will be shown.

- **show mac security sak**

  If one or more SAKs are configured in the switch, the **show mac security sak** command will show SAK-related details.

9.3.2.4 MACsec Key Retirement Immediate

The MACsec configures two keys for MKA negotiation: Primary and Fallback (as a backup). For a given MAC security profile configured on an interface, an actor is created per key and is responsible for MKA negotiation with the other peer. After configuring a new primary key, the old primary key actor is retained in the system until the MKA session succeeds with the configured new primary key. The same holds for the fallback key. Using the **`key retirement immediate`** command immediately removes the actor corresponding to the old key, be it primary or fallback, from the system.

MACsec Key Retirement Immediate Operations

- After configuring a new primary key in a MAC security profile, the old primary key actor is deleted from the system immediately.
- After configuring a new fallback key in a MAC security profile, the old fallback key actor is deleted from the system immediately.
- Removing the feature configuration from the MAC security profile will only prevent cleaning up old keys immediately when configuring new keys. It will not create old actors again.

Note: The **`key retirement immediate`** command only deletes the actor corresponding to the old key. It only cleans up the SAK programmed in the hardware after a new SAK is available to be programmed. However, as a side effect of deleting an actor, the system chooses a new principal actor (if an eligible actor is available), over which a new SAK will be distributed.

MACsec Key Retirement Immediate Feature Interactions

MACsec EAP-FAST Support

When using Dynamic MAC Security keys with **key retirement immediate**, then with every new primary key derived from 802.1X, the system deletes the old primary key actor. This action usually happens based on the reauth time interval configuration for 802.1X.

MACsec Fallback to Unprotected Traffic Support

The **key retirement immediate** is configured with the Fallback to Unprotected Traffic feature, and the transition between unprotected and protected traffic may become more frequent. This is because with the Key Retirement Immediate feature, whenever a new key is configured, existing successful MKA sessions corresponding to the old key are not maintained, which might bring down the number of successful MKA sessions to zero, eventually moving the interface to an unprotected traffic state as per the Fallback to Unprotected Traffic feature functionality.

9.3.2.4.1 MACsec Key Retirement Immediate Configuration

The **`show dot1x supplicant`** command is configured in the **mac security profile mode**. The configuration must be present on both key server and non-key server peers. Since the key server decides the principal actor for SAK distribution, it is recommended that this configuration be present in the key server to trigger the re-election of the principal actor immediately.

If **key retirement immediate** is configured only on the key server, the non-key server will still try to negotiate MKA over the old primary key, unnecessarily utilizing some system resources and some time even when not required.

If **key retirement immediate** is configured only on the non-key server, it will take ***6*** seconds (MKA Lifetime) to trigger any re-election on the key server due to session failure.

```
switch(config-mac-security-profile-sampleProfile)# [no] key retirement immediate
```

Configuration Scenarios

Configuring both Primary Key and Fallback Key without configuring **key retirement immediate**: When configuring a new primary, the actor corresponding to the old actor stays active until the MKA session succeeds on the new primary. With **key retirement immediate**, the system immediately deletes the actor corresponding to the old primary. Since Fallback is also configured, the key server will choose it as the new principal actor if it is eligible. After choosing a new principal actor, a new SAK is distributed, which will eventually be programmed and used for encryption and decryption.

When only the Primary Key is configured, the behavior is the same as described earlier, except no other actor will become principal until the new primary becomes successful. Until then, hardware will continue to use SAK generated with the old primary.

When the Fallback is a Principal actor and configured without **immediate key retirement**, when configuring a new fallback key, the old Fallback will stay in the system until the new Fallback becomes active or the primary becomes active. With **immediate key retirement**, the system deletes the fallback actor immediately. Until a new principal actor is elected, hardware will continue to use SAK generated with the old Fallback.

The **`show mac security participants`** command shows all the participants present in the system. When **key retirement immediate** is configured, the actor corresponding to old keys will no longer appear in the command output.

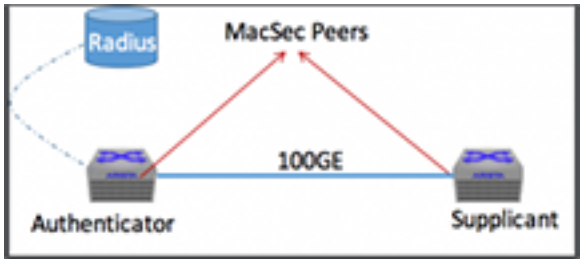
9.3.2.5 MACsec EAP-FAST Support

The Media Access Control Security (MACsec) with static keys feature supports dynamic Mac Security keys. Configure both peers for 802.1X authentication to derive Mac Security keys dynamically. Configure one peer as the Authenticator and the other peer as the Supplicant.

Upon a successful 802.1X authentication sequence between the peers, both the Authenticator and the Supplicant generate keying material. This keying material is then used to derive Mac Security keys to establish a MACsec Key Agreement (MKA) protocol session. This feature supports Arista devices acting as the Supplicant to derive Mac Security keys bidirectionally.

The following diagram illustrates a typical Mac Security over 802.1X topology:

Figure 9-11: MAC Security Topology



9.3.2.6 MACsec Proxy For VXLAN

The MACsec Proxy for VXLAN feature enables the MACsec service over VXLAN. MACsec over VXLAN is provided by mapping a Visual Networking Index (VNI), Remote VXLAN Tunnel Endpoint (VTEP) IP to a MACsec proxy subinterface.

Any packets routed to the MACsec proxy subinterface are encrypted and tunneled to the remote VTEP. On the receiving path, the packets are decrypted, then decapsulated, and forwarded. MKA negotiates and renews the encryption keys. For this purpose, a MACsec-capable front panel port has to be dedicated and cannot be plugged in, as it will be used to recycle packets being encrypted and decrypted.

9.3.2.6.1 Configuring MACsec Proxy For VXLAN

The switch platforms that use this feature are:

- 7280SRAM-48C6
- 7280CR2M-30
- 7500R2M-36CQ-LC

The mandatory steps to configure a MACsec proxy sub-interface on an Arista switch are:

1. Configure the parent interface to be a routed port.
2. Create a L3 sub-interface on the parent interface. This is the MACsec proxy sub-interface.
3. Create a L2 sub-interface on the parent interface. This is the MACsec patch sub-interface.
4. Configure and enable the MACsec proxy port on a sub-interface.
5. Configure the VXLAN tunnel.
6. Assign the forwarding VLAN ID for the MACsec patch sub-interface and VXLAN tunnel.

Example Configurations

a. Configure a ***100g*** MACsec interface as a routed port.

```
switch(config)# interface et49/1
switch(config-if-Et49/1)# no switchport
```

b. Create a new L3 sub-interface - ***et49/1.1*.**

```
switch(config-if-Et49/1)# interface et49/1.1
```

c. Create a new L2 sub-interface - ***et49/1.2***.

```
switch(config-if-Et49/1)# interface et49/1.2
```

d. Configure the MACsec proxy port, and enable MACsec on the proxy port.

```
switch(config)# interface et49/1.1
switch(config-if-Et49/1.1)# mac security proxy patch Ethernet49/1.2
switch(config-if-Et49/1.1)# mac security profile test1
switch(config-if-Et49/1.1)# ip address 2.2.2.1/24
```

e. Configure the VXLAN tunnel. The remote VTEP is provided as the flood VTEP.

```
switch(config)# interface VXLAN 1
switch(config-if-Vx1)# VXLAN source-interface Loopback0
switch(config-if-Vx1)# VXLAN udp-port 4789
switch(config-if-Vx1)# VXLAN vlan 20 vni 20
switch(config-if-Vx1)# VXLAN vlan 20 flood vtep 100.100.100.2
```

f. Configure the L2 MACsec patch interface to be in the same VLAN as VXLAN.

```
switch(config)# interface et49/1.2
switch(config-if-Et49/1.2)# vlan id 20
```

9.3.2.6.2 Displaying MACsec Proxy For VXLAN Information

Use **`show mac security interface`** command to display the proxy sub-interface information.

Examples

- Use **`show mac security mka counters`** command to display the MACsec counters and detailed values.

```
switch(config)# show mac security interface
Interface     SCI                     Controlled Port  Key in Use
Ethernet4/1/1 28:99:3a:82:6f:82::605  True             9d5bc0d3076ea4a08b99b9d9:1
Ethernet4/3/1 28:99:3a:82:6f:85::613  True             9d5bc0d3076ea4a08b99b9d9:1
```

-

```
switch(config)# show mac security mka counters
Interface      Rx Success  Rx Failure  Tx Success   Tx Failure
Ethernet4/1/1  287         0            288          0
Ethernet4/3/1  288         0            287          0

switch(config)# show mac security mka counters ethernet 49/1.1 detail
Interface: Ethernet49/1.1
    Tx packet success: 84
    Tx packet failure: 0
```

```
        Tx invalid: 0
    Rx packet success: 82
    Rx packet failure: 0
        Rx invalid: 0
        Rx eapol error: 0
        Rx basic parameter set error: 0
        Rx unrecognized CKN error: 0
        Rx ICV validation error: 0
        Rx live peer list error: 0
        Rx potential peer list error: 0
        Rx SAK use set error: 0
        Rx distributed SAK set error: 0
        Rx distributed CAK set error: 0
        Rx ICV Indicator error: 0
        Rx unrecognized parameter set error: 0
```

9.3.2.6.3 Limitations

The following limitations may apply when using this feature:

- An interface that switches from allowing unprotected traffic to allowing only protected traffic can experience a traffic disruption of up to ***4*** seconds.
- If the key server interface manages to establish an MKA session with its old credentials (CKN/CAK pair) while allowing unprotected traffic, a traffic disruption lasting up to ***6*** seconds may occur in addition to the duration mentioned earlier.

9.3.2.7 MACsec Fallback to Unprotected Traffic

When MACsec is enabled on an interface, it tries to establish MACsec Key Agreement (MKA) session(s) with its peer. If there are no successfully established MKA sessions, the interface can continue to protect the traffic with the last known negotiated key, and if such a key does not exist, it blocks the traffic. The MACsec Fallback to Unprotected Traffic feature introduces an optional configuration which, if provided, allows unprotected traffic whenever there is no successful MKA session with the peer in the following scenarios:

- If MACsec is enabled on an interface with this feature configured, the interface allows unprotected traffic immediately without waiting for the establishment of an MKA session.
- If a MACsec-enabled interface was blocking traffic because no MKA sessions were established, and its corresponding MACsec profile is changed to enable this feature, the interface will start allowing unprotected traffic immediately.
- If a MACsec-enabled interface previously allowed unprotected traffic and its corresponding MACsec profile is changed to disable this feature, the interface will block traffic immediately.
- While an interface is allowing unprotected traffic, it will stop doing so when a new Secure Association Key (SAK) is generated (if this interface is the key server) or when a SAK is received from the key server (if this interface is not the key server).
- If MACsec Fallback to Unprotected Traffic is configured and all MKA sessions between the peers fail, the peers will switch to unprotected traffic. If not configured, protected traffic could have continued with the last known negotiated key.

Primary MKA session-derived keys are prioritized over fallback MKA sessions to protect traffic between pairs. With this feature enabled, the priority order of traffic between peers is:

1. Protected using derived keys from primary MKA sessions.
2. Protected using derived keys from Fallback MKA sessions.
3. Unprotected traffic.

Note: Arista allows the configuration of a primary and a Fallback Connectivity Association Key (CAK) and Connectivity Association Key Name (CKN) pair on an interface. The interface attempts to establish an MKA session with its peer corresponding to each CAK/CKN pair.

9.3.2.7.1 MACsec Fallback to Unprotected Traffic Feature Interaction

This feature interacts with other related features in the following way:

- **MACsec EAP-FAST Support**: The feature configuration has no effect if using dynamic MAC Security keys (derived from 802.1X authentication).
- **MACsec Proxy Interfaces**: This feature does not work with MACsec proxy subinterfaces.
- **Key Retirement Immediate**: When configuring this feature with the **Key Retirement Immediate** feature on an interface, the transition between unprotected and protected traffic may become more frequent. This is because with the **Key Retirement Immediate** feature, the existing successful MKA session corresponding to the old key is not maintained whenever a new key is configured.

9.3.2.7.2 Limitations

The following limitations may apply when using this feature:

- An interface that switches from allowing unprotected traffic to allowing only protected traffic can experience a traffic disruption of up to ***4*** seconds.
- If the key server interface manages to establish an MKA session with its old credentials (CKN/CAK pair) while allowing unprotected traffic, a traffic disruption lasting up to ***6*** seconds may occur in addition to the duration mentioned earlier.

9.3.2.7.3 Configuring MACsec Fallback to Unprotected Traffic

EOS supports this feature on all MACsec capable cards except the 7500E-6CFPX-LC.

The MACsec Fallback to Unprotected Traffic feature is configured under MACsec profile mode using the **`traffic unprotected allow`** command. The **no** form of the command removes the configuration from

the switch. This configuration must be present in both the peers for the unprotected traffic to flow between them successfully.

Example

```
switch(config-mac-security-profile-sampleProfile)# no traffic unprotected allow
```

9.3.2.7.4 Displaying MACsec Fallback to Unprotected Traffic Information

The **`show mac security interface detail`** command can be used to verify if the interface is currently allowing unprotected traffic.

```
switch# show mac security interface Ethernet 6/1/1 detail
Interface: Ethernet4/1/1
    SCI: 28:99:3a:82:6f:82::605
    SSCI: 00000002
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Unprotected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)

Interface: Ethernet4/3/1
    SCI: 28:99:3a:82:6f:85::613
    SSCI: 00000001
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Protected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)
```

9.3.2.8 MACsec Commands

MACsec Configuration Commands

- an (MACsec)
- cipher
- entropy source hardware
- identifier (MACsec)
- key (MACsec)
- key retirement immediate
- l2-protocol
- license (Global Mode)

- license (MACsec)
- mac security
- mka key-server
- mka session
- profile (MACsec)
- replay
- sci
- secure channel (MACsec)
- traffic unprotected allow

MACsec Profile on a Subinterface

- mac security profile

MACsec Show Commands

- show mac security counters
- show mac security counters detail
- show mac security interface
- show mac security interface detail
- show mac security mka counters
- show mac security participants
- show mac security participants detail
- show mac security profile
- show mac security sak
- show mac security status

MACsec EAP FAST Support Commands

- dot1x
- dot1x pae supplicant
- dot1x timeout reauth-timeout-ignore always
- show dot1x supplicant
- supplicant profile

9.3.2.8.1 an (MACsec)

The **an** command defines an Association Number (AN) and a Secure Association Key (SAK) for use in the selected channel in MACsec. Up to 4 SAKs can be configured in the Rx direction, with ANs ranging from 0 to 3. The Tx channel can only have one AN and one SAK. The **no an** and **default an** commands remove the specified AN and its SAK from ***running-config***.

Command Mode

MAC Security Profile SAK Static Secure Channel Configuration

Command Syntax

`an` *an_number* **key** *key_type key_string*

`no an` *an_number*

`default an` *an_number*

Parameters

- ***an_number*** The Association Number. For the Rx channel, values range from 0 to 3. For the Tx channel, the only allowed value is 0. There is no default value.
- ***key_type*** The type of string specifying the SAK. There are three valid key types:
  - **0** indicates that the key string which follows is not encrypted.
  - **7** indicates that the key string which follows is hidden or obfuscated.
  - **8a** The following key is encrypted with AES-256-GCM.
- ***key_string*** The Secure Association Key itself, in hexadecimal octets.

Example

These commands add a static SAK with ***AN 1*** to the Rx channel for profile ***test***.

```
switch(config)# mac security
switch(config-mac-security)# profile test
switch(config-mac-security-profile-test)# key source sak static
switch(config-mac-security-profile-test-sak-static)# secure channel rx
switch(config-mac-security-profile-test-sak-static-rx)# an 1 key 0 111122223333444455556666778888
switch(config-mac-security-profile-test-sak-static-rx)#
```

9.3.2.8.2 cipher

The **cipher** command configures the cipher authentication for MAC security on the switch.

Command Mode

MACsec Profile

Command Syntax

`cipher` *encryption_standard*

Parameters

encryption_standard The cipher authentication options.

- **aes128-gcm-xpn** Advanced Encryption Standard (128-bit, Galois/Counter mode, Extended Packet Numbering).
- **aes256-gcm-xpn** Advanced Encryption Standard (256-bit, Galois/Counter mode, Extended Packet Numbering).

Example

The following command configures the **cipher aes128-gcm-xpn** for MAC security on the switch for the MACsec profile called test.

```
switch(config-mac-security-profile-test)# cipher aes128-gcm-xpn
switch(config-mac-security-profile-test)#
```

9.3.2.8.3 dot1x pae supplicant

The **`dot1x pae supplicant`** command applies the supplicant profile by enabling it on the Mac Security interface.

Command Mode

Interface Configuration

Command Syntax

```
dot1x pae supplicant
```

Example

The following command applies the supplicant profile test on the ***MACsec interface 6/1***.

```
switch(config-if-Et6/1)# dot1x pae supplicant test
```

9.3.2.8.4 dot1x timeout reauth-timeout-ignore always

The **dot1x timeout reauth-timeout-ignore always** command retains the current port state without blocking it, irrespective of when the authentication server is unreachable or in case of supplicant timeouts.

Command Mode

Interface Configuration

Command Syntax

```
dot1x timeout reauth-timeout-ignore always
```

Example

The following command retains the port status of ***interface Ethernet 6/1*** when there is an authentication server timeout.

```
switch(config-if-Et6/1)# dot1x timeout reauth-timeout-ignore always
```

9.3.2.8.5 dot1x

The **dot1x** command places the switch in the dot1x mode. In this mode, the user is allowed to configure various MACsec configurations.

Command Mode

Global Configuration

Command Syntax

```
dot1x
```

Example

The following command places the switch in the ***dot1x*** mode.

```
switch(config)# dot1x
switch(config-dot1x)#
```

9.3.2.8.6 eapol

In Arista EOS, Media Access Control Security (MACsec, IEEE 802.1AE) uses the **MACsec Key Agreement (MKA)** protocol to discover peers, negotiate security keys, and manage live sessions. EOS encapsulates MKA protocol data units (MKPDUs) inside **EAPoL (Extensible Authentication Protocol over LAN)** frames.

By default, EOS sends the EAPoL frames using the standard IEEE 802.1X link-local multicast MAC address (`0180.c200.0003`). However, in WAN MACsec scenarios, such as deploying MACsec over provider-managed Metro Ethernet, E-Line, or dark fiber networks, intermediate carrier devices often intercept, process, or entirely drop well-known link-local multicast addresses.

The **`eapol destination-mac`** command in the MAC Security Configuration Mode allows you to alter the destination MAC address of these protocol frames. By shifting to a non-reserved multicast address, a custom provider-assigned address, or a broadcast address, the EAPoL frames can pass transparently across the service provider infrastructure to reach the remote MACsec peer.

The **`[no | default]`** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

MAC Security Configuration

Command Syntax

`eapol mac destination` ***mac_address***

`no eapol mac destination`

`default eapol mac destination`

Parameters

- **`eapol`** - Specify EAPoL attributes.
- **`mac`** - Specify using MAC addresses.
- **`destination`** ***mac_address*** - Specify a destination MAC address in standard dotted-hexadecimal notation..

Example

Use the following commands to set the EAPoL destination MAC address to a multicast MAC address, :

```
switch(config)# mac security
switch(config-mac-sec)# eapol mac destination 0100.0ccc.ccfd
switch(config-mac-sec)#
```

9.3.2.8.7 entropy source hardware

The **`entropy source hardware`** command generates the cryptographic keys to strengthen the random number generator used by MACsec.

Command Mode

Management Configuration

Command Syntax

```
entropy source hardware
```

Example

The following command configures the entropy source hardware and generates the cryptographic keys.

```
switch(config)# management security
switch(config-mgmt-security)# entropy source hardware
```

9.3.2.8.8 fips restrictions

In Arista EOS, Federal Information Processing Standards (**FIPS**) mode dictates the cryptographic boundaries used to secure the system. When dealing with **MACsec (Media Access Control Security)**, enabling FIPS mode forces the MACsec Key Agreement (MKA) protocol and data plane encryption to adhere strictly to FIPS-approved cryptographic algorithms and key strengths.

The `fips restrictions` command within the MAC Security Configuration Mode enforces these rigorous security policies. When enabling FIPS mode for MACsec, the following conditions apply to the configuration:

- Disables non-compliant cryptographic algorithms such as legacy hashes or cipher suites.
- Ensures the utilization of only FIPS-compliant functions such as AES-GCM-128 or AES-GCM-256 for key generation, integrity checks, and payload encryption.
- Applies federal compliance requirements for system logging and self-tests.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

MAC Security Configuration

Command Syntax

```
fips restrictions

no fips restrictions>
```

Parameters

- **fips** - Specify FIPS settings for MAC Security.
- **restrictions - Apply FIPS restrictions to the switch.**

Example

Use the following commands to apply FIPS restrictions to the switch:

```
switch(config)# mac security
switch(config-mac-security)# fips restrictions
switch(config-mac-security)#
```

9.3.2.8.9 identifier (MACsec)

The **identifier** command defines a Secure Channel Identifier (SCI) for the Rx or Tx secure channel for use with MACsec static Secure Association Keys (SAKs). The SCI is a MAC address in the format H:H:H:H:H:H::P, where H is a hexadecimal octet and P is a decimal integer. The **no identifier** and **default identifier** commands remove the channel's SCI from ***running-config***.

Command Mode

MAC Security Profile SAK Static Secure Channel Configuration

Command Syntax

`identifier` *MAC_address*

`no identifier`

`default identifier`

Parameter

MAC_address The MAC address identifying the secure channel.

Example

These commands add the SCI 01:02:03:04:05:06::1234 to the Rx channel for profile "test."

```
switch(config)# mac security
switch(config-mac-security)# profile test
switch(config-mac-security-profile-test)# key source sak static
switch(config-mac-security-profile-test-sak-static)# secure channel rx
switch(config-mac-security-profile-test-sak-static-rx)# identifier 01:02:03:04:05:06::1234
switch(config-mac-security-profile-test-sak-static-rx)#
```

9.3.2.8.10 key (MACsec)

The **key** command configures the primary key to activate the MACsec profile

Note: Optionally a fallback CAK can also be configured on a profile. This CAK is picked up by MACsec to negotiate keys if the primary CAK fails. A CAK can be configured as a backup key using the fallback keyword with the key command.

Command Mode

MACsec Profile Configuration

Command Syntax

key <options>

Parameters

- **CKN** Connectivity association key name in hex octets. Options include:
  - ***0*** Specifies that an UNENCRYPTED key will follow.
  - ***7*** Specifies that an HIDDEN key will follow.
  - **CAK** Connectivity association key in hex octets.
  - **fallback** Configure the key as a fallback.
- **retirement** Retire the key. Options include:
  - **immediate** Retire the key immediately.
- **source** List of sources to derive MAC security keys. Options include:
  - **dot1xDerive** MAC security keys from IEEE 802.1X-based port authentication
  - **group-cak** Derive MAC security keys from Group CAK Distribution.
  - **sak static** Enter

Examples

- The following example configures the primary key for the sample profile for MAC security on the switch.

```
switch(config)# mac security
switch(config-mac-security)# profile sample_Profile
switch(config-mac-security-profile-sample_Profile)# key 0abcd1 0 1234abcd
```

- The following example configures the fallback CAK on a profile.

```
switch(config)# mac security
switch(config-mac-security)# profile sample_Profile
switch(config-mac-security-profile-sample_Profile)# key 0abcd1 0 1234abcd fallback
```

9.3.2.8.11 key retirement immediate

The **`key retirement immediate`** command configures the key retirement feature on the key server and assists the key server to decide the principal actor for SAK distribution by triggering the re-election of principal actor immediately. It is recommended that the key retirement is configured on both key server and non key server peers.

The **`no key retirement immediate`** command disable the key retirement function by removing the key retirement immediate command from the ***running-config***.

Command Mode

MACsec Profile

Command Syntax

```
key retirement immediate
```

Example

The following commands configures the key retirement immediate feature on a switch for a MACsec profile called ***sample***.

```
switch(config)# mac security
switch(config-mac-security)# profile sample
switch(config-mac-security-profile-sample)# key retirement immediate
```

9.3.2.8.12 license (Global Mode)

The **`license`** command configures EOS licenses on the switch under the global configuration mode. These licenses include the MACsec license.

Note: Contact your system engineer to acquire the required license codes before attempting to configure MACsec.

Command Mode

Global Configuration

Command Syntax

`license` [[**import** *URL*] | **update**]

Parameters

- **import** Import license from a URL.
  - ***URL*** The URL from which to import a license.
- **update** Trigger a check for licenses.

Example

The following example configures the MACsec license on the switch using a JSON file as shown.

```
switch# license import flash:EOSLic-1.json
switch#
```

9.3.2.8.13 license (MACsec)

The **`license`** command configures the MACsec license on the switch under the MAC Security configuration mode using a hex key.

The **`no license`** and **`default license`** commands delete the current license from ***running-config***.

Note: This method of license configuration is no longer being used except for backward compatibility.

Command Mode

MAC Security

Command Syntax

`license` *licensee_name license_value*

Parameters

- ***licensee_name*** Name of the licensee.
- ***license_value*** 8 digit hexadecimal key to authorize MAC security.

Example

The following example configures the MACsec license on the switch using an 8 digit hexadecimal key.

```
switch(config)# mac security
switch(config-mac-security)# license Test-LICNC AABBCCDD
switch(config-mac-security)#
```

9.3.2.8.14 l2-protocol

The command **`l2-protocol`** configures the Layer 2 protocol processing for MACsec. The **`no l2-protocol`** and the **`default l2-protocol`** remove the command from the configuration.

Command Mode

MAC Security Configuration

Command Syntax

`l2-protocol` ethernet-flow-control [bypass | encrypt]

`no l2-protocol` ethernet-flow-control [bypass | encrypt]

`default l2-protocol` ethernet-flow-control [bypass | encrypt]

Parameters

- **`ethernet-flow-control`** - Configures Ethernet Flow Control frame processing for MAC security.
  - **`bypass`** - Transmit frames without processing them.
  - **`encrypt`** - Transmit and receive frames with protection.

Example

The following example configures MAC security with L2 protocol and Ethernet Flow Control bypassing frame protection:

```
switch(config)# mac-security
switch(config-mac-security)# l2 protocol ethernet-flow-control bypass
```

9.3.2.8.15 mac security

The **`mac security`** command enables MAC security provision on the switch.

The **`no mac security`** and **`default mac security`** commands restore the switch to its default state by removing the corresponding mac security command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
mac security

no mac security

default mac security
```

Example

The following command places the switch in MAC security mode.

```
switch(config)# mac security
switch(config-mac-security)#
```

9.3.2.8.16 mac security profile

The **`mac security profile`** command applies a MACsec profile to an interface or subinterface.

The **`no mac security profile`** and **`default mac security profile`** commands remove the MACsec profile, disabling MACsec on the configuration-mode interface.

Command Mode

Interface Ethernet Configuration Mode

Command Syntax

`mac security profile` *profile-name*

`no mac security profile` *profile-name*

`default mac security profile` *profile-name*

Parameter

profile-name the MACsec profile name.

Example

The following commands enable MACsec on Ethernet subinterface ***1.10*** by applying the MACsec profile called ***test-profile***.

```
switch(config)# interface ethernet1
switch(config-if-Et1)# no switchport
switch(config-if-Et1)# interface ethernet1.10
switch(config-if-Et1.10)# encapsulation dot1q vlan 20
switch(config-if-Et1.10)# mac security profile test-profile
```

9.3.2.8.17 mka key-server

The **`mka key-server`** command configures key server among the MACsec peers.

Command Mode

MACsec Profile Configuration

Command Syntax

`mka key-server` [priority *value*]

Parameters

- **priority** MKA key server priority.
  - ***value*** Key server priority value. Value ranges from ***0*** to ***255***.

Example

The following example configures the key server value of ***10*** among the MACsec peers.

```
switch(config)# mac security
switch(config-mac-security)# profile sample_Profile
switch(config-mac-security-sample_Profile)# mka key-server priority 10
```

9.3.2.8.18 mka session

The **mka session** command configures period at which the SAK is refreshed .

Command Mode

MACsec Profile Configuration

Command Syntax

`mka session` [rekey-period *value*]

Parameters

- **rekey-period** Sets MKA session re-key period.
  - ***value*** Session re-key period in seconds. Value ranges from ***30*** to ***100000***.

Example

The following example configures the mka session rekey-period time of ***10*** seconds at which the SAK is refreshed.

```
switch(config)# mac security
switch(config-mac-security)# profile sample_Profile
switch(config-mac-security-sample_Profile)# mka session rekey-period 10
```

9.3.2.8.19 profile (MACsec)

The **profile** command places the switch in MAC Security Profile configuration mode and creates a MACsec profile if a profile of the specified name does not already exist. MACsec profiles contain the configuration information needed to establish a MACsec connection, and are applied to interfaces using the **mac security profile** command.

Command Mode

MAC Security Configuration

Command Syntax

`profile` *profile-name*

Parameter

profile-name Name of the MACsec profile.

Commands Available in MAC Security Profile Configuration Mode

- cipher
- key (MACsec)
- mka key-server
- mka session
- replay
- sci
- traffic unprotected allow

Example

The following commands create a MACsec profile called ***test*** and place the switch in MAC Security Profile configuration mode for that profile.

```
switch(config)# mac security
switch(config-mac-security)# profile test
switch(config-mac-security-profile-test)#
```

9.3.2.8.20 ptp bypass

The `ptp bypass` command in the MAC Security Configuration Mode establishing a **PTP MACsec Bypass** and skips the encryption and integrity checks for PTP data plane frames. PTP traffic transmits in the clear, allowing the PHY to perform precise hardware timestamping and maintain sub-microsecond synchronization across a link otherwise fully encrypted.

The **no** version of the command disables the feature and removes the configuration from the ***running-config***.

Command Mode

MAC Security Configuration

Command Syntax

ptp bypass

no ptp bypass

Parameters

- **ptp** - Configure PTP processing on the switch for MACsec.
- **bypass** - Specify to transmit and receive PTP traffic without encryption.

Example

Use the following commands to enable bypassing encryption for PTP traffic:

```
switch(config)# mac security
switch(config-mac-security)# ptp bypass
switch(config-mac-security)#
```

9.3.2.8.21 replay

The **`replay`** command configures the action to be taken when packets received are not in order, based on their packet numbers. The window size in replay protection specifies the window size within which out-of-order packets are allowed. This command is configured under the MACsec Profile configuration mode.

The **no** and **default** form of the command removes all the configurations related to `replay` command from the running configuration on the switch.

Command Mode

MACsec Profile

Command Syntax

`replay` protection {**disabled** | **window** *window_size*}

`no replay` protection {**disabled** | **window** *window_size*}

`default replay` protection {**disabled** | **window** *window_size*}

Parameters

- **protection** Specifies the action to be taken when packets received are not in order, based on their packet numbers..
- **disabled** Disables replay protection.
- **window** Specifies the allowable window within which an out-of-order packet can be received.
  - ***window_size*** The allowable value ranges from ***0*** tthrough **`4294967295`**.

Example

The following commands configures a MACsec profile called TEST and a replay protection with a window size of ***100*** is configured on the switch.

```
switch(config)# mac security
switch(config-mac-security)# profile TEST
switch(config-mac-security-profile-TEST)# replay protection window 100
```

9.3.2.8.22 sci

The **sci** command add a Secure Channel Identifier (SCI) in data packets for MACsec on the switch. Each MACsec device has a Secure Channel (SC) used to send traffic to other device. Each channel has an 8-byte Secure Channel Identifier (SCI). The first 6 bytes match the MAC address of the device transmitting through that channel. The remaining 2 bytes are a Port Identifier used to distinguish between multiple channels from the same device. The command is configured under the MACsec profile configuration mode.

Command Mode

MACsec Profile

Command Syntax

sci

Example

The following commands place the switch on MACsec profile configuration mode and add a SCI for the MACsec profile called **TEST**.

```
switch(config)# mac security
switch(config-mac-security)# profile TEST
switch(config-mac-security-profile-TEST)# sci
```

9.3.2.8.23 secure channel (MACsec)

The **secure channel** command enters MAC Security Profile Static SAK Secure Channel Configuration mode. In this mode, you can add Association Numbers (AN) and Secure Channel Identifiers (SCI) for the specified channel. The available channels are Rx (receive) and Tx (transmit).

Command Mode

MAC Security Profile Static SAK Configuration Mode

Command Syntax

`secure channel` {**Rx**|**Tx**}

Parameters

- **Rx** Enter the configuration mode for the Rx channel.
- **Tx** Enter the configuration mode for the Tx channel.

Available Commands

- an
- identifier

Example

These commands enter MAC Security Profile Static SAK Secure Channel configuration mode for the Tx channel.

```
switch(config)# mac security
switch(config-mac-security)# profile test
switch(config-mac-security-profile-test)# key source sak static
switch(config-mac-security-profile-test-sak-static)# secure channel tx
switch(config-mac-security-profile-test-sak-static-sc-tx)#
```

9.3.2.8.24 show dot1x supplicant

The **`show dot1x supplicant`** command displays the 802.1X supplicant status.

Command Mode

EXEC

Command Syntax

```
show dot1x supplicant
```

Example

The following example displays information about 802.1X supplicant status.

```
switch# show dot1x supplicant

Interface: Ethernet6/1
    Identity: arastra
    EAP method: fast
    Status: success
    Supplicant MAC: 44:4c:a8:34:bf:20
    Authenticator MAC: 00:1c:73:e0:d3:76
```

About the Output

- **Interface:** The port on which the supplicant is running.
- **Identity:** Configured supplicant identity.
- **EAP method:** Configured EAP method (Currently just EAP-FAST).
- **Status:** Supplicant Status. Can be one of the following:
  - Success Authentication has been successful.
  - Down Authentication sequence has not begun.
  - Failed Authentication has failed.
  - Connecting Authentication is in progress.
  - Unused Supplicant is uninitialized.
- **Supplicant MAC:** MAC address of the supplicant.
- **Authenticator MAC:** MAC address of the authenticator (peer). Existing Mac Security show commands can be used to look at Mac Security status.

9.3.2.8.25 show mac security counters detail

The **show mac security counters detail** command to displays the detail information about the MACsec security counters.

Command Mode

EXEC

Command Syntax

```
show mac security counters detail
```

Example

The following example displays detail information about MACsec security counters.

```
switch# show mac security counters detail
Ethernet4/1/1     Counter Name        Count
-------------------------------------------------------
                  outPktsEncrypted    112
                  outOctetsEncrypted  11984
                  outPktsUntagged     0
                  outPktsTooLong      0
                  outPktCtrl          224
                  inPktsDecrypted     2
                  inOctetsDecrypted   214
                  inPktsUnchecked     0
                  inPktsOK            2
                  inPktsNotValid      0
                  inPktsNotUsingSA    0
                  inPktsCtrl          223
                  inPktsNoTag         8
                  inPktsTagged        0
                  inPktsBadTag        0
                  inPktsNoSCI         0
                  inPktsLate          0

Ethernet4/3/1     Counter Name        Count
-------------------------------------------------------
                  outPktsEncrypted    2
                  outOctetsEncrypted  214
                  outPktsUntagged     0
                  outPktsTooLong      0
                  outPktCtrl          223
                  inPktsDecrypted     111
                  inOctetsDecrypted   11877
                  inPktsUnchecked     0
                  inPktsOK            111
                  inPktsNotValid      0
                  inPktsNotUsingSA    0
                  inPktsCtrl          224
                  inPktsNoTag         9
                  inPktsTagged        0
                  inPktsBadTag        0
                  inPktsNoSCI         0
                  inPktsLate          0
```

9.3.2.8.26 show mac security counters

The **`show mac security counters`** command to displays information about the MACsec security counters.

Command Mode

EXEC

Command Syntax

```
show mac security counters
```

Example

The following example displays information about MACsec security counters.

```
switch# show mac security counters
Port       InPktsDecrypted  InOctetsDecrypted  OutPktsEncrypted OutOctetsEncrypted
Et4/1/1                  2                214               109               11663
Et4/3/1                109              11663                 2                 214
```

9.3.2.8.27 show mac security interface detail

The **show mac security interface detail** command displays the detail information about the MACsec on the interface.

Command Mode

EXEC

Command Syntax

```
show mac security interface detail
```

Example

The following example displays detail information about MACsec on the interface.

```
switch# show mac security interface detail
Interface: Ethernet4/1/1
    SCI: 28:99:3a:82:6f:82::605
    SSCI: 00000002
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Protected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)

Interface: Ethernet4/3/1
    SCI: 28:99:3a:82:6f:85::613
    SSCI: 00000001
    Controlled port: True
    Key server priority: 16
    Session rekey period: 0
    Traffic: Protected
    Key in use: 9d5bc0d3076ea4a08b99b9d9:1
    Latest key: None
    Old key: 9d5bc0d3076ea4a08b99b9d9:1(RT)
```

About the Output

- **Interface**: Name of the interface.
- **Secure Channel Identifier (SCI)**: Combination of MAC address and port number. Used to uniquely identify a Mac Security port.
- **Controlled Port**: Indicates if Mac Security is enabled on the port. A value of True indicates that encryption is enabled on the port.
- **Key In Use**: The SAK identifier currently in use. Combination of Key Servers message identifier (see below) and key number.
- **Key Server priority**: Configured key server priority.

- **Session Rekey Period**: Configured session rekey period.
- **Latest Key**: Latest SAK being negotiated by Mac Security Key Agreement Protocol (MKA).
- **Old Key**: The last SAK negotiated by Mac Security Key Agreement Protocol (MKA).

Note: Latest and Old key are MKA protocol specific terminology and are used to refer to the last two keys in use. For all practical purposes, Key In Use field is used to identify the current key.

9.3.2.8.28 show mac security interface

The **`show mac security interface`** command shows information about MACsec on the interface.

Command Mode

EXEC

Command Syntax

```
show mac security interface
```

Examples

- The following example displays information about MACsec on the interface.

```
switch# show mac security interface
Interface     SCI                      Controlled Port Key in Use
Ethernet4/1/1 28:99:3a:82:6f:82::605  True            9d5bc0d3076ea4a08b99b9d9:1
Ethernet4/3/1 28:99:3a:82:6f:85::613  True            9d5bc0d3076ea4a08b99b9d9:1 switch#
```

- The following example displays the association numbers (ANs) of SAKs for both Rx and Tx on the interface ***Ethernet9/1***. Actual SAK values are never displayed in ***show*** command output.

```
switch# show mac security interface
Interface       SCI                       Controlled Port      Key in Use
Ethernet9/1     01:02:03:04:05:06::1235   True                 static SAK: Rx AN: 0,1 Tx AN: 0
 switch#
```

- The following example displays MACsec information for a unidirectional link. On the Rx side, the SCI is shown as ***00:00:00:00:00:00::0***, and only the Rx AN is shown.

```
switch# show mac security interface
Interface       SCI                       Controlled Port      Key in Use
Ethernet9/1     00:00:00:00:00:00::0000   True                 static SAK: Rx AN: 0 switch#
```

- The following example displays MACsec information on the Tx side of a unidirectional link. In this case, the configured SCI is shown, along with the Tx AN.

```
switch(config)# show mac security interface
Interface       SCI                       Controlled Port      Key in Use
Ethernet9/1     01:02:03:04:05:06::1235   True                 static SAK: Tx AN: 0
```

9.3.2.8.29 show mac security mka counters

The **show mac security mka counters** command to display information about the MACsec MKA counters.

Command Mode

EXEC

Command Syntax

```
show mac security mka counters
```

Example

The following example displays information about MACsec MKA counters.

```
switch# show mac security mka counters
Interface       Rx Success      Rx Failure      Tx Success      Tx Failure
Ethernet4/1/1   287             0               288             0
Ethernet4/3/1   288             0               287             00
```

9.3.2.8.30 show mac security participants detail

The **show mac security participants detail** command displays detail information about the MACsec participants.

Command Mode

EXEC

Command Syntax

```
show mac security participants detail
```

Example

The following example displays information about MACsec participants details.

```
switch# show mac security participants detail
Interface: Ethernet4/1/1
    CKN: abcd
      Message ID: 9d5bc0d3076ea4a08b99b9d9
      Elected self: True
      Success: True
      Principal: True
      Default: False
      KeyServer SCI: 28:99:3a:82:6f:82::605
      SAK transmit: True
      LLPN exhaustion: 0
      Distributed key identifier: 9d5bc0d3076ea4a08b99b9d9:1
      Live peer list: ['c79ad8882c2dd3a8e838a691']
      Potential peer list: []

    CKN: dead

About the Output

- **Connectivity Association Key Name (CKN):** Configured name of the key in use.
- **Message ID:** A random 92 bit string used as an identifier for an MKA participant.
- **Elected Self:** True if this participant is the elected key server.
- **Success:** True if this participant is live and has at least one live peer.
- **Principal:** True if this participant is the principal participant elected to distribute SAKs.
- **Default:** True if this participant is a fallback/backup participant (spawned when a fallback key is configured in a Mac Security profile).
- **Key Server SCI:** The SCI of the key server.
- **SAK Transmit:** True if the participant is ready to use the negotiated key for transmit.
- **LLPN Exhaustion:** Increments if the number of data packets sent using the current key exceeds a certain threshold. Because we use a 64 bit packet number cipher suite, this should never increment.
- **Distributed Key Identifier:** Message ID + key number of the most recently generated SAK.

9.3.2.8.31 show mac security participants

The **`show mac security participants interface`** command displays information about the MACsec participants.

Command Mode

EXEC

Command Syntax

```
show mac security interface
```

Example

The following example displays information about MACsec participants.

```
switch# show mac security participants
Interface: Ethernet4/1/1
    CKN: abcd
      Message ID: 9d5bc0d3076ea4a08b99b9d9
      Elected self: True
      Success: True
      Principal: True
      Default: False

    CKN: dead
      Message ID: 4ef4cf009161bd551b5e7434
      Elected self: True
      Success: True
      Principal: False
      Default: True

Interface: Ethernet4/3/1
    CKN: abcd
      Message ID: c79ad8882c2dd3a8e838a691
      Elected self: False
      Success: True
      Principal: True
      Default: False

    CKN: dead
      Message ID: 3dfd4486b5f68a81014a37ec
      Elected self: False
      Success: True
      Principal: False
      Default: True
```

9.3.2.8.32 show mac security profile

The **show mac security profile** command displays information about the specified MACsec profile. If no profile is specified, information about all profiles is shown.

Command Mode

EXEC

Command Syntax

`show mac security profile` [*profile_name*]

Parameters

profile_name The MACsec profile to show information about.

Example

The following command shows information for the MACsec profile ***test***.

```
switch# show mac security profile
Profile: test
    Cipher: aes256-gcm-xpn
    Primary CKN:
    Primary CAK SHA-256 hash:
    Fallback CKN:
    Fallback CAK SHA-256 hash:
    Source: cli
    Priority: 100
    SCI Inclusion: disabled
    Key retirement policy: delayed
    Unprotected traffic policy: allow active-sak
    MKA lifetime: 6 seconds
    MKA key server priority: 16
    Session rekey period: 0
    Bypassed protocols:
    Max AN value of SAK: 3
    Configured on:
switch#
```

9.3.2.8.33 show mac security sak

The **show mac security sak** command displays information about MACsec static secure association key (SAK) status for the specified Ethernet interface. If no interface is specified, all interfaces are shown. The following information is shown for each Ethernet interface.

- The name of the Ethernet interface.
- The installed SAK IDs.
- The SAK profile name.
- The total number of SAKs generated.
- The number of SAKs generated due to a new live peer.
- The number of SAKs generated due to a rekey timer.
- The number of SAKs generated due to packet number exhaustion.
- The SAK installation time in seconds in each direction.
- The number of forced new Tx SAK installations.

Command Mode

EXEC

Command Syntax

`show mac security sak [interface ethernet` *Ethernet_interface]*

Parameters

interface ethernet Show SAK status information about the specified Ethernet interface. If this option is omitted, information for all Ethernet interfaces is shown.

Ethernet_interface The Ethernet interface to show SAK status for.

Example

The following command displays the MACsec SAK status for the Ethernet interface Ethernet9/1.

```
switch(config-mac-security-profile-test)# show mac security sak
Interface: Ethernet9/1
Installed SAK ID: static SAK: Rx AN: 0,1 Tx AN: 0
Installed SAK from: static-SA
Total SAK generated: 0
SAK generated due to new live peer: 0
SAK generated due to rekey timer: 0
SAK generated due to packet number exhaustion: 0
SAK installation time( in seconds ):
Direction    0-1   1-2   2-3    3+
```

```
---------- ----- ----- ----- -----
Rx             1     0     0     0
Tx             1     0     0     0

Maximum Rx installation time: 0.0884998080001 seconds
Maximum Tx installation time: 0.0884941590002 seconds
Forced new Tx SAK installation count: 0
```

9.3.2.8.34 show mac security status

The **show mac security status** command displays the MACsec status information on a switch.

Command Mode

EXEC

Command Syntax

```
show mac security status
```

Example

The following command displays the MACsec status information.

```
switch# show mac security status
Active Profiles:                1
Data Delay Protection:          No
FIPS Mode:                      No
Secured Interfaces:             2
License:                        Enabled
```

9.3.2.8.35 supplicant profile

The **supplicant profile** command configures the supplicant profile containing all the credentials necessary for 802.1X authentication to succeed.

Command Mode

dot1x Configuration

Command Syntax

`supplicant profile` *profile_name options*

Parameters

- ***profile_name*** Name of the supplicant profile.
- The following parameters can be included after entering the profile mode:
  - **eap-method** Extensible Authentication Protocol (EAP) method. Option include:
    - **fastEAP** Flexible Authentication via Secure Tunneling (FAST).
  - **identity** Extensible Authentication Protocol (EAP) user identity. Option include:
    - **WORD** User identity name.
  - **passphrase** Extensible Authentication Protocol (EAP) password. Options include:
    - ***0*** Specifies that an UNENCRYPTED key will follow.
    - ***7*** Specifies that an HIDDEN key will follow.
    - **LINE** The UNENCRYPTED (clear-text) shared key.

Examples

- The following commands place the switch in the supplicant profile mode.

```
switch(config)# dot1x
switch(config-dot1x)# supplicant profile test
switch(config-dot1x-supp-profile-test)#
```

- The following commands configures the EAP FAST method for the supplicant profile called ***test profile*** for MAC security on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# supplicant profile test
switch(config-dot1x-supp-profile-test)#eap-method fast
```

- The following commands configures the Identity for the supplicant profile called test profile for MAC security on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# supplicant profile test
switch(config-dot1x-supp-profile-test)# identity New_User
```

- The following commands configures the passphrase for the supplicant profile called ***test profile*** for MAC security on the switch.

```
switch(config)# dot1x
switch(config-dot1x)# supplicant profile test
switch(config-dot1x-supp-profile-test)# passphrase 7 070E334D5D1D0B04
```

9.3.2.8.36 traffic unprotected allow

The **`traffic unprotected allow`** command configures the switch to allow the unprotected traffic whenever there is no successful MKA session established with the peer.

The **`no traffic unprotected allow`** command disable the MACsec Fallback to Unprotected Traffic function by removing the traffic unprotected allow command from ***running-config***.

Command Mode

MACsec Profile

Command Syntax

```
traffic unprotected allow

no traffic unprotected allow
```

Example

The following commands configures the MACsec Fallback traffic unprotected allow feature on a switch for a MACsec profile called sample.

```
Switch(config)# mac security
Switch(config-mac-security)# profile sample
Switch(config-mac-security-profile-sample)# no traffic unprotected allow
```

9.3.3 Internet Protocol Security (IPsec)

This section describes Arista's IPsec implementation. Topics in this section include:

- IPsec Introduction
- IPsec Overview
- Configuring IPsec
- Configuring PKI
- IPsec Commands

9.3.3.1 IPsec Introduction

Internet Protocol Security (IPsec) is a protocol suite for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet of a communication session. IPsec includes protocols for establishing mutual authentication between agents periodically during the session and negotiation of cryptographic keys to be used during the session. IPsec supports network-level peer authentication, data origin authentication, data integrity, data confidentiality (encryption), and replay protection.

IPsec protects data traffic between sites, such as between an enterprise's Branch, HQ, and Data center sites.

IPsec uses the following protocols to perform various functions:

- **Authentication Headers** (AH) provide connectionless integrity and data origin authentication for IP datagrams and protect against replay attacks.
- **Encapsulating Security Payloads** (ESP) provides confidentiality, data origin authentication, connectionless integrity, and an anti-replay service (a form of partial sequence integrity).
- **Internet Key Exchange** (IKE) is a key management protocol that provides security for virtual private networks (VPNs) negotiations and network access to random hosts. It is also described as a method for exchanging keys for encryption and authentication over an unsecured medium, such as the Internet.

9.3.3.2 IPsec Overview

9.3.3.2.1 Security Associations

Security Associations (SA) provide the bundle of algorithms and data that provide the parameters necessary for AH and ESP operations. The Internet Security Association and Key Management Protocol (ISAKMP) provides a framework for authentication and key exchange, with actual authenticated keying material provided by manual configuration with pre-shared keys, Internet Key Exchange (IKE and IKEv2), and other mechanisms.

IPsec uses the Security Parameter Index (SPI) and the destination address in the packet header to determine the necessary protection for an outgoing packet. The SPI is an index to the security association database (SADB). The SPI uniquely identifies a security association for the packet in combination with the destination address.

The system performs a similar procedure for an incoming packet, where IPsec gathers decryption and verification keys from the security association database.

Full bidirectional communication requires at least two SAs, one for each direction. The following parameters define SA:

- Security Algorithms (AH) or Encapsulating Security Payloads (ESP) and keys.
- **Mode:** Tunnel or Transport.
- **Key Management Method:** Manual or IKE.
- **Lifetime:** Expressed in hours or minutes (minimum configurable value is 10 minutes).

9.3.3.2.2 Mode of Operation

IPsec on Arista switches operates in tunnel mode. In tunnel mode, the entire IP packet is encrypted and authenticated, then encapsulated into a new IP packet with a new IP header.

IPsec uses tunnel mode to create virtual private networks (VPN) for network-to-network communications, such as secure connections between routers across different sites. Tunnel mode serves as the foundation for the majority of network-to-network IPsec implementations.

9.3.3.2.3 Key Management

Key management on Arista switches uses the Internet Key Exchange (IKE) method. Internet Key Exchange (IKE) supports automated generation and renegotiation of SAs (includes keys) between the devices at a configured interval, making it much more scalable and secure.

IPsec needs SAs to define the algorithms and keys to protect traffic. IKE establishes the SA so IPsec can protect traffic.

There are two IKE versions, IKEv1 and IKEv2. IKEv2 builds on IKEv1, but both are still widely used today.

9.3.3.2.3.1 IKEv1

IKEv1 has two phases.

- IKEv1 Phase 1
- IKEv1 Phase 2

IKEv1 Phase 1

- Uses main or aggressive mode exchange
- Negotiates IKE SA
- Used for control plane
- Peer authentication

IKEv1 Phase 2

- Uses quick mode exchange
- Negotiates IPsec SAs

Note: There are two different SAs established. The IKE SA protects only the IKE key management session using the IKE policy defined. The policy should include the following parameters:

- Encryption algorithm
- Hash MAC (HMAC) algorithm
- Peer authentication procedure
- Diffie-Hellman group for initial key exchange
- SA lifetime

IKE initially performs a Diffie-Hellman (DH) exchange at the start of the IKE session. A Diffie-Hellman (DH) exchange allows participants to produce a shared secret value. The strength of the technique is that it allows participants to create the secret value over an unsecured medium without passing the secret value through the wire. From that exchange, peers get shared keying material, which is then used for IKE encryption and integrity functions. The strength of that keying material is that it can be used for faster performance by choosing lower key sizes for Diffie-Hellman exchanges. Diffie-Hellman exchanges' key length (strength) can be changed using different DH groups.

When an IKE session's lifetime expires, a new Diffie-Hellman exchange is performed between peers, and the IKE SA is re-established.

The IPsec protection policy, resulting in IPsec SAs, defines network traffic protection. These IPsec SAs are usually negotiated over IKE sessions. The parameters that define the IPsec protection policy are:

- Encryption Algorithm
- Hash MAC (HMAC) Algorithm

The key material for IPsec SA (also called Child SA) is derived from keying material from IKEv1 phase 1.

There are two different modes for phase 1:

- Main Mode
- 6 packet exchange
- Full identity protection and better anti-DoS protection
- Aggressive Mode
- 3 packet faster session establishment
- Identities are exchanged in clear
- Weak DoS protection

Authentication

- **Pre-Shared Keys (PSK):** As the name suggests, a shared secret is distributed out-of-band to the peers. The peers use this information and nonce parameters to create a hash to authenticate messages.
- **PKI Certificates:** Here, peers' certificates are exchanged, and hashes are calculated over these certificates to authenticate each other.

9.3.3.2.3.2 IKEv2

IKEv2 differs from IKEv1 in the following ways:

- Faster set up because of the reduced number of messages.
- More secure.
- ESP is reused for all IKEv2 messages.
- Suite-B support.
- There is no aggressive mode, so IKEv2 always provides identity protection.
- Additional authentication methods.
- Local and remote can use different authentication methods and use different pre-shared keys.
- Authentication performed unidirectionally in IKEv2.

9.3.3.2.3.3 IPSec Key Length Support

EOS provides a restriction on the combinations of IKE and IPSec algorithms used for a security combination.

EOS supports the following set of algorithms for IKE:

Table 12: IKE Algorithms

Algorithm	Description
3des	Three key triple DES
aes128	128-bit Advanced Encryption Standard
aes192	192-bit Advanced Encryption Standard
aes256	256-bit Advanced Encryption Standard

EOS supports the following set of algorithms for IPSec

Table 13: IPSec Algorithms

Algorithm	Description
3des	Three key triple DES
aes128	128-bit Advanced Encryption Standard
aes128gcm128	128-bit Advanced Encryption Standard-Galois/Counter Mode (AES-GCM) with 128-bit Integrity Check Value (ICV)
aes128gcm64	128-bit Advanced Encryption Standard-Galois/Counter Mode (AES-GCM) with 64-bit Integrity Check Value (ICV)
aes256	256-bit Advanced Encryption Standard
aes256gcm128	256-bit Advanced Encryption Standard-Galois/Counter Mode (AES-GCM) with 128-bit Integrity Check Value (ICV)
null	Null encryption

EOS supports the following key sizes for the algorithms:

Table 14: Key Sizes

Algorithm	Key Size
3des	168 bits
aes128/aes128gcm64/aes128/gcm128	128 bits
aes192	192 bits
aes256 / aes256gcm128	256 bits
null	0 bits

EOS supports the following allowed combination of IKE and IPSec algorithms:

Table 15: Combinations of IKE and IPSec Algorithms

IKE Algorithm	IPSec Algorithm
3des	3des, null
aes128	3des, aes128, aes128gcm64, aes128gcm128, null
aes192	3des, aes128, aes128gcm64, aes128gcm128, null
aes256	3des, aes128, aes128gcm64, aes128gcm128, aes256, aes256gcm128, null

To enable key length checking, use the following commands:

```
switch(config)# ip security
switch(config-ipsec)# encryption key-length aligned
switch(config-ipsec)#
```

By default, EOS disables key length checking for IKE and IPSec. All new and existing sessions work as expect. When enabled, all new sessions undergo key length checking and existing sessions reset and undergo re-evaluation for the key length. Only sessions that adhere to the key length restrictions return to an active status.

If a key length fails to meet the criteria, the **show ip security connection** command displays the following output:

```
switch# show ip security connection
Legend: (P) policy based VPN tunnel
Tunnel           Source           Dest      Status              Uptime   Input            Output
    Rekey Time

Tunnel152        10.1.0.1         10.1.0.2   NotKeyLenAligned  N/A      0 bytes          0 bytes
    41 minutes
                                                                          0 pkts           0 pkts
```

The following command displays the status of the key length checking feature:

```
switch# show ip security encryption key-length status
Key length alignment: disabled
```

9.3.3.2.4 Route-based VPN

A route-based VPN employs routed tunnel interfaces as the virtual network's endpoints. All traffic passing through a tunnel interface traverses the VPN. Rather than relying on an explicit policy to dictate which traffic enters the VPN, static and dynamic IP routes are formed to direct the desired traffic through the VPN tunnel interface.

Since route-based VPNs support dynamic routing information through VPN tunnels, EOS supports only route-based VPNs for dynamic routing support and easier configuration and management.

In route-based VPN, features like NAT, ACL, and QoS are applied to packets before they are encrypted by applying these features to the tunnel interface and can be applied to encrypted packets by applying these features on the physical interface carrying the tunnel traffic.

Virtual Template Interface (VTI)

A new tunnel interface type, **vti**, represents the VPN tunnel. This tunnel interface will participate in the routing, and any packets forwarded to it will be encrypted and forwarded to the other end of the tunnel. Note that this does not add a new header to the packet.

9.3.3.3 Configuring IPsec

Complete the following steps to configure IPsec tunnels over the switch.

This configuration uses the default IKE version 2 procedure.

1. Use **ip security** command to enter IP security mode.

   ```
   switch(config)# ip security
   ```

2. To use IKE version 1, complete the following before completing the default IKE version the steps below.

   ```
   switch(config)# ip security
   switch(config-ipsec)# ike policy ike-peerRtr
   switch(config-ipsec-ike)# version 1
   ```

3. Create an IKE Policy to be used to communicate with the peer to establish IKE. You have the option of configuring multiple IKE policies.

   The default IKE Policy values are:

   - **Encryption:** AES256 / AES128
   - **Integrity:** SHA256 / SHA128
   - **DH group:** Group 14
   - **IKE lifetime:** 8 hours

```
switch(config-ipsec)# ike policy ike-router
switch(config-ipsec-ike)# encryption aes256
switch(config-ipsec-ike)# integrity sha256
switch(config-ipsec-ike)# dh-group 24
switch(config-ipsec-ike)# version 2
```

4. If the router is behind a NAT, configure the local-id with the local public IP address. The public IP corresponds to the underlying interface over which the IKE communications are done with the peer.

```
switch(config-ipsec-ike)# local-id <public ip address>
```

5. Create an IPsec Security Association policy to be used in the data path for encryption and integrity. Use the option of enabling Perfect Forward Secrecy by configuring a DH group to the SA. In this example, ***AES256*** is used for encryption, ***SHA 256*** is used for integrity, and Perfect Forward Secrecy is enabled (the DH group is 14).

```
switch(config-ipsec)# sa policy sa-vrouter
switch(config-ipsec-sa)# esp encryption aes256
switch(config-ipsec-sa)# esp integrity sha256
switch(config-ipsec-sa)# pfs dh-group 14
switch(config-ipsec-sa)# sa lifetime 2
switch(config-ipsec-sa)# exit
```

6. Bind or associate the IKE and SA policies together using an IPsec profile. Provide a shared-key, which must be common on both peers. The default profile assigns default values for all parameters that are not explicitly configured in the other profiles. In this example, the IKE Policy ***ike-peerRtr*** and SA Policy ***sa-peerRtr*** are applied to profile ***peer-Rtr***. Dead Peer Detection is enabled and configured to delete the connection when the peer is down for more than ***50*** seconds. The peer ***peer-Rtr*** is set to be the responder.

```
switch(config-ipsec)# profile default
switch(config-ipsec-profile)# ike-policy ikedefault
switch(config-ipsec-profile)# sa-policy sadefault
switch(config-ipsec-profile)# shared-key arista
switch(config-ipsec-profile)# connection start
switch(config-ipsec)# profile vrouter
switch(config-ipsec-profile)# ike-policy ike-vrouter
switch(config-ipsec-profile)# sa-policy sa-vrouter
switch(config-ipsec-profile)# dpd 10 50 clear
switch(config-ipsec-profile)# connection add
```

7. Configure the WAN interface to be the underlying interface for the tunnel. You must specify an L3 address for the tunnel. If you do not, the switch cannot route packets using the tunnel.

```
switch(config)# interface Et1
switch(config-if-Et1)# no switchport
switch(config-if-Et1)# ip address 1.0.0.1/24
```

```
switch(config-if-Et1)# mtu 1500
```

8. Apply the IPsec profile to a new tunnel interface. You create the new tunnel interface as part of this step and configure the tunnel as a VTI IPsec tunnel. In this example, the new tunnel interface is ***Tunnel0***. The new tunnel interface is configured to use IPsec. The other end of the tunnel also needs to be configured as a GRE-over-IPsec tunnel.

```
switch(config)# interface tunnel0
switch(config-if-Tu0)# ip address 1.0.3.1/24
switch(config-if-Tu0)# mtu 1394
switch(config-if-Tu0)# tunnel source 1.0.0.1
switch(config-if-Tu0)# tunnel destination 1.0.0.2
switch(config-if-Tu0)# tunnel ipsec profile vrouter
```

Example Configuration

```
ip security
ike policy ikebranch1
integrity sha256
dh-group 15
!
sa policy sabranch1
sa lifetime 2
pfs dh-group 14
!
profile hq
mode tunnel
ike-policy ikebranch1
sa-policy sabranch1
connection add
shared-key keyAristaHq
dpd 10 50 clear
!
interface Tunnel1
mtu 1404
ip address 1.0.3.1/24
tunnel source 1.0.0.1
tunnel destination 1.0.0.2
tunnel ipsec profile hq
!
interface Ethernet1
no switchport
ip address 1.0.0.1/24
!
```

9.3.3.3.1 Displaying IPsec Information

- Use the `show ip security policy` command to display the IPsec policy information.

```
switch# show ip security policy
Policy Name   Authentication   Encryption   Integrity    Lifetime  Rekey  DH Group
ike-policy    Pre-shared       256-bit AES  256bit Hash  8 hours   False  3072 bit
```

- Use the `show ip security profile` command to display the IP security profile information.

```
switch# show ip security profile
Profile name      IKE Policy Name      SA
ipsec-profile     ike-policy           sa-policy
```

9.3.3.4 Configuring PKI

Configure PKI as a certificate-based authentication for the IPsec protocol.

Enabling PKI for an IKE Policy

Configure the authentication mode as PKI for the IKE policy. The IPsec refers to this policy when using PKI authentication.

Use the following commands to enable PKI authentication for the IKE policy, MyPKI:

```
switch(config)#ip security
switch(config-ipsec)#ike policy MyPolicy
switch(config-ipsec)#authentication pki
switch(config-ipsec)#exit
switch(config-ipsec)#show active
    ip security
    ike policy MyPolicy
    authentication pki
```

Configuring the PKI Profile

Configure the PKI profile used by an IPsec profile. This profile refers to the SSL profile for authentication.

```
switch(config)#ip security
switch(config-ipsec)#profile MyProfile
switch(config-ipsec)#pki-profile pki-abc
switch(config-ipsec)#ike-profile MyPKI
switch(config-ipsec)#exit
switch(config-ipsec)#show active
   profile MyProfile
      ...
   ike-policy MyPKI
   pki-profile pki-abc
      ...
 !
```

When configuring IPsec, consider the following information:

- For PKI, each rekey performs reauthentication.
- DPS paths always use the VTEP-IP as the ID when configuring a local ID for each IKE policy.
- If the IKE policy does not have a local ID, the ID comes from the certificate subject name (SN).
- If the IKE policy has a local ID, the certificate used in the corresponding PKI profile should contain this ID in the Subject Alternative Names (SAN) field. If the local ID contains the FQDN, it must be present in the DNS or email field in the SAN depending on if the FQDN contains a domain address or email-ID.
  - Multiple connections on one device can use the same certificate by specifying all of the IDs for each connection in the certificate SAN.
- For tunnels sharing a common endpoint, use different certificates for each tunnel or configure a unique local ID for each tunnel. This avoids duplicate connections.

Displaying PKI IPsec Information

Use the **show ip security policy** to display the authentication mode for security policies:

```
switch#show ip security policy
Policy Name               Authentication   Crypto Suite  Encryption    Integrity     Lifetime
 Rekey  DH Group
-----------               --------------   ------------  ----------    ---------     --------
 -----  --------
a                         Pre-shared        -            128-bit AES   256bit Hash   8 hours
 False  3072 bit
MyPKI                     PKI               -            128-bit AES   256bit Hash   8 hours
 False  3072 bit
```

Use the **show ip security profile** to display information about PKI profile configured for an IPsec profile.

```
switch#show ip security profile
Profile name              IKE Policy Name          SA                       PKI Profile
-------------             -----------------      ---------                 ------------
MyPKI                     ike-xyz                sa-xyz                    pki-xyz
```

9.3.3.5 IPsec Commands

- ike policy
- interface tunnel (IPsec)
- ip security
- profile (IPsec)
- sa policy
- show ip security applied-profile
- show ip security connection
- show ip security policy
- show ip security profile
- show ip security security-association

9.3.3.5.1 ike policy

The **ike policy** command configures the Internet Security Association and Key Management Protocol on the switch and related policies. Configure the IKE policy in IP security configuration mode.

The **no ike policy** command deletes the IKE policy configuration from the switch.

The **exit** command returns the switch to the global configuration mode.

Command Mode

IP Security Configuration

Command Syntax

ike policy ***policy-name***

no ike policy ***policy-name***

Parameters

- ***policy-name*** - Specify the IKE policy name.

The ***policy-name*** uses the following parameters to configure the policy after placing the in IKE policy configuration mode:

- **authentication** - Specify the authentication type.
  - **pki** - Specify Public Key Infrastructure.
  - **pre-share** - Specify a preshared key.
- **crypto suite** - Specify a crypto algorithm suite type.
  - ***name*** - Specify a name for the crypto suite.
  - **[after | before]** - Insert the crypto suite before or after the following crypto suite.
  - ***name***
- **dh-group** - Specify the Diffie-Hellman Group value.
  - **1** - Diffie-Hellman group 1 (768 bit)
  - **14** - Diffie-Hellman group 14 (2048 bit)
  - **15** - Diffie-Hellman group 15 (3072 bit)
  - **16** - Diffie-Hellman group 16 (4096 bit)
  - **17** - Diffie-Hellman group 17 (6144 bit)

- **19** - Diffie-Hellman group 19 (256 bit ecp)
- **2** - Diffie-Hellman group 2 (1024 bit)
- **20** - Diffie-Hellman group 20 (384 bit ecp)
- **21** - Diffie-Hellman group 21 (521 bit ecp)
- **24** - Diffie-Hellman group 24 (2048 bit, 256 bit subgroup)
- **5** - Diffie-Hellman group 5 (1536 bit)

- **encryption** - Specify the encryption type.
  - **3des** - Three key triple DES
  - **aes128** - AES - 128-bit Advanced Encryption Standard
  - **aes128gcm128** - 128 bit AES-GCM with 128 bit ICV
  - **aes128gcm64** - 128 bit AES-GCM with 64 bit ICV
  - **aes192** - AES - 192-bit Advanced Encryption Standard
  - **aes256** - AES - 256-bit Advanced Encryption Standard
  - **aes256gcm128** - 256 bit AES-GCM with 128 bit ICV
- **ike-lifetime [** ***hours*** **|** ***minutes*****]** - Sets the IkeLifetime for an ISAKMP security association. Specify a value in hours or minutes with a minimum of 10 minutes.
- **integrity** - Specify the Integrity algorithm.
  - **md5** - Message Digest Algorithm 5
  - **sha1** - Secure Hash Standard 1 (160 bit)
  - **sha256** - Secure Hash Standard 2 (256 bit)
  - **sha384** - Secure Hash Standard 2 (384 bit)
  - **sha512** - Secure Hash Standard 2 (512 bit)
- **local-id** - Specify the local IKE identification.
  - ***ipv4_address*** - Configure an IPv4 address.
  - ***ipv6_address*** - Configure an IPv6 address.
  - **fqdn** - Configure a Fully Qualified Domain Name for identification.
- **remote-id** - Specify the remote peer IKE identification.
  - ***ipv4_address*** - Configure an IPv4 address.
  - ***ipv6_address*** - Configure an IPv6 address.
  - **dn** - Configure an X.500 Distinguished Name for identification.
  - **fqdn** - Configure a Fully Qualified Domain Name for identification.

- **`version`** - Specify the IKE version.

Example

This command configures the IKE policy MyIKEPolicy for IP security configuration.

```
switch(config)# ip security
switch(config-ipsec)# ike policy MyIKEPolicy
switch(config-ipsec)#
```

9.3.3.5.2 interface tunnel (IPsec)

The **`interface tunnel`** command places the switch in the Interface Tunnel Configuration Mode.

Interface tunnel configuration mode does not provide a group change mode. The ***running-config*** changes immediately after executing the commands.

The **`no interface tunnel`** command deletes the interface tunnel configuration.

The **`exit`** command returns the switch to the global configuration mode.

Command Mode

Global Configuration

Command Syntax

`interface tunnel` ***value***

`no interface tunnel` ***value***

Parameter

value - Specify the tunnel interface number. The value ranges from ***0*** to ***255***.

Example

This command places the switch in Interface Tunnel Configuration Mode with a tunnel value of ***10***.

```
switch(config)# interface tunnel 10
switch(config-if-Tu10)#
```

9.3.3.5.3 ip security

The **ip security** command places the switch in the IP Security Configuration Mode.

IP security configuration mode is not a group change mode. The ***running-config*** changes immediately after executing the commands.

The **no ip security** command deletes the IP security configuration.

The **exit** command returns the switch to the global configuration mode.

Command Mode

Global Configuration

Command Syntax

ip security

no ip security

Example

This command places the switch in IP security configuration mode.

```
switch(config)# ip security
switch(config-ipsec)# ike policy IKE1
switch(config-ipsec-IKE1)# exit
switch(config-ipsec)# sa policy SA1
switch(config-SA1)#
```

9.3.3.5.4 ip security encryption key-length

The **ip security encryption key-length** command in the IP Security Configuration Mode enables key-length checking for IKE and IPSec algorithms.

The **[no | default]** versions of the command disables the feature and removes it from the ***running-config***.

Command Mode

IP Security Configuration

Command Syntax

ip security encryption key-length aligned

no ip security encryption key-length

default ip security encryption key-length

Parameters

- **encryption key-length aligned** - Align IKE and IPSec encryption keys.

Example

Use the following commands to enable key-length alignment for IKE and IPSec encryption keys:

```
switch(config)# ip security
switch(config-ip-sec)# encryption key-length aligned
switch(config-ip-sec)#
```

9.3.3.5.5 profile (IPsec)

The **profile** command configures the IP security profile on the switch. Configure the profile in IP security configuration mode.

The **no profile** command deletes the IP security profile configuration from the switch.

The **exit** command returns the switch to the global configuration mode.

Command Mode

IP Security Configuration

Command Syntax

profile ***profile-name***

no profile ***profile-name***

Parameters

- ***profile-name*** Specifies the IP security profile name.

The following parameters can be configured in SA policy configuration mode:

- **connection** - Specify the type of IPsec Connection (Initiator/Responder/Dynamic).
- **dpd** - Specify the Dead Peer Detection in an interval between 2 and 3600 seconds.
- **flow** - Specify to set the flow in parallel.
- **ike-policy** - Specify the ISAKMP policy.
- **mode** - Specify the IP security mode type.
- **sa-policy** - Specify the name of the security association.
- **shared-key** - Specify a shared key value.

Example

This command configures the IP security profile test for IP security configuration.

```
switch(config)# ip security
switch(config-ipsec)# profile test
switch(config-ipsec-profile)#
```

9.3.3.5.6 sa policy

The **sa policy** command specifies a Security Association (SA) policy used for IPsec configuration, and enters IP security SA policy configuration mode to configure the named policy.

The **no sa policy** command deletes the specified SA policy configuration from the switch.

The **exit** command returns the switch to the global configuration mode.

Command Mode

IP Security Configuration

Command Syntax

sa policy ***policy_name***

no sa policy ***policy_name***

Parameters

- ***policy_name*** - Specifies the SA policy name.

Configure the following parameters in IP security SA policy configuration mode:

- **anti-replay** - Specify the IPsec duplicate IP datagram detection mode.
- **esp** - Specify the type of Encapsulation Security Payload.
- **pfs** - Add Perfect Forward Secrecy.
- **sa lifetime** - Specify a lifetime for the Security Association. Configure the lifetime in hours or minutes.

Example

This command applies the SA policy called ***test*** and adds a lifetime of 30 minutes for IP security and enters IP security SA policy configuration mode for the test policy.

```
switch(config)# sa policy test
switch(config-ipsec-sa)# sa lifetime 30 minutes
```

9.3.3.5.7 show ip security applied-profile

The **`show ip security applied-profile`** command displays the IP security profile names and the corresponding interfaces with the profile.

Command Mode

EXEC

Command Syntax

`show ip security applied-profile`

Example

This command displays the IP security ***profile-1*** and the corresponding interfaces with the profile.

```
switch# show ip sec applied-profile
Profile Name                Interface
ipsec-profile-1             Tunnel1,
                            Tunnel2,
                            Tunnel3,
                            Tunnel4,
                            Tunnel5,
                            Tunnel6,
                            Tunnel7,
                            Tunnel8,
                            Tunnel9,
                            Tunnel10,
                            Tunnel11,
                            Tunnel12,
                            Tunnel13,
                            Tunnel14,
                            Tunnel15,
                            Tunnel16,
                            Tunnel17,
                            Tunnel18,
                            Tunnel19,
                            Tunnel20,
                            Tunnel21,
                            Tunnel22,
                            Tunnel23,
                            Tunnel24,
                            Tunnel25,
                            Tunnel26,
```

9.3.3.5.8 show ip security connection

The **`show ip security connection`** command displays the IP security connection status information.

Command Mode

EXEC

Command Syntax

`show ip security connection`

Example

These commands display the IP security connection status information.

```
switch# show ip sec conn tunnel 1
Tunnel   Source     Dest     Status       Uptime     Input    Output        Rekey Time
Tunnel1  11.1.1.1   11.2.1.1 Established  19 hours   0 bytes  0 bytes       4 hours
                                                     0 pkts   62937679 pkts

switch# show ip sec conn tunnel 1 detail
Tunnel1:
   source address 11.1.1.1, dest address 11.2.1.1
   state: Established
   uptime: 19 hours, 7 minutes, 23 seconds
   Inbound SPI 0xca5560f4:
      request id 193, mode tunnel replay-window 16384, seq 0x0
      stats errors:
         replay-window 0, replay 0, integrity_failed 0
      lifetime config:
         softlimit 4534352933249 bytes, hardlimit 6442450944000 bytes
         softlimit 2077499095 pkts, hardlimit 4000000000 pkts
         expire add soft 85619 secs, hard 86400 secs
      lifetime current:
         0 bytes, 0 pkts
         add time Mon May 13 17:33:54 2019, use time Mon May 13 17:33:54 2019
   Outbound SPI 0xc60da749:
      request id 193, mode tunnel replay-window 16384, seq 0x0
      stats errors:
         replay-window 0, replay 0, integrity_failed 0
      lifetime config:
         softlimit 3286021368749 bytes, hardlimit 6442450944000 bytes
         softlimit 2480571031 pkts, hardlimit 4000000000 pkts
         expire add soft 85418 secs, hard 86400 secs
      lifetime current:
         0 bytes, 62937679 pkts
         add time Mon May 13 17:33:54 2019, use time Mon May 13 18:06:42 2019
```

9.3.3.5.9 show ip security encryption

The **`show ip security encryption`** command displays the IP security encryption status information.

Command Mode

EXEC

Command Syntax

show ip security encryption key-length status

Example

This command displays the IP security encryption status:

```
switch# show ip security encryption key-length status
Key length alignment: disabled
```

9.3.3.5.10 show ip security policy

The **`show ip security policy`** command displays the IP security policy information.

Command Mode

EXEC

Command Syntax

`show ip security policy`

Example

This command displays IP security policy configuration information.

```
switch# show ip security policy
Policy Name   Authentication  Encryption   Integrity    Lifetime  Rekey  DH Group

ike-policy    Pre-shared      256-bit AES  256bit Hash  8 hours   False  3072 bit
```

9.3.3.5.11 show ip security profile

The **show ip security profile** command displays the IP security profile information.

Command Mode

EXEC

Command Syntax

show ip security profile

Example

This command displays IP security profile configuration information.

```
switch# show ip security profile
Profile name            IKE Policy Name        SA
ipsec-profile           ike-policy             sa-policy
```

9.3.3.5.12 show ip security security-association

The **show ip security security-association** command displays the IP security SA information.

Command Mode

EXEC

Command Syntax

show ip security security-association

Example

This command displays the IP security SA information.

```
switch#  show ip sec security-association
SA Name      ESP Encryption   ESP Integrity    Lifetime  PFS Group
sa-policy-1  256-bit AES      256bit Hash      24 hours  2k bit
```

9.3.4 Macro-Segmentation Service (CVX)

Arista Macro-Segmentation Service (MSS) is a CloudVision-based service that supports the integration of vendor firewalls with the Arista network fabric.

Topics in this section include:

- Overview
- How MSS Works
- Configuration
- MSS Integration with Check Point
- MSS for Layer 3 Firewall Enhancements
- MSS Commands

9.3.4.1 Overview

The advent of contemporary networking features such as mobile applications and the Internet of Things (IoT) brings additional security challenges unprotected by legacy infrastructure. These security breaches cannot be handled by installing a firewall at the Internet edge. Arista Macro-Segmentation Service (MSS) addresses the security breach issue by securing access, protecting critical data, and ensuring end-user privacy.

Arista MSS provides a CloudVision-based service that provides the point of integration between individual vendor firewalls or a firewall manager and the Arista network fabric. MSS supports flexibility on where to place the service devices and workloads, Physical-to-Physical (P-to-P) and Physical-to-Virtual (P-to-V).

MSS components include:

- Arista leaf-spine switch fabric
- Arista CloudVision
- Vendor firewall attached to a spine or service leaf switches. Different vendor firewalls can be attached to different switches to enhance scalability.

The component topology supports consistency in application deployment, scale, manageability, and scalability of the network and service layers. For details, see:

- Benefits
- Terminology
- Usage Scenarios

9.3.4.1.1 Benefits

The key benefits include:

- MSS provides enhanced security between physical and virtual workloads in the data center.

- MSS automatic and seamless service insertion ability eliminates manual traffic steering for workloads or tenants.
- MSS applies the security policies to the host and application throughout the network.
- MSS provides flexibility as there are no proprietary frame formats, tagging, or encapsulation.

9.3.4.1.2 Terminology

Familiarize with the following MSS terminology:

- **Intercept Switch/VTEP**: The TOR switch and VXLAN tunnel endpoint connected to the host, from which traffic gets intercepted. In the topology diagram, Intercept-1 and Intercept-2 are intercept switches.
- **Service Switch/VTEP**: The TOR switch and VXLAN tunnel endpoint connected to a firewall. In the topology diagram, Service-1 is the service switch.
- **VXLAN**: Virtual eXtensible LAN - a standards-based method of encapsulating Layer 2 traffic across a Layer 3 fabric.
- **CVX**: Arista CloudVision eXchange (CVX) is part of CloudVision and is a virtualized instance of the same Extensible Operating System (EOS) that runs on physical switches. It functions as a point of integration between customer firewalls or firewall policy managers and the Arista network to steer traffic to the firewall.

9.3.4.1.3 Usage Scenarios

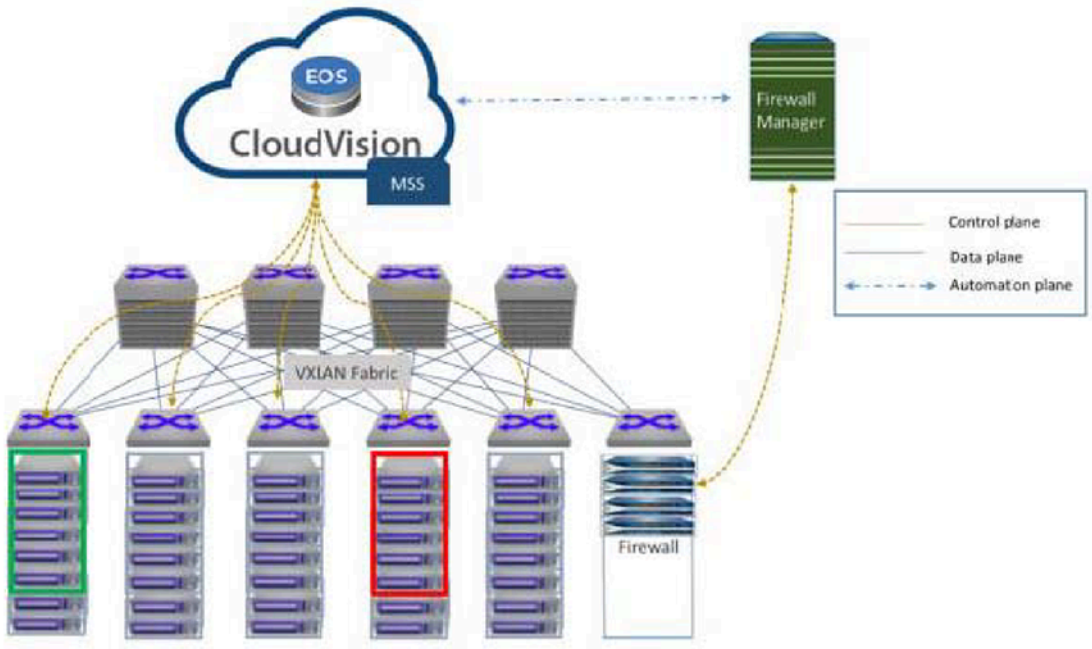
The following usage scenarios describe a few major security challenges in today's data center that are successfully handled by MSS.

1. Securing server-to-server traffic.

   This scenario provides information about the role of MSS in securing network traffic between physical-to-physical (P-to-P) and physical to virtual (P-to-V) servers. Prior to MSS, network infrastructure devices followed the firewall sandwich setup where firewalls were placed in line between the security zones. This setup would impact scalability and performance of the servers.

Using MSS, this restriction on firewall placement is reduced. Firewalls are now attached to a service leaf switch in the network fabric and they still protect hosts without concern about their physical location. The following topology demonstrates the usage scenario.

Figure 9-12: Securing server-server traffic



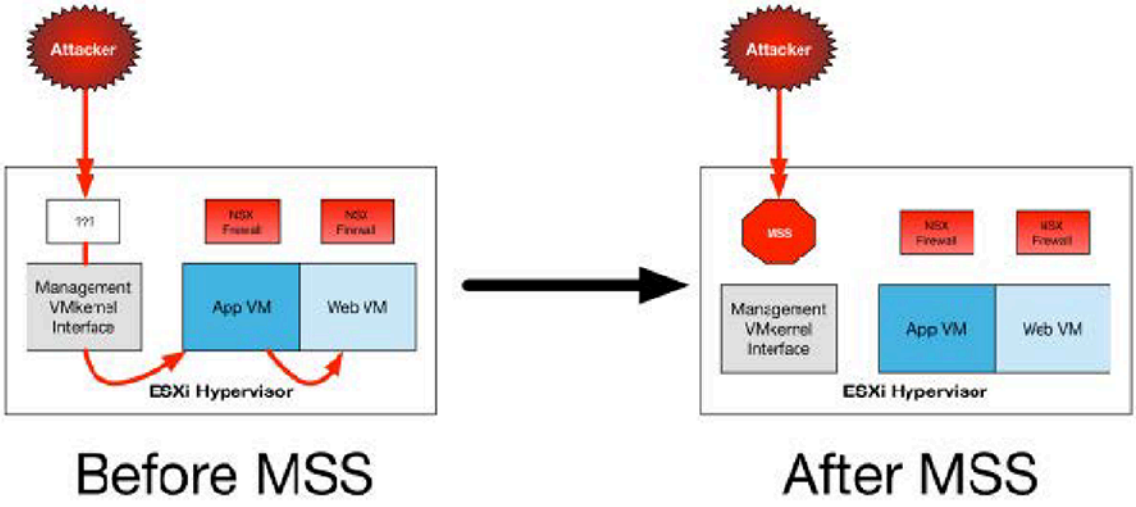
2. Monitoring and securing management traffic.

   This usage scenario demonstrates how MSS successfully monitors and secures management interfaces in the data center.

   The modern data center caters to managing the application, storage, virtualization, network, analytics and other layers. With virtualization, the hypervisor management also needs to be secured to prevent unwanted access to a hypervisor management interface. In the event of a rogue access, Arista's MSS protects management interfaces. The explicitly allowed hosts can gain access through a jump host or

administrator end-user computing instances. The following topology diagram illustrates the role of MSS in a data center.

Figure 9-13: Monitoring and Securing management traffic



9.3.4.2 How MSS Works

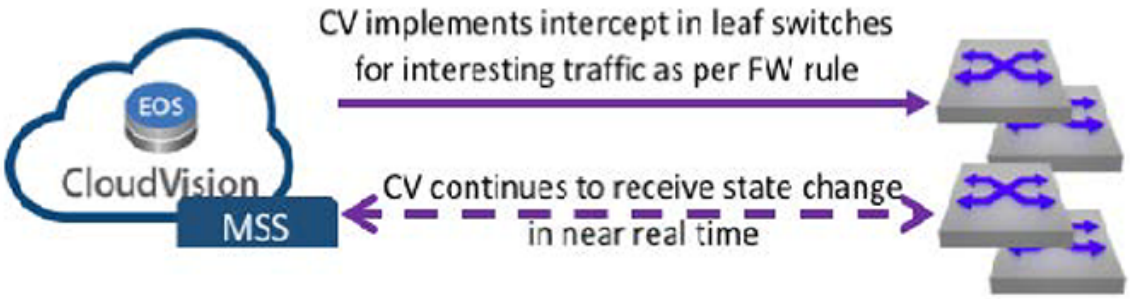
The following steps provide information about how MSS works as a service in the data center.

1. MSS is enabled on the CloudVision eXchange (CVX) and the Arista switches are configured to stream their active state to CVX. This allows CVX to build a database of hosts and firewalls attached to the network and also to identify physical ports and IP addresses. CVX is also configured to communicate and synchronize policies from a vendor's firewall.

2. CVX sends a request to the firewall or firewall manager to provide information about the security policies which are tagged for MSS usage.

3. The MSS service on CVX determines the flow based forwarding rules to be pushed to the switches in the network.

Figure 9-14: CVX intercept



4. The leaf switch starts sending intercepted traffic to the service leaf when the intercept has been applied to the leaf switch.

Figure 9-15: Leaf switches intercept

5. Traffic is forwarded completely unmodified to the firewall after it enters the service leaf where the firewall is attached. Based on the configuration policy, the firewall applies the required actions such as inspection, log, allow, or deny.

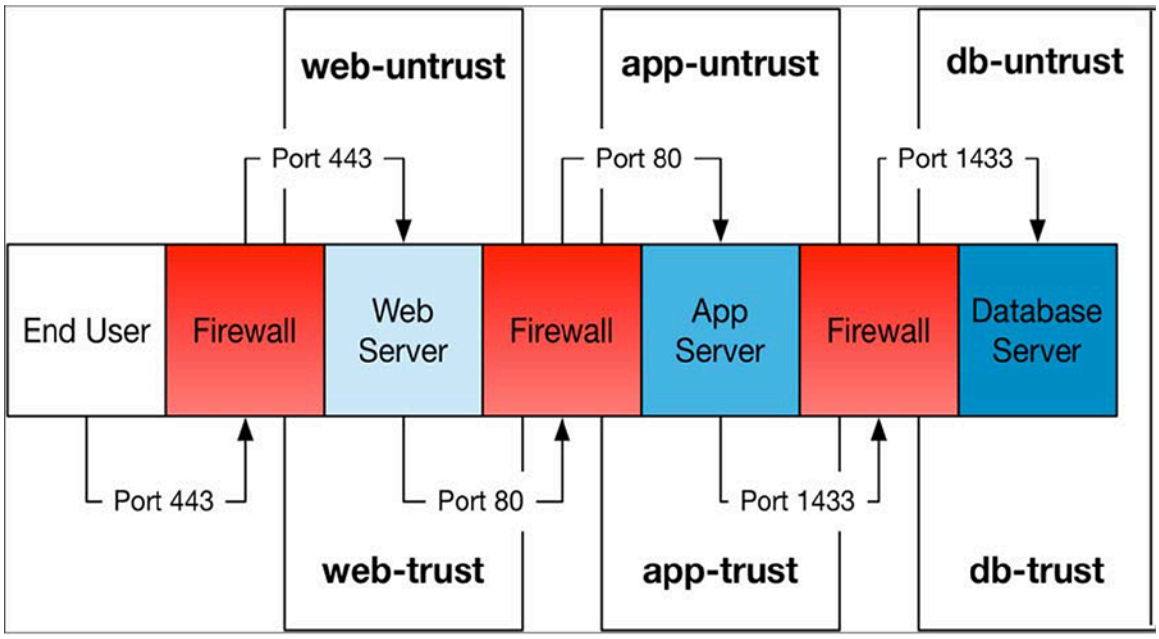
6. The service leaf switch sends the inspected traffic to its final destination or to the destination based on the firewall policy.

9.3.4.3 Configuration

The following sections provide detailed information about MSS configuration, system requirements, recommendations, and limitations.

The traffic flow below is an example of a typical MSS deployment with a 3-tiered application. The goal of this design is to limit access between hosts in the following zones: web-untrust, app-untrust, db-untrust, web-trust, app-trust, and db-trust.

Figure 9-16: Traffic flow in an MSS deployment

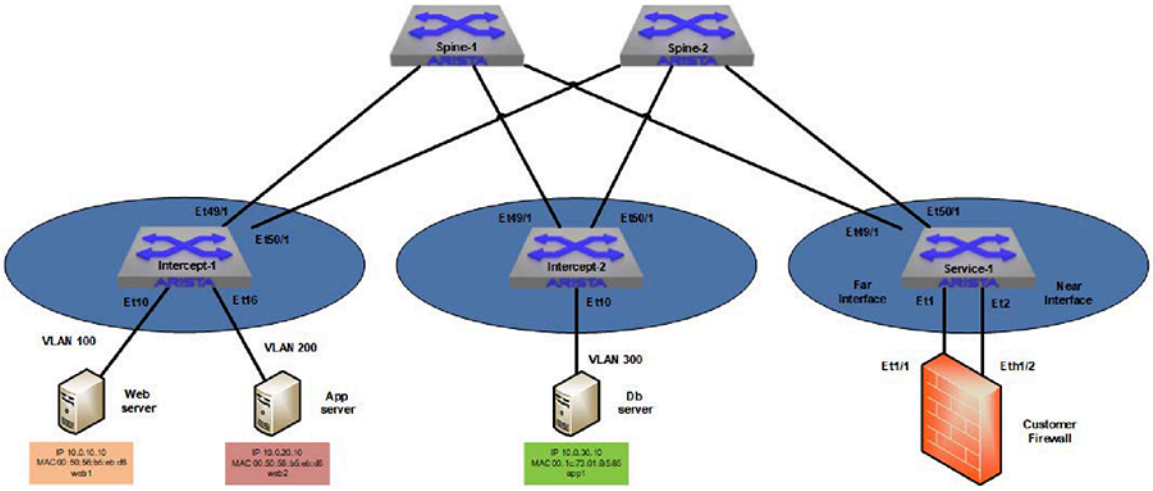


End users in the untrust zone access the web server through the TCP/443 port. Traffic flows through the active firewall to the web server interface in the web-untrust security zone. The web server interface in the web-trust security zone accesses the application server interface in the app-untrust security zone through port TCP/80 after traversing the firewall. From there, the application server interface in the app-trust security zone accesses the database through TCP/1433 in the db-untrust zone.

The following physical topology indicates the MSS setup.

The hosts are attached to a pair of intercept leaf switches. A firewall connects to a service leaf switch using a pair of physical interfaces with a subinterface per zone or vWire.

Figure 9-17: Physical Topology of the MSS



- System Requirements
- Recommendations and Limitations
- Configuring MSS

9.3.4.3.1 System Requirements

The system requirements to effectively run MSS are listed below.

- Arista CloudVision eXchange (CVX).
- Arista 7280SR, 7280TR, 7280CR, 7020SR, 7020TR series switches; 7050X, 7050X2, 7060X, and 7060X2 series top of rack (TOR) switches.
- Connected to the hosts to intercept traffic from the firewall devices.
- The network must be a VXLAN-enabled fabric with CVX running the VXLAN Control Service (VCS) or EVPN.

9.3.4.3.2 Recommendations and Limitations

Firewall

The firewall policy name must not have any whitespace character in the name. As an example, ***PCI policy*** is an unacceptable policy name. An acceptable name would be ***PCI_policy***.

9.3.4.3.3 Configuring MSS

These sections describe steps to configure MSS.

- Deploying CVX
- Enabling the VXLAN Control Service on CVX
- Configuring the Access Switches and the Service Switch Ports
- Enabling DirectFlow on Access Switches and Service Switches
- Enabling VXLAN Routing on the TOR Switches
- Configuring MSS on CVX
- Configuring the Firewall

9.3.4.3.3.1 Deploying CVX

Deploy CloudVision and configure the Arista TOR switches to connect to it. A CVX cluster of three instances with host names of ***cvx01***, ***cvx02***, and ***cvx03*** are configured as an example.

Note: As a best practice, always deploy the CV in a HA cluster with a minimum of three instances.

9.3.4.3.3.2 Enabling the VXLAN Control Service on CVX

Enable the VXLAN Control Service (VCS) on every CVX instance after deploying the three Arista CVX instances to manage the TOR switches.

VCS allows hardware VXLAN Tunnel End Points (VTEPs) to share state with each other in order to establish VXLAN tunnels without the need for a multicast control plane.

Example

CVX instance cvx01

```
cvx01(config-cvx)# service VXLAN
cvx01(config-cvx-VXLAN)# no shutdown
```

Similarly, VCS is enabled on the ***cvx02*** and ***cvx03*** devices.

9.3.4.3.3.3 Configuring the Access Switches and the Service Switch Ports

Configure the switch ports that are connected to the hosts, whose traffic should be steered to the firewalls and the service switch ports which are connected to the firewalls.

Access Switch Configuration

The switch ports connected to the hosts, whose traffic needs to be intercepted, need to be configured as 802.1q trunks with the VLAN that is mapped to the VNI requiring interception. Unique VLAN IDs are configured for each tier of the application.

Access Switch (Intercept-1)

```
intercept-1# configure
intercept-1(config)# interface et10
intercept-1(config-if-Et10)# description web server
intercept-1(config-if-Et10)# switchport mode trunk
intercept-1(config-if-Et10)# switchport trunk allowed vlan 100

intercept-1(config)# interface et16
intercept-1(config-if-Et16)# description app server
intercept-1(config-if-Et16)# switchport mode trunk
intercept-1(config-if-Et16)# switchport trunk allowed vlan 200
```

Access Switch (Intercept-2)

```
intercept-2# configure
intercept-2(config)# interface et10
intercept-2(config-if-Et1)# description db server
intercept-2(config-if-Et1)# switchport mode trunk
intercept-2(config-if-Et1)# switchport trunk allowed vlan 300
```

Note: For untagged traffic, configure a native VLAN on the port using the **switchport trunk native vlan** command.

Service Switch (Service-1)

```
service-1# configure
service-1(config)# interface port-channel 10
service-1(config-if-Po10)# description Far Interface
service-1(config-if-Po10)# switchport mode trunk
service-1(config-if-Po10)# switchport trunk allowed vlan none
service-1(config-if-Po10)# spanning-tree bpdufilter enable

service-1(config)# interface port-channel 20
service-1(config-if-Po20)# description Near Interface
service-1(config-if-Po20)# switchport mode trunk
service-1(config-if-Po20)# switchport trunk allowed vlan none
service-1(config-if-Po20)# spanning-tree bpdufilter enable
```

Note: Dynamically mapped VLANs are not shown in the switch port configuration. You can view them by running the **`show vlan`** command on the switch once a policy is applied.

9.3.4.3.3.4 Enabling DirectFlow on Access Switches and Service Switches

Arista MSS uses DirectFlow to intercept traffic while the VXLAN is used to carry tunnel traffic from the intercepted host to the firewall and back. DirectFlow should be enabled on every intercept switch as well as the service switches.

Switch Service-1

```
service-1# configure
service-1(config)# directflow
service-1(config-directflow)# no shutdown
```

Switch Intercept-1

```
intercept-1# configure
intercept-1(config)# directflow
intercept-1(config-directflow)# no shutdown
```

Switch Intercept-2

```
intercept-2# configure
intercept-2(config)# directflow
intercept-2(config-directflow)# no shutdown
```

9.3.4.3.3.5 Enabling VXLAN Routing on the TOR Switches

CVX uses Address Resolution Protocol (ARP) to determine where intercept hosts are physically located in the network. VXLAN routing should be configured on every TOR switch that will be intercepting traffic to ensure that CVX is aware of every host ARP entry.

The following configuration shows the routing configuration for each tier of the application, but not the entire VXLAN configuration. For more information on how to configure VXLAN and VXLAN routing, refer to the VXLAN section of the *Arista EOS Configuration Guide*.

Switch Intercept-1

```
intercept-1# configure
intercept-1(config)# ip routing
intercept-1(cofig)# interface vlan100
intercept-1(config-if-Vl100)# ip address virtual 10.0.10.254/24
intercept-1(config)# interface vlan200
intercept-1(config-if-Vl200)# ip address virtual 10.0.20.254/24
intercept-1(config)# interface vlan300
```

```
intercept-1(config-if-Vl300)# ip address virtual 10.0.30.254/24
```

Switch Intercept-2

```
intercept-2# configure
intercept-2(config)# ip routing
intercept-2(cofig)# interface vlan100
intercept-2(config-if-Vl100)# ip address virtual 10.0.10.254/24
intercept-2(config)# interface vlan200
intercept-2(config-if-Vl200)# ip address virtual 10.0.20.254/24
intercept-2(config)# interface vlan300
intercept-2(config-if-Vl300)# ip address virtual 10.0.30.254/24
```

Switch Service-1

```
service-1# configure
service-1(config)# ip routing
service-1(cofig)# interface vlan100
service-1(config-if-Vl100)# ip address virtual 10.0.10.254/24
service-1(config)# interface vlan200
service-1(config-if-Vl200)# ip address virtual 10.0.20.254/24
service-1(config)# interface vlan300
service-1(config-if-Vl300)# ip address virtual 10.0.30.254/24
```

9.3.4.3.3.6 Configuring MSS on CVX

This step enables configuring Arista MSS on CVX. The topology diagram depicts three CVX instances in a cluster and the configuration is the same for every instance. The active and standby vendor firewalls are configured. If Panorama is used, only Panorama should be configured.

Example

In the example, the primary vendor firewall has a DNS name of ***fw-ha-node-1***. The standby firewall has a DNS name of ***fw-ha-node-2***. The username and password are set as ***admin***.

CVX instance *cvx01*

```
cvx01# configure
cvx01(config)# cvx
cvx01(config-cvx)# no shutdown
cvx01(config-cvx)# service mss
cvx01(config-cvx-mss)# no shutdown
cvx01(config-cvx-mss)# vni range 20000-30000
cvx01(config-cvx-mss)# dynamic device-set panfw1
cvx01(config-cvx-mss-panfw1)# tag Arista_MSS
cvx01(config-cvx-mss-panfw1)# type palo-alto firewall
cvx01(config-cvx-mss-panfw1)# state active
cvx01(config-cvx-mss-panfw1)# device fw-ha-node-1
cvx01(config-cvx-mss-panfw1-fw-ha-node-1)# username admin password 0 admin
```

CVX instance *cvx02*

```
cvx02# configure
cvx02(config)# cvx
cvx02(config-cvx)# no shutdown
cvx02(config-cvx)# service mss
cvx02(config-cvx-mss)# no shutdown
cvx02(config-cvx-mss)# vni range 20000-30000
cvx02(config-cvx-mss)# dynamic device-set panfw1
cvx02(config-cvx-mss-panfw1)# tag Arista_MSS
cvx02(config-cvx-mss-panfw1)# type palo-alto firewall
cvx02(config-cvx-mss-panfw1)# state active
cvx02(config-cvx-mss-panfw1)# device fw-ha-node-1
cvx02(config-cvx-mss-panfw1-fw-ha-node-1)# username admin password 0 admin
```

CVX instance *cvx03*

```
cvx03# configure
cvx03(config)# cvx
cvx03(config-cvx)# no shutdown
cvx03(config-cvx)# service mss
cvx03(config-cvx-mss)# no shutdown
cvx03(config-cvx-mss)# vni range 20000-30000
cvx03(config-cvx-mss)# dynamic device-set panfw1
cvx03(config-cvx-mss-panfw1)# tag Arista_MSS
cvx03(config-cvx-mss-panfw1)# type palo-alto firewall
cvx03(config-cvx-mss-panfw1)# state active
cvx03(config-cvx-mss-panfw1)# device fw-ha-node-1
cvx03(config-cvx-mss-panfw1-fw-ha-node-1)# username admin password 0 admin
```

9.3.4.3.3.7 Configuring the Firewall

Three policies are created in addition to the default implicit deny policy for inter-zone traffic. The implicit deny ensures that the inter-zone traffic is not allowed unless a policy explicitly allows for it.

The first policy ***untrust_to_web1*** is from the ***untrust*** zone to the ***web1*** zone, that allows HTTPS traffic from anywhere to the web server web.

The third policy ***web2_to_app1*** is from the ***web2*** zone to the app1 zone that allows HTTP traffic between the web server web and the application server app.

The fifth policy ***app2_to_db1*** is from the ***app2*** zone to the ***db1*** zone that allows database traffic on port ***TCP/1433*** between the application server app and the database server db.

The second, fourth, and sixth policies prevent the firewall to drop a session for which does not see the initial connection to the protected resource. This could happen if the protected resource has not sent any traffic previous to this point.

Refer to the following images for more clarity about the above policies and interface configuration.

Figure 9-18: Firewall Policy Configuration

	Name	Tags	Type	Source Zone	Source Address	Destination Zone	Destination Address	Rule Usage Hit Count	Rule Usage Last Hit	Rule Usage First Hit	Application	Service	Action
1	vl 150 allow	offload	universal	vl 1200	150.0.1.0/30	phy int	160.0.5.1/32	0	-	-	any	UDP_dst_2000-1	Allow
2	test	offload	universal	vl 1200	170.0.1.0/30	any	any	0	-	-	any	application-default	Allow
3	vl 150 drop	offload	universal	vl 1200	150.0.1.0/30	any	any	0	-	-	any	udp_10000 UDP_dst_2000-1	Drop
4	vl 150 offload	offload	universal	vl 1200	150.0.1.0/29	any	any	0	-	-	any	application-default	Allow
5	vl 170-171	mss	universal	vl 1200	170.0.1.0/30	phy int	171.0.7.0/30	0	-	-	any	udp 17100	Allow
6	vl 150	mss	universal	vl 1200	150.0.1.0/27	any	any	0	-	-	any	application-default	Allow
7	intrazone-default	none	intrazone	any	any	(intrazone)	any	0	-	-	any	any	Allow
8	interzone-default	none	interzone	any	any	any	any	160	2019-03-11 13:38:35	2019-02-11 20:03:33	any	any	Allow

Figure 9-19: Firewall Interface Configuration

Interface	Interface Type	Management Profile	Link State	IP Address	Virtual Router	Tag	VLAN / Virtual-Wire	Security Zone	Features	Comment
ethernet1/1	Aggregate (ae1)			none	none	Untagged	none	none		Po 100 - near interface
ethernet1/2	Aggregate (ae1)			none	none	Untagged	none	none		po 100 - near interface
ethernet1/3	Aggregate (ae2)			none	none	Untagged	none	none		po 101 - far interface
ethernet1/4	Aggregate (ae2)			none	none	Untagged	none	none		po 101 - far interface
ethernet1/5	Layer2			none	none	Untagged	none	none		
ethernet1/6	Virtual Wire			none	none	Untagged	none	none		
ethernet1/7	Tap			none	none		none	none		
ethernet1/8	Layer2			none	none	Untagged	none	none		
ethernet1/9	Layer2			none	none	Untagged	none	none		
ethernet1/10	Aggregate (ae7)			none	none	Untagged	none	none		
ethernet1/11	Aggregate (ae8)			none	none	Untagged	none	none		
ethernet1/12	Aggregate (ae7)			none	none	Untagged	none	none		
ethernet1/13	Aggregate (ae8)			none	none	Untagged	none	none		
ethernet1/14	Tap			none	none		none	none		
ethernet1/15	Virtual Wire			none	none	Untagged	none	none		
ethernet1/16	Virtual Wire			none	none	Untagged	none	none		
ethernet1/17	Layer3	allow ping		none	none	Untagged	none	none		
ethernet1/17.1200	Layer3	allow ping		199.2.0.2/21 199:2::100:2/64	default	1200	none	vl 1200		
ethernet1/17.1201	Layer3	allow ping		199.2.8.2/21	default	1201	none	vl 1201		

Create a rule that Arista MSS will use to intercept and redirect traffic and add a firewall policy with the default Arista_MSS tag as shown in the example above. MSS intercepts all traffic from endpoints identified in policies that match the tag values configured in CVX. The firewall will apply all rules (tagged or untagged) to all traffic.

Note: LLDP should always be enabled on the firewall interfaces attached to the service switches. To minimize reconvergence time on the network changes, reduce the LLDP transmit interval and hold time multiples on the firewall, while keeping the LLDP hold time above the LLDP timer configured on the connected Arista switches.

Alternatively, the **`device interface map`** command can be used on CVX to manually map a device to Arista switch interfaces. To map multiple devices, add a mapping entry for each device.

```
dynamic device-set fw1
```

```
device dc-firewall-1
map device-interface ethernet1/1 switch 00:1c:73:7e:21:bb interface Ethernet1
map device-interface ethernet1/2 switch 00:1c:73:7e:21:bb interface Ethernet9
```

The first policy ***untrust_to_web1*** is from the untrust zone to the web1 zone, that allows HTTPS traffic from anywhere to the web server web.

The third policy ***web2_to_app1*** is from the web2 zone to the app1 zone that allows HTTP traffic between the web server web and the application server app.

The fifth policy ***app2_to_db1*** is from the app2 zone to the db1 zone that allows database traffic on port TCP/1433 between the application server app and the database server db.

The second, fourth, and sixth policies prevent the firewall to drop a session for which does not see the initial connection to the protected resource. This could happen if the protected resource has not sent any traffic previous to this point.

Refer to the following images for more clarity about the above policies and interface configuration.

Figure 9-20: Firewall Policy Configuration

				Source		Destination		Rule Usage					
	Name	Tags	Type	Zone	Address	Zone	Address	Hit Count	Last Hit	First Hit	Application	Service	Action
1	vl 150 allow	offload	universal	vl 1200	150.0.1.0/30	phy int	160.0.5.1/32	0	-	-	any	UDP_dst_2000-1	Allow
2	test	offload	universal	vl 1200	170.0.1.0/30	any	any	0	-	-	any	application-default	Allow
3	vl 150 drop	offload	universal	vl 1200	150.0.1.0/30	any	any	0	-	-	any	udp_10000 UDP_dst_2000-1	Drop
4	vl 150 offload	offload	universal	vl 1200	150.0.1.0/29	any	any	0	-	-	any	application-default	Allow
5	vl 170-171	mss	universal	vl 1200	170.0.1.0/30	phy int	171.0.7.0/30	0	-	-	any	udp 17100	Allow
6	vl 150	mss	universal	vl 1200	150.0.1.0/27	any	any	0	-	-	any	application-default	Allow

8	interzone-default	none	interzone	any	any	any	any	160	2019-03-11 13:38:35	2019-02-11 20:03:33	any	any	Allow

Figure 9-21: Firewall Interface Configuration

Interface	Interface Type	Management Profile	Link State	IP Address	Virtual Router	Tag	VLAN / Virtual-Wire	Security Zone	Features	Comment
ethernet1/1	Aggregate (ae1)			none	none	Untagged	none	none		Po 100 - near interface
ethernet1/2	Aggregate (ae1)			none	none	Untagged	none	none		po 100 - near interface
ethernet1/3	Aggregate (ae2)			none	none	Untagged	none	none		po 101 - far interface
ethernet1/4	Aggregate (ae2)			none	none	Untagged	none	none		po 101 - far interface
ethernet1/5	Layer2			none	none	Untagged	none	none		
ethernet1/6	Virtual Wire			none	none	Untagged	none	none		
ethernet1/7	Tap			none	none		none	none		
ethernet1/8	Layer2			none	none	Untagged	none	none		
ethernet1/9	Layer2			none	none	Untagged	none	none		
ethernet1/10	Aggregate (ae7)			none	none	Untagged	none	none		
ethernet1/11	Aggregate (ae8)			none	none	Untagged	none	none		
ethernet1/12	Aggregate (ae7)			none	none	Untagged	none	none		
ethernet1/13	Aggregate (ae8)			none	none	Untagged	none	none		
ethernet1/14	Tap			none	none		none	none		
ethernet1/15	Virtual Wire			none	none	Untagged	none	none		
ethernet1/16	Virtual Wire			none	none	Untagged	none	none		
ethernet1/17	Layer3	allow ping		none	none	Untagged	none	none		
ethernet1/17.1200	Layer3	allow ping		199.2.0.2/21 199:2::100:2/64	default	1200	none	vl 1200		
ethernet1/17.1201	Layer3	allow ping		199.2.8.2/21	default	1201	none	vl 1201		

Create a rule that Arista MSS will use to intercept and redirect traffic and add a firewall policy with the default ***Arista_MSS*** tag as shown in the example above. MSS intercepts all traffic from endpoints identified in policies that match the tag values configured in CVX. The firewall will apply all rules (tagged or untagged) to all traffic.

Note: LLDP should always be enabled on the firewall interfaces attached to the service switches. To minimize reconvergence time on the network changes, reduce the LLDP transmit interval and hold time multiples on the firewall, while keeping the LLDP hold time above the LLDP timer configured on the connected Arista switches.

Alternatively, the **`device interface map`** command can be used on CVX to manually map a device to Arista switch interfaces. To map multiple devices, add a mapping entry for each device.

```
dynamic device-set fw1
device dc-firewall-1
map device-interface ethernet1/1 switch 00:1c:73:7e:21:bb interface Ethernet1
map device-interface ethernet1/2 switch 00:1c:73:7e:21:bb interface Ethernet9
```

9.3.4.4 MSS Integration with Check Point

Macro Segmentation Service (MSS) is configurable for Check Point Software Technologies (Check Point) Firewalls. The configuration and deployment requires the use of Check Point Management Server (Gaia), a security management platform which allows central management of Check Point gateway security devices.

Requirements

The following requirements apply to the deployment.

- ***MSS version R80.30 version 1.5*** and above and a special URL access on the Management Server using a Gateway API provided by Check Point.
- ***Gateway version R80.30*** with API version 1.2 and above.
- ***Check Point Management Server release R31*** and above.

Configuration and Deployment

The following components of the solution require configuration:

- Check Point Gateway firewalls
- Check Point Management Server
- Arista leaf switches
- CVX

Check Point Firewalls (Gateways)

Interface Configuration

Configure IPv4 addresses on the routed L3 interfaces on the firewall interfaces connected to the Arista TORs.

IPv4 Static Routes Configuration

Configure IPv4 static routes to include routes to all subnets of the hosts which MSS will be intercepting either using a WebUI or CLI as shown below. The nexthop gateway addresses are the gateway of the subnet to which the firewall interfaces. The static route information is used by MSS to identify which firewall interface is connected to the subnet to which the intercepted traffic needs to be forwarded.

```
set static-route 192.0.2.0/24 nexthop gateway address 192.0.2.155 on
```

The following displays the configuration.

```
gateway1> show route static
Codes: C - Connect ed, S - Static, R - RIP, B - BGP (D - Default),
       O - OSPF IntraArea (IA - InterArea, E - External, N - NSSA),
       A - Aggregate, K - Kernel Remnant, H - Hidden, P - Suppressed,
       U - Unreachable, i - Inactive

S               0.0.0.0/0           via 172.2.18.12, Mgmt, cost 0, age 3134690
S               10.6.10.0/24        via 10.6.100.2, eth1, cost 0, age 3134690
S               10.6.20.0/24        via 10.6.200.2, eth2, cost 0, age 3134690
```

Check Point Management Server Configuration

The Check Point firewall devices intended to be used with Arista MSS must be registered and fully manageable via a Check Point Management Server.

- Identify or define a new security policy network layer to be considered by MSS where 'TestPolicy' is the security policy network layer that is referenced in the CVX configuration.
- Create firewall access rules (to be used by Arista MSS).
- In the access rule, the supported source and destination object types are Host, Network, and Security Zone.
- In the “Services & Applications,” the following services are supported: 1: ICMP, IGMP, IPv4, TCP, EGP, UDP, IPv6, RSVP, GRE, OSPFIGP, SCTP.
- Add tags in the policy comments/description field in this format: "tags(<tag1>, <tag2>, ...)", e.g. “tags(Arista_MSS1, Arista_MSS2)”
  - Arista MSS inspects management server access rules that have an embedded "tags( )" string in the comments field. Individual tags are extracted from within the enclosing parentheses and compared with the tags configured in the Arista MSS device-set on CVX.

1-to-1 HA Cluster Configuration

The following figure shows the 1-to-1 HA cluster. The HA interface pairs connected to the Arista switches should have Virtual IP addresses where the intercepted traffic will be forwarded. The active firewall sends out a GARP with its own MAC to indicate where traffic sent to the VIP should be forwarded.

Arista Leaf Switches Configuration

The following configures the switch interfaces connected to the firewall.

```
switchport trunk native vlan <interface vlan>
switchport mode trunk
spanning-tree portfast
spanning-tree bpdufilter enable

interface Vlan<interface vlan>
   ip address virtual <interface IPv4 address>/<mask>
```

CVX Configuration

The following displays the CVX configuration with Standalone Check Point firewall.

```
!! Standalone firewall
cvx
   no shutdown
   service mss
      no shutdown
      !
      dynamic device-set chkpt
         device <management-server-ip-or-dnsName>
            username admin password 7 PKigsm//o3IcnW5rqoZXWQ==
            protocol https 4434   (or the configured https port like 443)
            group <management-server-network-layer>
         !
         device member <checkpoint-device-name>
            map device-interface eth1 switch 00:1c:73:7e:28:11 interface Ethernet39
            map device-interface eth2 switch 00:1c:73:7e:28:11 interface Ethernet40
```

```
         type check-point management-server
         policy tag offload Arista_MSS_offload
         policy tag redirect Arista_MSS
         state active
```

The checkpoint-device-name used in the **`device member`** command is the name used in the Management Server to identify that firewall. A sample CVX configuration with Check Point firewalls in 1-to-1 High Availability cluster configuration will include more than one device member as follows:

```
!! HA Active/Passive firewall pair
cvx
   no shutdown
   service mss
      no shutdown
      !
      dynamic device-set chkpt
         device <management-server-ip-or-dnsName>
            username admin password 7 PKigsm//o3IcnW5rqoZXWQ==
            protocol https 4434   (or the configured https port like 443)
            group <management-server-network-layer>
         !
         device member <checkpoint-device1-name>
            map device-interface eth1 switch 00:1c:73:7e:28:11 interface Ethernet39
            map device-interface eth2 switch 00:1c:73:7e:28:11 interface Ethernet40
         device member <checkpoint-device2-name>
            map device-interface eth1 switch 00:1c:73:7e:28:11 interface Ethernet41
            map device-interface eth2 switch 00:1c:73:7e:28:11 interface Ethernet42
         type check-point management-server
         policy tag offload Arista_MSS_offload
         policy tag redirect Arista_MSS
         state active
```

9.3.4.5 MSS for Layer 3 Firewall Enhancements

The **verbatim** qualifier enhances the Macro Segmentation Service (MSS) with two policy actions: **redirect** and **offload**. For firewall policies tagged with the **redirect** tag, MSS extracts IP addresses from the policy and forwards all traffic destined to or generated from that set of IP addresses to the firewall. The additional **verbatim** tag, redirecting bidirectional traffic is restricted to the subset that matches the additional qualifiers of a firewall policy to a firewall (such as the source, destination IP addresses or subnets, protocol, L4 ports).

The **verbatim** tag can also be paired with the **offload** tag for a policy which installs necessary DirectFlow rules at the TORs to drop or allow the traffic matching the exact qualifiers in the policy definition. If the **verbatim** tag is not used with the offload tag, the behavior is to offload enforcement for all traffic matching the specific policy rule, while redirecting the remainder of the (non-matching) traffic to the firewall to ensure the security policy for the protected host remains in compliance. The addition of the **verbatim** tag removes this implicit redirection

Configuring for Verbatim Use

Firewall Configuration

The verbatim is a modifier of the original policy enforcement scheme and works with multiple firewalls such as those from Palo Alto Networks and Fortinet.

Policy Semantics

IP address extraction for **redirect** or **redirect** tag:

- If IP addresses are specified in source or destination field, Mss extracts those for redirection.
- If no IP addresses are specified, then Mss extracts the subnets corresponding to the source and destination zone for redirection.
- If no zones are specified, then Mss extracts all subnets in the **default** virtual-router for redirection.

Constraints on **offload** tag policies:

- Must have IP address specified in source or destination field if the corresponding zone is an **external** zone (zone towards default route).

Constraints on **redirect verbatim** tag policies:

- Must have IP address specified in source or destination field if the corresponding zone is an **external** zone (zone towards default route).
- Must have either zone or IP specified in both source and destination field. ‘Any’, ‘All’, or similar constructs are not supported for source or destination fields.

Policies with broadcast or multicast destination:

Only **offload** and **offloadverbatim** tags are supported for policies with IPv4 broadcast or IPv4 multicast destination.

CVX Configuration

The following configuration commands set 'tag-list' as the verbatim modifier on a per device basis for the **redirect** and **offload** tags.

```
cvx
   service mss
      dynamic device-set <device-set-name>
         device <device-name>
           [no | default] policy tag redirect <tag-list>
           [no | default] policy tag offload <tag-list>
           [no | default] policy tag modifier verbatim <tag-list>
```

TCAM Profile Configuration

The following depicts a recommended TCAM profile to be used with MSS.

Note: This is an example for some of the devices that are currently supported.

```
hardware tcam
   profile direct-flow-mssl3-VXLAN
      feature acl port ip
         sequence 50
         key size limit 160
```

```
         key field dscp dst-ip ip-frag ip-protocol l4-dst-port l4-ops l4-src-port src-ip tcp-
control ttl
         action count drop
         packet ipv4 forwarding bridged
         packet ipv4 forwarding routed
         packet ipv4 forwarding routed multicast
         packet ipv4 mpls ipv4 forwarding mpls decap
         packet ipv4 mpls ipv6 forwarding mpls decap
         packet ipv4 non-VXLAN forwarding routed decap
         packet ipv4 VXLAN eth ipv4 forwarding routed decap
         packet ipv4 VXLAN eth ipv6 forwarding routed decap

```

The following displays the profile. The platform does not support any arbitrarily created PMF profile. If the PMF profile cannot be programmed, the show command will print '**ERROR**' in the status column.

```
switch# show hardware tcam profile
                    Configuration           Status
FixedSystem         direct-flow-mssl3-VXLAN  direct-flow-mssl3-VXLAN
```

Limitations

- DirectFlow needs to be enabled at the TOR so that the policies enforced by MSS are correctly programmed.
- *Group* option is available only for some switches.
- Deployments with a mix of switches require special considerations. The following table summarizes supported configurations in different deployment models.

Table 16: Configuration Summary

Both compute and service TORs: DCS-7050X, DCS-7050X2, DCS-7050X3, DCS-7060X, DCS-7060X2	group, verbatim	• redirect • offload • redirect, verbatim • offload, verbatim
Both compute and service TORs: DCS-7020R, DCS-7280R, DCS-7280R2, DCS-7500R, DCS-7500R2	verbatim	• redirect, verbatim • offload, verbatim
Both compute and service TORs: DCS-7050X, DCS-7050X2, DCS-7050X3, DCS-7060X, DCS-7060X2, DCS-7020R, DCS-7280R, DCS-7280R2, DCS-7500R, DCS-7500R2	verbatim	• redirect, verbatim • offload, verbatim
DCS-7050X, DCS-7050X2, DCS-7050X3, DCS-7060X, DCS-7060X2 as compute TOR and other series as service TOR (with no intercepted hosts connected).	group, verbatim	• redirect • offload • redirect, verbatim • offload, verbatim

Backward Compatibility and Other Considerations

For existing deployments, (where any of DCS-7020R, DCS-7280R, DCS-7280R2, DCS-7500R, DCS-7500R2 switch platforms are used in the service rack), in order to upgrade hitlessly, upgrade the CVX cluster first and execute the following command prior to upgrading EOS on any switch:

```
cvx
   service mss
      policy enforcement rules group verbatim
```

The command **[no|default] policy enforcement rules {group verbatim | verbatim}** disables / enables policy enforcement.

Displaying CVX Status

The following displays the status of the mss policy.

```
switch# show service mss policy

<--snip-->
                Macro-Segmentation L3 Policy Table
------------------------------------------------------------------------------

9.3.4.6 MSS Commands

Configuration Commands

- dynamic device-set
- exception device
- group
- name-resolution interval (CVX-OpenStack)
- service mss
- state
- tag
- type palo-alto

CVX Show Commands

- show service mss dynamic device-set
- show service mss policy
- show service mss status
- show service mss zone

9.3.4.6.1 dynamic device-set

The **`dynamic device-set`** command configures a device such as a firewall to communicate with the MSS in the MSS configuration mode.

The **`no dynamic device-set`** command removes a previously configured device from the MSS configuration and returns to the CVX mode.

Command Mode

MSS Configuration

Command Syntax

`dynamic device-set` *device-set_name*

`no dynamic device-set` *device-set_name*

Parameter

device-set_name a unique name for the device set.

Example

This example creates a set of firewalls with the name ***panfw1***.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
cvx(config-cvx-mss)# vni range 30000-40000
cvx(config-cvx-mss)# dynamic device-set panfw1
cvx(config-cvx-mss-panfw1)#
```

Note: The **`vni range`** command configures a range of VXLAN Network Identifiers (VNI) that MSS uses to tunnel traffic to the firewall. If VNI range is not configured, the default VNIs in the range of ***1*** to ***16777214*** are used.

9.3.4.6.2 exception device

The **exception device** command bypasses or continues redirecting traffic to service device such as a firewall if the service device control-plane API is unreachable after initial policies have been processed.

The no exception device command.

Command Mode

MSS Configuration

Command Syntax

`exception device unreachable` [bypass | redirect]

`no exception device unreachable` [bypass | redirect]

`default exception device unreachable bypass`

Parameters

- **bypass**: bypass the service device.
- **redirect**: continue redirecting traffic to the service device.

Example

This example redirects traffic to the service device.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
cvx(config-cvx-mss)# vni range 30000-40000
cvx(config-cvx-mss)# dynamic device-set fw
cvx(config-cvx-mss-fw)# device firewall-dc7
cvx(config-cvx-mss-fw)# username admin password 7 PKigsmo3IcnW5rqoZXWQ
cvx(config-cvx-mss-fw)# state active
cvx(config-cvx-mss-fw)# type palo-alto firewall
cvx(config-cvx-mss-fw)# exception device unreachable redirect
```

9.3.4.6.3 group

The **group** command configures the Panorama device group name to be used with MSS.

The no group command removes the group from the MSS configuration when the Panorama firewall manager is used.

See the type Palo-Alto command for more information about the firewall manager.

Command Mode

Device-set mode

Command Syntax

`group` *group_name*

`no group` *group_name*

Parameters

group_name the name of the group.

Example

This command configures the group name as ***mssDevices***.

```
cvx(config)# cvx
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# dynamic device-set pano2
cvx(config-cvx-mss-pano2)# type palo-alto panorama
cvx(config-cvx-mss-pano2)# device myPanorama
cvx(config-cvx-mss-pano2-myPanorama)# group mssDevices
```

9.3.4.6.4 name-resolution interval (CVX-OpenStack)

The **`name-resolution interval`** command specifies the period between consecutive requests that the OpenStack controller sends to the Keystone service for VM and tenant name updates. Keystone is OpenStack's authentication and authorization service.

The default period is ***21600*** seconds (6 hours).

The name-resolution force (CVX-OpenStack) command performs an immediate update, as opposed to waiting for the periodic update.

Command Mode

CVX-OpenStack Configuration

Command Syntax

`name-resolution interval` period

Parameters

period: Keystone identity service polling interval (seconds).

Comment

`service openstack` places the switch in ***CVX-OpenStack*** configuration mode.

Example

These commands set the name resolution interval period at five hours.

```
switch(config)# cvx
switch(config-cvx)# service openstack
switch(config-cvx-openstack)# name-resolution interval 18000
switch(config-cvx-openstack)#
```

9.3.4.6.5 service mss

The **`service mss`** command enters the MSS configuration sub-mode.

The **`no service mss`** command exits the MSS configuration mode and returns to the CVX mode.

Command Mode

CVX Configuration

Command Syntax

```
service mss

no service mss

default service mss
```

Example

This example enables MSS on CVX and enters the MSS config mode.

Note: The **`no shutdown`** command enables MSS on the CloudVision eXchange (CVX).

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
```

9.3.4.6.6 show service mss dynamic device-set

The **`show service mss dynamic device-set`** command displays detailed information about a specific service device set. Information such as device group members, high availability, network, resource details are displayed.

Note: Interfaces from multiple switches can be placed in the same zone by the device.

Command Mode

EXEC

CVX Configuration

Command Syntax

`Show service mss dynamic device-set` *device_set_name* [device *device_name* [group-members | high-availability | neighbors | network | policies | resources]]

Parameters

- ***device_set_name*** defines the device set name.
- **device *device name*** defines the service device properties such as the DNS hostname or IP address of the service device.
- **group members** lists device-group members for an aggregation manager.
- **high-availability** displays service device high availability information.
- **neighbors** displays the service devices ethernet interface neighbor information.
- **network** displays the service devices network interface information.
- **policies** displays the list of policies read from service device that have the MSS tag.
- **resources** displays the service devices system resource information.

Related Commands

- show service mss status
- show service mss policy

Examples

- This command displays information about interfaces that are placed in a zone by the ***device1***.

```
switch# show service mss zone
Source: static
------------------------------------------------
Device: device1
```

- This command displays information about interfaces that are placed in a zone by the ***device1***.

```
switch# show service mss zone
Source: static
------------------------------------------------
Device: device1
Zone: zone1
Switch: 00:00:00:00:00:01
Hostname: switch1.arista.com
Interfaces:
Ethernet1/1
Allowed VLAN: 1000-1010
Port-Channel2/1:
Allowed VLAN: 1000-2000
Switch: 00:00:00:00:00:02
Hostname: switch2.arista.com
Interfaces:
Ethernet10/1
Allowed VLAN: 1000-1010
Zone: zone2
Switch: 00:00:00:00:00:01
Hostname: switch1.arista.com
Interfaces:
Ethernet10/1
Allowed VLAN: 1000-1010
Ethernet 20/1
Allowed VLAN: 1000-2000
```

9.3.4.6.7 show service mss policy

The **`show service mss policy`** command displays generic information about the configuration and operational state of the macro-segmentation service (MSS) policies on a device.

Command Mode

EXEC

CVX Configuration

Command Syntax

`show service mss policy` [[device *device_name*][name *policy-name*][source (static | *plugin_name*)]]

Parameters

- **device *device name*** defines the service device name.
- **name *policy-name*** the filter policy name.
- **source** the source of the policy.
- **static** the policy configured using the command line interface.
- ***plugin_name*** the service device type.

Related Commands

- show service mss status
- show service mss zone

Example

This command displays information about the MSS policy ***policy1*** enabled on the device.

```
cvx# show service mss policy name policy1
Source  Device    Policy  Config   Status
------  --------  ------  -------  -------------  -------------
vendor  Firewall  pan100  policy1  Enabled        Initialized
```

The **`Config`** column indicates the configuration state of a policy. The different states are: **`Enabled`**, **`dry run`**, and **`disabled`** states.

The **`Status`** column indicates the operational state of a policy. The different status types are **`initialized`**, **`pending`**, **`initializing`**, **`active`**, **`reinitializing`**, **`dry-run Complete`**, and **`deactivating`**.

9.3.4.6.8 show service mss status

The **show service mss status** command displays the status of a macro-segmentation service (MSS) on the device.

Command Mode

EXEC

CVX Configuration

Command Syntax

```
show service mss status
```

Related Commands

- show service mss policy
- show service mss zone

Examples

- This command displays the MSS status on the device as Enabled.

```
switch# show service mss status
State: Enabled
Service VNIs: 1500-1600,1800,1900-2000
```

- This command displays the MSS status on the device as Disabled.

```
switch# show service mss status
State: Disabled
Service VNIs: 1-16777214
```

9.3.4.6.9 show service mss zone

The **`show service mss zone`** command displays information about the interfaces that are placed in a single zone by the service device. Along with the show service mss policy command, we can use this command to identify issues with the policy configuration.

Interfaces from multiple switches can be placed in the same zone by the device.

Command Mode

EXEC

CVX Configuration

Command Syntax

`show service mss zone` [[device *device_name*]|[name *zone_name*]|[source (static | *dynamic_source*)]]

Parameters

- **device *device name*** defines the service device properties.
- **name *policy-name*** the filter zone name.
- **source** the source of the zone.
- **static** the zone configured using the command line interface.
- ***dynamic_source*** the service device type.

Related Commands

- show service mss status
- show service mss policy

Example

This command displays information about interfaces that are placed in a zone by the ***device1***.

```
switch# show service mss zone
Source: static
---------------------------------------
Device: device1
Zone: zone1
Switch: 00:00:00:00:00:01
Hostname: switch1.arista.com
Interfaces:
Ethernet1/1
Allowed VLAN: 1000-1010
Port-Channel2/1:
Allowed VLAN: 1000-2000
Switch: 00:00:00:00:00:02
```

```
Hostname: switch2.arista.com
Interfaces:
Ethernet10/1
Allowed VLAN: 1000-1010
Zone: zone2
Switch: 00:00:00:00:00:01
Hostname: switch1.arista.com
Interfaces:
Ethernet10/1
Allowed VLAN: 1000-1010
Ethernet 20/1
Allowed VLAN: 1000-2000
```

9.3.4.6.10 state

The **state** command configures device set as active or disabled or suspended state.

The no state command disables the previously configured state of the device set.

Command Mode

MSS Configuration

Command Syntax

`state` [active | shutdown | suspend]

`no state`

Parameters

- **active**: the active state of the device set. Policy monitoring and network traffic redirection are enabled.
- **shutdown**: the disabled state of the device set. Policy monitoring and network traffic redirection is stopped.
- **suspend**: the suspended state of the device set. Policy monitoring is suspended but there is no change in the existing traffic redirection.

Example

This output example configures the device set state as active.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
cvx(config-cvx-mss)# vni range 30000-40000
cvx(config-cvx-mss)# dynamic device-set panfw1
cvx(config-cvx-mss-panfw1)# tag Arista_MSS
cvx(config-cvx-mss-panfw1)# type palo-alto firewall
cvx(config-cvx-mss-panfw1)# state active
```

9.3.4.6.11 tag

The **tag** command specifies the tag or tags that MSS searches when it is reading the security policy from the firewall or firewall manager in the ***dynamic device-se***t configuration mode. You can specify more than one tag as well.

The no tag command removes the tag from the MSS configuration.

Note: The tag specified should always match with the firewall policy tags in the vendor firewall policy for the MSS to read the policy and set up the intercept.

Command Mode

MSS Configuration

Command Syntax

`tag` *tag_name*

`no tag`

`default tag`

Parameter

tag_name: a unique name for the tag.

Examples

- This command specifies the tag with the name ***Arista_MSS***.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
cvx(config-cvx-mss)# vni range 30000-40000
cvx(config-cvx-mss)# dynamic device-set panfw1
cvx(config-cvx-mss-panfw1)# tag Arista_MSS
```

- This command specifies multiple tags with names ***mss1***, ***mss2***, and ***mss3***.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# no shutdown
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# no shutdown
cvx(config-cvx-mss)# vni range 30000-40000
cvx(config-cvx-mss)# dynamic device-set panfw1
cvx(config-cvx-mss-panfw1)# tag mss1 mss2 mss3
```

9.3.4.6.12 type palo-alto

The **`type palo-alto`** command configures the firewall type to be used in the MSS configuration.

The **`no type palo-alto`** command disables the firewall type from the MSS configuration.

Command Mode

MSS Configuration

Command Syntax

`type palo-alto` [firewall | panorama]

`no type palo-alto`

Parameters

- **firewall**: the Palo Alto Networks firewall.
- **panorama**: the Palo Alto Networks Panorama firewall manager.

Example

This command configures the Palo Alto Networks firewall type.

```
cvx# configure
cvx(config)# cvx
cvx(config-cvx)# service mss
cvx(config-cvx-mss)# dynamic device-set panfw1
cvx(config-cvx-mss-panfw1)# type palo-alto firewall
```

Chapter 10

Quality of Service and Traffic Management

This chapter describes Arista's Quality of Service (QoS) implementation and Traffic Management, including configuration instructions and command descriptions. Topics covered by this chapter include:

- Quality of Service
- Traffic Management

10.1 Quality of Service

This chapter describes the EOS Quality of Service (QoS) implementation, including configuration instructions and command descriptions. Topics covered by this chapter include the following:

- Quality of Service Conceptual Overview
- QoS Configuration: Platform-Independent Features
- QoS Configuration: Arad Platform Switches
- QoS Configuration: Jericho Platform Switches
- QoS Configuration: FM6000 Platform Switches
- QoS Configuration: Petra Platform Switches
- QoS Configuration: Trident and Tomahawk Platform Switches
- QoS Configuration: Trident II and Helix Platform Switches
- Support for Configuring Color Extended Communities
- ACL based QoS Configuration
- Configuring IPv6 Flow Label Matches for QoS
- Differentiated MMU Discard Counters
- txQueue Percentage-based Shaping
- Configuring Round Robin Scheduling on Shaped Subinterfaces
- Explicit Congestion Notification (ECN)
- Latency-based Explicit Congestion Notification
- Configuring a Low Latency Transmit Queue Scheduler Profile
- Quality of Service Configuration Commands

- Chipset Mapping for QoS

10.1.1 Quality of Service Conceptual Overview

QoS processes apply to traffic that flows through Ethernet ports and control planes. These processes can modify data fields (CoS or DSCP) or assign data streams to traffic classes for prioritized handling. Transmission queues are configurable for individual Ethernet ports to shape traffic based on its traffic class. Many switches also support traffic policies that apply to data that is filtered by access control lists.

The following sections describe QoS features:

- Identifying the Switch Platform
- QoS Data Fields and Traffic Classes
- Transmit Queues and Port Shaping
- Explicit Congestion Notification (ECN)
- ACL Policing
- Quality of Service (QoS) Profiles

10.1.1.1 Identifying the Switch Platform

QoS configuration varies significantly by switch platform. A list of Arista switch model numbers and their corresponding switch platforms (chipsets) can be found in the Chipset Mapping for QoS.

On some switches, the platform can also be determined by entering **`platform ?`** in the CLI.

Example

This command shows that the example switch is running on the Trident platform.

```
switch(config)# platform ?
  trident  Trident chip
switch(config)#
```

10.1.1.2 QoS Data Fields and Traffic Classes

Quality of Service (QoS) defines a method of differentiating data streams to provide varying levels of service to the different streams.

Criteria determining a packet's priority level include packet field contents and the port where data packets are received. QoS settings are translated into traffic classes, which are then used by switches to manage all traffic flows. Traffic flow management varies with each switch platform.

10.1.1.2.1 QoS Data Fields

Quality of service decisions are based on the contents of the following packet fields:

- CoS (three bits): Class of service (CoS) is a 3-bit field in Ethernet frame headers using VLAN tagging. The field specifies a priority value between zero and seven. Class of service operates at Layer 2.
- DSCP (six bits): Differentiated Service Code Point (DSCP) is a 6-bit field in the Type Of Service (TOS) field of IP packet headers.

10.1.1.2.2 Port Settings – Trust Mode and Traffic Class

Ethernet and port channel interfaces support three QoS trust modes:

- **CoS Trust:** Ports use inbound packet CoS field contents to derive the traffic class.
- **DSCP Trust:** Ports use inbound packets DSCP field contents to derive the traffic class.
- **Untrusted:** Ports use their default values to derive the traffic class, ignoring packet contents.

The default mode setting is **CoS trust** for switched ports and **DSCP trust** for routed ports.

Ports are associated with default CoS, DSCP, and traffic class settings; defaults vary by platform.

These sections describe procedures for configuring port settings:

- CoS and DSCP Port Settings – Arad Platform Switches
- CoS and DSCP Port Settings – FM6000 Platform Switches
- CoS and DSCP Port Settings – Petra Platform Switches
- CoS and DSCP Port Settings – Trident and Tomahawk Platform Switches
- CoS and DSCP Port Settings – Trident II and Helix Platform Switches

10.1.1.2.3 Rewriting CoS and DSCP

CoS Rewrite

Switches can rewrite the CoS field for outbound tagged packets. The new CoS value is configurable, and is derived from a data stream's traffic class as specified by the traffic class-to-CoS rewrite map. CoS rewrite is disabled on all the traffic received on CoS trusted ports.

On Arad, Jericho, FM6000, Trident and Tomahawk, Trident II, and Helix platform switches, CoS rewrite can be enabled or disabled on DSCP trusted ports and untrusted ports.

- CoS rewrite is globally enabled by default for packets received on untrusted ports and DSCP trusted ports if at least one port is explicitly configured in **DSCP trust** or **untrusted** mode.
- CoS rewrite is globally disabled by default for packets received on untrusted ports and DSCP trusted ports if there are no ports explicitly configured in **DSCP trust** or **untrusted** mode.

On Petra platform switches, CoS rewrite is always enabled on DSCP trusted ports and untrusted ports.

DSCP Rewrite

Switches can rewrite the DSCP field for outbound IP packets. On FM6000, Trident and Tomahawk, Trident II, and Helix platform switches, DSCP rewrite is disabled by default on all ports and always disabled for traffic received on DSCP trusted ports. On Petra, Arad, and Jericho platform switches, DSCP rewrite is always disabled.

FM6000, Trident and Tomahawk, Trident II, and Helix platform switches provide a command that enables or disables DSCP rewrite for packets received on CoS trusted ports and untrusted ports. The new DSCP value is configurable, based on the data stream's traffic class, as specified by the traffic class-to-DSCP rewrite map.

These sections describe procedures for rewriting CoS and DSCP fields:

- CoS Rewrite – Arad Platform Switches
- CoS and DSCP Rewrite – FM6000 Platform Switches
- CoS Rewrite – Petra Platform Switches
- CoS and DSCP Rewrite – Trident and Tomahawk Platform Switches
- CoS and DSCP Rewrite – Trident II and Helix Platform Switches

10.1.1.2.4 Traffic Classes

Data stream distribution is based on their traffic classes. Data stream management varies by switch platform. Traffic classes are derived from these data stream, inbound port, and switch attributes:

- CoS field contents.
- DSCP field contents.
- Inbound port trust setting.
- CoS default setting (Arad, Jericho, FM6000, Trident and Tomahawk, Trident II, and Helix platform switches).
- DSCP default setting (Arad, Jericho, FM6000, Trident and Tomahawk, and Trident II platform switches).
- Traffic class default setting (Petra platform switches).

When a port is configured to derive a data stream's traffic class from the CoS or DSCP value associated with the stream, the traffic class is determined from a conversion map.

- A CoS-to-traffic class map derives a traffic class from a CoS value.
- A DSCP-to-traffic class map derives a traffic class from a DSCP value.

Map entries are configurable through CLI commands. Default maps determine the traffic class value when CLI map entry commands are not configured. Default maps vary by switch platform.

These sections describe traffic class configuration procedures:

- Traffic Class Derivations – Arad Platform Switches

- Traffic Class Derivations – Jericho Platform Switches
- Traffic Class Derivations – FM6000 Platform Switches
- Traffic Class Derivations – Petra Platform Switches
- Traffic Class Derivations – Trident and Tomahawk Platform Switches
- Traffic Class Derivations – Trident II and Helix Platform Switches

10.1.1.3 Transmit Queues and Port Shaping

Transmit queues are logical partitions of an Ethernet port's egress bandwidth. Data streams are assigned to queues based on their traffic class, then sent as scheduled by port and transmit settings. Support varies by switch platform. A queue's label determines its priority: queues with the suffix ***0*** have the lowest priority.

Parameters that determine transmission schedules include:

- **Traffic class-to-transmit queue** mapping determines the transmit queue for transmitting data streams based on traffic class. The set of available transmit maps vary by switch platforms:
  - **Arad, Jericho, FM6000, Trident II, and Helix platforms:** one map for all unicast and multicast traffic.
  - **Trident and Tomahawk platform:** one map for unicast traffic and one map for multicast traffic.
  - **Petra platform:** one map for unicast traffic. Queue shaping is not available for multicast traffic.
- **Port shaping** specifies a port's maximum egress bandwidth.
- **Queue shaping** specifies a transmit queue's maximum egress bandwidth, and implementation varies by platform.
  - **Trident and Tomahawk platform:** queue shaping is configurable separately for unicast and multicast queues.
  - **Trident II platform:** queue shaping is configurable for transmit queues. Port shaping and queue shaping are supported only in store-and-forward switching mode.
  - **Petra platform:** queue shaping is not available for multicast traffic.
  - **Helix platform:** queue shaping is configurable for transmit queues.
  - **FM6000 platform:** switches do not support simultaneous port shaping and queue shaping. Enabling port shaping on an FM6000 switch disables queue shaping, regardless of the previous configuration.
- **Guaranteed bandwidth** guarantees the allocation of a specified bandwidth for a transmit queue. Guaranteed bandwidth is supported only on Trident II platforms.
- **Queue priority** specifies the priority at which a transmit queue is serviced. The switch defines two queue priority types:
  - ***Strict priority queues*** are serviced in the order of their priority rank - subject to each queue's configured maximum bandwidth. Data is not handled for a queue until all queues with higher priority are emptied or their transmission limit is reached. These queues typically carry low latency real time traffic and require highest available priority.

- ***Round robin queues*** are serviced simultaneously subject to assigned bandwidth percentage and configured maximum bandwidth. All round robin queues have lower priority than strict priority queues. Round robin queues can be starved by strict priority queues.

- **Queue scheduling** determines how packets from different transmit queues are serviced to be sent out on the port.

- **Queue bandwidth allocation** specifies the time slice (percentage) assigned to a round robin queue, relative to all other round robin queues.

These sections describe transmit queue and port shaping configuration procedures:

- Transmit Queues and Port Shaping – Arad Platform Switches
- Transmit Queues and Port Shaping – Jericho Platform Switches
- Transmit Queues and Port Shaping – FM6000 Platform Switches
- Transmit Queues and Port Shaping – Petra Platform Switches
- Transmit Queues and Port Shaping – Trident and Tomahawk Platform
- Transmit Queues and Port Shaping – Trident II and Helix Platform Switches

10.1.1.4 Explicit Congestion Notification (ECN)

Explicit Congestion Notification (ECN) is an IP and TCP extension that facilitates end-to-end network congestion notification without dropping packets. ECN recognizes early congestion and sets flags that signal affected hosts. Trident and Tomahawk, Trident II, and Helix platform switches extend ECN support to non-TCP packets. LAG interfaces on Strata platforms support ECN counters.

ECN usage requires that it is supported and enabled by both endpoints. Although only unicast flows are modified by ECN markers, the multicast, broadcast, and unmarked unicast flows can affect network congestion and influence the indication of unicast packet congestion.

10.1.1.4.1 ECN Conceptual Overview

The ECN field in the IP header (bits 6 and 7 in the IPv4 TOS or IPv6 traffic class octet) advertises ECN capabilities:

- ***00***: Router does not support ECN.
- ***10***: Router supports ECN.
- ***01***: Router supports ECN.
- ***11***: Congestion encountered.

Networks typically signal congestion by dropping packets. After an ECN-capable host negotiates ECN, it signals impending congestion by marking the IP header of packets encountering the congestion instead of dropping the packets. The recipient echoes the congestion indication back to the sender, which reduces its transmission rate as if it had detected a dropped packet.

Switches support ECN for unicast queues through Weighted Random Early Detection (WRED), an Active Queue Management (AQM) algorithm that extends Random Early Detection (RED) to define multiple thresholds for an individual queue. WRED determines congestion by comparing average queue size with queue thresholds. Average queue size depends on the previous average and current queue size:

- average queue size = (old_avg * (1-2^(-weight))) + (current_queue_size * 2^(-weight))
- where weight is the exponential weight factor used for averaging the queue size.
- Packets are marked based on WRED as follows:

- If average queue size is below the minimum threshold, packets are queued as in normal operation without ECN.
- If average queue size is greater than the maximum threshold, packets are marked for congestion.
- If average queue size is between minimum and maximum queue threshold, packets are either queued or marked. The proportion of packets that are marked increases linearly from 0% at the minimum threshold to 100% at the maximum threshold.

Treatment of packets marked as not ECN capable varies by platform.

These sections describe ECN configuration procedures:

- ECN Configuration – Arad Platform Switches
- ECN Configuration – Trident and Tomahawk Platform Switches

10.1.1.5 ACL Policing

ACL policing monitors the ingress data rates for a particular class of traffic and performs the action configured when the traffic exceeds the user configured value. Therefore, it allows the user to control ingress bandwidth based on packet classification. The incoming traffic is metered and marked by the policing, and based on the metering results the actions are performed.

ACL policing uses a token bucket shaping algorithm for packet transmission. Packets are eligible for transmission when token count is positive, and when token count is negative the next packet will have to wait until the token count turns positive again. The tokens are renewed at 96ns time interval (Tc). The tokens are collected in the policer bucket up to a max burst size of 16KB, and any traffic beyond this shape rate and burst size is buffered in the shared memory. The packets are dropped if there is a memory overflow.

Note: The policer bucket is refilled at a sweeper period of 0.333 millisecond. This is applicable for all the platforms.

For example, assume that shaping is disabled, and the link is at 10 Gbps at 1.25 bytes/nsec. In such case a each refill cycle adds tokens worth 120 bytes. For a shape rate of 500 Mbps, each refill cycle adds 6 bytes. And for 64 byte worth of tokens EOS needs 11 refill cycles = 1us. A 64 byte packet coming immediately after a jumbo frame waits longer compared to a jumbo frame coming after 64 byte packet.

Token size depends on the interface speed, following the last example:

- For 10 Gbps, each refill cycle adds tokens worth 120 bytes.
- For 1 Gbps, each refill cycle adds tokens worth 12 bytes.

At lower shaping rates (less than 10 Mbps), granularity and rounding errors may alter the actual shaping rate by 20% from the specified rate, and the rounding errors are much less at higher speeds. For example, At 100 Mbps you see 98.9 Mbps configured in hardware. You can use the **`show qos interfaces`** command to verify the interface speed.

The policing uses three types of traffic metering and coloring mechanisms.

- **Single Rate Two Color Marker**
- **Single Rate Three Color Marker**
- **Two Rate Three Color Marker**

Single Rate Two Color Marker

It meters the packet stream and marks packets based on committed burst size (bc) and excess burst size (be).

Single Rate Three Color Marker

It meters the packet stream and marks packets based on single rate committed information rate (cir), and committed burst size (bc) and excess burst size (be). The packets are marked in green if it does not exceed the set burst size, and marked in yellow if it does exceed the burst size but not the excess burst size, and marked red otherwise. The packets are marked in two color modes.

- **Color-blind Mode**: In color-blind mode the incoming packet color is ignored.
- **Color-aware Mode**: In color-aware mode it is assumed that incoming packet is colored by preceding entity. And, in color-aware mode, a packet never get better than it was. If the input color of the packet is green, it can be marked as green, yellow, or red. But if the input color is yellow, then it can be marked only yellow or red.

Two Rate Three Color Marker

It meters the packet stream and marks its packets based on two rates, peak information rate (pir) and committed information rate (cir), and associated burst sizes (bc and be).The packet is marked red if rate exceeds ‘pir’, and yellow if it exceeds ‘cir’ but not 'pir' and marked green if rate is lower than 'cir'. The two rate mode is configured by setting four parameters pir, cir, bc, and be.

The ACL policing is supported on platforms specified in the table below.

Table 17: ACL Policing Support Matrix

Platform Supported	ACL Policing	ACL Policing on LAG Interface
Trident	Yes	Yes
Trident II	Yes	Yes
Trident+	Yes	Yes
FM6000	Yes	Yes
Arad	Yes	Only Per-Port
Jericho	Yes	Yes
Helix	Yes	Yes
XP	Yes	Yes
Trident 3	Yes	Yes
Tomahawk	Yes	Yes
Tomahawk 2	Yes	Yes
Tofino	No	No

10.1.1.5.1 Configuring ACL Policing

The policer is applied to the class inside the policy map. Policy maps can contain one or more policy map classes, each with different match criteria and policers. The following is the default behavior on conditions and available policing actions:

- Police command creates a per-interface policer. If you attach per-interface policers to multiple ingress ports, each one polices the matched traffic on each ingress port separately. Per interface statistics gathered for conformed/allowed traffic and exceeded/dropped traffic.

- When there is no policer configured within a class, all traffic is transmitted without any policing. If there are any actions configured, the configured actions are applied.
  - conform-action (green): transmit (default).
  - exceed-action (yellow): drop (default).
  - violate-action (red): drop (default).

- The policer bucket is refilled at a sweeper period of 0.333 milliseconds, and the tokens in the policer bucket are renewed at 96ns time interval (Tc). This is applicable for all the platforms.

Steps to Configure ACL Policing

These commands set the CIR, burst size, and creates a class and applies the policing to the policy map:

1. Create a policy map.
2. Create a class-map.
3. Apply the policer to the policy map created.

Examples

- These commands configure the ACL policing for a policy map.

```
switch# configure terminal
switch(config)# policy-map [type qos] policy-name
switch(config-pmap)# class { class-name }
switch(config-pmap-c)# [no] police cir cir [{bps|kbps|mbps}] bc
committed-burst-size [{bytes|kbytes|mbytes}]
```

- These commands configure ACL policing in single-rate, two-color mode.

```
switch(config)# class-map type qos match-any class1
switch(config-cmap-class1)# match ip access-group acl1
switch(config-cmap-class1)# exit

switch(config)# policy-map type quality-of-service policy1
switch(config-pmap)# class class1
switch(config-pmap-c)# police cir 512000 bc 96000
switch(config-pmap-c)# exit
switch(config-pmap)#
```

Displaying ACL Policing Information

Examples

- This command shows the contents of all policy maps on the switch.

```
switch(config)# show policy-map
Service-policy p

 Class-map: c (match-any)
    Match: ip access-group name a
       police rate 1000 mbps burst-size 100 bytes
 Class-map: class-default (match-any)
Service-policy p
 Class-map: c (match-any)
    Match: ip access-group name a
       police rate 1000 mbps burst-size 100 bytes
 Class-map: class-default (match-any)
```

- This command shows the interface-specific police counters for ***interface Ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input counters
```

```
Service-policy input: policy1
Hardware programming status: Successful

Class-map: class1 (match-any) Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes Conformed 4351 packets, 1857386 bytes
Conformed 2536 packets, 3384260 bytes

Class-map: class-default (match-any) matched packets: 0
```

- This command shows the counters associated with the policy map called ***p1***.

```
switch(config)# show policy-map type qos p1 input counters
Service-policy input: p1 Class-map: c1 (match-any)
Match: ip access-group name a1
Police cir 512000 bps bc 96000 bytes Interface: Ethernet1
Conformed 4351 packets, 1857386 bytes
Exceeded 2536 packets, 3384260 bytes
Interface: Ethernet2
Conformed 2351 packets, 957386 bytes
Exceeded 1536 packets, 1384260 bytes
Class-map: class-default (match-any)
Matched packets : 3229
```

- This command shows the QoS policy map for ***interface Ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input type qos
Interface: Ethernet 1 Service-policy input: policy1
Hardware programming status: Successful Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 9000 bytes
Class-map: class2 (match-any)
Match: ip access-group name acl2 set dscp 2
Class-map: class3 (match-any) Match: ip access-group name acl3
Police cir 1280000 bps bc 9000 bytes
Class-map: class-default (match-any)
```

10.1.1.6 Quality of Service (QoS) Profiles

QoS profiles are sets of QoS configuration instructions defined and applied at the interface level. A QoS profile serves the traffic better by reducing disorder in the running configuration. QoS profiles can modify all interface-level QoS configurations, and are supported on fabric, Ethernet, and port-channel interfaces. Control-plane policies cannot be applied using QoS profiles. Because configuration can be applied through QoS profiles or directly at the interface level, multiple configurations can be applied to the same interface. In such cases, QoS configurations with non-default values, whether configured through the CLI at the interface level or through a QoS profile, are given priority. In the case of multiple non-default values being configured, the interface-level CLI configuration is given priority.

Policy maps incorporating traffic resolution commands can also be applied by a QoS profile. If two policy maps are applied to the same interface (one through a QoS profile and another directly to the CLI).

Policy maps cannot be used on fabric interfaces. If a QoS profile which includes a policy map is applied to a fabric interface, a warning message will be displayed and the policy map will not be applied to the interface, but any additional supported configurations in the QoS profile will be applied. On SVIs and subinterfaces, QoS profiles are not supported, so policy maps must be applied directly through the CLI for these interfaces.

Note: For tx-queue configuration, conflicts between QoS profiles and configuration entered via the CLI are resolved at the tx-queue level and not at the tx-queue attribute level. If any non-default configuration has been entered for the tx-queue through the CLI, all tx-queue configuration included in the QoS profile is ignored.

10.1.1.6.1 IPv6 Flow Label Matches for QoS

Certain packets may include a flow label in their IPv6 headers when the source requests special handling by routers, such as for a media stream or other “real-time” service, among others. A flow consists of packets which share a single flow label, which is preserved throughout their passage from source to destination.

QoS policy map rules can match IPv6 traffic based on their flow labels. This requires a special TCAM profile (qos-match-ipv6-flow-label). These rules require either an exact match, using the “eq” operator, or both a label and a mask.

10.1.2 QoS Configuration: Platform-Independent Features

10.1.2.1 Creating QoS Profiles

QoS profiles are created by using the qos profile command. This also places the switch in QoS profile configuration mode, where the QoS parameters applied to interfaces are configured. To delete a QoS profile from the running configuration, use the no form of the command.

Example

This command creates a QoS profile named ***Test-Profile*** and places the switch in QoS profile configuration mode for the profile.

```
switch(config)# qos profile Test-Profile
switch(config-qos-profile-Test-Profile)#
```

10.1.2.2 Configuring QoS Profiles

The parameters that a QoS profile applies to interfaces are configured in QoS profile configuration mode by issuing the same QoS configuration commands that are available in interface configuration mode. **QoS profile** configuration mode is a group change mode, and changes made in the mode are not saved until the mode is exited. To abandon all changes made while in the mode, use the **`abort`** command.

Example

These commands enter QoS profile configuration mode for a QoS profile named ***Test Profile***, configure the CoS value and transmit queue, and save the changes to the profile.

```
switch(config)# qos profile Test-Profile
switch(config-qos-profile-Test-Profile)# qos cos 3
```

```
switch(config-qos-profile-Test-Profile)# priority-flow-control on
switch(config-qos-profile-Test-Profile)# exit
switch(config)#
```

These commands enter QoS profile configuration mode for a QoS profile named ***Latency***, configure the maximum latency value for VOQ tail-drop threshold, and save the changes to the profile. The latency value can be specified to a maximum of ***50*** ms. Both milliseconds and microseconds may be used.

```
switch(config)# qos profile Latency
switch(config-qos-profile-Latency)# tx-queue 3
switch(config-qos-profile-Latency)# latency maximum <1-50000> microseconds
switch(config-qos-profile-Latency)# latency maximum <1-50> milliseconds
switch(config-qos-profile-Latency)# exit
switch(config)#
```

10.1.2.3 Attaching Policy-Map to a QoS Profile

The qos profile command places the switch in QoS profile configuration mode. The profile applies the QoS configurations to Ethernet and Port-Channel, and even to the Fabric interfaces, if it exists. A profile specifies the policy-map and other QoS supported configurations. The policy-map is then attached to the QoS profile using **`service-policy`** command.

Profiles are created in QoS-profile configuration mode, then applied to an interface in interface configuration mode.

Examples

- This command places the switch in QoS profile configuration mode, the policy-map is then attached to the profile using **`service-policy`** command in this mode.

  ```
  switch(config)# qos profile TP
  switch(config-qos-profile-TP)#
  ```

- This command applies the policy-map to the QoS profile.

  ```
  switch(config-qos-profile-TP)# service-policy type qos input PM-1
  ```

10.1.2.4 Applying a QoS profile on an Interface

The service-profile command applies a QoS profile to the configuration mode interface.

Example

This command applies the QoS profile TP to ***interface ethernet 13***.

```
switch(config)# interface ethernet 13
switch(config-if-Et13)# service-profile TP
```

10.1.2.5 Displaying the QoS Profile Information

The show qos profile command displays information about the QoS profiles configured and their parameters. To display the attribute of a specific profile, add the name of the profile. To display a list of configured QoS profiles and the interfaces on which they are configured, add the **summary** keyword.

Examples

- This command displays the configured profiles and their configuration.

```
switch# show qos profile
qos profile p
 qos cos 1
no priority-flow-control pause watchdog
priority-flow-control priority 1 no-drop
priority-flow-control priority 2 no-drop
qos profile p2
qos cos 3
priority-flow-control priority 0 no-drop
```

- This command displays the contents of a specific profile.

```
switch# show qos profile p2
qos profile p2
qos cos 3
priority-flow-control priority 0 no-drop
```

- This command displays the interfaces on which each profile is applied.

```
switch# show qos profile summary
Qos Profile: p
Configured on: Et13,7
Fabric
Po12
Qos Profile: p2
Configured on: Et56
```

10.1.3 QoS Configuration: Arad Platform Switches

Implementing QoS on an Arad platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – Arad Platform Switche
- Traffic Class Derivations – Arad Platform Switches
- CoS Rewrite – Arad Platform Switches
- Transmit Queues and Port Shaping – Arad Platform Switches
- ECN Configuration – Arad Platform Switches
- ACL Policing – Arad Platform Switches

Note: QoS traffic policy is supported on Trident and Tomahawk, Trident II, FM6000, Arad, and Jericho.

10.1.3.1 CoS and DSCP Port Settings – Arad Platform Switches

Port Settings – Trust Mode and Traffic Class describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is **CoS**. The port-trust default for routed ports is **DSCP**.

- **`qos trust cos`** specifies **CoS** as the port's port-trust mode.
- **`qos trust dscp`** specifies **DSCP** as the port's port-trust mode.
- **`no qos trust`** specifies **untrusted** as the port's port-trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

These commands configure and display the following trust modes:

- ***Ethernet 3/5/1:*** **dscp**
- ***Ethernet 3/5/2:*** **untrusted**
- ***Ethernet 3/5/3:*** **cos**
- ***Ethernet 3/5/4:*** **default** as a switched port
- ***Ethernet 3/6/1:*** **default** as a routed port

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# qos trust dscp
switch(config-if-Et3/5/1)# interface ethernet 3/5/2
switch(config-if-Et3/5/2)# no qos trust
switch(config-if-Et3/5/2)# interface ethernet 3/5/3
switch(config-if-Et3/5/3)# qos trust cos
switch(config-if-Et3/5/3)# interface ethernet 3/5/4
switch(config-if-Et3/5/4)# switchport
switch(config-if-Et3/5/4)# default qos trust
switch(config-if-Et3/5/4)# interface ethernet 3/6/1
switch(config-if-Et3/6/1)# no switchport
switch(config-if-Et3/6/1)# default qos trust
switch(config-if-Et3/6/1) #show qos interface ethernet 3/5/1 - 3/6/1 trust
Port                                    Trust Mode
                              Operational           Configured
---------------------------------------------------------------
Ethernet3/5/1                 DSCP                  DSCP
Ethernet3/5/2                 UNTRUSTED             UNTRUSTED
Ethernet3/5/3                 COS                   COS
Ethernet3/5/4                 COS                   DEFAULT
Ethernet3/6/1                 DSCP                  DEFAULT

switch(config-if-Et3/6/1)#
```

Configuring Default Port Settings

Default CoS and DSCP values are assigned to each Ethernet and port channel interface. These commands specify the configuration mode interface commands specify the port's default CoS and DSCP values.

- qos cos configures a port's default CoS value.
- qos dscp configures a port's default DSCP value.

Example

These commands configure default CoS (***4***) and DSCP (***44***) values on ***Ethernet interface 3/6/2***.

```
switch(config)# interface ethernet 3/6/2
switch(config-if-Et3/6/2)# qos cos 4
switch(config-if-Et3/6/2)# qos dscp 44
switch(config-if-Et3/6/2)# show active
interface Ethernet3/6/2
   qos cos 4
   qos dscp 44
switch(config-if-Et3/6/2)# show qos interfaces ethernet 3/6/2
Ethernet3/6/2:
   Trust Mode: COS
   Default COS: 4
   Default DSCP: 44

switch(config-if-Et3/6/2)#
```

10.1.3.2 Traffic Class Derivations – Arad Platform Switches

Traffic Classes describes traffic classes.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's traffic class.

Table 18: Traffic Class Derivation Source: Arad Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default CoS (port)	Default CoS (port)	Default DSCP (port)
Untagged IP	Default CoS (port)	Default CoS (port)	DSCP (packet)
Tagged Non-IP	Default CoS (port)	CoS (packet)	Default DSCP (port)
Tagged IP	Default CoS (port)	CoS (packet)	DSCP (packet)

CoS and DSCP Port Settings – Arad Platform Switches describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS values. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the chip upon which it is received.

Example

This command assigns the traffic class of ***5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ---------------------------
     tc:   1  5  2  5  4  5  6  5

switch(config)#
```

The following table displays the default CoS to Traffic Class map on Arad platform switches.

Table 19: Default CoS to Traffic Class Map: Arad Platform Switches

Inbound CoS	Untagged	0	1	2	3	4	5	6	7
Traffic Class	Derived: use default CoS as inbound	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns the traffic class of ***0*** to DSCP values of ***12***, ***24***, ***41***, and ***44-47***.

```
switch(config)# qos map dscp 12 24 41 44 45 46 47 to traffic-class 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     2  2  2  2  0  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  0  5  5  0  0  0  0  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

switch(config)#
```

The following table displays the default DSCP to traffic class map on Arad platform switches.

Table 20: Default DSCP to Traffic Class Map: Arad Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.3.3 CoS Rewrite – Arad Platform Switches

Rewriting CoS and DSCP describes the CoS rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

This command assigns the CoS of two to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-cos map:
     tc:   0  1  2  3  4  5  6  7
     ---------------------------
     cos:  1  2  2  2  4  2  6  7

switch(config)#
```

The following table displays the default Traffic Class to CoS rewrite value map on Arad platform switches.

Table 21: Default Traffic Class to CoS Rewrite Value Map: Arad Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

DSCP rewrite is always disabled on Arad platform switches.

10.1.3.4 Transmit Queues and Port Shaping – Arad Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

Arad platform switches provide 16 physical queues for each egress port: eight unicast and eight multicast queues. Data is scheduled to the physical queues based on transmit queue assignments.

Multicast queue capacity that remains after multicast traffic is serviced is available for unicast traffic of a corresponding priority. Similarly, unicast queue capacity that remains after unicast traffic is serviced is available for overflow multicast traffic. Under conditions of unicast and multicast congestion, egress traffic is evenly split between unicast and multicast traffic.

A data stream's traffic class determines the transmit queue it uses. The switch defines a single traffic class–transmit queue map for unicast and multicast traffic on all Ethernet and port channel interfaces. The show qos maps command displays the traffic class–transmit queue map.

The following table displays the default traffic class to transmit queue map on Arad platform switches.

Table 22: Default Traffic Class to Transmit Queue Map: Arad Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue	0	1	2	3	4	5	6	7

Transmit queue parameters are configured in tx-queue configuration command mode, which is entered from ***interface-ethernet*** configuration mode.

Mapping Traffic Classes to a Transmit Queue

The qos map traffic-class to tx-queue command assigns traffic classes to a transmit queue. Multiple commands complete the traffic class-transmit queue map. Traffic class ***7*** and transmit queue ***7*** are always mapped to each other. This association is not editable.

Example

These commands assign traffic classes of ***1***, ***3***, and ***5*** to ***transmit queue 1***, traffic classes ***2***, ***4***, and ***6*** to transmit queue ***2***, and traffic class ***0*** to transmit queue ***0***, then display the resultant map.

```
switch(config)# qos map traffic-class 1 3 5 to tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to tx-queue 2
switch(config)# qos map traffic-class 0 to tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     ---------------------------------
     tx-queue:   0  1  2  1  2  1  2  7

switch(config)#
```

Entering Tx-Queue Configuration Mode

The tx-queue (Arad/Jericho) command places the switch in tx-queue configuration mode to configure a transmit queue on the configuration mode interface. Tx-queue 7 is not configurable. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

This command enters Tx-queue configuration mode for ***transmit queue 4*** of ***interface Ethernet 3/3/3***.

```
switch(config)# interface ethernet 3/3/3
switch(config-if-Et3/3/3)# tx-queue 4
switch(config-if-Et3/3/3-txq-4)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies its maximum outbound traffic bandwidth. A transmit queue's shape rate specifies the queue's maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

- To configure a port's shape rate, enter shape rate (Interface – Arad/Jericho) from the port's interface configuration mode.
- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – Arad/Jericho) from the queue's tx-queue configuration mode.

Examples

- This command configures a port shape rate of ***5*** Gbps on ***interface Ethernet 3/5/1***.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# shape rate 5000000
switch(config-if-Et3/5/1)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

   Port shaping rate: 5000012 / 5000000 kbps

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   -------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D

switch(config-if-Et3/5/1)#
```

- These commands configure a shape rate of ***1*** Gbps on transmit queues ***3*** and ***4*** of ***interface Ethernet 3/4/1***.

```
switch(config)# interface ethernet 3/4/1
switch(config-if-Et3/4/1)# tx-queue 4
switch(config-if-Et3/4/1-txq-4)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-4)# tx-queue 3
switch(config-if-Et3/4/1-txq-3)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-3)# show qos interface ethernet 3/4/1
Ethernet3/4/1:

   Port shaping rate: disabled

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   -------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
```

```
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -      999 / 1000 ( Mbps )   SP / SP    D
   3      - / -      999 / 1000 ( Mbps )   SP / SP    D
   2      - / -        - / -    (  -  )    SP / SP    D
   1      - / -        - / -    (  -  )    SP / SP    D
   0      - / -        - / -    (  -  )    SP / SP    D

switch(config-if-Et3/4/1-txq-3)#
```

Configuring Queue Priority

The priority (Arad/Jericho) command configures a transmit queue's priority type:

- The **`priority strict`** command configures the queue as a strict priority queue.
- The **`no priority`** command configures the queue as a round robin queue.

A queue's configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The bandwidth percent (Arad/Jericho) command configures a round robin queue's bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

Examples

- These commands configure queues ***0*** through ***3*** (***interface Ethernet 3/5/1***) as round robin, then allocate bandwidth for three queues at ***30%*** and one queue at ***10%***.

  The **`no priority`** statement for queue *3* also configures queues ***0***, ***1***, and ***2*** as round robin queues. Removing this statement reverts the other queues to **`strict priority`** type unless ***running-config*** contains a **`no priority`** statement for one of these queues.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# no priority
switch(config-if-Et3/5/1-txq-3)# bandwidth percent 10
switch(config-if-Et3/5/1-txq-3)# tx-queue 2
switch(config-if-Et3/5/1-txq-2)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-2)# tx-queue 1
switch(config-if-Et3/5/1-txq-1)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-1)# tx-queue 0
switch(config-if-Et3/5/1-txq-0)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-0)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)         (units)
   ------------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -        - / -    (  -  )    SP / SP    D
   3     10 / 10       - / -    (  -  )    RR / RR    D
   2     30 / 30       - / -    (  -  )    RR / SP    D
   1     30 / 30       - / -    (  -  )    RR / SP    D
   0     30 / 30       - / -    (  -  )    RR / SP    D

switch(config-if-Et3/5/1-txq-0)#
```

- Changing the bandwidth percentage for queue ***3*** to ***30*** changes the operational bandwidth of each queue to its configured bandwidth divided by ***120%*** (10%+20%+30%+60%).

```
switch(config-if-Et3/5/1-txq-0)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-3)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

   Port shaping rate: disabled

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   ------------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -        - / -    (  -  )    SP / SP    D
   3     24 / 30       - / -    (  -  )    RR / RR    D
   2     24 / 30       - / -    (  -  )    RR / SP    D
   1     24 / 30       - / -    (  -  )    RR / SP    D
   0     24 / 30       - / -    (  -  )    RR / SP    D

Note: Values are displayed as Operational/Configured

switch(config-if-Et3/5/1-txq-3)#
```

10.1.3.5 ECN Configuration – Arad Platform Switches

Explicit Congestion Notification (ECN) describes Explicit Congestion Notification (ECN).

ECN is independently configurable on all egress queues of each Ethernet interface. ECN settings for Port-Channels are applied on each of the channel's member Ethernet interfaces. Average queue length is tracked for transmit queues. When it reaches maximum threshold, all subsequent packets are marked.

Although the switch does not limit the number of queues that can be configured for ECN, hardware table limitations restrict the number of queues that can simultaneously implement ECN.

The **random-detect ecn (Arad/Jericho)** command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes.

Example

These commands enable ECN marking of unicast packets from ***unicast transmit queue 4*** of ***interface Ethernet 3/5/1***, setting thresholds at ***128*** kbytes and ***1280*** kbytes.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 4
switch(config-if-Et3/5/1-txq-4)# random-detect ecn minimum-threshold 128 kbytes maximum-threshold
 1280 kbyte
switch(config-if-Et3/5/1-txq-4)# show active
interface Ethernet3/5/1
   tx-queue 4
      random-detect ecn minimum-threshold 128 kbytes maximum-threshold 1280 kbytes
switch(config-if-Et3/5/1-txq-4)#
```

10.1.3.6 ACL Policing – Arad Platform Switches

ACL Policing describes ACL policing.

Implementing ACL policing consists of configuring the following:

- policy-map settings.
- class-name.
- committed information rate (CIR) the data speed committed to any given circuit regardless of the number of users.
- burst size the maximum burst size in bytes the network commits to moving under normal conditions.

The default unit for the metering rate CIR is bits per second; the default unit for the burst size is bytes.

The policer is applied to the class inside the policy map. Policy maps can contain one or more policy map classes, each with different match criteria and policer.

Default behavior and available policing actions are as follows:

- Policy map can be applied on multiple interfaces. Interfaces on the same chip will share the policer. (Applicable for Arad only.)
- If there is no policer configured within a class, all traffic is transmitted without any policing.
- If there are any actions configured, the configured actions are applied:
  - Conform-action (green): transmit (default).
  - Violate-action (red): drop (default).

Example

These commands configure ACL policing in single-rate, two-color mode.

```
switch(config)# class-map type qos match-any class1
switch(config-cmap-class1)# match ip access-group acl1
switch(config-cmap-class1)# exit
switch(config)# policy-map type quality-of-service policy1
switch(config-policy1)# class class1
switch(config-policy1-class1)# police cir 512000 bc 96000
switch(config-policy1-class1)# exit
switch(config-policy1)# exit
switch(config)#
```

Displaying ACL Policing Information

Examples

- This command shows the contents of all policy maps on the switch.

```
switch(config)# show policy-map
Service-policy policy1

Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes
```

```
Class-map: class-default (match-any)
switch(config)#
```

- This command shows the interface-specific police counters for ***interface Ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input counters
Service-policy input: policy1
Hardware programming status: Successful

Class-map: class1 (match-any) Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes Conformed 4351 packets, 1857386 bytes
Conformed 2536 packets, 3384260 bytes

Class-map: class-default (match-any) matched packets: 0

switch(config)#
```

- This command shows the counters associated with the policy map called ***p1***.

```
switch(config)# show policy-map type qos p1 input counters
Service-policy input: p1 Class-map: c1 (match-any)
Match: ip access-group name a1
Police cir 512000 bps bc 96000 bytes Interface: Ethernet1
Conformed 4351 packets, 1857386 bytes
Exceeded 2536 packets, 3384260 bytes
Interface: Ethernet2
Conformed 2351 packets, 957386 bytes
Exceeded 1536 packets, 1384260 bytes
Class-map: class-default (match-any)
Matched packets : 3229

switch(config)#
```

- This command shows the QoS policy map for ***interface Ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input type qos
Interface: Ethernet 1 Service-policy input: policy1
Hardware programming status: Successful Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 9000 bytes
Class-map: class2 (match-any)
Match: ip access-group name acl2 set dscp 2
Class-map: class3 (match-any) Match: ip access-group name acl3
Police cir 1280000 bps bc 9000 bytes
Class-map: class-default (match-any)

switch(config)#
```

10.1.4 QoS Configuration: Jericho Platform Switches

Implementing QoS on an Jericho platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – Jericho Platform Switches
- Traffic Class Derivations – Jericho Platform Switches
- CoS Rewrite – Jericho Platform Switches
- Transmit Queues and Port Shaping – Jericho Platform Switches

- ACL Policing – Jericho Platform Switches

> **Note:** QoS traffic policy is supported on Trident and Tomahawk, Trident II, FM6000, Arad, and Jericho.

10.1.4.1 CoS and DSCP Port Settings – Jericho Platform Switches

Port Settings – Trust Mode and Traffic Class describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is **CoS**. The port-trust default for routed ports is **DSCP**.

- **`qos trust cos`** specifies **CoS** as the port's port-trust mode.
- **`qos trust dscp`** specifies **DSCP** as the port's port-trust mode.
- **`no qos trust`** specifies **untrusted** as the port's port-trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

These commands configure and display the following trust modes:

- ***Ethernet 3/5/2:*** **untrusted**.
- ***Ethernet 3/5/3:*** **cos**.
- ***Ethernet 3/5/4:*** **default** as a switched port.
- ***Ethernet 3/6/1:*** **default** as a routed port.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# qos trust dscp
switch(config-if-Et3/5/1)# interface ethernet 3/5/2
switch(config-if-Et3/5/2)# no qos trust
switch(config-if-Et3/5/2)# interface ethernet 3/5/3
switch(config-if-Et3/5/3)# qos trust cos
switch(config-if-Et3/5/3)# interface ethernet 3/5/4
switch(config-if-Et3/5/4)# switchport
switch(config-if-Et3/5/4)# default qos trust
switch(config-if-Et3/5/4)# interface ethernet 3/6/1
switch(config-if-Et3/6/1)# no switchport
switch(config-if-Et3/6/1)# default qos trust
switch(config-if-Et3/6/1)# show qos interface ethernet 3/5/1 - 3/6/1 trust
Port                                        Trust Mode
                                Operational           Configured
---------------------------------------------------------------
Ethernet3/5/1                   DSCP                  DSCP
Ethernet3/5/2                   UNTRUSTED             UNTRUSTED
```

```
Ethernet3/5/3                   COS                     COS
Ethernet3/5/4                   COS                     DEFAULT
Ethernet3/6/1                   DSCP                    DEFAULT

switch(config-if-Et3/6/1)#
```

Configuring Default Port Settings

Default **CoS** and **DSCP** values are assigned to each Ethernet and port channel interface. These commands specify the configuration mode interface commands specify the port's default **CoS** and **DSCP** values.

- qos cos configures a port's default CoS value.
- qos dscp configures a port's default DSCP value.

Example

These commands configure default **CoS** (***4***) and **DSCP** (***44***) values on ***interface Ethernet 3/6/2***.

```
switch(config)# interface ethernet 3/6/2
switch(config-if-Et3/6/2)# qos cos 4
switch(config-if-Et3/6/2)# qos dscp 44
switch(config-if-Et3/6/2)# show active
interface Ethernet3/6/2
   qos cos 4
   qos dscp 44
switch(config-if-Et3/6/2)# show qos interfaces ethernet 3/6/2
Ethernet3/6/2:
   Trust Mode: COS
   Default COS: 4
   Default DSCP: 44

switch(config-if-Et3/6/2)#
```

10.1.4.2 Traffic Class Derivations – Jericho Platform Switches

Traffic Classes describes traffic classes.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's traffic class on Jericho platform switches.

Table 23: Traffic Class Derivation Source: Jericho Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default CoS (port)	Default CoS (port)	Default DSCP (port)
Untagged IP	Default CoS (port)	Default CoS (port)	DSCP (packet)
Tagged Non-IP	Default CoS (port)	CoS (packet)	Default DSCP (port)
Tagged IP	Default CoS (port)	CoS (packet)	DSCP (packet)

CoS and DSCP Port Settings – Arad Platform Switches describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS values. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the chip upon which it is received.

Example

This command assigns the traffic class of ***5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ---------------------------
     tc:   1  5  2  5  4  5  6  5

switch(config)#
```

The following table displays the default CoS to Traffic Class map on Jericho platform switches.

Table 24: Default CoS to Traffic Class Map: Jericho Platform Switches

Inbound CoS	Untagged	0	1	2	3	4	5	6	7
Traffic Class	Derived: use default CoS as inbound	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns the traffic class of 0 to DSCP values of ***12***, ***24***, ***41***, and ***44-47***.

```
switch(config)# qos map dscp 12 24 41 44 45 46 47 to traffic-class 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     2  2  2  2  0  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  0  5  5  0  0  0  0  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7
```

```
switch(config)#
```

The following table displays the default DSCP to traffic class map on Jericho platform switches.

Table 25: Default DSCP to Traffic Class Map: Jericho Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.4.3 CoS Rewrite – Jericho Platform Switches

Rewriting CoS and DSCP describes the CoS rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

This command assigns the CoS of two to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-cos map:
     tc:   0  1  2  3  4  5  6  7
     ---------------------------
     cos:  1  2  2  2  4  2  6  7

switch(config)#
```

The following table displays the default Traffic Class to CoS rewrite value map on Jericho platform switches.

Table 26: Default Traffic Class to CoS Rewrite Value Map: Jericho Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

DSCP rewrite is always disabled on Jericho platform switches.

10.1.4.4 Transmit Queues and Port Shaping – Jericho Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

Jericho platform switches provide 16 physical queues for each egress port: eight unicast and eight multicast queues. Data is scheduled to the physical queues based on transmit queue assignments.

Multicast queue capacity that remains after multicast traffic is serviced is available for unicast traffic of a corresponding priority. Similarly, unicast queue capacity that remains after unicast traffic is serviced is available for overflow multicast traffic. Under conditions of unicast and multicast congestion, egress traffic is evenly split between unicast and multicast traffic.

A data stream's traffic class determines the transmit queue it uses. The switch defines a single traffic class–transmit queue map for unicast and multicast traffic on all Ethernet and port channel interfaces. The show qos maps command displays the traffic class–transmit queue map.

The following table displays the default traffic class to transmit queue map on Jericho platform switches.

Table 27: Default Traffic Class to Transmit Queue Map: Jericho Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue	0	1	2	3	4	5	6	7

Transmit queue parameters are configured in tx-queue configuration command mode, which is entered from interface-ethernet configuration mode.

Mapping Traffic Classes to a Transmit Queue

The qos map traffic-class to tx-queue command assigns traffic classes to a transmit queue. Multiple commands complete the traffic class-transmit queue map. Traffic class 7 and transmit queue 7 are always mapped to each other. This association is not editable.

Example

These commands assign traffic classes of ***1***, ***3***, and ***5*** to ***transmit queue 1***, traffic classes ***2***, ***4***, and ***6*** to ***transmit queue 2***, and ***traffic class 0*** to ***transmit queue 0***, then display the resultant map.

```
switch(config)# qos map traffic-class 1 3 5 to tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to tx-queue 2
switch(config)# qos map traffic-class 0 to tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     ---------------------------------
     tx-queue:   0  1  2  1  2  1  2  7

switch(config)#
```

Entering Tx-Queue Configuration Mode

The tx-queue (Arad/Jericho) command places the switch in tx-queue configuration mode to configure a transmit queue on the configuration mode interface. ***Tx-queue 7*** is not configurable. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

This command enters Tx-queue configuration mode for ***transmit queue 4*** of ***interface ethernet 3/3/3***.

```
switch(config)# interface ethernet 3/3/3
switch(config-if-Et3/3/3)# tx-queue 4
switch(config-if-Et3/3/3-txq-4)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies its maximum outbound traffic bandwidth. A transmit queue's shape rate specifies the queue's maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

- To configure a port's shape rate, enter shape rate (Interface – Arad/Jericho) from the port's interface configuration mode.
- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – Arad/Jericho) from the queue's tx-queue configuration mode.

Examples

- This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 3/5/1***.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# shape rate 5000000
switch(config-if-Et3/5/1)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

   Port shaping rate: 5000012 / 5000000 kbps

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   ----------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D

switch(config-if-Et3/5/1)#
```

- These commands configure a shape rate of ***1*** Gbps on transmit queues ***3*** and ***4*** on ***interface ethernet 3/4/1***.

```
switch(config)# interface ethernet 3/4/1
switch(config-if-Et3/4/1)# tx-queue 4
switch(config-if-Et3/4/1-txq-4)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-4)# tx-queue 3
switch(config-if-Et3/4/1-txq-3)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-3)# show qos interface ethernet 3/4/1
Ethernet3/4/1:

   Port shaping rate: disabled

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   ----------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
```

```
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -      999 / 1000 ( Mbps )   SP / SP    D
   3      - / -      999 / 1000 ( Mbps )   SP / SP    D
   2      - / -        - / -    (  -  )    SP / SP    D
   1      - / -        - / -    (  -  )    SP / SP    D
   0      - / -        - / -    (  -  )    SP / SP    D

switch(config-if-Et3/4/1-txq-3)#
```

Configuring Queue Priority

The priority (Arad/Jericho) command configures a transmit queue's priority type:

- The **`priority strict`** command configures the queue as a strict priority queue.
- The **`no priority`** command configures the queue as a round robin queue.

A queue's configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The bandwidth percent (Arad/Jericho) command configures a round robin queue's bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

Examples

- These commands configure queues ***0*** through ***3*** (***interface ethernet 3/5/1***) as round robin, then allocate bandwidth for three queues at ***30%*** and one queue at ***10%***.

  The **`no priority`** statement for queue ***3*** also configures queues ***0***, ***1***, and ***2*** as round robin queues. Removing this statement reverts the other queues to **strict priority** type unless ***running-config*** contains a **`no priority`** statement for one of these queues.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# no priority
switch(config-if-Et3/5/1-txq-3)# bandwidth percent 10
switch(config-if-Et3/5/1-txq-3)# tx-queue 2
switch(config-if-Et3/5/1-txq-2)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-2)# tx-queue 1
switch(config-if-Et3/5/1-txq-1)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-1)# tx-queue 0
switch(config-if-Et3/5/1-txq-0)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-0)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   -----------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -        - / -    (  -  )    SP / SP    D
   3     10 / 10       - / -    (  -  )    RR / RR    D
   2     30 / 30       - / -    (  -  )    RR / SP    D
   1     30 / 30       - / -    (  -  )    RR / SP    D
   0     30 / 30       - / -    (  -  )    RR / SP    D

switch(config-if-Et3/5/1-txq-0)#
```

- Changing the bandwidth percentage for queue ***3*** to ***30*** changes the operational bandwidth of each queue to its configured bandwidth divided by ***120%*** (10%+20%+30%+60%).

```
switch(config-if-Et3/5/1-txq-0)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-3)# show qos interfaces ethernet 3/5/1
Ethernet3/5/1:

   Port shaping rate: disabled

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   -----------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -        - / -    (  -  )    SP / SP    D
   3     24 / 30       - / -    (  -  )    RR / RR    D
   2     24 / 30       - / -    (  -  )    RR / SP    D
   1     24 / 30       - / -    (  -  )    RR / SP    D
   0     24 / 30       - / -    (  -  )    RR / SP    D

Note: Values are displayed as Operational/Configured

switch(config-if-Et3/5/1-txq-3)#
```

10.1.4.5 ACL Policing – Jericho Platform Switches

ACL Policing describes ACL policing.

Implementing ACL policing consists of configuring the following:

- **policy-map settings**.
- **class-name**.
- **committed information rate (CIR)** the data speed committed to any given circuit regardless of the number of users.
- **burst size** the maximum burst size in bytes the network commits to moving under normal conditions.

The default unit for the metering rate CIR is bits per second; the default unit for the burst size is bytes.

The policer is applied to the class inside the policy map. Policy maps can contain one or more policy map classes, each with different match criteria and policer.

Default behavior and available policing actions are as follows:

- Policy map can be applied on multiple interfaces. Interfaces on the same chip will share the policer. (Applicable for Arad and Jericho only.)
- If there is no policer configured within a class, all traffic is transmitted without any policing.
- If there are any actions configured, the configured actions are applied:
  - Conform-action (green): transmit (default).
  - Violate-action (red): drop (default).

Example

These commands configure ACL policing in single-rate, two-color mode.

```
switch(config)# class-map type qos match-any class1
switch(config-cmap-class1)# match ip access-group acl1
switch(config-cmap-class1)# exit
switch(config)# policy-map type quality-of-service policy1
switch(config-policy1)# class class1
switch(config-policy1-class1)# police cir 512000 bc 96000
switch(config-policy1-class1)# exit
switch(config-policy1)# exit
switch(config)#
```

Displaying ACL Policing Information

Examples

- This command shows the contents of all policy maps on the switch.

```
switch(config)# show policy-map
Service-policy policy1

Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes

Class-map: class-default (match-any)
switch(config)#
```

- This command shows the interface-specific police counters for ***interface ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input counters
Service-policy input: policy1
Hardware programming status: Successful

Class-map: class1 (match-any) Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes Conformed 4351 packets, 1857386 bytes
Conformed 2536 packets, 3384260 bytes

Class-map: class-default (match-any) matched packets: 0

switch(config)#
```

- This command shows the counters associated with the policy map called ***p1***.

```
switch(config)# show policy-map type qos p1 input counters
Service-policy input: p1 Class-map: c1 (match-any)
Match: ip access-group name a1
Police cir 512000 bps bc 96000 bytes Interface: Ethernet1
Conformed 4351 packets, 1857386 bytes
Exceeded 2536 packets, 3384260 bytes
Interface: Ethernet2
Conformed 2351 packets, 957386 bytes
Exceeded 1536 packets, 1384260 bytes
Class-map: class-default (match-any)
Matched packets : 3229

switch(config)#
```

- This command shows the QoS policy map for ***interface ethernet 1***.

```
switch(config)# show policy-map interface Ethernet 1 input type qos
Interface: Ethernet 1 Service-policy input: policy1
```

```
Hardware programming status: Successful Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 9000 bytes
Class-map: class2 (match-any)
Match: ip access-group name acl2 set dscp 2
Class-map: class3 (match-any) Match: ip access-group name acl3
Police cir 1280000 bps bc 9000 bytes
Class-map: class-default (match-any)

switch(config)#
```

10.1.5 QoS Configuration: FM6000 Platform Switches

Implementing QoS on an FM6000 platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – FM6000 Platform Switches
- Traffic Class Derivations – FM6000 Platform Switches
- CoS and DSCP Rewrite – FM6000 Platform Switches
- Transmit Queues and Port Shaping – FM6000 Platform Switches

10.1.5.1 CoS and DSCP Port Settings – FM6000 Platform Switches

Port Settings – Trust Mode and Traffic Class describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is **cos**. The port-trust default for routed ports is **dscp**.

- `qos trust cos` specifies **cos** as the port's port-trust mode.
- `qos trust dscp` specifies dscp as the port's port-trust mode.
- `no qos trust` specifies untrusted as the port's port-trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

These commands configure and display the following trust modes:

- ***Ethernet 15:*** **dscp**.
- ***Ethernet 16:*** **untrusted**.
- ***Ethernet 17:*** **cos**.
- ***Ethernet 18:*** **default** as a switched port.

- ***Ethernet 19:*** **default** as a routed port.

```
switch(config)# interface ethernet 15
switch(config-if-Et15)# qos trust dscp
switch(config-if-Et15)# interface ethernet 16
switch(config-if-Et16)# no qos trust
switch(config-if-Et16)# interface ethernet 17
switch(config-if-Et17)# qos trust cos
switch(config-if-Et17)# interface ethernet 18
switch(config-if-Et18)# switchport
switch(config-if-Et18)# default qos trust
switch(config-if-Et19)# interface ethernet 19
switch(config-if-Et19)# no switchport
switch(config-if-Et19)# default qos trust
switch(config-if-Et19)# show qos interface ethernet 15 - 19 trust
Port                                     Trust Mode
                              Operational           Configured
---------------------------------------------------------------
Ethernet15                    DSCP                  DSCP
Ethernet16                    UNTRUSTED             UNTRUSTED
Ethernet17                    COS                   COS
Ethernet18                    COS                   DEFAULT
Ethernet19                    DSCP                  DEFAULT

switch(config-if-Et19)#
```

Configuring Default Port Settings

Default CoS and DSCP settings are assigned to individual port channel and Ethernet interfaces. These configuration mode interface commands specify the port's default CoS and DSCP values.

- qos cos configures a port's default CoS value.

- qos dscp configures a port's default DSCP value.

Example

These commands configure default CoS (***4***) and DSCP (***44***) settings on ***interface ethernet 19***.

```
switch(config)# interface ethernet 19
switch(config-if-Et19)# qos cos 4
switch(config-if-Et19)# qos dscp 44
switch(config-if-Et19)# show active
interface Ethernet19
   qos cos 4
   qos dscp 44
switch(config-if-Et19)# show qos interfaces ethernet 19
Ethernet19:
   Trust Mode: COS
   Default COS: 4
   Default DSCP: 44

switch(config-if-Et19)#
```

10.1.5.2 Traffic Class Derivations – FM6000 Platform Switches

Traffic Classes describes traffic classes.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's traffic class.

Table 28: Traffic Class Derivation Source: FM6000 Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default CoS (port)	Default CoS (port)	Default DSCP (port)
Untagged IP	Default CoS (port)	Default CoS (port)	DSCP (packet)
Tagged Non-IP	Default CoS (port)	CoS (packet)	Default DSCP (port)
Tagged IP	Default CoS (port)	CoS (packet)	DSCP (packet)

CoS and DSCP Port Settings – FM6000 Platform Switches describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS settings. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the port upon which it is received.

Example

This command assigns the traffic class of ***5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ---------------------------
     tc:   1  5  2  5  4  5  6  5

switch(config)#
```

The following table displays the default CoS to Traffic Class map on FM6000 platform switches.

Table 29: Default CoS to Traffic Class Map: FM6000 Platform Switches

Inbound CoS	Untagged	0	1	2	3	4	5	6	7
Traffic Class	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns the traffic class of three to the DSCP values of ***12***, ***13***, ***25***, and ***37***.

```
switch(config)# qos map dscp 12 13 25 37 to traffic-class 3
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  3  3  0  0  2  2  2  2
      2 :     2  2  2  2  3  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  3  4  4
      4 :     5  5  5  5  5  5  5  5  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

switch(config)#
```

The following displays the default DSCP to Traffic Class map on FM6000 platform switches.

Table 30: Default DSCP to Traffic Class Map: FM6000 Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.5.3 CoS and DSCP Rewrite – FM6000 Platform Switches

Rewriting CoS and DSCP describes the CoS and DSCP rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

This command assigns the CoS rewrite value of two to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     --------------------------------
     tx-queue:   0  1  2  3  4  5  6  7

switch(config)#
```

The following table displays the default traffic class–CoS rewrite map on FM6000 platform switches.

Table 31: Default Traffic Class to CoS Rewrite Map: FM6000 Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

The DSCP rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-DSCP rewrite map. The qos map traffic-class to dscp command assigns a DSCP rewrite value to a list of traffic classes. Multiple commands create the complete traffic class-DSCP rewrite map.

Example

This command assigns the DSCP rewrite value of ***37*** to traffic classes ***2***, ***4***, and ***6***.

```
switch(config)# qos map traffic-class 2 4 6 to dscp 37
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-dscp map:
     tc:    0  1  2  3  4  5  6  7
     ----------------------------
     dscp:  8  0 37 24 37 40 37 56

switch(config)#
```

The following table displays the default traffic class–DSCP rewrite map on on FM6000 platform switches.

Table 32: Default Traffic Class to DSCP Rewrite Map: FM6000 Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
DSCP Rewrite Value	8	0	16	24	32	40	48	56

10.1.5.4 Transmit Queues and Port Shaping – FM6000 Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

A data stream's traffic class determines the transmit queue it uses. The switch defines a single traffic class-transmit queue map for all Ethernet and port channel interfaces and is used for unicast and multicast traffic. The show qos maps command displays the traffic class to transmit queue map.

The following table displays the default traffic class to transmit queue map on FM6000 platform switches.

Table 33: Default Traffic Class to Transmit Queue Map: FM6000 Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue	0	1	2	3	4	5	6	7

Mapping Traffic Classes to a Transmit Queue

The qos map traffic-class to tx-queue command assigns traffic classes to a transmit queue. Multiple commands create the complete map.

Example

These commands assign traffic classes of ***1***, ***3***, and ***5*** to ***transmit queue 1***, traffic classes ***2***, ***4***, and ***6*** to ***transmit queue 2***, and ***traffic class 0*** to ***transmit queue 0***, then display the resultant map.

```
switch(config)# qos map traffic-class 1 3 5 to tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to tx-queue 2
switch(config)# qos map traffic-class 0 to tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     ---------------------------------
     tx-queue:   0  1  2  1  2  1  2  7

switch(config)#
```

Entering TX-Queue Configuration Mode

Transmit queues are configurable on Ethernet ports and port channels. Queue parameters are configured in tx-queue configuration command mode, which is entered from interface ethernet configuration mode. The tx-queue (FM6000) command places the switch in tx-queue configuration mode. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

This command enters tx-queue configuration mode for ***transmit queue 3*** of ***interface Ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# tx-queue 3
switch(config-if-Et5-txq-3)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies its maximum outbound traffic bandwidth. A transmit queue's shape rate specifies the queue's maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

Note: Enabling port shaping on an FM6000 interface disables queue shaping internally. Disabling port shaping restores queue shaping as specified in ***running-config***.

- To configure a port's shape rate, enter shape rate (Interface – FM6000) from the port's ***interface*** configuration mode.
- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – FM6000) from the queue's ***tx-queue*** configuration mode.

Example

These commands configure a shape rate of ***5*** Gbs on ***interface Ethernet 3***, then configure the shape rate for the following transmit queues:

- • transmit queues ***0***, ***1***, and ***2***: ***500*** Mbps.
  - transmit queues ***3***, ***4***, and ***5***: ***400*** Mbps.

```
switch(config)# interface ethernet 3
switch(config-if-Et3)# shape rate 5000000
switch(config-if-Et3)# tx-queue 0
switch(config-if-Et3-txq-0)# shape rate 500000
switch(config-if-Et3-txq-0)# tx-queue 1
switch(config-if-Et3-txq-1)# shape rate 500000
switch(config-if-Et3-txq-1)# tx-queue 3
switch(config-if-Et3-txq-3)# shape rate 400000
switch(config-if-Et3-txq-3)# tx-queue 4
switch(config-if-Et3-txq-4)# shape rate 400000
switch(config-if-Et3-txq-4)# tx-queue 5
switch(config-if-Et3-txq-5)# shape rate 400000
switch(config-if-Et3-txq-5)# exit
switch(config-if-Et3)# show qos interface ethernet 3
Ethernet3:

   Port shaping rate: 5000000Kbps

   Tx-Queue    Bandwidth     Shape Rate      Priority
               (percent)        (Kbps)
   ------------------------------------------------
          7          N/A     disabled         strict
          6          N/A     disabled         strict
          5          N/A       400000         strict
          4          N/A       400000         strict
          3          N/A       400000         strict
          2          N/A     disabled         strict
          1          N/A       500000         strict
          0          N/A       500000         strict

switch(config-if-Et3)#
```

Configuring Queue Priority

Queue priority rank is denoted by the queue number; transmit queues with higher numbers have higher priority. The priority (FM6000) command configures a transmit queue's priority type:

- **`priority strict`** configures the queue as a strict priority queue.
- **`no priority`** configures the queue as a round robin queue.

A queue's configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The bandwidth percent (FM6000) command configures a round robin queue's bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

Examples

- These commands configure ***transmit queue 3*** (on ***interface Ethernet 19***) as a round robin queue, then allocates ***10%***, ***20%***, ***30%***, and ***40%*** bandwidth to queues ***0*** through ***3***.

  The **`no priority`** statement for ***queue 3*** also configures queues ***0***, ***1***, and ***2*** as round robin queues. Removing this statement reverts the other queues to **`strict priority`** type unless ***running-config*** contains a **`no priority`** statement for one of these queues.

```
switch(config)# interface ethernet 19
switch(config-if-Et19)# tx-queue 3
switch(config-if-Et19-txq-3)# no priority
switch(config-if-Et19-txq-3)# bandwidth percent 40
switch(config-if-Et19-txq-3)# tx-queue 2
switch(config-if-Et19-txq-2)# bandwidth percent 30
switch(config-if-Et19-txq-2)# tx-queue 1
switch(config-if-Et19-txq-1)# bandwidth percent 20
switch(config-if-Et19-txq-1)# tx-queue 0
switch(config-if-Et19-txq-0)# bandwidth percent 10
switch(config-if-Et19-txq-0)# show qos interface ethernet 19
Ethernet19:
   Port shaping rate: disabled

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A     disabled        strict
          4         N/A     disabled        strict
          3          40     disabled   round-robin
          2          30     disabled   round-robin
          1          20     disabled   round-robin
          0          10     disabled   round-robin

switch(config-if-Et19-txq-0)#
```

- Changing the bandwidth percentage for queue ***3*** to ***60*** changes the operational bandwidth of each queue to its configured bandwidth divided by ***120%*** (10%+20%+30%+60%).

```
switch(config-if-Et19-txq-0) #tx-queue 3
switch(config-if-Et19-txq-3)# bandwidth percent 60
switch(config-if-Et19-txq-3)# show qos interface ethernet 19
Ethernet19:
   Port shaping rate: disabled

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A     disabled        strict
          4         N/A     disabled        strict
          3          49     disabled   round-robin
          2          24     disabled   round-robin
          1          16     disabled   round-robin
          0           8     disabled   round-robin
```

```
switch(config-if-Et19-txq-3)#
```

10.1.6 QoS Configuration: Petra Platform Switches

Implementing QoS on a Petra platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – Petra Platform Switches
- Traffic Class Derivations – Petra Platform Switches
- CoS Rewrite – Petra Platform Switches
- Transmit Queues and Port Shaping – Petra Platform Switches

10.1.6.1 CoS and DSCP Port Settings – Petra Platform Switches

Port Settings – Trust Mode and Traffic Class describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is **cos**. The port-trust default for routed ports is **dscp**.

- **`qos trust cos`** specifies **cos** as the port's port-trust mode.
- **`qos trust dscp`** specifies dscp as the port's port-trust mode.
- **`no qos trust`** specifies untrusted as the port's port-trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

These commands configure and display the following trust modes:

- ***Ethernet 3/25:*** **dscp**.
- ***Ethernet 3/26:*** **untrusted**.
- ***Ethernet 3/27:*** **cos**.
- ***Ethernet 3/28:*** **default** as a switched port.
- ***Ethernet 3/29:*** **default** as a routed port.

```
switch(config)# interface ethernet 3/25
switch(config-if-Et3/25)# qos trust dscp
switch(config-if-Et3/25)# interface ethernet 3/26
switch(config-if-Et3/26)# no qos trust
switch(config-if-Et3/26)# interface ethernet 3/27
switch(config-if-Et3/27)# qos trust cos
switch(config-if-Et3/27)# interface ethernet 3/28
switch(config-if-Et3/28)# switchport
```

```
switch(config-if-Et3/28)# default qos trust
switch(config-if-Et3/28)# interface ethernet 3/29
switch(config-if-Et3/29)# no switchport
switch(config-if-Et3/29)# default qos trust
switch(config-if-Et3/29)# show qos interface ethernet 3/25 - 3/29 trust
Port                                    Trust Mode
                              Operational           Configured
---------------------------------------------------------------
Ethernet3/25                  DSCP                  DSCP
Ethernet3/26                  UNTRUSTED             UNTRUSTED
Ethernet3/27                  COS                   COS
Ethernet3/28                  COS                   DEFAULT
Ethernet3/29                  DSCP                  DEFAULT

switch(config-if-Et3/29)#
```

Configuring Default Port Settings

Port channel and Ethernet interfaces are not assigned default CoS or DSCP settings.

10.1.6.2 Traffic Class Derivations – Petra Platform Switches

Traffic Classes describes traffic classes.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's default traffic class.

Table 34: Traffic Class Derivation Source: Petra Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default TC (chip)	Default TC (chip)	Default TC (chip)
Untagged IP	Default TC (chip)	Default TC (chip)	DSCP (packet)
Tagged Non-I	Default TC (chip)	CoS (packet)	Default TC (chip)
Tagged IP	Default TC (chip)	CoS (packet)	DSCP (packet)

Configuring Default Traffic Class

Petra platform switches assign a default traffic class to the set of Ethernet interfaces controlled by individual PetraA chips. Default traffic class values are configurable for each PetraA chip, not individual interfaces.

The platform petraA traffic-class command specifies the default traffic class used by all ports controlled by a specified chip. The show platform petraA traffic-class command displays traffic class assignments.

Examples

- This command configures the default traffic class to five for the ports ***32-39*** on ***linecard 3*** (7500 Series).

```
switch(config)# platform petraA petra3/4 traffic-class 5
switch(config)# show platform petraA module 3 traffic-class
Petra3/0 traffic-class: 1
Petra3/1 traffic-class: 1
Petra3/2 traffic-class: 1
Petra3/3 traffic-class: 1
Petra3/4 traffic-class: 5
Petra3/5 traffic-class: 1
```

```
switch(config)#
```

- This command configures the default traffic class to three for all ports on ***linecard 6*** (7500 Series).

```
switch(config)# platform petraA module 6 traffic-class 6
switch(config)# show platform petraA module 6 traffic-class
Petra6/0 traffic-class: 6
Petra6/1 traffic-class: 6
Petra6/2 traffic-class: 6
Petra6/3 traffic-class: 6
Petra6/4 traffic-class: 6
Petra6/5 traffic-class: 6
switch(config)#
```

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS settings. Multiple commands create a complete CoS–traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the port upon which it is received.

Example

This command assigns ***traffic class 4*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 4
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ----------------------------
     tc:   1  4  2  4  4  4  6  4

switch(config)#
```

The following table displays the default CoS to traffic class map on Petra platform switches.

Table 35: Default CoS to Traffic Class Map: Petra Platform Switches

Inbound CoS	untagged	0	1	2	3	4	5	6	7
Traffic Class	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns ***traffic class 3*** to the DSCP values of ***12***, ***13***, ***25***, and ***37***.

```
switch(config)# qos map dscp 12 13 14 25 48 to traffic-class 3
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ----------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  3  3  3  0  2  2  2  2
      2 :     2  2  2  2  3  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  5  5  5  5  5  5  5  3  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

switch(config)#
```

The following table displays the default DSCP to Traffic Class map on Petra platform switches.

Table 36: Default DSCP to Traffic Class Map: Petra Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.6.3 CoS Rewrite – Petra Platform Switches

Rewriting CoS and DSCP describes the CoS rewrite function.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class-CoS rewrite map.

Example

This command assigns the CoS of two to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-cos map:
     tc:   0  1  2  3  4  5  6  7
     ---------------------------
     cos:  1  2  2  2  4  2  6  7

switch(config)#
```

The following table displays the default Traffic Class to CoS rewrite value map on Petra platform switches.

Table 37: Default Traffic Class to CoS Rewrite Value Map: Petra Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

DSCP rewrite is always disabled on Petra platform switches.

10.1.6.4 Transmit Queues and Port Shaping – Petra Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

Petra platform switches provide four physical queues for each egress port: Unicast High, Unicast Low, Multicast High, and Multicast Low. Data is scheduled for the high or low queue based on its priority as defined by its transmit queue assignment (unicast traffic) or traffic class (multicast traffic), as shown in the table below. A Petra transmit queue is a data structure that defines scheduling of unicast traffic among physical egress queues.

Table 38: Traffic Distribution to Egress Port Queues

	High Priority Queue	**Low Priority Queue**
Unicast Traffic	Transmit Queues 5 – 7	Transmit Queues 0 – 4
Multicast Traffic	Traffic Classes 5 – 7	Traffic Classes 0 – 4

Multicast queue capacity that is available after multicast traffic is serviced is used for unicast traffic of a corresponding priority. Similarly, unicast queue capacity that is available after unicast traffic is serviced is used for overflow multicast traffic. Under conditions of unicast and multicast congestion, egress traffic is evenly split between unicast and multicast traffic.

Unicast Transmit Queues and Port Shaping describes unicast transmit queues and shaping. Multicast Egress Scheduling describes multicast priority and traffic classes.

10.1.6.4.1 Unicast Transmit Queues and Port Shaping

A data stream’s traffic class determines the transmit queue it uses. The switch defines a single traffic class–transmit queue map for unicast traffic on all Ethernet interfaces. The show qos maps command displays the traffic class–transmit queue map. The following table displays the default traffic class to transmit queue map on Petra platform switches.

Table 39: Default Traffic Class to Transmit Queue Map: Petra Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue	0	1	2	3	4	5	6	7

Transmit queue parameters are configured in tx-queue configuration command mode.

Mapping Traffic Classes to a Transmit Queue

The qos map traffic-class to tx-queue command assigns traffic classes to a transmit queue. Multiple commands complete the traffic class-transmit queue map. Traffic class ***7*** and transmit queue ***7*** are always mapped to each other. This association is not editable.

Example

These commands assign traffic classes of ***1***, ***3***, and ***5*** to ***transmit queue 1***, traffic classes ***2***, ***4***, and ***6*** to ***transmit queue 2***, and ***traffic class 0*** to ***transmit queue 0***, then display the resultant map.

```
switch(config)# qos map traffic-class 1 3 5 to tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to tx-queue 2
switch(config)# qos map traffic-class 0 to tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     ---------------------------------
     tx-queue:   0  1  2  1  2  1  2  7

switch(config)#
```

Entering Tx-Queue Configuration Mode

The tx-queue (Petra) command places the switch in tx-queue configuration mode to configure a transmit queue on the configuration mode interface. ***Tx-queue 7*** not configurable. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

This command enters tx-queue configuration mode for ***transmit queue 3*** of ***interface ethernet 3/28***.

```
switch(config)# interface ethernet 3/28
switch(config-if-Et3/28)# tx-queue 3
switch(config-if-Et3/28-txq-3)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies its maximum outbound traffic bandwidth. A transmit queue's shape rate specifies the queue's maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

- To configure a port's shape rate, enter shape rate (Interface – Petra) from the port's ***interface*** configuration mode.

- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – Petra) from the queue's ***tx-queue*** configuration mode.

Example

These commands configure a shape rate of ***5*** Gbs on ***interface Ethernet 3***, then configure the shape rate for the following transmit queues:

- transmit queues ***0***, ***1***, and ***2***: ***500*** Mbps.
- transmit queues ***3***, ***4***, and ***5***: ***400*** Mbps.

```
switch(config)# interface ethernet 3/28
switch(config-if-Et3/28)# shape rate 5000000
switch(config-if-Et3/28)# tx-queue 0
switch(config-if-Et3/28-txq-0)# shape rate 500000
switch(config-if-Et3/28-txq-0)# tx-queue 1
switch(config-if-Et3/28-txq-1)# shape rate 500000
switch(config-if-Et3/28-txq-1)# tx-queue 2
switch(config-if-Et3/28-txq-2)# shape rate 500000
switch(config-if-Et3/28-txq-5)# tx-queue 3
switch(config-if-Et3/28-txq-3)# shape rate 400000
switch(config-if-Et3/28-txq-3)# tx-queue 4
switch(config-if-Et3/28-txq-4)# shape rate 400000
switch(config-if-Et3/28-txq-4)# tx-queue 5
switch(config-if-Et3/28-txq-5)# shape rate 400000
switch(config-if-Et3/28-txq-5)# show qos interface ethernet 3/28
Ethernet3/28:

   Port shaping rate: 5000000Kbps

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A       400000        strict
          4         N/A       400000        strict
          3         N/A       400000        strict
          2         N/A       500000        strict
          1         N/A       500000        strict
          0         N/A       500000        strict

switch(config-if-Et3/28-txq-5)#
```

Configuring Queue Priority

The priority (Petra) command configures a transmit queue's priority type:

- The **`priority strict`** command configures the queue as a strict priority queue.
- The **`no priority`** command configures the queue as a round robin queue.

A queue's configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The bandwidth percent (Petra) command configures a round robin queue's bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

Examples

- These commands configure ***transmit queue 3*** (on ***interface Ethernet 3/28***) as a round robin queue, then allocates ***10%***, ***20%***, ***30%***, and ***40%*** bandwidth to queues ***0*** through ***3***.

The **no priority** statement for ***queue 3*** also configures queues ***0***, ***1***, and ***2*** as round robin queues. Removing this statement reverts the other queues to **strict priority** type unless ***running-config*** contains a **no priority** statement for one of these queues.

```
switch(config-if-Et3/28)# tx-queue 3
switch(config-if-Et3/28-txq-3)# no priority
switch(config-if-Et3/28-txq-3)# bandwidth percent 40
switch(config-if-Et3/28-txq-3)# tx-queue 2
switch(config-if-Et3/28-txq-2)# bandwidth percent 30
switch(config-if-Et3/28-txq-2)# tx-queue 1
switch(config-if-Et3/28-txq-1)# bandwidth percent 20
switch(config-if-Et3/28-txq-1)# tx-queue 0
switch(config-if-Et3/28-txq-0)# bandwidth percent 10
switch(config-if-Et3/28-txq-0)# show qos interface ethernet 3/28
Ethernet3/28:

   Port shaping rate: 5000000Kbps

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ---------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A       400000        strict
          4         N/A       400000        strict
          3          40       400000   round-robin
          2          30       500000   round-robin
          1          20       500000   round-robin
          0          10       500000   round-robin

switch(config-if-Et3/28-txq-0)#
```

- Changing the bandwidth percentage for queue ***3*** to ***60*** changes the operational bandwidth of each queue to its configured bandwidth divided by ***120%*** (10%+20%+30%+60%).

```
switch(config-if-Et3/28-txq-0)# tx-queue 3
switch(config-if-Et3/28-txq-3)# bandwidth percent 60
switch(config-if-Et3/28-txq-3)# show qos interface ethernet 3/28
Ethernet3/28:

   Port shaping rate: 5000000Kbps

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ---------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A       400000        strict
          4         N/A       400000        strict
          3          49       400000   round-robin
          2          24       500000   round-robin
          1          16       500000   round-robin
          0           8       500000   round-robin
switch(config-if-Et3/28-txq-3)#
```

10.1.6.4.2 Multicast Egress Scheduling

Multicast traffic is not affected by traffic class assignment or port shaping statements. Multicast traffic is assigned to port egress queues based on traffic class and uses strict priority to schedule egress between the high and low queues.

10.1.7 QoS Configuration: Trident and Tomahawk Platform Switches

Implementing QoS on a Trident and Tomahawk platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – Trident and Tomahawk Platform Switches
- Traffic Class Derivations – Trident and Tomahawk Platform Switches
- CoS and DSCP Rewrite – Trident and Tomahawk Platform Switches
- Transmit Queues and Port Shaping – Trident and Tomahawk Platform Switches
- ECN Configuration – Trident and Tomahawk Platform Switches

10.1.7.1 CoS and DSCP Port Settings – Trident and Tomahawk Platform Switches

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust-enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is **CoS**. The port-trust default for routed ports is **DSCP**.

- **`qos trust cos`** specifies **CoS** as the port's trust mode.
- **`qos trust dscp`** specifies **DSCP** as the port's trust mode.
- **`no qos trust`** specifies **untrusted** as the port's trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

- These commands configure and display the following trust modes:
  - ***Ethernet 15***: **dscp**
  - ***Ethernet 16***: **untrusted**
  - ***Ethernet 17***: **cos**
  - ***Ethernet 18***: **default** as a switched port
  - ***interface ethernet 19***: **default** as a routed port

```
switch(config)# interface ethernet 15
switch(config-if-Et15)# qos trust dscp
switch(config-if-Et15)# interface ethernet 16
switch(config-if-Et16)# no qos trust
switch(config-if-Et16)# interface ethernet 17
switch(config-if-Et17)# qos trust cos
switch(config-if-Et17)# interface ethernet 18
switch(config-if-Et18)# switchport
switch(config-if-Et18)# default qos trust
switch(config-if-Et18)# interface ethernet 19
switch(config-if-Et19)# no switchport
```

```
switch(config-if-Et19)# default qos trust
switch(config-if-Et19)# show qos interface ethernet 15 - 19 trust
Port                                        Trust Mode
                                Operational           Configured
-----------------------------------------------------------------
Ethernet15                      DSCP                  DSCP
Ethernet16                      UNTRUSTED             UNTRUSTED
Ethernet17                      COS                   COS
Ethernet18                      COS                   DEFAULT
Ethernet19                      DSCP                  DEFAULT

switch(config-if-Et19)#
```

Configuring Default Port Settings

Default CoS and DSCP settings are assigned to individual port channel and Ethernet interfaces. These configuration mode interface commands specify the port's default CoS and DSCP values.

- qos cos configures a port's default CoS value.
- qos dscp configures a port's default DSCP value.

Example

These commands configure default CoS (***4***) and DSCP (***44***) values on ***interface ethernet 7***.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# qos cos 4
switch(config-if-Et7)# qos dscp 44
switch(config-if-Et7)# show active
interface Ethernet7
   qos cos 4
   qos dscp 44
switch(config-if-Et7)# show qos interfaces ethernet 7
Ethernet7:
   Trust Mode: COS
   Default COS: 4
   Default DSCP: 44

switch(config-if-Et7)#
```

10.1.7.2 Traffic Class Derivations – Trident and Tomahawk Platform Switches

Traffic Classes describes traffic classes.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's traffic class.

Table 40: Traffic Class Derivation Source: Trident and Tomahawk Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default CoS (port)	Default CoS (port)	Default DSCP (port)
Untagged IP	Default CoS (port)	Default CoS (port)	DSCP (packet)
Tagged Non-IP	Default CoS (port)	CoS (packet)	Default DSCP (port)
Tagged IP	Default CoS (port)	CoS (packet)	DSCP (packet)

CoS and DSCP Port Settings – Trident and Tomahawk Platform Switches describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS settings. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the port upon which it is received.

Example

This command assigns the ***traffic class 5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ---------------------------
     tc:   1  5  2  5  4  5  6  5

switch(config)#
```

The following table displays the default CoS–traffic class map on Trident and Tomahawk platform switches.

Table 41: Default CoS to Traffic Class Map: Trident II Platform Switches

Inboun CoS	0	1	2	3	4	5	6	7
Traffic Class	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns the ***traffic class 0*** to DSCP values of ***12***, ***24***, ***41***, and ***44-47***.

```
switch(config)# qos map dscp 12 24 41 44 45 46 47 to traffic-class 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ----------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     2  2  2  2  0  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  0  5  5  0  0  0  0  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

switch(config)#
```

The following table displays the default DSCP–traffic class map on Trident and Tomahawk platform switches.

Table 42: Default DSCP to Traffic Class Map: Trident and Tomahawk Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.7.3 CoS and DSCP Rewrite – Trident and Tomahawk Platform Switches

Rewriting CoS and DSCP describes the CoS and DSCP rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

This command assigns the ***CoS 2*** to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-cos map:
     tc:   0  1  2  3  4  5  6  7
     ---------------------------
     cos:  1  2  2  2  4  2  6  7

switch(config)#
```

The following table displays the default Traffic Class to CoS rewrite value map on Trident and Tomahawk platform switches.

Table 43: Default Traffic Class to CoS Rewrite Value Map: Trident and Tomahawk Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

The DSCP rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-DSCP rewrite map. The qos map traffic-class to dscp command assigns a DSCP rewrite value to a list of traffic classes. Multiple commands create the complete traffic class-DSCP rewrite map.

Example

This command assigns the DSCP value of ***29*** to traffic classes ***2***, ***4***, and ***6***.

```
switch(config)# qos map traffic-class 2 4 6 to dscp 29
switch(config)# show qos map
   Number of Traffic Classes supported: 8

   Tc-dscp map:
     tc:    0  1  2  3  4  5  6  7
     ----------------------------
     dscp:  8  0 29 24 29 40 29 56

switch(config)#
```

The following displays the default traffic class to DSCP rewrite map on Trident and Tomahawk platform switches.

Table 44: Traffic Class to DSCP Rewrite Value Map: Trident and Tomahawk Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
DSCP	8	0	16	24	32	40	48	56

10.1.7.4 Transmit Queues and Port Shaping – Trident and Tomahawk Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

Trident and Tomahawk platform switches define ***12*** transmit queues: eight unicast (UC0 – UC7) and four multicast (MC0 – MC03). The traffic class–transmit queue maps are configured globally and apply to all Ethernet interfaces. The show qos maps command displays the traffic class–transmit queue maps.

The following table displays the default traffic class–transmit queue maps.

Table 45: Default Traffic Class to Transmit Queue Map: Trident and Tomahawk Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Unicast Transmit Queue	0	1	2	3	4	5	6	7
Multicast Transmit Queue	0	0	1	1	2	2	3	3

Mapping Traffic Classes to a Transmit Queue

These commands assign traffic classes to a transmit queue:

- qos map traffic-class to uc-tx-queue associates a unicast queue to a traffic class set.
- qos map traffic-class to mc-tx-queue associates a multicast queue to a traffic class set.

Multiple commands create the complete maps.

Example

These commands assign the following on ***interface ethernet 7***:

- traffic classes ***1***, ***3***, and ***5*** to ***unicast queue 1***
- traffic classes ***2***, ***4***, and ***6*** to ***unicast queue 5***
- traffic classes ***1***, ***2***, and ***3*** to ***multicast queue 1***
- traffic classes ***4***, ***5***, and ***6*** to ***multicast queue 3***
- ***traffic class 0*** to ***unicast queue 0*** and ***multicast queue 0***

```
switch(config)# default interface ethernet 7
switch(config)# qos map traffic-class 1 3 5 to uc-tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to uc-tx-queue 5
switch(config)# qos map traffic-class 1 2 3 to mc-tx-queue 1
switch(config)# qos map traffic-class 4 5 6 to mc-tx-queue 3
switch(config)# qos map traffic-class 0 to uc-tx-queue 0
switch(config)# qos map traffic-class 0 to mc-tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 12

   Tc - uc-tx-queue map:
     tc:           0  1  2  3  4  5  6  7
     ------------------------------------
     uc-tx-queue:  0  1  5  1  5  1  5  7

   Tc - mc-tx-queue map:
     tc:           0  1  2  3  4  5  6  7
     ------------------------------------
     mc-tx-queue:  0  1  1  1  3  3  3  3

switch(config)#
```

Entering a Transmit Queue Configuration Mode

Transmit queues are configurable on individual Ethernet ports. Parameters for individual transmit queues are configured in one of two transmit queue configuration modes. Transmit queue modes are accessed from an interface-ethernet configuration mode.

- uc-tx-queue places the switch in ***uc-tx-queue*** mode to configure a unicast transmit queue.
- mc-tx-queue places the switch in ***mc-tx-queue*** mode to configure a multicast transmit queue.

The show qos interfaces displays the transmit queue configuration for a specified port.

Examples

- This command enters the mode that configures ***unicast transmit queue 3*** of ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# uc-tx-queue 3
switch(config-if-Et5-uc-txq-3)#
```

- This command enters the mode to configure ***multicast transmit queue 3*** of ***interface ethernet 5***.

```
switch(config-if-Et5)# mc-tx-queue 2
switch(config-if-Et5-mc-txq-2)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies the port's maximum outbound traffic bandwidth. A shape rate can also be configured for all transmit queues on each port. All shape rate commands use kbps to specify data rates.

- To configure a port's shape rate, enter shape rate (Interface – Trident and Tomahawk) from the port's ***interface*** configuration mode.
- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – Trident and Tomahawk) from the queue's ***tx-queue*** configuration mode.

Example

These commands configure a shape rate of ***5*** Gbs on ***interface Ethernet 7***, then configure the shape rate for the following transmit queues:

- unicast transmit queues ***0*** and ***1***: ***500*** Mbps.
- unicast transmit queues ***3*** and ***4***: ***400*** Mbps.
- multicast transmit queues ***0*** and *2*: ***300*** Mbps.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# shape rate 5000000
switch(config-if-Et7)# uc-tx-queue 0
switch(config-if-Et7-uc-txq-0)# shape rate 500000
switch(config-if-Et7-uc-txq-0)# uc-tx-queue 1
switch(config-if-Et7-uc-txq-1)# shape rate 500000
switch(config-if-Et7-uc-txq-1)# uc-tx-queue 3
```

```
switch(config-if-Et7-uc-txq-3)# shape rate 400000
switch(config-if-Et7-uc-txq-3)# uc-tx-queue 5
switch(config-if-Et7-uc-txq-5)# shape rate 400000
switch(config-if-Et7-uc-txq-5)# mc-tx-queue 0
switch(config-if-Et7-mc-txq-0)# shape rate 300000
switch(config-if-Et7-mc-txq-0)# mc-tx-queue 2
switch(config-if-Et7-mc-txq-2)# shape rate 300000
switch(config-if-Et7-mc-txq-2)# exit
switch(config-if-Et7)# show qos interface ethernet 7
Ethernet7:

   Port shaping rate: 5000000Kbps

   Tx-Queue   Bandwidth    Shape Rate     Priority   Priority Group
              (percent)       (Kbps)
   ------------------------------------------------------------------
        UC7         N/A     disabled       strict                1
        UC6         N/A     disabled       strict                1
        MC3         N/A     disabled       strict                1
        UC5         N/A       400000       strict                0

        UC3         N/A       400000       strict                0
        UC2         N/A     disabled       strict                0
        MC1         N/A     disabled       strict                0
        UC1         N/A       500000       strict                0
        UC0         N/A       500000       strict                0
        MC0         N/A       300000       strict                0

switch(config-if-Et7)#
```

Configuring Queue Priority

Trident and Tomahawk platform switch queues are categorized into two priority groups. Priority group 1 queues have priority over priority 0 queues. The following lists display the priority group queues in order from higher priority to lower priority.

- Priority Group 1: UC7, UC6, MC3
- Priority Group 0: UC5, UC4, MC2, UC3, UC2, MC1, UC1, UC0, MC0

The priority (Trident and Tomahawk) command configures a transmit queue's priority type:

- The **`priority strict`** command configures the queue as a strict priority queue.
- The **`no priority`** command configures the queue as a round robin queue.

A queue's configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The bandwidth percent (Trident and Tomahawk) command configures a round robin queue's bandwidth share. The cumulative operational bandwidth of all round robin queues is always 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

Priority Group 1 queues (UC7, UC6, MC3) are not configurable as round robin queues. The **`bandwidth percent`** command is not available for these queues.

Examples

- These commands configure ***unicast transmit queue 3*** as a round robin queue, then allocates ***5%***, ***15%***, ***25%***, ***35%***, ***8%***, and ***12%*** bandwidth to unicast transmit queues ***0*** through ***3*** and multicast transmit queues ***0*** and ***1***, respectively.

  The **`no priority`** statement for ***queue 3*** also configures priority for all lower priority queues. Removing the statement reverts the other queues to **`strict priority`** type unless ***running-config*** contains a **`no priority`** statement for one of these queues.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# uc-tx-queue 3
switch(config-if-Et7-uc-txq-3)# no priority
switch(config-if-Et7-uc-txq-3)# bandwidth percent 5
switch(config-if-Et7-uc-txq-3)# uc-tx-queue 2
switch(config-if-Et7-uc-txq-2)# bandwidth percent 15
switch(config-if-Et7-uc-txq-2)# uc-tx-queue 1
switch(config-if-Et7-uc-txq-1)# bandwidth percent 25
switch(config-if-Et7-uc-txq-1)# uc-tx-queue 0
switch(config-if-Et7-uc-txq-0)# bandwidth percent 35
switch(config-if-Et7-uc-txq-0)# mc-tx-queue 1
switch(config-if-Et7-mc-txq-1)# bandwidth percent 12
switch(config-if-Et7-mc-txq-1)# mc-tx-queue 0
switch(config-if-Et7-mc-txq-0)# bandwidth percent 8
switch(config-if-Et7-mc-txq-0)# show qos interface ethernet 7
Ethernet7:

        MC0           6     disabled   round-robin                0

switch(config-if-Et7-uc-txq-3)#
```

10.1.7.5 ECN Configuration – Trident and Tomahawk Platform Switches

ECN is independently configurable on all egress queues of each Ethernet interface. ECN settings for Port-Channels are applied on each of the channel's member Ethernet interfaces. ECN is also globally configurable to mark packets from the shared pool used for dynamically allocating memory to the queues. Multicast packets contribute to the globally shared pool and can contribute to global level congestion that result in ECN marking of unicast packets queued after the multicast packets.

Average queue length is tracked for transmit queues and the global pool independently. When either entity reaches its maximum threshold, all subsequent packets are marked.

Although the switch does not limit the number of queues that can be configured for ECN, hardware table limitations restrict the number of queues (including the global shared pool) that can simultaneously implement ECN.

The qos random-detect ecn global-buffer (Trident and Tomahawk) command enables ECN marking for globally shared packet memory and specifies minimum and maximum queue threshold sizes.

Examples

- This command enables ECN marking of unicast packets from the global data pool and sets the minimum and maximum thresholds at ***20*** and ***500*** segments.

```
switch(config)# qos random-detect ecn global-buffer minimum-threshold 20 segments
maximum-threshold 500 segments
switch(config)#
```

- This command disables ECN marking of unicast packets from the global data pool.

```
switch(config)# no qos random-detect ecn global-buffer
switch(config)#
```

The random-detect ecn (Trident and Tomahawk) command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes.

- These commands enable ECN marking of unicast packets from ***transmit queue 4*** of ***interface Ethernet 15***, setting thresholds at ***10*** and ***100*** segments.

```
switch(config)# interface ethernet 15
switch(config-if-Et15)# uc-tx-queue 4
switch(config-if-Et15-uc-txq-4)# random-detect ecn minimum-threshold 10 segments
maximum-threshold 100 segments
switch(config-if-Et15-uc-txq-4)# show active
interface Ethernet15
   uc-tx-queue 4
      random-detect ecn minimum-threshold 10 segments maximum-threshold 100
segments
switch(config-if-Et15-uc-txq-4)# exit
switch(config-if-Et15)#
```

- This command disables ECN marking of unicast packets from ***transmit queue 4*** of ***interface Ethernet 15***.

```
switch(config-if-Et15-uc-txq-4)# no random-detect ecn
switch(config-if-Et15-uc-txq-4)# show active
interface Ethernet15
switch(config-if-Et15-uc-txq-4)# exit
switch(config-if-Et15)#
```

10.1.8 QoS Configuration: Trident II and Helix Platform Switches

Implementing QoS on a Trident platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- CoS and DSCP Port Settings – Trident II and Helix Platform Switches
- Traffic Class Derivations – Trident II and Helix Platform Switches
- CoS and DSCP Rewrite – Trident II and Helix Platform Switches
- Transmit Queues and Port Shaping – Trident II and Helix Platform Switches
- Ingress Policing on LAG
- Fabric QoS -- – Trident II Platform Switches

10.1.8.1 CoS and DSCP Port Settings – Trident II and Helix Platform Switches

Configuring Port Trust Settings

The qos trust command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is ***cos***. The port-trust default for routed ports is ***dscp***.

- **`qos trust cos`** specifies ***cos*** as the port's port-trust mode.
- **`qos trust dscp`** specifies ***dscp*** as the port's port-trust mode.
- **`no qos trust`** specifies ***untrusted*** as the port's port-trust mode.

The show qos interfaces trust command displays the trust mode of specified interfaces.

Example

These commands configure and display the following trust modes:

- ***Ethernet 7/1***: **dscp**.
- ***Ethernet 7/2***: **untrusted**.
- ***Ethernet 7/3***: **cos**.
- ***Ethernet 7/4***: **default** as a switched port.

- ***Ethernet 8/1***: **default** as a routed port.

```
switch(config)# interface ethernet 7/1
switch(config-if-Et7/1)# qos trust dscp
switch(config-if-Et7/1)# interface ethernet 7/2
switch(config-if-Et7/2)# no qos trust
switch(config-if-Et7/2)# interface ethernet 7/3
switch(config-if-Et7/3)# qos trust cos
switch(config-if-Et7/3)# interface ethernet 7/4
switch(config-if-Et7/4)# switchport
switch(config-if-Et7/4)# default qos trust
switch(config-if-Et7/4)# interface ethernet 8/1
switch(config-if-Et8/1)# no switchport
switch(config-if-Et8/1)# default qos trust
switch(config-if-Et8/1)# show qos interface ethernet 7/1 - 8/1 trust

Port                                        Trust Mode
                              Operational           Configured
---------------------------------------------------------------
Ethernet7/1                   DSCP                  DSCP
Ethernet7/2                   UNTRUSTED             UNTRUSTED
Ethernet7/3                   COS                   COS
Ethernet7/4                   COS                   DEFAULT
Ethernet8/1                   DSCP                  DEFAULT

switch(config-if-Et8/1)#
```

Configuring Default Port Settings

Default CoS and DSCP settings are assigned to individual port channel and Ethernet interfaces. These configuration mode interface commands specify the port's default CoS and DSCP values.

- qos cos configures a port's default CoS value.

- qos dscp configures a port's default DSCP value.

Example

These commands configure default ***CoS 4*** and ***DSCP 44*** values on ***interface ethernet 7/3***.

```
switch(config)# interface ethernet 7/3
switch(config-if-Et7/3)# qos cos 4
switch(config-if-Et7/3)# qos dscp 44
switch(config-if-Et7/3)# show active

interface Ethernet7/3
   qos cos 4
   qos dscp 44

switch(config-if-Et7/3)# show qos interfaces ethernet 7/3

Ethernet7/3:
   Trust Mode: COS
   Default COS: 4
   Default DSCP: 44

switch(config-if-Et7/3)#
```

10.1.8.2 Traffic Class Derivations – Trident II and Helix Platform Switches

Traffic Classes describes traffic classes.

Note: QoS traffic policy is supported on Trident II platform switches.

Traffic Class Derivation Source

The following table displays the source for deriving a data stream's traffic class.

Table 46: Traffic Class Derivation Source: Trident II Platform Switches

	Untrusted	CoS Trusted	DSCP Trusted
Untagged Non-IP	Default CoS (port)	Default CoS (port)	Default DSCP (port)
Untagged IP	Default CoS (port)	Default CoS (port)	DSCP (packet)
Tagged Non-IP	Default CoS (port)	CoS (packet)	Default DSCP (port)
Tagged IP	Default CoS (port)	CoS (packet)	DSCP (packet)

CoS and DSCP Port Settings – Trident II and Helix Platform Switches describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The qos map cos command assigns a traffic class to a list of CoS settings. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the port upon which it is received.

Example

This command assigns the ***traffic class 5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     ---------------------------
     tc:   1  5  2  5  4  5  6  5

switch(config)#
```

The following table displays the default CoS–traffic class map on Trident II platform switches.

Table 47: Default CoS to Traffic Class Map: Trident II Platform Switches

Inbound CoS	0	1	2	3	4	5	6	7
Traffic Class	1	0	2	3	4	5	6	7

Mapping DSCP to Traffic Class

The qos map dscp command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

Example

This command assigns the *traffic class 0* to DSCP values of ***12***, ***24***, ***41***, and ***44-47***.

```
switch(config)# qos map dscp 12 24 41 44 45 46 47 to traffic-class 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     2  2  2  2  0  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  0  5  5  0  0  0  0  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

switch(config)#
```

The following table displays the default DSCP–traffic class map on Trident II platform switches.

Table 48: Default DSCP to Traffic Class Map: Trident II Platform Switches

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class	1	0	2	3	4	5	6	7

10.1.8.3 CoS and DSCP Rewrite – Trident II and Helix Platform Switches

Rewriting CoS and DSCP describes the CoS and DSCP rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

This command assigns the CoS of two to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)#show qos map

   Number of Traffic Classes supported: 8

   Tc-cos map:
```

```
     tc:   0  1  2  3  4  5  6  7
     ---------------------------
     cos:  1  2  2  2  4  2  6  7

switch(config)#
```

The following table displays the default Traffic Class to CoS rewrite value map on Trident II platform switches.

Table 49: Default Traffic Class to CoS Rewrite Value Map: Trident II Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value	1	0	2	3	4	5	6	7

Traffic Class to DSCP Rewrite Map

The DSCP rewrite value is configurable and based on a data stream's traffic class, as specified by the traffic class-DSCP rewrite map. The qos map traffic-class to dscp command assigns a DSCP rewrite value to a list of traffic classes. Multiple commands create the complete traffic class-DSCP rewrite map.

Example

This command assigns the DSCP value of ***29*** to traffic classes ***2***, ***4***, and ***6***.

```
switch(config)# qos map traffic-class 2 4 6 to dscp 29
switch(config)# show qos map

   Number of Traffic Classes supported: 8

   Tc-dscp map:
     tc:    0  1  2  3  4  5  6  7
     ----------------------------
     dscp:  8  0 29 24 29 40 29 56

switch(config)#
```

The following table displays the default traffic class to DSCP rewrite map on Trident II platform switches.

Table 50: Traffic Class to DSCP Rewrite Value Map: Trident II Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
DSCP	8	0	16	24	32	40	48	56

10.1.8.4 Transmit Queues and Port Shaping – Trident II and Helix Platform Switches

Transmit Queues and Port Shaping describes transmit queues and port shaping.

A data stream's traffic class determines the transmit queue it uses. The switch defines a single traffic class-transmit queue map for all Ethernet interfaces and is used for unicast and multicast traffic. The traffic class to

transmit queue maps are configured globally and apply to all Ethernet and port channel interfaces. The show qos maps command displays the traffic class to transmit queue map.

Trident II platform switches have eight unicast (UC0 – UC7) and eight multicast (MC0 – MC7) queues. Each UCx-MCx queue set is combined into a single queue group (L1.x), which is exposed to the CLI through this command.

The following table displays the default traffic class to transmit queue maps.

Table 51: Default Traffic Class to Transmit Queue Map: Trident II Platform Switches

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue Group	0	1	2	3	4	5	6	7

Mapping Traffic Classes to a Transmit Queue

The qos map traffic-class to tx-queue command assigns traffic classes to a transmit queue. Multiple commands create the complete map.

Example

These commands assign traffic classes of ***1***, ***3***, and ***5*** to ***transmit queue 1***, traffic classes ***2***, ***4***, and ***6*** to ***transmit queue 2***, and ***traffic class 0*** to ***transmit queue 0***, then display the resultant map.

```
switch(config)# qos map traffic-class 1 3 5 to tx-queue 1
switch(config)# qos map traffic-class 2 4 6 to tx-queue 2
switch(config)# qos map traffic-class 0 to tx-queue 0
switch(config)# show qos maps
   Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8

   Tc - tx-queue map:
     tc:        0  1  2  3  4  5  6  7
     ---------------------------------
     tx-queue:  0  1  2  1  2  1  2  7

switch(config)#
```

Entering a Transmit Queue Configuration Mode

Transmit queues are configurable on Ethernet ports and port channels. Queue parameters are configured in tx-queue configuration command mode, which is entered from the appropriate interface configuration mode. The tx-queue (Trident II) command places the switch in tx-queue configuration mode. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

This command enters tx-queue configuration mode for ***transmit queue 3*** of ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# tx-queue 3
switch(config-if-Et5-txq-3)#
```

Configuring the Shape Rate – Port and Transmit Queues

A port's shape rate specifies the port's maximum outbound traffic bandwidth. A shape rate can also be configured for all transmit queues on each port. All shape rate commands use kbps to specify data rates.

- To configure a port's shape rate, enter shape rate (Interface – Trident II) from the port's ***interface*** configuration mode.

- To configure a transmit queue's shape rate, enter shape rate (Tx-queue – Trident II) from the queue's ***tx-queue*** configuration mode.

Example

These commands configure a shape rate of ***5*** Gbs on ***interface Ethernet 3***, then configure the shape rate for the following transmit queues:

- - transmit queues ***0***, ***1***, and ***2***: ***500*** Mbps
  - transmit queues ***3***, ***4***, and ***5***: ***400*** Mbps

```
switch(config)# interface ethernet 17/3
switch(config-if-Et17/3)# shape rate 5000000
switch(config-if-Et17/3)# tx-queue 0
switch(config-if-Et17/3-txq-0)# shape rate 500000
switch(config-if-Et17/3-txq-0)# tx-queue 1
switch(config-if-Et17/3-txq-1)# shape rate 500000
switch(config-if-Et17/3-txq-1)# tx-queue 3
switch(config-if-Et17/3-txq-3)# shape rate 400000
switch(config-if-Et17/3-txq-3)# tx-queue 4
switch(config-if-Et17/3-txq-4)# shape rate 400000
switch(config-if-Et17/3-txq-4)# tx-queue 5
switch(config-if-Et17/3-txq-5)# shape rate 400000
switch(config-if-Et17/3-txq-5)# exit
switch(config-if-Et17/3)# show qos interface ethernet 17/3
Ethernet17/3:

  Tx       Bandwidth                Shape Rate        Priority
 Queue     Guaranteed (units)         (units)
   ------------------------------------------------------------
   7        - / -    (  -  )       - / -    (  -  )    SP / SP
   6        - / -    (  -  )       - / -    (  -  )    SP / SP
   5        - / -    (  -  )     400 / 400  ( Mbps )   SP / SP
   4        - / -    (  -  )     400 / 400  ( Mbps )   SP / SP
   3        - / -    (  -  )     400 / 400  ( Mbps )   SP / SP
   2        - / -    (  -  )       - / -    (  -  )    SP / SP
   1        - / -    (  -  )     500 / 500  ( Mbps )   SP / SP

switch(config-if-Et17/3)#
```

Configuring Queue Priority

Queue priority rank is denoted by the queue number; transmit queues with higher numbers have higher priority. Trident II supports strict priority queues; round robin queues are not supported.

The bandwidth guaranteed (Trident II) command configures specifies the minimum bandwidth for outbound traffic on the transmit queue.

Example

These commands configure a minimum egress bandwidth of ***1*** Mbps for ***transmit queue 4*** on ***interface ethernet 17/3***.

```
switch(config-if-Et17/3)# tx-queue 4
switch(config-if-Et17/3-txq-4)# show qos interface ethernet 17/3

  Tx       Bandwidth                 Shape Rate        Priority
 Queue     Guaranteed (units)         (units)
   ---------------------------------------------------------------
   7        - / -    (  -  )       - / -    (  -  )    SP / SP
   6        - / -    (  -  )       - / -    (  -  )    SP / SP
   5        - / -    (  -  )     400 / 400  ( Mbps )   SP / SP
   4        1 / 1    ( Mbps )    400 / 400  ( Mbps )   SP / SP
   3        - / -    (  -  )     400 / 400  ( Mbps )   SP / SP
   2        - / -    (  -  )       - / -    (  -  )    SP / SP
   1        - / -    (  -  )     500 / 500  ( Mbps )   SP / SP
   0        - / -    (  -  )     500 / 500  ( Mbps )   SP / SP

switch(config-if-Et17/3-txq-4)#
```

10.1.8.5 Ingress Policing on LAG

Ingress policing on a port-channel polices the matched traffic from all member interfaces combined, i.e. it provides aggregate policing and statistics (DCS-7050X, DCS-7010T, DCS-7250X, and DCS-7300X series). When a per-interface policer is attached to a port-channel, one set of TCAM entries is created for all member interfaces. The associated interface bitmap is updated, and aggregate policing is performed on all member interfaces.

Examples

- These commands configure a service-policy (with policer action) on LAG by creating the service-policy and applying the service-policy on a port-channel.

```
switch(config)# policy-map policy-1
switch(config-pmap-qos-policy-1)# class class-1
switch(config-pmap-c-qos-policy-1-class-1)# police cir 512000 bps bc 96000
switch(config-pmap-c-qos-policy-1-class-1)# exit
switch(config-pmap-qos-policy-1)# exit
switch(config)# interface Et 4 / 5 / 4
switch(config-if-Et4/5/4)# channel-group 2 mode active
switch(config-if-Et4/5/4)# exit
switch(config)# interface po2
switch(config-if-Po2)# service-policy type qos input policy-1
switch(config-if-Po2)# exit
switch(config)#
```

- These commands configure ACL policing in single-rate, two-color mode.

```
switch(config)# class-map type qos match-any class1
switch(config-cmap-qos-class1)# match ip access-group acl1
switch(config-cmap-qos-class1)# exit
switch(config)# policy-map type quality-of-service policy1
switch(config-pmap-qos-policy1)# class class1
switch(config-pmap-c-qos-policy1-class1)# police cir 512000 bc 96000
switch(config-pmap-c-qos-policy1-class1)# exit
switch(config-pmap-qos-policy1)# exit
switch(config)# show policy-map
Service-policy policy1

  Class-map: class1 (match-any)
    Match: ip access-group name acl1
       police rate 512000 bps burst-size 96000 bytes
```

```
   Class-map: class-default (match-any)

switch(config)#
```

10.1.8.6 Fabric QoS -- – Trident II Platform Switches

EOS is optimized to support QoS configuration on the Fabric interfaces on 7250x and 7300 series switches. Configuring QoS on the Fabric interfaces in addition to front panel ports allows user to have end-to-end control and helps to manage traffic better over these switches. By default, tx queues are configured as strict priority on 7250X and 7300X series.

The following QoS configuration options are supported on Fabric interfaces on 7250x and 7300 series switches.

- **Guaranteed Bandwidth:** In order to prevent queue starvation on fabric ports EOS supports minimum bandwidth configuration on per queue basis across all fabric ports.
- **Explicit Congestion Notification (ECN):** EOS supports enabling ECN on a per queue basis across all fabric ports.
- **Priority Flow Control (PFC):** Queue back-pressure propagates across the backplane such that flow control messages can be generated to the upstream devices. This is done by enabling PFC for the desired backplane traffic-classes.
- **Weight Round Robin (WRR):** EOS supports configuring Weighted Round Robin (WRR) on a per queue basis across all fabric ports.

10.1.8.6.1 Configuring Fabric QoS on 7250X and 7300X Series

Fabric QoS is configured using a QoS profiles which is then applied on fabric interfaces on 7250x and 7300x series. Following are the steps to configure Fabric QoS.

1. Use **`qos profile`** command to create a QoS profile.
2. Use **`tx-queue (Trident II)`** command to configure a transmit queue on the configuration mode interface.
3. Use **`bandwidth guaranteed (Trident II)`** command to specifie the minimum bandwidth for outbound traffic on the transmit queue.
4. Use **`random-detect ecn (Trident)`** command to enable the ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes.
5. Use **`priority-flow-control priority`** command to configure the packet resolution setting on the configuration mode interface.
6. Use **`interface fabric`** command to configure Fabric interface.
7. Use **`service-profile`** command to apply the QoS profile to the Fabric interface.

Examples

- These commands create a QoS profile named ***fabricProfile*** with tx queue, bandwidth, ECN, PFC and DLB values defined in it and then the profile is attached to Fabric interface of the switch.

Note: To support PFC on a particular priority, DLB is disabled for that priority.

```
switch(config)# qos profile fabricProfile
switch(config-qos-profile-fabricProfile)# tx-queue 0
switch(config-qos-profile-fabricProfile-txq-0)# bandwidth guaranteed 10000 kbps
switch(config-qos-profile-fabricProfile-txq-0)# random-detect ecn
minimum-threshold 10 mbytes maximum-threshold 10 mbytes
switch(config-qos-profile-fabricProfile)# priority-flow-control priority 1
no-drop
switch(config-qos-profile-fabricProfile)# priority-flow-control priority 6
no-drop dlb
```

- Applying the QoS profile on **`interface fabric`** of the switch.

```
switch# configure terminal
switch(config)# interface fabric
switch(config-if-fabric)# service-profile fabricProfile
```

10.1.8.6.2 Displaying Fabric QoS Information

These show commands display the configured Fabric QoS information on the switch.

- **`show qos profile`** **[*profile Name*]:** Displays the list of QoS profiles configured on the switch.
- **`show qos interfaces fabric`:** Displays the profile applied on the fabric interface on the switch.

Examples

- This command displays the ***fabricProfile*** profile information.

```
switch# show qos profile fabricProfile
  qos profile fabricProfile
     priority-flow-control priority 1 no-drop
     priority-flow-control priority 6 no-drop dlb
     tx-queue 0
         bandwidth guaranteed 10000 kbps
         random-detect ecn minimum-threshold 10 mbytes maximum-threshold 10 mbytes
```

- This command displays the profile applied on the fabric interface.

```
switch# show qos interfaces fabric
   qos profile fabricProfile
```

10.1.9 Support for Configuring Color Extended Communities

EOS Release 4.23.1F introduces the ability to configure the color extended community in route-map set clauses and in an extcommunity-list for inbound and outbound policy application.

Use the color extended community for per-destination steering into Segment-Routing Traffic-Engineered (SR-TE) policies. If the next-hop and color of a BGP route match a particular policy (composed of an endpoint and color), any traffic bound to the destination can be steered according to the policy instead of forwarded via an IGP path or tunnel.

This section describes support for configuring color extended communities, including configuration instructions and command descriptions. Topics covered by this section include:

- Platform Compatibility
- Configuration
- Limitations

10.1.9.1 Platform Compatibility

Configuring color extended communities is supported on all platforms.

10.1.9.2 Configuration

Use the following command for color extended community expressions:

`color` **COLOR-VALUE** [color-only (exact-match | (endpoint-match (any | null)))]

Use this command in route-maps and extcommunity-lists to apply inbound and outbound policy.

Table 52: Color Extended Community

Configuring Color Extended Community in route-map mode	
Command(config-route-map mode)	**[no | default] set extcommunity COLOR-EXPRESSION** [additive | delete]
Action	Adds a color extended community to be applied to routes affected by the route-map. Multiple set clauses can be applied to a single route-map to configure multiple colors for routes. **Additive** adds the extended communities to those received, while **delete** deletes any matching extended color communities. Negating the command removes the entry from the route-map.
Default	None

Example	`switch(config)# route-map foo`
	`switch(config-route-map foo)# set extcommunity color 1`
	`switch(config-route-map foo)# set extcommunity color 2 color-only exact-match`
	`switch(config-route-map foo)# set extcommunity color 3 color-only endpoint-match null`
	`switch(config-route-map foo)# set extcommunity color 4 color-only endpoint-match any`

Table 53: Extcommunity Lists

Configuring Color Extended Community in extcommunity-list	
Command(config mode)	**[(no|default)] ip extcommunity-list WORD (permit|deny){COLOR-EXPRESSION}**
Action	Adds a color extended community to an extcommunity-list. Multiple color extended communities can be added to the list. Negating the command removes the corresponding color extended community from the list.
Default	None
Example	`switch(config)# ip extcommunity-list foo permit color 1 color 2` `switch(config)# ip extcommunity-list bar permit color 3 color-only endpoint-match null color 4 color-only endpoint-match any`

10.1.9.3 Limitations

The color extended community is only supported in multi-agent mode. Enable Multi-agent mode via the following command:

```
service routing protocols mode multi-agent
```

10.1.10 ACL-based QoS Configuration

10.1.10.1 ACL Based QoS (DCS-7160)

The IPv4 ACL based QoS is enabled on switches through policy-map configuration. The ACL based QoS can be configured on front panel ports, port-channel interfaces on **DCS-7160** series switches.

10.1.10.1.1 ACL based QoS on SVIs

The ACL based QoS policy applied on SVIs modify the QoS parameters for SVI traffic (L3 VLAN) based on ACL classification. The ACL based QoS on Switched Virtual Interface (SVI) ports is supported on DCS-7500E, DCS-7280E, DCS-7010, DCS-7050, DCS-7050X, DCS-7250X, DCS-7300X, DCS-7020TR.

10.1.10.1.2 ACL Sharing on QoS

The ACLs applied on QoS shares the hardware resources (TCAM) when potentially large QoS policy-maps are applied to multiple SVIs. For ACL based QoS on SVIs in sharing mode we share TCAM for class-maps without policer action and replicate entries for policer class-maps. The ACL Sharing on QoS is supported only on selected platforms.

The QoS actions is applicable only to the routed traffic flowing through the members of the corresponding VLAN.

The steps to configure ACL based QoS is as follows:

1. Create a access list using **`ip access-list`** command.
2. Create a class map and attach it to the access list using **`class-map`** command.
3. Create a policy and attach the class map to the policy created, using the **`policy-map`** command.
4. Apply the policy to the interface using the **`service-policy input`** command.

Examples

- These command configure the access list ***acl1***.

```
switch(config)# ip access-list acl1
switch(config-acl-acl1)# permit ip 10.1.1.1/24 any
switch(config-acl-acl1)# exit
```

- These commands configure the class map ***class1***.

```
switch(config)# class-map match-any class1
switch(config-cmap-qos-class1)# match ip access-group acl1
switch(config-cmap-qos-class1)# exit
```

- These commands configure the policy map ***policy1***.

```
switch(config)# policy-map policy1
switch(config-pmap-qos-policy1)# class class1
switch(config-pmap-c-qos-policy1-class1)# set dscp 20
```

```
switch(config-pmap-c-qos-policy1-class1)# set traffic-class 2
switch(config-pmap-c-qos-policy1-class1)# exit
switch(config-pmap-c-qos-policy1)# exit
```

- These commands apply the ***policy1*** to the ***interface ethernet 1/1***.

```
switch(config)# interface Et1/1
switch(config-if-Et1/1)# service-policy input policy1
switch(config-if-Et1/1)# exit
```

- These commands configure a ACL based QoS on the SVI interface ***VLAN10***.

```
switch(config)# interface vlan 10
switch(config-if-Vl10)# service-policy [type qos] input policy1
```

- This command enables the resource (hardware) sharing when a ACL based QoS is attached to VLAN interface. The no form of the command disables it.

```
switch(config)# hardware access-list qos resource sharing vlan in
```

- This command allows inbound broadcast IP packets with source IP address as one of the permitted hosts and denies the rest of the directed broadcast traffic.

```
switch(config)# ip directed-broadcast
 switch(config-ip-directed-broadcast)# field-set ipv4 prefix ALLOWED1
 switch(config-ipdb-field-set-ipv4-prefix-ALLOWED)# 10.1.1.1/32 20.1.1.1/32 30.1.1.1/32
 switch(config-ipdb-field-set-ipv4-prefix-ALLOWED)# commit

 switch(config-ip-directed-broadcast)# field-set ipv4 prefix ALLOWED2
 switch(config-ipdb-field-set-ipv4-prefix-ALLOWED)# 10.2.1.1/32 20.2.1.1/32 30.2.1.1/32
 switch(config-ipdb-field-set-ipv4-prefix-ALLOWED)# commit
```

Show Commands

The following show commands display the status of policy-maps programmed on the interface, for more information on these commands refer Quality of Service Commands.

- **`show policy-map [policy-name]`**: Displays the policy-map programming status.
- **`show policy-map interface interface id`**: Displays the policy-map that is currently programmed on the interface.
- **`show policy-map [policy-name] counters`**: Displays the policy-map traffic hits.
- **`show platform xp qos tcam [hits]`**: Displays the TCAM entries programmed for each policy-map as well as the traffic hits. The hits option is used to see the TCAM entries with nonzero traffic hits.
- **`show run | grep sharing`**: Displays if whether the ACL based QoS is enabled or disabled.

- **`show platform trident tcam shared vlan interface-class-id`**: Displays what SVIs are currently sharing the QoS policy-map.
- **`show platform trident tcam directed-broadcast`**: Displays the permitted hosts via field-set.
- **`show platform trident tcam qos detail`**: Displays the list of all the SVIs that are sharing the TCAM entries.

10.1.10.1.3 Limitations

- Maximum number of TCAM entries that can be programmed in hardware for all QoS policy-maps on the box is ***1024***.
- Layer 4 port ranges are not supported for ACL based QoS. The ranges will be expanded into multiple TCAM rules and programmed in the hardware.
- Configured policer rate should be above 1mbps and recommended burst value is ***2000*** bytes.
- Policer action cannot be associated with policy-maps applied to Port-Channels.

The following are the limitations specific to DCS-7500E, DCS-7280E and DCS-7020TR:

The user cannot apply more than 31 QoS service policies per chip on L3 interfaces.

- When different QoS service policies are applied to the SVI and its member interfaces, the behavior is indeterministic.
- When QoS service policies are applied on SVIs with partial failures due to limited hardware resources, any event that triggers a forwarding agent restart will lead to indeterministic behavior.
- When QoS service policies are applied on 2 SVIs, any event that triggers the VLAN membership change of a member interface may result in a policy-map programming failure. To change the VLAN membership, remove the interface from the first VLAN and then add it to the other.
- Outgoing COS rewrite is not supported.
- QoS policy-map counters are not supported.

The following are the limitations specific to DCS-7010, DCS-7050, DCS-7050X, DCS-7250X, DCS-7300X:

- TCAM resources will not be shared for the same policy-map applied to multiple SVIs.
- Policy-map applied to a SVI will result in TCAM allocation on all chips irrespective of whether the SVI members are present or not.

When QoS service policies are applied to both SVI and its member interfaces and packets hit both policies, the behavior is indeterministic.

10.1.11 Configuring IPv6 Flow Label Matches for QoS

In addition to criteria like COS and DSCP, QoS decisions can be based on the IPv6 flow labels of packets. To use IPv6 flow labels as a criterion for QoS decisions, use the `permit` command to create ACL rules to select packets based on their IPv6 flow labels using an exact match and an optional mask, and then apply the access list to a class map in a QoS policy map, which can then be applied to individual interfaces. This requires a TCAM profile which must be installed explicitly.

Install the QoS Flow Label TCAM Profile

Open the QoS flow label TCAM profile Web page at https://www.arista.com/en/support/toi/tcam-profile?pn=qos-match-ipv6-flow-label. Copy the entire contents of the file which starts with the following commands:

```
hardware tcam
system profile qos-match-ipv6-flow-label
```

There are approximately 130 lines.

Paste this into the CLI of the switch. Each command in the file will be executed in turn when you paste the file contents. When the paste completes, if the cursor is at the end of the last command, type **enter** to execute it.

Confirm the QoS Flow Label TCAM Profile Installation

Configure the TCAM with the `hardware tcam` command, and use the `system profile` command to confirm that the “qos-match-ipv6-flow-label” profile has been installed. If the profile is installed, the **?** operator will show “qos-match-ipv6-flow-label” as an available profile.

Example

The following commands confirm whether the “qos-match-ipv6-flow-label” profile is installed and available to be applied.

```
switch(config)# hardware tcam
switch(config-tcam)# system profile qos-match?
WORD  qos-match-ipv6-flow-label
switch(config-tcam)# exit
switch(config)#
```

Apply the QoS Flow Label TCAM Profile

If the profile "qos-match-ipv6-flow-label" is listed, use the `system profile` command to apply it. Confirm that the profile has been successfully applied with the `show hardware tcam profile` command.

Example

The following commands apply the profile “qos-match-ipv6-flow-label” to the TCAM configuration, then confirm that the profile has been applied. The warning is normal, as the restart of forwarding agents is part of the procedure.

```
switch(config)# hardware tcam
switch(config-tcam)# system profile qos-match-ipv6-flow-label
!
WARNING!
Changing TCAM profile will cause forwarding agent(s) to exit and restart.
All traffic through the forwarding chip managed by the restarting
forwarding agent will be dropped.

Proceed [y/n] y
switch(config-tcam)# exit
switch(config)# show hardware tcam profile
                    Configuration            Status
FixedSystem         qos-match-ipv6-flow-label qos-match-ipv6-flow-label
switch(config)#
```

Create IPv6 ACL Rules

Configure an access list with the **`ipv6 access-list`** command. Then create rules with the **`permit ipv6`** command.

Example

The following commands create an IPv6 ACL rule which matches the flow label ***23*** in the access list ***L1***.

```
switch(config)# ipv6 access-list L1
switch(config-ipv6-acl-L1)# permit ipv6 any any flow-label eq 23
switch(config-ipv6-acl-L1)# exit
switch(config)#
```

Add Access List to QoS Class Map

Configure a QoS class map with the **`class-map`** command. Then add an access list to the class map with the **`match`** command.

Example

The following commands create a QoS class map called ***C1***, and then add the access list ***L1***.

```
switch(config)# class-map type qos match-any C1
switch(config-cmap-qos-C1)# match ipv6 access-group L1
switch(config-cmap-qos-C1)# exit
switch(config)#
```

Add Class Map to Policy Map

Configure a QoS policy map, creating it if necessary, with the **`policy-map`** command. Then add a class map to the policy map and define the traffic class.

Example

The following commands configure the QoS policy map ***P1*** and add the class map ***C1***, and then assign the class to traffic class ***4***.

```
switch(config)# policy-map type quality-of-service P1
switch(config-pmap-quality-of-service-P1)# class C1
switch(config-pmap-c-quality-of-service-P1-C1)# set traffic-class 4
switch(config-pmap-c-quality-of-service-P1-C1)# exit
switch(config-pmap-quality-of-service-P1)# exit
switch(config)#
```

Configure An Interface with QoS Policy

Configure an interface with the **`interface`** command. Apply the QoS policy to the interface with the **`service-policy`** command.

Example

The following commands configure the Ethernet interface ***1/1***, and apply the QoS policy ***P1*** to the interface.

```
switch(config)# interface Ethernet 1/1
switch(config-if-Et1/1)# service-policy type qos input P1
switch(config-if-Et1/1)# exit
switch(config)#
```

Example

The following commands confirm that the policy map ***P1*** has been programmed successfully.

```
switch(config)# show policy-map P1
Service-policy input: P1
  Hardware programming status: Successful

  Class-map: C1 (match-any)
    Match: ipv6 access-group name L1
       set traffic-class 4

  Class-map: class-default (match-any)

switch(config)# show ipv6 access-lists L1
IPV6 Access List L1
        10 permit ipv6 any any flow-label eq 23
switch(config)#
```

10.1.12 Differentiated MMU Discard Counters

To count discarded packets through tagging, assign drop-precendes for a certain class of packets on platforms that support such tagging.

Configuring Differentiated MMU Discard Counters

The following steps configure the Differentiated MMU Discard Counters.

1. Configure an IP access-lists to match traffic

```
switch(config)# ip access-list acl1
switch(config-acl-acl1)# permit 41 any any !!41 = 0x29 = IPv6
```

2. Add the access-list to a class-map

```
switch(config)# class-map type qos match-any class1
switch(config-cmap-qos-class1)# match ip access-group acl1
```

3. Add the class-map to a policy-map

```
switch(config)# policy-map type quality-of-service policy1
switch(config-pmap-quality-of-service-policy1)# class class1
```

4. Add drop-precedence action to the policy-map

```
switch(config-pmap-c-quality-of-service-policy1-class1)# set drop-precedence 2
```

5. Create qos profile with the policy map assigned

```
switch(config)# qos profile qos1
switch(config-qos-profile-qos1)# service-policy input policy1
```

6. Apply the policy-map to the interface

```
switch(config)# int et3/1
switch(config-if-Et3/1)# service-profile qos1
```

Repeat step 6 on all interfaces that receive traffic to be counted. Packets are tagged on ingress. If the same packet gets dropped on egress as an MMU discard, the corresponding counter gets incremented.

Displaying Differentiated MMU Discard Counters

The **`show interface counters queue drop-precedence`** command displays the drop-precedence counters. Based on the above configuration, drop-precedence 2 counts IPv6 packets.

```
switch# show interface counters queue drop-precedence
intf        0          1          2
Et1/1     100          0        200
Et1/2     200          0        300
…
```

10.1.13 txQueue Percentage-based Shaping

When you enable this feature using the **`qos tx-queue shape rate percent`** *percentage* **`adaptive`** command, QoS calculates the txQueue shape rate based the available bandwidth and not the link speed. For instance, if the interface has a link speed of 100Gbps, and the subinterface configured to 50%, then the subinterface has a link speed of 50Gbps.

Configuring txQueue Percentage-based Shaping

Use the following command to configure traffic for a 50Gps interface for adaptive shaping on interfaces.

```
switch(config)# qos tx-queue shape rate percentage adaptive
! Change will take effect only after switch reboot.
```

Reboot the switch.

Displaying txQueue Adaptive Information

Use the **show qos tx-queue** to display the status of the configuration. One of the following messages displays after entering the command:

No Configuration

```
switch# show qos tx-queue
Shape rate percent : Non-Adaptive
```

Configuration Successful After Switch Reboot

```
switch# show qos tx-queue
Shape rate percent : Adaptive
```

Configuration Successful but No Switch Reboot

```
switch# show qos tx-queue
Shape rate percent : Non-Adaptive (reboot required for Adaptive)
```

10.1.14 Tx Queue Precision Shaping

In Arista EOS, **Tx Queue Precision Shaping** addresses a fundamental hardware challenge by maintaining consistent traffic rates with the low configured bandwidth, typically in the kilobit or low megabit range.

EOS leverages the underlying switch ASIC high-precision timers to clock the egress of data. Instead of rounding the shape rate to the nearest hardware-supported increment, which might be 5–10% off at low speeds, precision shaping allows the switch to hit the target rate with much higher fidelity.

Configuring Tx Queue Precision Shaping

To configure precision shaping, use the following command:

```
switch(config)# qos tx-queue shape rate precision 50Mbps
```

```
! Change will take effect only after switch reboot.
```

The last parameter of the command indicates the minimum speed that requires precision. Currently, EOS only supports **50Mbps**.

To disable precision shaping mode, use the **[no | default]** versions of the command.

To display information about Tx Queue Precision Shaping, use the **show qos tx-queue shape rate precision** command:

```
switch# show qos tx-queue shape rate precision
  Configured    Operational
--------------- -----------
 50 Mbps          None
```

10.1.15 Configuring Round Robin Scheduling on Shaped Subinterfaces

To enable subinterface Round Robin scheduling on the switch, use the following command:

```
switch(config)# qos subinterface scheduling parent round-robin
! Change will only take effect after switch reboot.
```

To disable subinterface Round Robin scheduling on the switch, use the following command:

```
switch(config)# no qos subinterface scheduling parent round-robin
! Change will only take effect after switch reboot.
```

Displaying Round Robin Scheduling Information

When enabled, the command **show platform sand subinterface capabilities** displays the Round Robin scheduling information on the switch:

```
switch# show platform sand subinterface capabilities
SubInterface:
------------------

     Supported:
     ----------
     Minimum port shape rate(kbps)                                  : 1000
     Maximum port shape rate(kbps)                                  : 400000000
     Number of voqs per subinterface when shaping is applied        : 4
     Traffic class to Voq mapping
                TC0-1    : Voq0
                TC2-3    : Voq1
                TC4-5    : Voq2
                TC6-7    : Voq3
     Traffic class to scheduling mode
                TC0-1    : WRR( weight 1 )
                TC2-3    : WRR( weight 2 )
                TC4-5    : WRR( weight 3 )
```

```
               TC6-7    : SP
         ( Higher weight implies more credits )
    Voq tail-drop threshold(MegaByte)                          : 12.500000
    Voq tail-drop threshold(Buffer Descriptor)                 : 12500
    Maximum number of subinterfaces with voq supported on the system: 512
    Maximum number of subinterfaces with voq supported per core
                                          System Core 0  : 512
                                          System Core 1  : 512
    Scheduling between parent and shaped subinterfaces:        : Round Robin
```

10.1.16 Explicit Congestion Notification (ECN)

Explicit Congestion Notification (ECN) is an IP and TCP extension that facilitates end-to-end network congestion notification without dropping packets. ECN recognizes early congestion and sets flags that signal affected hosts. Trident and Tomahawk, Trident II, and Helix platform switches extend ECN support to non-TCP packets. LAG interfaces on Strata platforms support ECN counters.

ECN usage requires that it is supported and enabled by both endpoints. Although only unicast flows are modified by ECN markers, the multicast, broadcast, and unmarked unicast flows can affect network congestion and influence the indication of unicast packet congestion.

10.1.16.1 Configuring Latency-based ECN

Latency-based ECN can configured on a per transmit queue basis. Use the following commands to configure a transmit queue on interface *Ethernet 1/1* with a delay threshold of 33 milliseconds:

```
switch(config)# interface Ethernet 1/1
switch(config-if-Et1/1)# tx-queue 3
switch(config-if-Et1/1-txq-3)# random-detect ecn delay threshold 33 milliseconds
```

Configure a **`delay threshold`** as a value between 1 to 4294967 microseconds or a value between 1 to 4294 milliseconds.

Displaying the ECN Configuration

Use the following command to display information about the ECN configuration:

```
switch(config)# show qos interfaces Ethernet 1/1 ecn
Ethernet1/1:
                             ECN       ECN ECN                          ECN          ECN
                          Minimum   Maximum Delay                       Mark-Prob Weight
Tx-Queue Threshold Unit  Threshold Threshold Threshold
-------- -------------- --------- --------- ------------------------- --------- ------
7 -                      -         - -                         - / -          -
6 -                      -         - -                         - / -          -
5 -                      -         - -                         - / -          -
4 -                      -         - -                         - / -          -
3 -                      -         - 33000.000 / 33000.000 (L) - / -          -
2 -                      -         - -                         - / -          -
1 -                      -         - -                         - / -          -
0 -                      -         - -                         - / -          -

Delay Threshold Type: G -> Global     L -> Local
Note: Values are displayed as Configured/Operational
```

10.1.17 Latency-based Explicit Congestion Notification

Explicit Congestion Notification (ECN) provides a mechanism of notifying about network traffic congestion without dropping packets. Notification occurs in two ways:

- Queue Length ECN - Marks the ECN-capable Transport (ECT) packets when the average Virtual Output Queue (VOQ) length exceeds the configured ECN threshold value.
- Latency-based ECN - Notifies the congestion by marking the ECT packets if the packets take longer than the configured threshold to dequeue from the VOQ.

Both types of notification result in the egress marking of the packet when experiencing the congestion beyond the configured threshold.

Configure ECN on a transmit queue of an interface, and only switches with front panel ports and port-channels support ECN.

Supported Platforms

- DCS-7280R3 series
- DCS-7500R3 series
- DCS-7800R3 series
- DCS-7130

10.1.18 Configuring a Low Latency Transmit Queue Scheduler Profile

Configuring a low latency transmit queue scheduler profile provides an alternative operating mode for queues with reduced latency. By default, the switch has a balanced profile focused on maintaining sustained throughput and avoiding excessive latency. In certain scenarios, this profile may not provide an optimal configuration for latency-sensitive scenarios with critical flow completion time. In this case, configure a responsive low latency scheduler profile validated against the hardware capabilities.

The responsive profile provides maximum benefits in scenarios with low fan-in and bursty flows and reduces the maximum latency from 40 microseconds to 8 microseconds when a flow starts or stops.

Compatible Platforms

The following platforms support the responsive profile feature:

- DCS-7280R3
- DCS-7500R3
- DCS-7800R3

Configuring the Responsive Profile

Enable unified credit rates to allow the scheduler profile to provide credits to the low latency queues at rates optimized for hardware. Use the following command to enable unified credit rates:

```
switch(config)# platform fap voq credit rates unified
```

Then configure the responsive profile on a transmit queue with the following command:

```
switch(config)# qos tx-queue 0-7 scheduler profile responsive
```

Configure up to eight (8) responsive profiles.

10.1.19 Quality of Service Commands

QoS Data Field and Traffic Class Configuration Commands

- color
- hardware access-list qos resource sharing vlan in
- ip extcommunity-list
- platform petraA traffic-class
- qos cos
- qos dscp
- qos map cos
- qos map dscp
- qos map dscp to traffic-class
- qos map dscp to traffic-class (MPLS tunnel termination VRF)
- qos map traffic-class to cos
- qos map traffic-class to dscp
- qos map traffic-class to mc-tx-queue
- qos map traffic-class to tx-queue
- qos map traffic-class to uc-tx-queue
- qos profile
- qos rewrite cos
- qos rewrite dscp

- qos subinterface
- qos subinterface scheduling
- qos trust
- service-policy type qos input
- service-profile
- set extcommunity

QoS and ECN Display Commands

- show interface counters queue drop-precedence
- show platform petraA traffic-class
- show platform trident tcam shared vlan interface-class-id
- show platform trident tcam qos detail
- show platform xp qos tcam hit
- show policy-map
- show policy-map interface
- show qos interfaces
- show qos interfaces latency maximum
- show qos interfaces trust
- show qos interfaces random-detect ecn
- show qos maps
- show qos map dscp to traffic-class
- show qos profile
- show run|grep sharing
- show qos profile summary
- show qos random-detect ecn

ECN Configuration Commands

- qos random-detect ecn allow non-ect chip-based (Tomahawk and Trident)
- qos random-detect ecn global-buffer (Helix)
- qos random-detect ecn global-buffer (Trident and Tomahawk)
- random-detect ecn (Arad/Jericho)
- random-detect ecn (Helix)

- random-detect ecn (Trident and Tomahawk)
- random-detect ecn delay threshold

Transmit Queue and Port Shaping Commands – Arad and Jericho Platforms

- bandwidth percent (Arad/Jericho)
- priority (Arad/Jericho)
- shape rate (Interface – Arad/Jericho)
- shape rate (Tx-queue – Arad/Jericho)
- tx-queue (Arad/Jericho)

Transmit Queue and Port Shaping Commands – FM6000 Platform

- bandwidth percent (FM6000)
- priority (FM6000)
- shape rate (Interface – FM6000)
- shape rate (Tx-queue – FM6000)
- tx-queue (FM6000)

Transmit Queue and Port Shaping Commands – Helix Platform

- bandwidth guaranteed (Helix)
- shape rate (Interface – Helix)
- shape rate (Tx-queue – Helix)
- tx-queue (Helix)

Transmit Queue and Port Shaping Commands – Petra Platform

- bandwidth percent (Petra)
- priority (Petra)
- shape rate (Interface – Petra)
- shape rate (Tx-queue – Petra)
- tx-queue (Petra)

Transmit Queue and Port Shaping Commands – Trident and Tomahawk Platform

- bandwidth percent (Trident and Tomahawk)
- mc-tx-queue
- priority (Trident and Tomahawk)

- shape rate (Interface – Trident and Tomahawk)
- shape rate (Tx-queue – Trident and Tomahawk)
- uc-tx-queue

Transmit Queue and Port Shaping Commands – Trident II Platform

-
- bandwidth guaranteed (Trident II)
- shape rate (Tx-queue – Trident II)
- shape rate (Interface – Trident II)
- tx-queue (Trident II)
- interface fabric (Trident II)

10.1.19.1 bandwidth guaranteed (Trident II)

The **bandwidth guaranteed** command specifies the minimum bandwidth for outbound traffic on the transmit queue. By default, no bandwidth is guaranteed to any transmit queue.

The **no bandwidth guaranteed** and **default bandwidth guaranteed** commands remove the minimum bandwidth guarantee on the transmit queue by deleting the corresponding **bandwidth guaranteed** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

```
bandwidth guaranteed rate DATA_MIN

no bandwidth guaranteed

default bandwidth guaranteed
```

Parameters

DATA_MIN minimum bandwidth. Value range varies with data unit:

- ***8*** to ***40000000*** kbytes per second.
- ***8*** to ***40000000*** **kbps** kbytes per second.
- ***1*** to ***60000000*****pps** packets per second.

Related Command

tx-queue (Trident II) places the switch in tx-queue configuration mode.

Example

These commands configure a minimum egress bandwidth of ***1*** Mbps for ***transmit queue 4*** of ***interface ethernet 17/3***.

```
switch(config)# interface ethernet 17/3
switch(config-if-Et17/3)# tx-queue 4
switch(config-if-Et17/3-txq-4)# bandwidth guaranteed 1000 kbps
switch(config-if-Et17/3-txq-4)# show qos interfaces ethernet 17/3

Ethernet17/3:
   Trust Mode: COS
   Default COS: 0
   Default DSCP: 0
```

```
   Port shaping rate: disabled

  Tx       Bandwidth                 Shape Rate        Priority
 Queue     Guaranteed (units)         (units)
   ---------------------------------------------------------------
   7        - / -    (  -  )       - / -    (  -  )    SP / SP
   6        - / -    (  -  )       - / -    (  -  )    SP / SP
   5        - / -    (  -  )       - / -    (  -  )    SP / SP
   4        1 / 1    ( Mbps )      - / -    (  -  )    SP / SP
   3        - / -    (  -  )       - / -    (  -  )    SP / SP
   2        - / -    (  -  )       - / -    (  -  )    SP / SP
   1        - / -    (  -  )       - / -    (  -  )    SP / SP
   0        - / -    (  -  )       - / -    (  -  )    SP / SP

Note: Values are displayed as Operational/Configured

switch(config-if-Et17/3-txq-4)#
```

10.1.19.2 bandwidth guaranteed (Helix)

The **bandwidth guaranteed** command specifies the minimum bandwidth for outbound traffic on the transmit queue. By default, no bandwidth is guaranteed to any transmit queue.

The **no bandwidth guaranteed** and **default bandwidth guaranteed** commands remove the minimum bandwidth guarantee on the transmit queue by deleting the corresponding **bandwidth guaranteed** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`bandwidth guaranteed` **DATA_MIN**

`no bandwidth guaranteed`

`default bandwidth guaranteed`

Parameters

DATA_MIN Minimum bandwidth. Value range varies with data unit:

- ***8*** to ***40000000*** ***8*** to ***40000000*** kbytes per second.
- ***8*** to ***40000000*** **kbps** ***8*** to ***40000000*** kbytes per second.
- ***1*** to ***60000000*** **pps** ***1*** to ***60000000*** packets per second.

Related Command

tx-queue (Helix) places the switch in tx-queue configuration mode.

Example

These commands configure a minimum egress bandwidth of ***1*** Mbps for ***transmit queue 4*** of ***interface ethernet 17/3***.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# tx-queue 4
switch(config-if-Et17-txq-4)# bandwidth guaranteed 1000 kbps
switch(config-if-Et17-txq-4)# show qos interfaces ethernet 17

Ethernet17/3:
   Trust Mode: COS
   Default COS: 0
   Default DSCP: 0
```

```
   Port shaping rate: disabled

  Tx       Bandwidth                 Shape Rate        Priority

   0        - / -    (  -  )       - / -    (  -  )    SP / SP

Note: Values are displayed as Operational/Configured

switch(config-if-Et17-txq-4)#
```

10.1.19.3 bandwidth percent (Arad/Jericho)

The **bandwidth percent** command configures the bandwidth share of the transmit queue when configured for round robin priority. Bandwidth is allocated to all queues based on the cumulative configured bandwidth of all the port's round robin queues.

The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

The **no bandwidth percent** and **default bandwidth percent** commands restore the default bandwidth share of the transmit queue by removing the corresponding **bandwidth percent** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

```
bandwidth percent proportion

no bandwidth percent

default bandwidth percent
```

Parameter

proportion Bandwidth percentage assigned to queues. Values range from ***1*** to ***100***.

Related Command

tx-queue (Arad/Jericho) places the switch in tx-queue configuration mode.

Examples

- These commands configure queues ***0*** through ***3*** (***interface ethernet 3/5/1***) as round robin, then allocate bandwidth for three queues at ***30%*** and one queue at ***10%***.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# no priority
switch(config-if-Et3/5/1-txq-3)# bandwidth percent 10
switch(config-if-Et3/5/1-txq-3)# tx-queue 2
switch(config-if-Et3/5/1-txq-2)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-2)# tx-queue 1
switch(config-if-Et3/5/1-txq-1)# bandwidth percent 30
```

```
switch(config-if-Et3/5/1-txq-1)# tx-queue 0
switch(config-if-Et3/5/1-txq-0)# bandwidth percent 30
switch(config-if-Et3/5/1-txq-0)# show qos interfaces ethernet 3/5/1

Ethernet3/5/1:

  Tx    Bandwidth       Shape Rate        Priority  ECN

Note: Values are displayed as Operational/Configured

switch(config-if-Et3/5/1-txq-3)#
```

10.1.19.4 bandwidth percent (FM6000)

The **bandwidth percent** command configures the bandwidth share of the transmit queue when configured for round robin priority. Bandwidth is allocated to all queues based on the cumulative configured bandwidth of all the port's round robin queues.

The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

The **no bandwidth percent** and **default bandwidth percent** commands restore the default bandwidth share of the transmit queue by removing the corresponding **bandwidth percent** command ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

```
bandwidth percent proportion

no bandwidth percent

default bandwidth percent
```

Parameter

proportion Configured bandwidth percentage. Value ranges from ***1*** to ***100***. Default value is ***0***.

Related Command

tx-queue (FM6000) places the switch in tx-queue configuration mode.

Examples

- These commands configure queues ***0*** through ***3*** (***interface Ethernet 19***) as round robin, then allocate bandwidth for three queues at ***30%*** and one queue at ***10%***.

```
switch(config)# interface Ethernet 19
switch(config-if-Et19)# tx-queue 3
switch(config-if-Et19-txq-3)# no priority
switch(config-if-Et19-txq-3)# bandwidth percent 10
switch(config-if-Et19-txq-3)# tx-queue 2
switch(config-if-Et19-txq-2)# bandwidth percent 30
switch(config-if-Et19-txq-2)# tx-queue 1
switch(config-if-Et19-txq-1)# bandwidth percent 30
```

```
switch(config-if-Et19-txq-1)# tx-queue 0
switch(config-if-Et19-txq-0)# bandwidth percent 30
switch(config-if-Et19-txq-0)# show qos interface ethernet 19

10.1.19.5 bandwidth percent (Petra)

The **bandwidth percent** command configures the bandwidth share of the transmit queue when configured for round robin priority. Bandwidth is allocated to all queues based on the cumulative configured bandwidth of all the port's round robin queues.

The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

The **no bandwidth percent** and **default bandwidth percent** commands restore the default bandwidth share of the transmit queue by removing the corresponding **bandwidth percent** command ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`bandwidth percent` *proportion*

`no bandwidth percent`

`default bandwidth percent`

Parameter

proportionBandwidth percentage assigned to queues. Values range from ***1*** to ***100***.

Related Command

tx-queue (Petra) places the switch in tx-queue configuration mode.

Examples

- These commands configure queues ***0*** through ***3*** (***interface ethernet 3/28***) as round robin, then allocate bandwidth for three queues at ***30%*** and one queue at ***10%***.

```
switch(config)# interface ethernet 3/28
switch(config-if-Et3/28)# tx-queue 3
switch(config-if-Et3/28-txq-3)# no priority
switch(config-if-Et3/28-txq-3)# bandwidth percent 10
switch(config-if-Et3/28-txq-3)# tx-queue 2
switch(config-if-Et3/28-txq-2)# bandwidth percent 30
switch(config-if-Et3/28-txq-2)# tx-queue 1
switch(config-if-Et3/28-txq-1)# bandwidth percent 30
```

```
switch(config-if-Et3/28-txq-1)# tx-queue 0
switch(config-if-Et3/28-txq-0)# bandwidth percent 30
switch(config-if-Et3/28-txq-0)# show qos interface ethernet 3/28

10.1.19.6 bandwidth percent (Trident and Tomahawk)

The **bandwidth percent** command configures the bandwidth share of the transmit queue when configured for round robin priority. Bandwidth is allocated to all queues based on the cumulative configured bandwidth of all the port's round robin queues.

The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port's operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.

The **no bandwidth percent** and **default bandwidth percent** commands restore the default bandwidth share of the transmit queue by removing the corresponding **bandwidth percent** command ***running-config***.

Command Mode

Mc-Tx-Queue configuration

Uc-Tx-Queue configuration

Command Syntax

```
bandwidth percent proportion

no bandwidth percent

default bandwidth percent
```

Parameter

proportion Bandwidth percentage assigned to queues. Values range from ***1*** to ***100***.

Related Commands

- mc-tx-queue places the switch in mc-tx-queue configuration mode.
- uc-tx-queue places the switch in uc-tx-queue configuration mode.

Examples

- These commands configure ***unicast transmit queue 3*** (and all other queues of lower priority) as round robin, then allocate bandwidth for unicast transmit queues ***1***, ***2***, and ***3*** at ***30%*** and ***multicast transmit queue 1*** at ***10%***.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# uc-tx-queue 3
switch(config-if-Et7-uc-txq-3)# no priority
```

```
switch(config-if-Et7-uc-txq-3)# bandwidth percent 30
switch(config-if-Et7-uc-txq-3)# uc-tx-queue 2
switch(config-if-Et7-uc-txq-2)# bandwidth percent 30

10.1.19.7 color

Use the **color** command for the ability to configure the color extended community in route-map set clauses and in an extcommunity-list for inbound and outbound policy application.

Command Mode

Route-maps and extcommunity-lists

Command Syntax

color **COLOR-VALUE** [color-only [exact-match | [endpoint-match [any | null]]]]

Parameters

- **COLOR-VALUE** A single policy color value, range ***0*** to ***4294967295***.
- **color-only** Allows configuration of color-only bits.
- **exact-match** Explicitly sets the color-only bits of the extended community to ***00*** (optional).
- **endpoint-match any** Sets the color-only bits of the extended community to ***10***.
- **endpoint-match null** Sets the color-only bits of the extended community to ***01***.

Example

```
switch(config)# route-map foo
switch(config0route-map-foo)# set community color 2 color-only endpoint-match any
```

10.1.19.8 dscp to traffic-class (DSCP map)

The **dscp to traffic-class** command configures the specified QoS map to map one or more DSCP classes to a traffic class. Only one traffic class may be specified per command. The command can be repeated to configure additional traffic classes. The configuration is modified immediately. Each **dscp to traffic-class** command overwrites the existing entries in the map.

The **default dscp to traffic-class** and **no dscp to traffic-class** commands restore the global map values for the given DSCP classes.

Command Mode

DSCP Map Configuration

Command Syntax

`dscp` *dscp_classes* `to traffic-class` *traffic_class*

`default dscp` *dscp_classes* `to traffic-class`

`no dscp` *dscp_classes* `to traffic-class`

Parameters

- ***dscp_classes*** The DSCP class or classes to map to a new traffic-class value. These can be provided as a single value, a range given with a hyphen (such as 20-25), a comma separated list (such as 1,4,9), or a combination (such as 20-25, 35). The range for each value is 0-63.
- ***traffic_class*** The traffic class to map the specified DSCP class or classes to.

Example

These commands configure the DSCP-to-traffic-class map ***map1*** to map DSCP class ***35*** to traffic class ***7***, and DSCP classes ***20-25*** to traffic class ***6***.

```
switch(config)# qos map dscp to traffic-class name map1
switch(config-dscp-map-map1)# dscp 35 to traffic-class 7
switch(config-dscp-map-map1)# dscp 20-25 to traffic-class 6
```

10.1.19.9 hardware access-list qos resource sharing vlan in

The **hardware access-list qos resource sharing vlan in** command enables the ACL based QoS resources sharing on a VLAN interface.

The **no hardware access-list qos resource sharing vlan in** disables the ACL based QoS resources sharing on a VLAN interface. By default this function is disabled.

Command Mode

Global Configuration

Command Syntax

```
hardware access-list qos resource sharing vlan in

no hardware access-list qos resource sharing vlan in
```

Example

This commands enables the ACL based QoS resources sharing on a VLAN interface.

```
switch(config)# hardware access-list qos resource sharing vlan in
```

10.1.19.10 interface fabric (Trident II)

The **`interface fabric`** command places the switch in Fabric-interface configuration mode and allows the user to attach the QoS profile to the fabric interface of the switch.

Command Mode

Global Configuration

Command Syntax

```
interface fabric
```

Example

This command places the switch in Fabric-interface configuration mode.

```
switch(config)# interface fabric
switch(config-if-fabric)#
```

10.1.19.11 ip extcommunity-list

The **ip extcommunity-list** command adds a color extended community to an extcommunity-list. Multiple color extended communities can be added to the list. Negating the command removes the corresponding color extended community from the list.

Command Mode

Configuration mode

Command Syntax

`ip extcommunity-list` **WORD** [permit | deny][**COLOR-EXPRESSION**]

`no ip extcommunity-list` **WORD** [permit | deny] **COLOR-EXPRESSION**]

`default ip extcommunity-list` **WORD** [permit | deny][**COLOR-EXPRESSION**]

Parameters

- **WORD** Community list name.
- **permit** Specifies community to accept.
- **deny** Specifies comminity to reject.
- **COLOR-EXPRESSION** Color extended community.

Example

```
switch(config)# ip extcommunity-list foo permit color 1 color 2
switch(config)# ip extcommunity-list bar permit color 3 color-only endpoint-match null color 4
 color-only endpoint-match any
```

10.1.19.12 mc-tx-queue

The **mc-tx-queue** command places the switch in mc-tx-queue configuration mode to configure a multicast transmit queue on the configuration mode interface. Mc-tx-queue configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

Trident and Tomahawk switches have four multicast queues (***MC0 – MC03***) and eight unicast queues (***UC0 – UC7***), categorized into two priority groups. All queues are exposed through the CLI and are user configurable.

- **Priority Group 1:** ***UC7***, ***UC6***, ***MC3***
- **Priority Group 0:** ***UC5***, ***UC4***, ***MC2***, ***UC3***, ***UC2***, ***MC1***, ***UC1***, ***UC0***, ***MC0***

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no mc-tx-queue** and **default mc-tx-queue** commands remove the configuration for the specified transmit queue by deleting the all corresponding **mc-tx-queue** mode commands from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`mc-tx-queue` *queue_level*

Parameter

queue_level The multicast transmit queue number. Values range from ***0*** to ***3***.

Commands Available in tx-queue Configuration Mode

- bandwidth percent (Trident and Tomahawk)
- priority (Trident and Tomahawk)
- shape rate (Tx-queue – Trident and Tomahawk)

Related Command

uc-tx-queue Configures unicast transmit queues on Trident and Tomahawk platform switches.

Example

This command enters mc-tx-queue configuration mode for ***multicast transmit queue 3*** of ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# mc-tx-queue 3
switch(config-if-Et5-mc-txq-3)#
```

10.1.19.13 platform petraA traffic-class

The **`platform petraA traffic-class`** command configures the default traffic class used by all ports on a specified chip. The default traffic class is implemented by Petra platform switches to replace qos cos and qos dscp commands. Traffic class values range from ***0*** to ***7***. The default traffic class is ***1***.

When **platform ?** returns **Petra**:

- **CoS trusted ports:** inbound untagged packets are assigned to the default traffic class. Tagged packets are assigned to the traffic class that corresponds to the contents of its CoS field.
- **DSCP trusted ports:** inbound non-IP packets are assigned to the default traffic class. IP packets are assigned to the traffic class that corresponds to the contents of its DSCP field.
- **Untrusted ports:** all inbound packets are assigned to the default traffic class.

The **`no platform petraA traffic-class`** and **`default platform petraA traffic-class`** commands restore the default traffic class of one for all ports on the specified chips by deleting the corresponding **`platform petraA traffic-class`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`platform petraA` [**CHIP_NAME**] traffic-class *tc_value*

`no platform petraA` [**CHIP_NAME**] traffic-class

`default platform petraA` [**CHIP_NAME**] traffic-class

Parameters

CHIP_NAME Trust mode assigned to the specified ports. Port designation options include:

- ***no parameter*** All ports on the switch.
- **module *cardX*** All ports on specified linecard (7500 Series).
- **petra *cardX / chipY*** All ports on PetraA chip ***chipY*** on linecard ***cardX*** (7500 Series).
- **petra *-chipZ*** All ports on PetraA chip chipZ (7048 Series)

7500 Series

Switches can contain up to eight linecards. ***CardX*** varies from ***3*** to ***10***.

Each linecard contains six PetraA chips. Each chip controls eight ports. ***ChipY*** varies from ***0*** to ***5***:

- ***0*** controls ports ***1*** through ***8***:
  - ***1*** controls ports ***9*** through ***16***.
  - ***2*** controls ports ***17*** through ***24***.
  - ***3*** controls ports ***25*** through ***32***.
  - ***4*** controls ports ***33*** through ***40***.
  - ***5*** controls ports ***41*** through ***48***.

7048 Series

Each switch contains two PetraA chips. ***ChipZ*** varies from ***0*** to ***1***:

- ***0*** controls ports ***1*** through ***32***.
  - ***1*** controls ports ***33*** through ***52***.
- ***tc_value*** Traffic class value. Values range from ***0*** to ***7***. Default value is ***1***.

Related Command

show platform petraA traffic-class displays the traffic class assignment on all specified Petra chips.

Example

This command configures the default ***traffic class 6*** for ports ***25-32*** on linecard ***5***.

```
switch(config)# platform petraA petra5/3 traffic-class 6
switch(config)#
```

10.1.19.14 priority (Arad/Jericho)

The **`priority`** command specifies the priority of the transmit queue. The switch supports two queue priorities:

- **strict priority**: contents are removed from the queue - subject to maximum bandwidth limits, before data from lower priority queues. The default setting on all queues is strict priority.
- **round robin priority**: contents are removed proportionately from all round robin queues - subject to maximum bandwidth limits assigned to the strict priority queues.

Tx-queue 7 is set to strict priority and is not configurable.

When a queue is configured as a round robin queue, all lower priority queues also function as round robin queues. A queue's numerical label denotes its priority: higher labels denote higher priority. ***Tx-queue 6*** has higher priority than ***Tx-queue 5***, and ***Tx-queue 0*** has the lowest priority.

The **`priority strict`** and **`default priority`** commands configure a transmit queue to function as a strict priority queue unless a higher priority queue is configured as a round robin queue.

The **`no priority`** command configures a transmit queue as a round robin queue. All lower priority queues also function as round robin queues regardless of their configuration.

Command Mode

Tx-Queue Configuration

Command Syntax

```
priority strict

no priority

default priority
```

Related Command

tx-queue (Arad/Jericho) places the switch in tx-queue configuration mode.

Example

These commands perform the following on ***interface ethernet 3/4/1***:

- Displays the default state of all transmit queues.
- Configures ***transmit queue 3*** as a round robin queue.

- Displays the effect of the **`no priority`** command on all transmit queues on the interface.

```
switch(config)# interface ethernet 3/4/1
switch(config-if-Et3/4/1)# show qos interfaces ethernet 3/4/1

Ethernet3/4/1:

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)        (units)
   ------------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D

Note: Values are displayed as Operational/Configured

switch(config-if-Et3/4/1-txq-3)#
```

10.1.19.15 priority (FM6000)

The **`priority`** command specifies the priority of the transmit queue. The switch supports two queue priorities:

- **strict priority**: contents are removed from the queue - subject to maximum bandwidth limits, before data from lower priority queues. The default setting on all queues is strict priority.
- **round robin priority**: contents are removed proportionately from all round robin queues - subject to maximum bandwidth limits assigned to the strict priority queues.

When a queue is configured as a round robin queue, all lower priority queues also function as round robin queues. A queue's numerical label denotes its priority: higher labels denote higher priority. ***Tx-queue 6*** has higher priority than ***Tx-queue 5***, and ***Tx-queue 0*** has the lowest priority.

The **`priority strict`** and **`default priority`** commands configure a transmit queue to function as a strict priority queue unless a higher priority queue is configured as a round robin queue.

The **`no priority`** command configures a transmit queue as a round robin queue. All lower priority queues also function as round robin queues regardless of their configuration.

Command Mode

Tx-Queue Configuration

Command Syntax

```
priority strict

no priority

default priority
```

Related Command

tx-queue (FM6000) places the switch in tx-queue configuration mode.

Example

These commands perform the following on ***interface ethernet 19***:

- Displays the default state of all transmit queues.
- Configures ***transmit queue 3*** as a round robin queue.

- Displays the effect of the **`no priority`** command on all transmit queues on the interface.

```
switch(config)# interface ethernet 19
switch(config-if-Et19)# show qos interface ethernet 19

Ethernet19:
   Trust Mode: COS

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------

switch(config-if-Et3/28-txq-3)#
```

10.1.19.17 priority (Trident and Tomahawk)

The **`priority`** command specifies the priority of the transmit queue. The switch supports two queue priorities:

- **strict priority**: contents are removed from the queue - subject to maximum bandwidth limits, before data from lower priority queues. The default setting on all other queues is strict priority.
- **round robin priority**: contents are removed proportionately from all round robin queues - subject to maximum bandwidth limits assigned to the strict priority queues.

Trident and Tomahawk switches have eight unicast queues (***UC0 – UC7***) and four multicast queues (M***C0 – MC03***), categorized into two priority groups. ***Priority group 1*** queues have priority over ***priority 0*** queues. The following lists display the priority group queues in order from higher priority to lower priority.

- **Priority Group 1: *UC7***, ***UC6***, ***MC3***
- **Priority Group 0: *UC5***, ***UC4***, ***MC2***, ***UC3***, ***UC2***, ***MC1***, ***UC1***, ***UC0***, ***MC0***

Priority group 1 queues are strict priority queues and are not configurable as round robin. ***Priority 0*** queues are strict priority by default and are configurable as round robin. When a queue is configured as a round robin queue, all lower priority queues automatically function as round robin queues.

The **`priority strict`** and **`default priority`** commands configure a transmit queue to function as a strict priority queue unless a higher priority queue is configured as a round robin queue.

The **`no priority`** command configures a transmit queue as a round robin queue. All lower priority queues also function as round robin queues regardless of their configuration.

Command Mode

Mc-Tx-Queue configuration

Uc-Tx-Queue configuration

Command Syntax

```
priority strict

no priority

default priority
```

Related Commands

- mc-tx-queue places the switch in mc-tx-queue configuration mode.

- uc-tx-queue places the switch in uc-tx-queue configuration mode.

Example

These commands perform the following on ***interface ethernet 7***:

- Displays the default state of all transmit queues.
- Configures ***transmit queue 3*** as a round robin queue.
- Displays the effect of the **`no priority`** command on all transmit queues on the interface.

```
switch(config) #interface ethernet 7
switch(config-if-Et7)# show qos interface ethernet 7

switch(config-if-Et7-uc-txq-3)#
```

10.1.19.18 qos cos

The **qos cos** command specifies the default class of service (CoS) value of the configuration mode interface. CoS values range from ***0*** to ***7***. Default value is ***0***.

Arad, Jericho, fm6000, Trident, Tomahawk, and **Trident II** platform switches:

- CoS trusted ports: the default CoS value determines the traffic class for inbound untagged packets. Tagged packets are assigned to the traffic class that corresponds to the contents of its CoS field.
- Untrusted ports: the default CoS value determines the traffic class for all inbound packets.

Petra platform switches:

- CoS trusted ports: inbound untagged packets are assigned to the default traffic class, as configured by platform petraA traffic-class. Tagged packets are assigned to the traffic class that corresponds to the contents of its CoS field.
- Untrusted ports: all inbound packets are assigned to the default traffic class.

The **no qos cos** and **default qos cos** commands restore the port's default CoS value to zero by deleting the corresponding **qos cos** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

```
qos cos cos_value

no qos cos

default qos cos
```

Parameter

cos_valueCoS value assigned to port. Value ranges from ***0*** to ***7***. Default value is ***0***.

Example

This command configures the default ***CoS 4*** on ***interface ethernet 8***.

```
switch(config-if-Et8)# qos cos 4
switch(config-if-Et8)#
```

10.1.19.19 qos dscp

The **qos dscp** command specifies the default Differentiated Services Code Point (DSCP) value of the configuration mode interface. The default DSCP determines the traffic class for non-IP packets that are inbound on DSCP trusted ports. DSCP trusted ports determine the traffic class for inbound packets as follows:

- **Arad, Jericho, fm6000, Trident, Tomahawk,** and **Trident II** platform switches:
  - non-IP packets: default DSCP value specified by **qos dscp** determines the traffic class.
  - IP packets: assigned to the traffic class corresponding to its DSCP field contents.
- **Petra** platform switches:
  - non-IP packets: assigned to default traffic class configured by platform petraA traffic-class.
  - IP packets: assigned to the traffic class corresponding to its DSCP field contents.

The **no qos dscp** and **default qos dscp** commands restore the port's default DSCP value to zero by deleting the corresponding **qos dscp** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

```
qos dscp dscp_value

no qos dscp

default qos dscp
```

Parameter

dscp_value DSCP value assigned to the port. Value ranges from ***0*** to ***63***. Default value is ***0***.

Example

This command sets the default DSCP of ***44*** on ***interfacee thernet 7***.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# qos dscp 44
switch(config-if-Et7)
```

10.1.19.20 qos map cos

The **qos map cos** command associates a traffic class to a list of class of service (CoS) settings. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's CoS field or the port upon which it is received. You can also configure a custom drop precedence for the QoS map.

The **no qos map cos** and **default qos map cos** commands restore the specified CoS values to the default traffic class setting by deleting the corresponding **qos map cos** statements from ***running-config***.

Command Mode

Global Configuration

Command Syntax

qos map cos ***cos_value_1*** **[*cos_value_2 ... cos_value_n*] to traffic-class** ***tc_value*** **[drop-precedence** ***dp_value*****]**

no qos map cos ***cos_value_1*** **[*cos_value_2 ... cos_value_n*]**

default qos map cos ***cos_value_1*** **[*cos_value_2 ... cos_value_n*]**

Parameters

- ***cos_value_x*** - Class of Service (CoS) value. Value ranges from ***0*** to ***7***.
- ***tc_value*** - Traffic class value. Value range varies by platform.
- **drop-precedence** ***dp_value*** - Specify a custom drop precedence from 0 to 2.

Default CoS to traffic class map varies by platform (Table 54: Default CoS to Traffic Class Map).

Default Inbound CoS to Traffic Class Map

Table 54: Default CoS to Traffic Class Map displays the default CoS to traffic class map for each platform.

Table 54: Default CoS to Traffic Class Map

Inbound CoS	untagged	0	1	2	3	4	5	6	7
Traffic Class (Arad /Jericho)	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7
Traffic Class (FM6000)	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7
Traffic Class (Helix)	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7
Traffic Class (Petra)	Assigned default traffic class	1	0	2	3	4	5	6	7
Traffic Class (Trident and Tomahawk)	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7
Traffic Class (Trident II)	Derived: use default CoS as inbound CoS	1	0	2	3	4	5	6	7

Related Commands

- qos cos specifies the default CoS.
- platform petraA traffic-class specifies the default traffic class.

Example

This command assigns the ***traffic class 5*** to the classes of service ***1***, ***3***, ***5***, and ***7***.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)#
```

10.1.19.21 qos map dscp

The **qos map dscp** command associates a traffic class to a set of Differentiated Services Code Point (DSCP) values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet's DSCP field or the chip upon which it is received.

This command configures the global DSCP to traffic-class map. To create additional named maps that can be attached to specific VRFs, use the `qos map dscp to traffic-class` command with the **name** option.

The **no qos map dscp** and **default qos map dscp** commands restore the specified DSCP values to their default traffic class settings by deleting corresponding **qos map dscp** statements from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map dscp` *dscpv_1* [*dscpv_2...dscpv_n*] to traffic-class *tc_value*

`no qos map dscp` *dscpv_1* [*dscpv_2...dscpv_n*]

`default qos map dscp` *dscpv_1* [*dscpv_2...dscpv_n*]

Parameters

- ***dscpv_x*** Differentiated Services Code Point (DSCP) value. Value ranges from ***0*** to ***63***.
- ***tc_value*** Traffic class value. Value range varies by platform.

Default map varies by platform (Table 55: Default DSCP to Traffic Class Map).

Default Inbound DSCP to Traffic Class Map

Table 55: Default DSCP to Traffic Class Map displays the default DSCP to traffic class map for each platform.

Table 55: Default DSCP to Traffic Class Map

Inbound DSCP	0-7	8-15	16-23	24-31	32-39	40-47	48-55	56-63
Traffic Class (Arad /Jericho)	1	0	2	3	4	5	6	7
Traffic Class (FM6000)	1	0	2	3	4	5	6	7
Traffic Class (Helix)	1	0	2	3	4	5	6	7
Traffic Class (Petra)	1	0	2	3	4	5	6	7
Traffic Class (Trident and Tomahawk)	1	0	2	3	4	5	6	7
Traffic Class (Trident II)	1	0	2	3	4	5	6	7

Example

This command assigns the ***traffic class 3*** to the DSCP values of ***12***, ***13***, ***25***, and ***37***.

```
switch(config)# qos map dscp 12 13 25 37 to traffic-class 3
switch(config)#
```

10.1.19.22 qos map dscp to traffic-class

The **qos map dscp to traffic-class** command puts the switch in DSCP Map Configuration mode for the specified QoS map. If the map does not already exist, it is created as a copy of the global DSCP-to-traffic-class map. In DSCP Map Configuration mode, the `dscp to traffic-class` command is available to make changes to the map.

The **no** and **default** forms of the command remove the specified custom map.

Command Mode

Global Configuration

Command Syntax

`qos map dscp to traffic-class name` *map_name*

`no qos map dscp to traffic-class name` *map_name*

`default qos map dscp to traffic-class name` *map_name*

Parameters

- ***map_name*** The name of the map to configure. If the map does not exist, it is created as a copy of the global DSCP-to-traffic-class map.

Example

This command creates the map ***map1*** and places the switch in DSCP Map Configuration mode.

```
switch(config)#qos map dscp to traffic-class name map1
switch(config-dscp-map-map1)#
```

10.1.19.23 qos map dscp to traffic-class (MPLS tunnel termination VRF)

The **qos map dscp to traffic-class** command assigns a DSCP-to-traffic-class map to a VRF, replacing the global map or previous custom map. The switch uses this map to assign a traffic class to data packets routed to this VRF on the basis of the DSCP fields of these packets.

The **no qos map dscp to traffic-class** and **default qos map dscp to traffic-map** commands remove the assignment of a custom map from the VRF, restoring the global map. default traffic class settings by deleting corresponding **qos map dscp** statements from ***running-config***.

Command Mode

MPLS Tunnel Termination VRF Configuration

Command Syntax

`qos map dscp to traffic-class` *map_name*

`no qos map dscp to traffic-class` *map_name*

`default qos map dscp to traffic-class` *map_name*

Parameter

- ***map_name*** DSCP to traffic-class map name.

Example

These commands assign the ***map1*** QoS DSCP-to-traffic-class map to the ***newVRF1*** and ***newVRF2*** VRFs.

```
switch(config)# mpls tunnel termination
switch(config-mpls-tunnel-termination)# vrf newVRF1
switch(config-tunnel-termination-vrf-newVRF1)# qos map dscp to traffic-class map1
switch(config-tunnel-termination-vrf-newVRF1)# exit
switch(config-mpls-tunnel-termination)# vrf newVRF2
switch(config-tunnel-termination-vrf-newVRF2)# qos map dscp to traffic-class map1
switch(config-tunnel-termination-vrf-newVRF2)# exit
switch(config-tunnel-termination)#
```

10.1.19.24 qos map traffic-class to cos

The **`qos map traffic-class to cos`** command associates a class of service (CoS) to a list of traffic classes. Multiple commands create a complete traffic class to CoS map. The switch uses this map in CoS rewrite operations to fill the CoS field in outbound packets. This map is applicable to DSCP trusted ports and untrusted ports. CoS rewrite is disabled on CoS trusted ports. The show qos maps command displays the CoS to traffic class map.

The **`no qos traffic-class to cos`** and **`default qos traffic-class to cos`** commands restore the specified traffic class values to their default CoS settings by removing the corresponding **`qos map traffic-class to cos`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to cos` *cos_value*

`no qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to cos`

`default qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to cos`

Parameters

- ***tc_num_x*** Traffic class value. Value range varies by switch platform.
- ***cos_value*** Class of Service (CoS) value. Value ranges from ***0*** to ***7***.

Default Inbound Traffic Class to CoS Map

Table 56: Default Traffic Class to CoS Rewrite Value Map displays the default traffic class to CoS map for each platform.

Table 56: Default Traffic Class to CoS Rewrite Value Map

Traffic Class	0	1	2	3	4	5	6	7
CoS Rewrite Value (Arad and / Jericho)	1	0	2	3	4	5	6	7
CoS Rewrite Value (FM6000)	1	0	2	3	4	5	6	7
CoS Rewrite Value (Helix)	1	0	2	3	4	5	6	7
CoS Rewrite Value (Petra)	1	0	2	3	4	5	6	7
CoS Rewrite Value (Trident and Tomahawk)	1	0	2	3	4	5	6	7
CoS Rewrite Value (Trident II)	1	0	2	3	4	5	6	7

Example

This command assigns the ***CoS 2*** to traffic classes ***1***, ***3***, and ***5***.

```
switch(config)# qos map traffic-class 1 3 5 to cos 2
switch(config)#
```

10.1.19.25 qos map traffic-class to dscp

The **`qos map traffic-class to dscp`** command associates a Differentiated Services Code Point (DSCP) value to a list of traffic classes. Multiple commands create a complete traffic class to DSCP map. The switch uses this map in DSCP rewrite operations to fill the DSCP field in outbound packets. This map is applicable to CoS trusted ports and untrusted ports but disabled by default on these ports. DSCP rewrite is disabled on DSCP trusted ports. The show qos maps command displays the traffic class to DSCP map.

The **`no qos traffic-class to dscp`** and **`default qos traffic-class to dscp`** commands restore the specified traffic class values to their default DSCP settings by removing the corresponding **`qos map traffic-class to dscp`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to dscp` *dscp_value*

`no qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to dscp`

`default qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to dscp`

Parameters

- ***tc_num_x*** Traffic class value. Value range varies by switch platform.
- ***dscp_value*** Differentiated Services Code Point (DSCP) value. Value ranges from ***0*** to ***63***.

Default Inbound Traffic Class to DSCP Map

Table 57: Default Traffic Class to DSCP Rewrite Value Map displays the default traffic class to DSCP map for each platform.

Table 57: Default Traffic Class to DSCP Rewrite Value Map

Traffic Class	0	1	2	3	4	5	6	7
DSCP Rewrite Value (FM6000)	8	0	16	24	32	40	48	56
DSCP Rewrite Value (Helix)	8	0	16	24	32	40	48	56
DSCP Rewrite Value (Trident and Tomahawk)	8	0	16	24	32	40	48	56
DSCP Rewrite Value (Trident II)	8	0	16	24	32	40	48	56

Example

This command assigns the DSCP value of ***17*** to traffic classes ***1***, ***2***, and ***4***.

```
switch(config)# qos map traffic-class 1 2 4 to dscp 17
switch(config)#
```

10.1.19.26 qos map traffic-class to mc-tx-queue

The **qos map traffic-class to mc-tx-queue** command associates a multicast transmit queue to a list of traffic classes. Multiple commands create a complete traffic class to mc-tx-queue map. The switch uses this map to route outbound packets to transmit queues, which in turn schedules their transmission from the switch. The show qos maps command displays the traffic class to multicast transmit queue map.

The **no qos traffic-class to mc-tx-queue** and **default qos traffic-class to mc-tx-queue** commands restore the default traffic class to multicast transmit queue map for the specified traffic class values by removing the corresponding **qos map traffic-class to mc-tx-queue** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to mc-tx-queue` *mtq_value*

`no qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to mc-tx-queue`

`default qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to mc-tx-queue`

Parameters

- ***tc_num_x*** Traffic class value. Value ranges from ***0*** to ***7***.
- ***mtq_value*** Multicast transmit queue number. Value ranges from ***0*** to ***3***.

Default Inbound Traffic Class to Multicast Transmit Queue Map

Table 58: Default Traffic Class to Multicast Transmit Queue Map displays the default traffic class to multicast transmit queue map for Trident and Tomahawk platform switches.

Table 58: Default Traffic Class to Multicast Transmit Queue Map

Traffic Class	0	1	2	3	4	5	6	7
Multicast Transmit Queue (Trident and Tomahawk)	0	0	1	1	2	2	3	3

Related Commands

- qos map traffic-class to uc-tx-queue (Trident and Tomahawk) associates traffic classes to a multicast transmit queue.

- qos map traffic-class to tx-queue (all other platforms) associates traffic classes to a transmit queue.

Example

This command maps traffic classes ***0***, ***4***, and ***5*** to ***mc-tx-queue 2***.

```
switch(config)# qos map traffic-class 0 4 5 to mc-tx-queue 2
switch(config)#
```

10.1.19.27 qos map traffic-class to tx-queue

The **qos map traffic-class to tx-queue** command associates a transmit queue (tx-queue) to a list of traffic classes. Multiple commands create a complete traffic to tx-queue map. The switch uses this map to route outbound packets to transmit queues, which in turn schedules their transmission from the switch. The show qos maps command displays the transmit queue to traffic class map.

The **no qos traffic-class to tx-queue** and **default qos traffic-class to tx-queue** commands restore the specified traffic class values to their default transmit queue settings by removing the corresponding **qos map traffic-class to tx-queue** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to tx-queue` *txq_value*

`no qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to tx-queue`

`default qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to tx-queue`

Parameters

- ***tc_num_x*** Traffic class value. Value range varies by platform.
- ***txq_value*** Transmit queue value. Value range varies by platform.

Restrictions

FM6000: When Priority Flow Control (PFC) is enabled, traffic classes are mapped to their corresponding transmit queues, regardless of existing **qos map traffic-class to tx-queue** statements.

Arad, Jericho, and Petra: ***Traffic class 7*** always maps to ***transmit queue 7***. This association is not editable.

Default Inbound Traffic Class to Transmit Queue Map

Table 59: Default Traffic Class to Transmit Queue Map displays the transmit queue to traffic class map.

Table 59: Default Traffic Class to Transmit Queue Map

Traffic Class	0	1	2	3	4	5	6	7
Transmit Queue (Arad /Jericho)	0	1	2	3	4	5	6	7
Transmit Queue (FM6000)	0	1	2	3	4	5	6	7
Transmit Queue (Helix)	0	1	2	3	4	5	6	7
Transmit Queue (Petra)	0	1	2	3	4	5	6	7
Transmit Queue (Trident II)	0	1	2	3	4	5	6	7

Related Commands

- qos map traffic-class to mc-tx-queue (Trident and Tomahawk) associates traffic classes to a unicast transmit queue.
- qos map traffic-class to uc-tx-queue (Trident and Tomahawk) associates traffic classes to a multicast transmit queue.

Example

This command maps traffic classes ***0***, ***4***, and ***5*** to ***tx-queue 4***.

```
switch(config)# qos map traffic-class 0 4 5 to tx-queue 4
switch(config)#
```

10.1.19.28 qos map traffic-class to uc-tx-queue

The **`qos map traffic-class to uc-tx-queue`** command associates a unicast transmit queue to a list of traffic classes. Multiple commands create a complete traffic class to unicast transmit queue map. The switch uses this map to route outbound packets to transmit queues, which in turn schedules their transmission from the switch. The show qos maps command displays the traffic class to unicast transmit queue map.

The **`no qos traffic-class to uc-tx-queue`** and **`default qos traffic-class to uc-tx-queue`** commands restore the default traffic class to unicast transmit queue map for the specified traffic class values by removing the corresponding **`qos map traffic-class to uc-tx-queue`** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to uc-tx-queue` *utq_value*

`no qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to uc-tx-queue`

`default qos map traffic-class` *tc_num_1* [*tc_num_2 ... tc_num_n*] `to uc-tx-queue`

Parameters

- ***tc_num_x*** Traffic class value. Value ranges from ***0*** to ***7***.
- ***utq_value*** Unicast transmit queue number. Value ranges from ***0*** to ***7***.

Default Inbound Traffic Class to Unicast Transmit Queue Map

Table 60: Default Traffic Class to Unicast Transmit Queue Map displays the default traffic class to Unicast transmit queue map for Trident and Tomahawk platform switches.

Table 60: Default Traffic Class to Unicast Transmit Queue Map

Traffic Class	0	1	2	3	4	5	6	7
Unicast Transmit Queue (Trident and Tomahawk)	0	1	2	3	4	5	6	7

Related Commands

- qos map traffic-class to mc-tx-queue (Trident and Tomahawk) associates traffic classes to a unicast transmit queue.
- qos map traffic-class to tx-queue (all other platforms) associates traffic classes to a transmit queue.

Example

This command maps traffic classes ***0***, ***4***, and ***5*** to ***unicast transmit queue 4***.

```
switch(config)# qos map traffic-class 0 4 5 to uc-tx-queue 4
switch(config)#
```

10.1.19.29 qos profile

The **qos profile** command places the switch in QoS profile configuration mode and for the specified profile and creates the profile if it does not already exist. QoS profiles are used to apply the same QoS configuration to multiple interfaces.

The **no qos profile** and **default qos profile** command deletes the QoS profile from the running configuration.

The **exit** command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

`qos profile` *profile_name*

`no qos profile` *profile_name*

`default qos profile` *profile_name*

Parameter

profile_name QoS profile name.

Note: Commands use a subset of the listed fields. Available subset depends on the specified parameter. Use CLI syntax assistance to view options for specific parameter when creating a QoS profile.

Example

This command places the switch in QoS profile configuration mode for policy map policy map ***TP*** and creates the policy map if it does not already exist.

```
switch(config)# qos profile TP
switch(config-qos-profile-TP)#
```

10.1.19.30 qos random-detect ecn allow non-ect chip-based (Tomahawk and Trident)

The **qos random-detect ecn allow non-ect chip-based** enables per color queue thresholds using color based queue thresholds and drop-precedence values along with drop of non-ect traffic by allowing non-ect and set drop-precedence 1 in a policy map simultaneously.

The **no qos random-detect ecn allow non-ect chip-based** and **default qos random-detect ecn allow non-ect chip-based** commands disbales the use of non-ect and set drop-precedence 1 simultaneously in a policy map in the **running-config**.

Command Mode

Global Configuration

Command Syntax

```
qos random-detect ecn allow non-ect chip-based

no qos random-detect ecn allow non-ect chip-based

default qos random-detect ecn allow non-ect chip-based
```

Example

The following command enables the use of non-ect and ***set drop-precedence 1*** simultaneously in a policy map.

```
switch(config)# qos random-detect ecn allow non-ect chip-based
```

10.1.19.31 qos random-detect ecn global-buffer (Helix)

The **qos random-detect ecn global-buffer** command enables ECN marking for globally shared packet memory and specifies minimum and maximum queue threshold sizes. Hosts can advertise their ECN capabilities in the ToS DiffServ field's two least significant bits:

- **00** Non ECN Capable transport.
- **10** ECN Capable transport.
- **01** ECN Capable transport.
- **11** Congestion encountered.

Congestion is determined by comparing average queue size with queue thresholds. Average queue size is calculated through a formula based on the previous average and current queue size. Packets are marked based on this average size and the specified thresholds:

- Average queue size below minimum threshold: Packets are queued normally.
- Average queue size above maximum threshold: Packets are marked **congestion encountered**.
- Average queue size between minimum and maximum thresholds. Packets are queued or marked **congestion encountered**. The proportion of marked packets varies linearly with average queue size:
  - 0% are marked when average queue size is less than or equal to minimum threshold.
  - 100% are marked when average queue size is greater than or equal to maximum threshold.

  When transmitted packets are marked **Non ECN Capable**, congestion packets are dropped, not marked.

The **no qos random-detect ecn global-buffer** and **default qos random-detect ecn global-buffer** commands disables ECN marking for the shared buffer by removing the **qos random-detect ecn global-buffer** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos random-detect ecn global-buffer minimum-threshold` **MIN** maximum-threshold **MAX**

`no qos random-detect ecn global-buffer`

`default qos random-detect ecn global-buffer`

Parameters

MIN and **MAX** parameters must use the same data unit.

- **MIN** Minimum threshold. Options include:
  - ***1*** to ***19456*** **segments** 208-byte segments units.
  - ***1*** to ***4*** **mbytes** Megabyte units.
  - ***1*** to ***4046*** **kbytes** Kilobyte units.
  - ***1*** to ***4046848*** **bytes** Byte units.
- **MAX** Maximum threshold. Options include:
  - ***1*** to ***19456*** **segments** 208-byte segments units.
  - ***1*** to ***4*** **mbytes** Megabyte units.
  - ***1*** to ***4046*** **kbytes** Kilobyte units.
  - ***1*** to ***4046848*** **bytes** Byte units.

Guidelines

Packet memory is divided into 46080 208-byte cells, whose allocation is managed by the memory management unit (MMU). The MMU tracks the cells that each entity uses and determines the number of cells that can be allocated to an entity.

Related Command

random-detect ecn (Helix) enables ECN marking for a unicast transmit queue.

Examples

- This command enables ECN marking of unicast packets from the global data pool and sets the minimum and maximum thresholds at ***20*** and ***500*** segments.

```
switch(config)# qos random-detect ecn global-buffer minimum-threshold 20 segments
maximum-threshold 500 segments
switch(config)#
```

- This command disables ECN marking of unicast packets from the global data pool.

```
switch(config)# no qos random-detect ecn global-buffer
switch(config)#
```

10.1.19.32 qos random-detect ecn global-buffer (Trident and Tomahawk)

The **qos random-detect ecn global-buffer** command enables ECN marking for globally shared packet memory and specifies minimum and maximum queue threshold sizes. Hosts can advertise their ECN capabilities in the ToS DiffServ field's two least significant bits:

- **00** Non ECN Capable transport.
- **10** ECN Capable transport.
- **01** ECN Capable transport.
- **11** Congestion encountered.

Congestion is determined by comparing average queue size with queue thresholds. Average queue size is calculated through a formula based on the previous average and current queue size. Packets are marked based on this average size and the specified thresholds:

- Average queue size below minimum threshold: Packets are queued normally.
- Average queue size above maximum threshold: Packets are marked **congestion encountered**.
- Average queue size between minimum and maximum thresholds. Packets are queued or marked **congestion encountered**. The proportion of marked packets varies linearly with average queue size:
  - 0% are marked when average queue size is less than or equal to minimum threshold.
  - 100% are marked when average queue size is greater than or equal to maximum threshold.

  When transmitted packets are marked **Non ECN Capable**, congestion packets are dropped, not marked.

The **no qos random-detect ecn global-buffer** and **default qos random-detect ecn global-buffer** commands disables ECN marking for the shared buffer by removing the **qos random-detect ecn global-buffer** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

`qos random-detect ecn global-buffer minimum-threshold` **MIN** maximum-threshold **MAX**

`no qos random-detect ecn global-buffer`

`default qos random-detect ecn global-buffer`

Guidelines

Packet memory is divided into 46080 208-byte cells, whose allocation is managed by the memory management unit (MMU). The MMU tracks the cells that each entity uses and determines the number of cells that can be allocated to an entity.

Parameters

MIN and **MAX** parameters must use the same data unit.

- **MIN** Minimum threshold. Options include:
  - ***1*** to ***46080*** **segments** 208-byte segments units.
  - ***1*** to ***9*** **mbytes** Megabyte units.
  - ***1*** to ***9584*** **kbytes** Kilobyte units.
  - ***1*** to ***9584640*** **bytes** Byte units.
- **MAX** Maximum threshold. Options include:
  - ***1*** to ***46080*** **segments** 208-byte segments units.
  - ***1*** to ***9*** **mbytes** Megabyte units.
  - ***1*** to ***9584*** **kbytes** Kilobyte units.
  - ***1*** to ***9584640*** **bytes** Byte units.

Related Command

random-detect ecn (Trident and Tomahawk) enables ECN marking for a unicast transmit queue.

Examples

- This command enables ECN marking of unicast packets from the global data pool and sets the minimum and maximum thresholds at ***20*** and ***500*** segments.

```
switch(config)# qos random-detect ecn global-buffer minimum-threshold 20 segments maximum-thres
hold 500 segments
switch(config)#
```

- This command disables ECN marking of unicast packets from the global data pool.

```
switch(config)# no qos random-detect ecn global-buffer
switch(config)#
```

10.1.19.33 qos rewrite cos

The **qos rewrite cos** command enables the rewriting of the CoS field for outbound tagged packets that were received on DSCP trusted ports and untrusted ports. CoS rewrite is always disabled on CoS trusted ports. The CoS value that is written into the packet is based on the data stream's traffic class. CoS rewriting is active by default.

The **no qos rewrite cos** command disables CoS rewriting on the switch. The default **qos rewrite cos** command restores the default setting of enabling CoS rewriting by removing the **no qos rewrite cos** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
qos rewrite cos

no qos rewrite cos

default qos rewrite cos
```

Related Command

qos map traffic-class to cos configures the traffic class to CoS rewrite map.

Example

This command enables CoS rewrite.

```
switch(config)# qos rewrite cos
switch(config)#
```

10.1.19.34 qos rewrite dscp

The **qos rewrite dscp** command enables the rewriting of the DSCP field for outbound tagged packets that were received on CoS trusted ports and untrusted ports. DSCP rewrite is always disabled on DSCP trusted ports. The DSCP value that is written into the packet is based on the data stream's traffic class. DSCP rewriting is disabled by default.

The **no qos rewrite dscp** and **default qos rewrite dscp** commands disable DSCP rewriting on the switch by removing the **no qos rewrite dscp** command from ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
qos rewrite dscp

no qos rewrite dscp

default qos rewrite dscp
```

Related Command

qos map traffic-class to dscp configures the traffic class to DSCP rewrite map.

Example

This command enables DSCP rewrite.

```
switch(config)# qos rewrite dscp
switch(config)#
```

10.1.19.35 qos rewrite ipv4 ipv6

The **qos rewrite [ipv4-over-udp | ipv6-over-udp]** command in the Global Configuration Mode enables rewriting the DSCP of the GUE encapsulated headers on IP-over-UDP tunnels while preserving the TOS value of the inner IP payload for IPv4 and IPv6.

The **[no | default]** versions of the command removes the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

qos rewrite [ipv4-over-udp | ipv6-over-udp] inner dscp disabled

Parameters

- **[ipv4-over-udp | ipv6-over-udp]** - Configure IPv4 or IPv6 over UDP encapsulation parameters.
- **inner** - Configure inner payload QoS rewrite parameters.
- **dscp disabled** - Disable DHCP rewrite.

Example

Use the following command to rewrite the DSCP of the GUE and preserve the TOS value over IPv4 over UDP:

```
switch(config)# qos rewrite ipv4-over-udp inner dscp disabled
switch(config)#
```

10.1.19.36 qos tx-queue shape rate precision

The **qos tx-queue shape rate precision** command in the Global Configuration Mode configures Tx Queue Precision Shaping on switches with a low configured rate. The **[no | default]** versions of the command disables the configuration.

Command Mode

Global Configuration

Command Syntax

```
qos tx-queue shape rate precision 50Mbps

no qos tx-queue shape rate precision

default qos tx-queue shape rate precision
```

Parameters

- **precision 50Mbps** - Specifies the minimum speed that requires precision shaping. Currently, EOS only supports 50Mbps.

Example

Use the following command to configure Tx Queue Precision Shaping on a switch:

```
switch(config)# qos tx-queue shape rate precision 50Mbps
! Change will take effect only after switch reboot.
```

10.1.19.37 qos subinterface

The **qos subinterface** command in the Global Configuration Mode configures subinterface behaviors for Quality of Service (QoS).

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

```
qos subinterface [port-channel [load-balancing | rebalancing]] [tx-queue
[allocation always] [count [4 | 8]]
```

```
no qos subinterface
```

```
default qos subinterface
```

Parameters

- **qos subinterface** - Configure QoS subinterface behavior for an interface.
- **port-channel** - Configure port channel parameters:
  - **load-balancing** - Enable load balancing on the QoS subinterface.
  - **rebalancing** - Enable rebalancing the anchor interface assignment.
- **tx-queue** - Configure transmit queue parameters:
  - **allocation always** - Configure the VOQ allocation policy to set unconditional VOQ allocation for all subinterfaces.
  - **count [4 | 8]** - Configure the number of transmit queues per subinterface to 4 or 8 transmit queues.

Example

Use the following command to set the QoS port channel as load balancing:

```
switch(config)# qos subinterface port-channel load-balancing
switch(config)#
```

10.1.19.38 qos subinterface scheduling

The **qos subinterface** command in the Global Configuration Mode configures subinterface scheduling behaviors for Quality of Service (QoS).

The **[no | default]** versions of the command disable the feature and remove the configuration from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

qos subinterface scheduling [parent round-robin] [priority propagation]

no qos subinterface

default qos subinterface

Parameters

- **qos subinterface scheduling** - Configure QoS subinterface scheduling behavior for an interface.
- **parent** - Configure parent interface parameters:
  - **round-robin** - Configure round robin scheduling between subinterfaces and the parent interface.
- **priority** - Configure scheduling priority:
  - **propagation** - Configure scheduling of traffic classes across subinterfaces with priority propagation.

Example

Use the following command to configure a QoS subinterface with round robin scheduling:

```
switch(config)# qos subinterface scheduling parent round-robin
switch(config)#
```

10.1.19.39 qos trust

The **qos trust** command configures the quality of service port trust mode for the configuration mode interface. Trust-enabled ports classify traffic by examining the traffic's CoS or DSCP value. Port trust mode default setting is **cos** for switched interfaces and **dscp** for routed interfaces.

The **default qos trust** command restores the default trust mode on the configuration mode interface by removing the corresponding **qos trust** or **no qos trust** statement from ***running-config***.

The **no qos trust** command performs the following:

- **no qos trust** places the port in ***untrusted*** mode.
- **no qos trust cos** removes the corresponding **qos trust cos** statement.
- **no qos trust dscp** removes the corresponding **qos trust dscp** statement.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`qos trust` [**MODE**]

`no qos trust` [**MODE**]

`default qos trust`

Parameters

- ***MODE*** Trust mode assigned to the port. Options include:
  - **cos** Enables cos trust mode.
  - **dscp** Enables dscp trust mode.

Examples

- This command configures trust mode of dscp for ***interface ethernet 7***.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# qos trust dscp
switch(config-if-Et7)# show active
interface Ethernet7
   qos trust dscp
switch(config-if-Et7)#
```

- This command configures trust mode of untrusted for ***Port Channel interface 23***.

```
switch(config)# interface port-channel 23
switch(config-if-Po23)# no qos trust
switch(config-if-Po23)# show active
interface Port-Channel23
   no qos trust
switch(config-if-Po23)#
```

10.1.19.40 random-detect ecn (Arad/Jericho)

The **random-detect ecn** command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes. Hosts can advertise their ECN capabilities in the ToS DiffServ field's two least significant bits:

- **00** Non ECN Capable transport.
- **10** ECN Capable transport.
- **01** ECN Capable transport.
- **11** Congestion encountered.

Congestion is determined by comparing average queue size with queue thresholds. Average queue size is calculated through a formula based on the previous average and current queue size. Packets are marked based on this average size and the specified thresholds:

- Average queue size below minimum threshold: Packets are queued normally.
- Average queue size above maximum threshold: Packets are marked **congestion encountered**.
- Average queue size between minimum and maximum thresholds. Packets are queued or marked **congestion encountered**. The proportion of marked packets varies linearly with average queue size:
  - 0% are marked when average queue size is less than or equal to minimum threshold.
  - 100% are marked when average queue size is greater than or equal to maximum threshold.

  When transmitted packets are marked **Non ECN Capable**, congestion packets are dropped, not marked.

The **no random-detect ecn** and **default qos random-detect ecn** commands disables ECN marking for the shared buffer by removing the **qos random-detect ecn** command from ***running-config***.

Command Mode

Tx-Queue configuration

Command Syntax

`random-detect ecn` minimum-threshold [**MIN** | **MAX**]| maximum-threshold [**MIN** | **MAX**]

`no random-detect ecn`

`default random-detect ecn`

Parameters

MIN and **MAX** parameters must use the same data unit.

- **MIN** Minimum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***256*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***256000*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***256000000*** **bytes** - Specify the number of Byte units.
- **MAX** Maximum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***256*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***256000*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***256000000*** **bytes** - Specify the number of Byte units.

Related Command

tx-queue (Arad/Jericho) places the switch in tx-queue configuration mode.

Example

These commands enable ECN marking of unicast packets from ***unicast transmit queue 4*** of ***interface Ethernet 3/5/1***, setting thresholds at ***128*** kbytes and ***1280*** kbytes.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 4
switch(config-if-Et3/5/1-txq-4)# random-detect ecn minimum-threshold 128 kbytes
maximum-threshold 1280 kbyte
switch(config-if-Et3/5/1-txq-4)# show active
interface Ethernet3/5/1
   tx-queue 4
      random-detect ecn minimum-threshold 128 kbytes maximum-threshold 1280 kbytes
switch(config-if-Et3/5/1-txq-4)#
```

10.1.19.41 random-detect ecn (Helix)

The **random-detect ecn** command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes. Hosts can advertise their ECN capabilities in the ToS DiffServ field's two least significant bits:

- **00** Non ECN Capable transport.
- **10** ECN Capable transport.
- **01** ECN Capable transport.
- **11** Congestion encountered.

Congestion is determined by comparing average queue size with queue thresholds. Average queue size is calculated through a formula based on the previous average and current queue size. Packets are marked based on this average size and the specified thresholds:

- Average queue size below minimum threshold: Packets are queued normally.
- Average queue size above maximum threshold: Packets are marked **congestion encountered**.
- Average queue size between minimum and maximum thresholds. Packets are queued or marked **congestion encountered**. The proportion of marked packets varies linearly with average queue size:
  - ***0%*** are marked when average queue size is less than or equal to minimum threshold.
  - ***100%*** are marked when average queue size is greater than or equal to maximum threshold.

  When transmitted packets are marked Non ECN Capable, congestion packets are dropped, not marked.

  Average queue length is tracked for transmit queues and the global pool independently. When either entity reaches its maximum threshold, all subsequent packets are marked.

The **no random-detect ecn** and **default random-detect ecn** commands disable ECN marking on the configuration mode queue, deleting the corresponding **random-detect ecn** command from ***running-config***.

Command Mode

Tx-Queue configuration

Command Syntax

`random-detect ecn` minimum-threshold [**MIN** | **MAX**] maximum-threshold [**MIN** | **MAX**]

`no random-detect ecn`

```
default random-detect ecn
```

Parameters

MIN and **MAX** parameters must use the same data unit.

- **MIN** Minimum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***46080*** **segments** - Specify the number of 208-byte segments units.
  - ***1*** to ***9*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***9584*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***9584640*** **bytes** - Specify the number of Byte units.
- **MAX** Maximum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***46080*** **segments** - Specify the number of 208-byte segments units.
  - ***1*** to ***9*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***9584*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***9584640*** **bytes** - Specify the number of Byte units.

Related Commands

- tx-queue (Helix) places the switch in tx-queue configuration mode.
- qos random-detect ecn global-buffer (Helix) enables ECN marking for globally shared packet memory.

Examples

- These commands enable ECN marking of unicast packets from ***transmit queue 4*** of ***interface ethernet 15***, setting thresholds at ***10*** and ***100*** segments.

```
switch(config)# interface ethernet 15
switch(config-if-Et15)# uc-tx-queue 4
switch(config-if-Et15-txq-4)# random-detect ecn minimum-threshold 10 segments
maximum-threshold 100 segments
switch(config-if-Et15-txq-4)# show active
interface Ethernet15
   tx-queue 4
      random-detect ecn minimum-threshold 10 segments maximum-threshold 100
segments
switch(config-if-Et15-txq-4)# exit
switch(config-if-Et15)
```

- This command disables ECN marking of unicast packets from ***transmit queue 4*** of ***interface ethernet 15***.

```
switch(config-if-Et15-txq-4)# no random-detect ecn
switch(config-if-Et15-txq-4)# show active
```

```
interface Ethernet15
switch(config-if-Et15-txq-4)# exit
switch(config-if-Et15)#
```

10.1.19.42 random-detect ecn (Trident and Tomahawk)

The **`random-detect ecn`** command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes. Hosts can advertise their ECN capabilities in the ToS DiffServ field's two least significant bits:

- **00** Non ECN Capable transport.
- **10** ECN Capable transport.
- **01** ECN Capable transport.
- **11** Congestion encountered.

Congestion is determined by comparing average queue size with queue thresholds. Average queue size is calculated through a formula based on the previous average and current queue size. Packets are marked based on this average size and the specified thresholds:

- Average queue size below minimum threshold: Packets are queued normally.
- Average queue size above maximum threshold: Packets are marked **`congestion encountered`**.
- Average queue size between minimum and maximum thresholds. Packets are queued or marked **`congestion encountered`**. The proportion of marked packets varies linearly with average queue size:
  - ***0%*** are marked when average queue size is less than or equal to minimum threshold.
  - ***100%*** are marked when average queue size is greater than or equal to maximum threshold.

  When transmitted packets are marked **`Non ECN Capable`**, congestion packets are dropped, not marked.

  Average queue length is tracked for transmit queues and the global pool independently. When either entity reaches its maximum threshold, all subsequent packets are marked.

The **`no random-detect ecn`** and **`default random-detect ecn`** commands disable ECN marking on the configuration mode queue, deleting the corresponding **`random-detect ecn`** command from ***running-config***.

Command Mode

Uc-Tx-Queue configuration

Command Syntax

`random-detect ecn` minimum-threshold [**MIN** | **MAX**] maximum-threshold [**MIN** | **MAX**]

```
no random-detect ecn

default random-detect ecn
```

Parameters

MIN and **MAX** parameters must use the same data unit.

- **MIN** Minimum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***46080*** **segments** - Specify the number of 208-byte segments units.
  - ***1*** to ***9*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***9584*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***9584640*** **bytes** - Specify the number of Byte units.
- **MAX** Maximum threshold. Options include:
  - ***1*** **to** ***100*** - Specify the threshold value in percent.
  - ***1*** to ***46080*** **segments** - Specify the number of 208-byte segments units.
  - ***1*** to ***9*** **mbytes** - Specify the number of Megabyte units.
  - ***1*** to ***9584*** **kbytes** - Specify the number of Kilobyte units.
  - ***1*** to ***9584640*** **bytes** - Specify the number of Byte units.

Related Commands

- uc-tx-queue places the switch in the ***uc-tx-queue*** configuration mode.
- qos random-detect ecn global-buffer (Trident and Tomahawk) enables ECN marking for globally shared packet memory.

Examples

- These commands enable ECN marking of unicast packets from ***unicast transmit queue 4*** of ***interface ethernet 15***, setting thresholds at ***10*** and ***100*** segments.

```
switch(config)# interface ethernet 15
switch(config-if-Et15)# uc-tx-queue 4
switch(config-if-Et15-uc-txq-4)# random-detect ecn minimum-threshold 10 segments
maximum-threshold 100 segments
switch(config-if-Et15-uc-txq-4)#show active
interface Ethernet15
   uc-tx-queue 4
      random-detect ecn minimum-threshold 10 segments maximum-threshold 100
segments
switch(config-if-Et15-uc-txq-4)# exit
switch(config-if-Et15)#
```

- This command disables ECN marking of unicast packets from ***unicast transmit queue 4*** of ***interface ethernet 15***.

```
switch(config-if-Et15-uc-txq-4)# no random-detect ecn
switch(config-if-Et15-uc-txq-4)# show active
interface Ethernet15
switch(config-if-Et15-uc-txq-4)# exit
switch(config-if-Et15)#
```

10.1.19.43 random-detect ecn delay threshold

The **random-detect ecn delay threshold** command configures latency-based ECN on a per transmit queue basis.

The **[no|default]** version of the command disables the configuration and deletes the **random-detect ecn delay threshold** from the **running-config**.

Command Mode

Interface Configuration

Command Syntax

```
random-detect ecn delay threshold [microseconds | milliseconds ]
```

Parameters

- **random-detect** - Set WRED-based congestion control parameters.
- **ecn** - Set ECN parameters.
- **delay** - Set the delay parameter.
- **threshold** - Configure the threshold to trigger latency-based ECN.
  - ***microseconds*** - Configure a value from 1 to 4294967 microseconds.
  - ***milliseconds*** - Configure a value from 1 to 4294 milliseconds.

Example

Use the following commands to configure transmit queue 1 on Ethernet 1/1 for latency-based ECN:

```
switch(config)# interface Ethernet 1/1
switch(config-if-Et1/1)# tx-queue 3
switch(config-if-Et1/1-txq-3)# random-detect ecn delay threshold 33 milliseconds
```

10.1.19.44 service-policy type qos input

The **service-policy type qos input** command applies the specified policy map to a QoS profile. The profile is then applied to an interface in interface configuration mode using the service-profile command.

The **no service-policy type qos** and **default service-policy type qos** command deletes the policy map from the profile.

The **exit** command returns the switch to global configuration mode.

Command Mode

QoS Profile Configuration

Command Syntax

service-policy type qos input ***policy_map_name***

no service-policy type qos input ***policy_map_name***

default service-policy type qos input ***policy_map_name***

Parameter

policy_map_name - Specify a QoS policy map name.

Example

This command applies the policy map ***PM-1*** to the QoS profile ***TP***.

```
switch(config-qos-profile-TP)# service-policy type qos input PM-1
switch(config-qos-profile-TP)#
```

10.1.19.45 service-profile

The command applies the QoS profile to the configuration mode interface.

The **`no service-profile`** and the **`default service-profile`** command removes the QoS profile from the interface.

The **`exit`** command returns the switch to global configuration mode.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`service-profile` *profile_name*

`no service-profile` *profile_name*

`default service-profile` *profile_name*

Parameter

profile_name QoS profile name.

Example

This commands applies the QoS profile ***TP*** to ***interfaceethernet 13***.

```
switch(config)# interface ethernet 13
switch(config-if-Et13)# service-profile TP
```

10.1.19.46 set extcommunity

The **`set extcommunity`** command adds a color extended community to be applied to routes affected by the route-map. Multiple set clauses can be applied to a single route-map to configure multiple colors for routes. Negating the command removes the entry from the route-map.

Command Mode

Config-route-map mode

Command Syntax

`set extcommunity` **COLOR-EXPRESSION** [additive | delete]

`no set extcommunity` **COLOR-EXPRESSION** [additive | delete]

`default set extcommunity` **COLOR-EXPRESSION** [additive | delete]

Parameters

- **COLOR-EXPRESSION** The color extended community to be applied to routes affected by the route-map.
- **additive** Adds the extended communities to those received.
- **delete** Deletes any matching extended color communities.

Example

```
switch(config)# route-map foo
switch(config-route-map foo)# set extcommunity color 1
switch(config-route-map foo)# set extcommunity color 2 color-only exact-match
switch(config-route-map foo)# set extcommunity color 3 color-only endpoint-match null
switch(config-route-map foo)# set extcommunity color 4 color-only endpoint-match any
```

10.1.19.47 shape rate (Interface – Arad/Jericho)

The **`shape rate`** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Tx-queue – Arad/Jericho) command. By default, outbound transmission rate is not bounded by a shape rate.

The **`no shape rate`** and **`default shape rate`** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **`shape rate`** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` *byte_limit* [kbps]

`no shape rate`

`default shape rate`

Parameters

byte_limit Shape rate applied to interface (Kbps). Value ranges from ***162*** to ***100000000***.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 3/5/1***.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# shape rate 5000000
switch(config-if-Et3/5/1)# show qos interfaces ethernet 3/5/1

Ethernet3/5/1:

   Port shaping rate: 5000012 / 5000000 kbps

  Tx    Bandwidth       Shape Rate        Priority  ECN
 Queue  (percent)         (units)
   ------------------------------------------------------
   7      - / -        - / -    (  -  )    SP / SP    D
   6      - / -        - / -    (  -  )    SP / SP    D
   5      - / -        - / -    (  -  )    SP / SP    D
   4      - / -        - / -    (  -  )    SP / SP    D
   3      - / -        - / -    (  -  )    SP / SP    D
   2      - / -        - / -    (  -  )    SP / SP    D
   1      - / -        - / -    (  -  )    SP / SP    D
   0      - / -        - / -    (  -  )    SP / SP    D
```

```
switch(config-if-Et3/5/1)#
```

10.1.19.48 shape rate (Interface – FM6000)

The **shape rate** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Tx-queue – FM6000) command. By default, outbound transmission rate is not bounded by a shape rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` *byte_limit* [kbps]

`no shape rate`

`default shape rate`

Parameter

byte_limit Shape rate applied to interface (Kbps). Value ranges from ***7000*** to ***10000000***.

Guidelines

Enabling port shaping on an FM6000 interface disables queue shaping internally. Disabling port shaping restores queue shaping as specified in ***running-config***.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# shape rate 5000000
switch(config-if-Et5)#
```

10.1.19.49 shape rate (Interface – Helix)

The **shape rate** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Interface – Helix) command. By default, outbound transmission rate is not bounded by a shape rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` **DATA_LIMIT**

`no shape rate`

`default shape rate`

Parameters

- **DATA_LIMIT** Shape rate applied to interface. Value range varies with data unit:
  - ***8*** to ***40000000*** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***40000000*****kbps** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***60000000*****pps** ***8*** to ***60000000*** packets per second.

Guidelines

Shaping rates of at least ***8*** kbps are supported. At shaping rates smaller than ***1*** Mbps, granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 17***.

```
switch(config)# interface ethernet 17
switch(config-if-Et17)# shape rate 5000000 kbps
switch(config-if-Et17)# show qos interface ethernet 17/3
```

```
Ethernet17:
   Trust Mode: COS
   Default COS: 0
   Default DSCP: 0

   Port shaping rate: 5000000 / 5000000 kbps

  Tx       Bandwidth                 Shape Rate        Priority
 Queue     Guaranteed (units)         (units)
   ---------------------------------------------------------------
   7        - / -    (  -  )       - / -    (  -  )    SP / SP
   6        - / -    (  -  )       - / -    (  -  )    SP / SP

switch(config-if-Et17)#
```

10.1.19.50 shape rate (Interface – Petra)

The **`shape rate`** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Tx-queue – Petra) command. By default, outbound transmission rate is not bounded by a shape rate.

The **`no shape rate`** and **`default shape rate`** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **`shape rate`** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` *data_limit* [kbps]

`no shape rate`

`default shape rate`

Parameters

data_limit Shape rate applied to interface (Kbps). Value ranges from ***100*** to ***10000000***.

Guidelines

The following port shaping rates are supported:

- 1G ports: above 100 kbps.
- 10G ports: above 7900 kbps.

Commands that specify a smaller shape rate disable port shaping on the interface.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 3/3***.

```
switch(config)# interface ethernet 3/3
```

```
switch(config-if-Et3/3)# shape rate 5000000
switch(config-if-Et3/3)# show active
interface Ethernet3/3
   shape rate 5000000
switch(config-if-Et3/3)#
```

10.1.19.51 shape rate (Interface – Trident and Tomahawk)

The **shape rate** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Tx-queue – Trident and Tomahawk) command. By default, outbound transmission rate is not bounded by a shape rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` **DATA_LIMIT**

`no shape rate`

`default shape rate`

Parameters

- **DATA_LIMIT** Shape rate applied to interface. Value range varies with data unit:
  - ***8*** to ***40000000*** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to 40000000**kbps** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***60000000*****pps** ***8*** to ***60000000*** packets per second.

Guidelines

Shaping rates of at least ***8*** kbps are supported. At shaping rates smaller than ***1*** Mbps, granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# shape rate 5000000
switch(config-if-Et5)#
```

10.1.19.52 shape rate (Interface – Trident II)

The **shape rate** command specifies the maximum bandwidth for outbound traffic on the configuration mode interface, also known as queue shaping. The shape rate for individual transmit queues is configured by the shape rate (Tx-queue – Trident II) command. By default, outbound transmission rate is not bounded by a shape rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the configuration mode interface by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`shape rate` **DATA_LIMIT**

`no shape rate`

`default shape rate`

Parameters

DATA_LIMIT Shape rate applied to interface. Value range varies with data unit:

- - ***8*** to ***40000000*** **kbps** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***40000000*** **kbps** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***60000000*** **pps** ***8*** to ***60000000*** packets per second.

Guidelines

Shaping rates of at least ***8*** kbps are supported. At shaping rates smaller than 1 Mbps, granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

Example

This command configures a port shape rate of ***5*** Gbps on ***interface ethernet 17/3***.

```
switch(config)# interface ethernet 17/3
```

```
switch(config-if-Et17/3)# shape rate 5000000 kbps
switch(config-if-Et17/3)# show qos interface ethernet 17/3

Ethernet17/3:
   Trust Mode: COS
   Default COS: 0
   Default DSCP: 0

   Port shaping rate: 5000000 / 5000000 kbps

  Tx       Bandwidth                 Shape Rate        Priority
 Queue     Guaranteed (units)         (units)
   ------------------------------------------------------------
   7        - / -    (  -  )       - / -    (  -  )    SP / SP
   6        - / -    (  -  )       - / -    (  -  )    SP / SP

switch(config-if-Et17/3)#
```

10.1.19.53 shape rate (Tx-queue – Arad/Jericho)

The **shape rate** command specifies the maximum bandwidth for outbound traffic on the transmit queue, also known as queue shaping. The shape rate for interfaces is configured by the shape rate (Interface – Arad/Jericho) command. By default, the configured outbound transmission rate is not bounded by a transmit queue shape rate.

Shaping rates greater than ***50000*** kbps are supported. At lower shaping rates (less than ***10*** Mbps), granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the configuration mode queue by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`shape rate` *byte_limit* [kbps]

`no shape rate`

`default shape rate`

Parameters

byte_limit Shape rate applied to interface (Kbps). Value ranges from ***50000*** to ***100000000***.

Related Command

tx-queue (Arad/Jericho) places the switch in tx-queue configuration mode.

Related Information

shape rate (Interface – Arad/Jericho)

Example

These commands configure a shape rate of ***1*** Gbps on transmit queues ***3*** and ***4*** of ***interface ethernet 3/4/1***.

```
switch(config)# interface ethernet 3/4/1
switch(config-if-Et3/4/1)# tx-queue 4
```

```
switch(config-if-Et3/4/1-txq-4)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-4)# tx-queue 3
switch(config-if-Et3/4/1-txq-3)# shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-3)# show qos interface ethernet 3/4/1

Ethernet3/4/1:

   Port shaping rate: disabled

  Tx    Bandwidth       Shape Rate        Priority  ECN

10.1.19.54 shape rate (Tx-queue – FM6000)

The **shape rate**command specifies the maximum bandwidth for outbound traffic on the transmit queue, also known as queue shaping. The shape rate for interfaces is configured by the shape rate (Interface – FM6000) command. By default, the configured outbound transmission rate is not bounded by a transmit queue shape rate.

Queue shaping on an FM6000 port is supported only when port shaping is not enabled on the interface. Enabling port shaping on a port disables queue shaping internally. Disabling port shaping restores queue shaping as specified by ***running-config***.

Shaping rates greater than ***460*** kbps are supported. At lower shaping rates (less than ***10*** Mbps), granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

The **no shape rate** and **default shape rate** commands remove the shape rate bandwidth limit on the transmit queue by deleting the corresponding **shape rate** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`shape rate` *byte_limit* [kbps]

`no shape rate`

`default shape rate`

Parameters

byte_limit Shape rate applied to interface (Kbps). Value ranges from ***464*** to ***10000000***.

Related Commands

- tx-queue (FM6000) places the switch in tx-queue configuration mode.
- shape rate (Interface – FM6000) configures the shape rate for a configuration mode interface.

Example

These commands configure a shape rate of ***1*** Gbps (***1,000,000*** Kbps) on transmit queues ***3*** and ***4*** of ***interface ethernet 19***.

```
switch(config)# interface ethernet 19
switch(config-if-Et19)# tx-queue 4
```

```
switch(config-if-Et19-txq-4)# shape rate 1000000
switch(config-if-Et19-txq-4)# tx-queue 3
switch(config-if-Et19-txq-3)# shape rate 1000000
switch(config-if-Et19-txq-3)# show qos interface ethernet 19

Ethernet19:
   Trust Mode: COS

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------
          6         N/A     disabled        strict
          5         N/A     disabled        strict
          4         N/A      1000000        strict
          3          25      1000000   round-robin
          2          25     disabled   round-robin
          1          25     disabled   round-robin
          0          25     disabled   round-robin

switch(config-if-Et19-txq-3)#
```

10.1.19.55 shape rate (Tx-queue – Helix)

The **`shape rate`** command specifies the maximum bandwidth for outbound traffic on the transmit queue, also known as queue shaping. The shape rate for interfaces is configured by the shape rate (Interface – Helix) command. By default, the configured outbound transmission rate is not bounded by a transmit queue shape rate.

The **`no shape rate`** and **`default shape rate`** commands remove the shape rate bandwidth limit on the configuration mode transmit queue by deleting the corresponding **`shape rate`** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`shape rate` *byte_limit* [kbps]

`no shape rate`

`default shape rate`

Parameters

DATA_LIMIT Shape rate applied to the queue. Value range varies with data unit:

- • ***8*** to ***40000000*** ***8*** to 40,000,000 kbytes per second.
  - ***8*** to ***40000000*** **kbps** ***8*** to ***40000000*** kbytes per second.
  - ***8*** to ***60000000*** **pps** ***8*** to ***60000000*** packets per second.

Restrictions

Queue shaping is not supported in cut-through mode.

Related Commands

- tx-queue (Helix) places the switch in ***tx-queue*** configuration mode.
- shape rate (Interface – Helix) configures the shape rate for a configuration mode interface.

Example

These commands configure a shape rate of ***1*** Gbps (***1,000,000*** Kbps) on transmit queues ***3*** and ***4*** of ***interface Eethernet 17/3***.

```
switch(config)# interface ethernet 17/3
switch(config-if-Et17/3)# tx-queue 4
switch(config-if-Et17/3-txq-4)# shape rate 1000000 kbps
switch(config-if-Et17/3-txq-4)# tx-queue 3
switch(config-if-Et17/3-txq-3)# shape rate 1000000 kbps

10.1.19.56 shape rate (Tx-queue – Petra)

The **`shape rate`** command specifies the maximum bandwidth for outbound traffic on the configuration mode transmit queue, also known as queue shaping. The shape rate for interfaces is configured by the shape rate (Interface – Petra) command. By default, the configured outbound transmission rate is not bounded by a transmit queue shape rate.

Queue shaping applies only to unicast traffic. Shaping rates of at least 162 Kbps are supported.

The **`no shape rate`** and **`default shape rate`** commands remove the shape rate bandwidth limit on the configuration mode queue by deleting the corresponding **`shape rate`** command from ***running-config***.

Command Mode

Tx-Queue Configuration

Command Syntax

`shape rate` **DATA_LIMIT**

`no shape rate`

`default shape rate`

Parameters

DATA_LIMIT Shape rate applied to the queue. Value range varies with data unit:

- ***8*** to ***40000000*** **kbps** Range is from ***8*** to ***40000000*** kbytes per second.
- ***8***to ***60000000*****pps** Range is from ***8*** to ***60000000*** packets per second.

Shaping rates greater than ***460*** kbps are supported. At lower shaping rates (less than ***10*** Mbps), granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

Related Commands

- tx-queue (Petra) places the switch in ***tx-queue*** configuration mode.
- shape rate (Interface – Petra) configures the shape rate for a configuration mode interface.

Example

These commands configure a shape rate of ***1*** Gbps (***1,000,000*** Kbps) on transmit queues ***3*** and ***4*** of ***interface ethernet 3/28***.

```
switch(config)# interface ethernet 3/28
switch(config-if-Et3/28)# tx-queue 4
switch(config-if-Et3/28-txq-4)# shape rate 1000000
switch(config-if-Et3/28-txq-4)# tx-queue 3
switch(config-if-Et3/28-txq-3)# shape rate 1000000
switch(config-if-Et3/28-txq-3)# show qos interface ethernet 3/28

Ethernet3/28:

   Tx-Queue   Bandwidth    Shape Rate     Priority
              (percent)       (Kbps)
   ------------------------------------------------
          7         N/A     disabled        strict
          6         N/A     disabled        strict
          5         N/A     disabled        strict
          4         N/A      1000000        strict
          3          25      1000000   round-robin
          2          25     disabled   round-robin
          1          25     disabled   round-robin

10.1.19.57 shape rate (Tx-queue – Trident and Tomahawk)

The **`shape rate`** command specifies the maximum bandwidth for outbound traffic on the configuration mode transmit queue, also known as queue shaping. The shape rate for interfaces is configured by the shape rate (Interface – Trident and Tomahawk) command. By default, the configured outbound transmission rate is not bounded by a transmit queue shape rate.

The **`no shape rate`** and **`default shape rate`** commands remove the shape rate limit from the configuration mode transmit queue by deleting the corresponding **`shape rate`** command from ***running-config***.

Command Mode

Mc-Tx-Queue configuration

Uc-Tx-Queue configuration

Command Syntax

`shape rate` **DATA_LIMIT**

`no shape rate`

`default shape rate`

Parameters

DATA_LIMIT Shape rate applied to the queue. Value range varies with data unit:

- ***8*** to ***40000000*** **kbps** Range is from ***8*** to ***40000000*** kbytes per second.
- ***8*** to ***60000000*** **pps** Range is from ***8*** to ***60000000*** packets per second.

Related Commands

- mc-tx-queue places the switch in ***mc-tx-queue*** configuration mode.
- uc-tx-queue places the switch in ***uc-tx-queue*** configuration mode.
- shape rate (Interface – Trident and Tomahawk) configures the shape rate for a configuration mode interface.

Guidelines

Shaping rates of at least ***8*** kbps are supported. At shaping rates smaller than ***1*** Mbps, granularity and rounding errors may skew the actual shaping rate by ***20%*** from the specified rate.

When two queues source traffic from the same traffic class and the higher priority queue is shaped, that queue consumes all internal buffers, starving the lower priority queue even if bandwidth is available.

Example

These commands configure a shape rate of ***1*** Gbps (***1,000,000*** Kbps) on ***unicast transmit queues 3*** and ***multicast transmit 4*** of ***interface ethernet 7***.

```
switch(config)# interface ethernet 7
switch(config-if-Et7)# uc-tx-queue 3
switch(config-if-Et7-uc-txq-3)# shape rate 1000000
switch(config-if-Et7-uc-txq-3)# mc-tx-queue 2
switch(config-if-Et7-mc-txq-2)# shape rate 1000000
switch(config-if-Et7-mc-txq-2)# show qos interface ethernet 7

Ethernet7:
   Tx-Queue   Bandwidth    Shape Rate     Priority   Priority Group
              (percent)       (Kbps)
   ------------------------------------------------------------------
        UC7         N/A     disabled        strict                1
        UC6         N/A     disabled        strict                1
        MC3         N/A     disabled        strict                1
        UC5         N/A     disabled        strict                0
        UC4         N/A     disabled        strict                0
        MC2         N/A      1000000        strict                0
        UC3          20      1000000   round-robin                0
        UC2          16     disabled   round-robin                0
        MC1          16     disabled   round-robin                0

10.1.19.59 show interface counters queue drop-precedence

The **show interface counters queue drop-precedence** command displays the drop-precedence counters.

Command Mode

EXEC

Command Syntax

```
show interface counters queue drop-precedence
```

Example

This command displays the drop precedence counts on two interfaces.

```
switch# show interface counters queue drop-precedence
intf        0          1          2
Et1/1     100          0        200
Et1/2     200          0        300 switch#
```

10.1.19.60 show platform petraA traffic-class

The **`show platform petraA traffic-class`** command displays the traffic class assignment on all specified Petra chips. Each chip controls eight Ethernet interfaces. The default traffic class of an interface is specified by the traffic class assigned to the chip that controls the interface.

Traffic class assignments are configured with the platform petraA traffic-class command.

Valid command options include:

- **show platform petraA traffic-class** Traffic class of all chips on all linecard.
- **show platform petraA CHIP_NAME traffic-class** Traffic class of specified chip.
- **show platform petraA MODULE_NAME traffic-class** Traffic class of all chips on specified linecard.

Command Mode

EXEC

Command Syntax

```
show platform petraA traffic-class

show platform petraA CHIP_NAME traffic-class

show platform petraA MODULE_NAME traffic-class
```

Parameters

- **CHIP_NAME** Name of Petra chip on linecard that control Ethernet ports. Options include:
  - **petra *cardX* / *chipY*** All ports on PetraA chip ***chipY*** on linecard ***cardX*** (7500 Series).
  - **petra *chipZ*** All ports on PetraA chip ***chipZ*** (7048 Series).

7500 Series

Switches can contain up to eight linecards. ***cardX*** varies from ***3*** to ***10***.

Each linecard contains six PetraA chips. Each chip controls eight ports. ***chipY*** varies from ***0*** to ***5***:

- 0 controls ports 1 through 8
- 1 controls ports 9 through 16
- 2 controls ports 17 through 24
- 3 controls ports 25 through 32
- 4 controls ports 33 through 40

- 5 controls ports 41 through 48

7048 Series

Each switch contains two PetraA chips. ***chipZ*** varies from ***0*** to ***1***:

- 0 controls ports 1 through 32
- 1 controls ports 33 through 52

- **MODULE_NAME** Name and number of linecard (7500 Series). Options include:
  - **module linecard *mod_num*** Linecard number (***3*** to ***10***).
  - **module *mod_num*** Linecard number (***3*** to ***10***).

Related Command

platform petraA traffic-class configures the default traffic class used by all ports on a specified chip.

Example

This command displays the traffic class of all chips on ***linecard 3***.

```
switch# show platform petraA module linecard 3 traffic-class
Petra3/0 traffic-class: 1
Petra3/1 traffic-class: 1
Petra3/2 traffic-class: 1
Petra3/3 traffic-class: 1
Petra3/4 traffic-class: 5
Petra3/5 traffic-class: 1 switch#
```

10.1.19.61 show platform trident tcam qos detail

The **show platform trident tcam qos detail** command displays the list of all the SVIs that are sharing the TCAM entries.

Command Mode

EXEC

Command Syntax

```
show platform trident tcam qos detail
```

Example

This command displays the list of all the SVIs that are sharing the TCAM entries.

```
switch(config)# show platform trident tcam qos detail

=== Policy-map p01 type qos on switch Linecard0/0 ===
Interfaces : Vlan2 Vlan1
=-= Interface BitMap =-=
0x00000000000000001FFFFFE
```

10.1.19.62 show platform trident tcam shared vlan interface-class-id

The **`show platform trident tcam shared vlan interface-class-id`** command displays what SVIs are currently sharing the QoS policy-map in the below output under QoS PMAP Data.

Command Mode

EXEC

Command Syntax

```
show platform trident tcam shared vlan interface-class-id
```

Example

This command displays what SVIs are currently sharing the QoS policy-map in the below output under QoS PMAP Data.

```
switch(config)# show platform trident tcam shared vlan interface-class-id

=== Shared RACL Data on switch Linecard0/0 ===
=== Shared QoS Policy-map Data on switch Linecard0/0 ===
Interface Class Id             VLANs
1                               1 2
```

10.1.19.63 show platform xp qos tcam hit

The **`show platform xp qos tcam hit`** command displays the TCAM entries programmed for each policy-map as well as the traffic hits. The hits option is used to see the TCAM entries with nonzero traffic hits.

Command Mode

EXEC

Command Syntax

```
show platform xp qos tcam hit
```

Example

This command displays the QoS TCAM hits on ***interface ethernet 10/1***.

```
switch# show platform xp qos tcam hit

```

10.1.19.64 show policy-map interface

The **show policy-map interface** command displays contents of the policy map applied to specified the interface.

Command Mode

EXEC

Command Syntax

`show policy-map interface` *interface_name*

Parameters

interface_name Interface for which command returns data. Options include:

- ***no parameter*** Returns data for all interfaces.
- ethernet ***e_range*** Ethernet interfaces specified by ***e_range***.
- **port-channel *p_range*** Port channel interfaces specified by ***p_range***.

Example

This command displays the name and contents of the policy map applied to ***interface Ethernet 1***.

```
switch# show policy-map interface ethernet 1
Service-policy input: p1
 Hardware programming status: Successful

 Class-map: c2001 (match-any)
    Match: vlan 2001 0xfff
       set dscp 4

 Class-map: c2002 (match-any)
    Match: vlan 2002 0xfff
       set dscp 8

 Class-map: c2003 (match-any)
    Match: vlan 2003 0xfff
       set dscp 12
```

10.1.19.65 show policy-map

The **show policy-map** command displays the policy map information for the configured policy map.

Command Mode

EXEC

Command Syntax

`show policy-map` *policy_map_name* [counters][interface | summary]

Parameters

- ***policy_map_name*** QoS policy map name.
- **counters** Specifies the policy map traffic match count (This parameter is applicable only on DCS-7010, DCS-7050X, DCS7250X, DCS-7300X and DCS-7280(E/R), DCS-7500(E/R) series switches.)
- **interface** Specifies the service policy on an interface.
- **summary** Policy map summary.

Examples

- The **show policy-map command** displays the information for the policy map ***policy1***.

```
switch# show policy-map policy1
Service-policy policy1
Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes
Class-map: class-default (match-any)
```

- The **show policy-map counters** command displays the policy map traffic match count for the policy map configured.

```
switch# show policy-map policy1 counters

Service-policy input: policy1
 Hardware programming status: Successful
 Class-map: class1 (match-any)
    Match: vlan 20-40,1000-1250
       police rate 100 mbps burst-size 100 kbytes
        Interface: Ethernet16/1
          Conformed 28621 packets, 7098008 bytes -------------- packet match count

Class-map: class-default (match-any)
      Matched Packets: 19 -------------- packet match count
```

10.1.19.66 show qos interfaces random-detect ecn

The **show qos interfaces random-detect ecn** command displays the Explicit Congestion Notification (ECN) configuration for each transmit queue on the specified interfaces.

Command Mode

EXEC

Command Syntax

`show qos interfaces` [**INTERFACE_NAME**] `random-detect ecn`

Parameters

INTERFACE_NAME Interface for which command returns data. Options include:

- **no parameter** Returns data for all interfaces.
- **ethernet *e_range*** Ethernet interfaces specified by ***e_range***.
- **port-channel *p_range*** Port-Channel Interfaces specified by ***p_range***.

Example

This command configures ECN parameters for transmit queues ***0*** through ***3*** on ***interface ethernet 3/5/1***, then displays that configuration.

```
switch(config)# interface ethernet 3/5/1
switch(config-if-Et3/5/1)# tx-queue 0
switch(config-if-Et3/5/1-txq-0)# random-detect ecn minimum-threshold 2560 kbytes
maximum-threshold 256000 kbytes
switch(config-if-Et3/5/1-txq-0)# tx-queue 1
switch(config-if-Et3/5/1-txq-1)# random-detect ecn minimum-threshold 25600 kbytes
maximum-threshold 128000 kbytes
switch(config-if-Et3/5/1-txq-1)# tx-queue 2
switch(config-if-Et3/5/1-txq-2)# random-detect ecn minimum-threshold 25600 bytes
maximum-threshold 128000 bytes
switch(config-if-Et3/5/1-txq-2)# tx-queue 3
switch(config-if-Et3/5/1-txq-3)# random-detect ecn minimum-threshold 25 mbytes
maximum-threshold 128 mbytes
switch(config-if-Et3/5/1-txq-3)# show qos interfaces ethernet 3/5/1 random-detect
ecn

Ethernet3/5/1:

   Tx-Queue   Mininimum Threshold    Maximum Threshold    Threshold Unit
   --------------------------------------------------------------------
          7                     -                    -                 -
          6                     -                    -                 -
          5                     -                    -                 -
          4                     -                    -                 -
          3                    25                  128            mbytes
          2                 25600               128000             bytes
          1                 25600               128000            kbytes
          0                  2560               256000            kbytes

switch(config-if-Et3/5/1-txq-3)#
```

10.1.19.67 show qos interfaces trust

The **show qos interfaces trust** command displays the configured and operational QoS trust mode of all specified interfaces.

Command Mode

EXEC

Command Syntax

`show qos interfaces` [**INTERFACE_NAME**] `trust`

Parameters

INTERFACE_NAME Interface for which command returns data. Options include:

- **no parameter** Returns data for all interfaces.
- **ethernet *e_range*** Ethernet interfaces specified by ***e_range***.
- **port-channel *p_range*** Port-Channel Interfaces specified by ***p_range***.

Example

These commands configure a variety of QoS trust settings on a set of interfaces, then displays the QoS trust mode on these interfaces.

```
switch(config)# interface ethernet 1/1
switch(config-if-Et1/1)# qos trust cos
switch(config-if-Et1/1)# interface ethernet 1/2
switch(config-if-Et1/2)# qos trust dscp
switch(config-if-Et1/2)# interface ethernet 1/3
switch(config-if-Et1/3)# no qos trust
switch(config-if-Et1/3)# interface ethernet 1/4
switch(config-if-Et1/4)# default qos trust
switch(config-if-Et1/4)# interface ethernet 2/1
switch(config-if-Et2/1)# no switchport
switch(config-if-Et2/1)# default qos trust
switch(config-if-Et2/1)# show qos interface ethernet 1/1 - 2/4 trust

Port                                    Trust Mode
                                Operational           Configured
-------------------------------------------------------------------
Ethernet1/1                     COS                   COS
Ethernet1/2                     DSCP                  DSCP
Ethernet1/3                     UNTRUSTED             UNTRUSTED
Ethernet1/4                     COS                   DEFAULT
Ethernet2/1                     DSCP                  DEFAULT
Ethernet2/2                     COS                   DEFAULT
Ethernet2/3                     COS                   DEFAULT
Ethernet2/4                     COS                   DEFAULT

switch(config-if-Et2/1)#
```

10.1.19.68 show qos interfaces

The **show qos interfaces** command displays the QoS, DSCP, and transmit queue configuration on a specified interface. Information provided by this command includes the ports trust setting, the default CoS value, and the DSCP value.

Command Mode

EXEC

Command Syntax

show qos interfaces **INTERFACE_NAME**

Parameters

INTERFACE_NAME Interface For which command returns data. Options include:

- **no parameter** Returns data for all interfaces.
- **ethernet *e_num*** Ethernet interface specified by ***e_num***.
- **port-channel *p_num*** Port-Channel Interface specified by ***p_num***.

Example

This command lists the QoS configuration for ***interface ethernet 4***.

```
switch> show qos interfaces ethernet 4

Ethernet4:
   Trust Mode: COS
   Default COS: 0
   Default DSCP: 0

   Port shaping rate: 5000000Kbps

   Tx-Queue   Bandwidth    ShapeRate      Priority
              (percent)       (Kbps)
   ------------------------------------------------
          0          50     disabled   round-robin
          1          50     disabled   round-robin
          2         N/A     disabled        strict
          3         N/A      1000000        strict
          4         N/A      1000000        strict
          5         N/A      1500000        strict
          6         N/A      2000000        strict switch>
```

10.1.19.69 show qos interfaces latency maximum

The **`show qos interfaces latency maximum`** command displays the maximum latency tail-drop threshold active on each Tx queue for a specified interface.

Command Mode

EXEC

Command Syntax

`show qos interfaces` *INTERFACE_NAME* `latency maximum`

Parameters

INTERFACE_NAME: Name of the interface.

Example

This command lists the maximum latency for VOQ tail drop on ***interface ethernet 23/1***.

```
switch# show qos interfaces ethernet 23/1 latency maximum

Ethernet23/1:
Tx Queue            Maximum Latency
--------            ---------------
       7                          -
       6                          -
       5                          -
       4                          -
       3                      10 ms
       2                          -
       1                          -
       0                          -

switch# show qos profile
qos profile latency
    tx-queue 3
        latency maximum 4000 microseconds
    Tx-queue 4
        latency maximum 30 milliseconds
```

10.1.19.70 show qos maps

The **show qos maps** command lists the number of traffic classes that the switch supports and displays the CoS-Traffic Class, DSCP-Traffic Class, Traffic Class-CoS, and Traffic Class-Transmit Queue maps.

Command Mode

EXEC

Command Syntax

```
show qos maps
```

Example

This command displays the QoS maps that are configured on the switch.

```
switch> show qos maps
Number of Traffic Classes supported: 8
   Number of Transmit Queues supported: 8
   Cos Rewrite:  Disabled
   Dscp Rewrite:  Disabled

   Cos-tc map:
     cos:  0  1  2  3  4  5  6  7
     --------------------------
     tc:   1  0  2  3  4  5  6  7

   Dscp-tc map:
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     2  2  2  2  3  3  3  3  3  3
      3 :     3  3  4  4  4  4  4  4  4  4
      4 :     5  5  5  5  5  5  5  5  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7

   Tc-cos map:
     tc:   0  1  2  3  4  5  6  7
     --------------------------
     cos:  1  0  2  3  4  5  6  7

   Tc-dscp map:
     tc:    0  1  2  3  4  5  6  7
     ----------------------------
     dscp:  8  0 16 24 32 40 48 56

   Tc - tx-queue map:
     tc:         0  1  2  3  4  5  6  7
     --------------------------------
     tx-queue:  0  1  2  3  4  5  6  7 switch>
```

10.1.19.71 show qos map dscp to traffic-class

The **`show qos map dscp to traffic-class`** command shows all DSCP to traffic-class maps, or one specified DSCP to TC map.

Command Mode

Privileged EXEC mode

Command Syntax

`show qos map dscp to traffic-class` [*map_name*]

Parameters

- ***map_name*** The name of the DSCP to traffic-class map. If this is not specified, all DSCP to TC maps are shown.

Example

This command shows the DSCP to TC map named ***map1.***

```
switch#show qos map dscp to traffic-class map1
   DSCP to TC map: map1
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     ---------------------------------------
      0 :     1  1  1  1  1  1  1  0  0
      1 :     0  0  0  0  0  0  2  2  2  2
      2 :     6  6  6  6  6  6  3  3  3  3
      3 :     3  3  4  4  4  7  4  4  4  4
      4 :     5  5  5  5  5  5  5  5  6  6
      5 :     6  6  6  6  6  6  7  7  7  7
      6 :     7  7  7  7 switch#
```

10.1.19.72 show qos profile summary

The **`show qos profile summary`** command displays the QoS profile summary of those which are part of the running configuration.

Command Mode

EXEC

Command Syntax

```
show qos profile summary
```

Example

This command shows a summary of all QoS profiles configured on the switch.

```
switch(config)# show qos profile summary
Qos Profile: p
Configured on: Et13,7
Fabric
Po12
Qos Profile: p2
Configured on: Et56
```

10.1.19.73 show qos profile

The **show qos profile** command displays the contents of the specified QoS profile or of all QoS profiles in the running configuration.

Command Mode

EXEC

Command Syntax

`show qos profile` *profile_name*

Parameter

profile_name QoS profile name.

Examples

- This command displays the contents of all QoS profiles configured on the switch.

```
switch(config)# show qos profile
qos profile p
qos cos 1
no priority-flow-control pause watchdog
priority-flow-control priority 1 no-drop
priority-flow-control priority 2 no-drop
qos profile p2
qos cos 3
priority-flow-control priority 0 no-drop
```

- This command displays the configuration attached and information specific to ***QoS profile p2***.

```
switch# show qos profile p2
qos profile p2
qos cos 3
priority-flow-control priority 0 no-drop
```

10.1.19.74 show qos random-detect ecn

The command displays the global Explicit Congestion Notification (ECN) configuration.

Command Mode

EXEC

Command Syntax

```
show qos random-detect ecn
```

Example

These commands configure global ECN parameters, then displays that configuration.

```
switch(config)# qos random-detect ecn global-buffer minimum-threshold 2 mbytes
maximum-threshold 5 mbytes
switch(config)# show qos random-detect ecn

   Minimum Threshold:  2
   Maximum Threshold:  5
   Threshold Unit:  mbytes

switch(config)#
```

10.1.19.75 show qos tx-queue shape rate precision

The **show qos tx-queue shape rate precision** command displays information about Tx Queue Precision Shaping on a switch.

Command Mode

EXEC

Command Syntax

show qos tx-queue shape rate precision

Example

Use the following command to display the Tx Queue Precision Shaping configuration on a switch:

```
switch# show qos tx-queue shape rate precision
   Configured    Operational
---------------- -----------
50 Mbps          None
```

10.1.19.76 show run|grep sharing

The **`show run|grep sharing`** command displays whether the QoS policy-map sharing on SVIs is enabled or disabled.

Command Mode

EXEC

Command Syntax

```
show run|grep sharing
```

Example

This command displays whether the QoS policy-map sharing on SVIs is enabled or disabled.

```
switch# show run|grep sharing
hardware access-list qos resource sharing vlan in ----
```

If this message is displayed then QoS policy-map sharing on SVIs is enabled.

10.1.19.77 tx-queue (Arad/Jericho)

The **tx-queue** command places the switch in Tx-queue configuration mode to configure a transmit queue on the configuration mode interface. Tx-queue configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

Arad and Jericho platform switches have eight queues, ***0*** through ***7***, and all queues are exposed through the CLI. However, ***queue 7*** is not user-configurable. ***Queue 7*** is always mapped to ***traffic class 7***, which is reserved for control traffic.

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no tx-queue** and **default tx-queue** commands remove the configuration for the specified transmit queue by deleting all corresponding **tx-queue** mode statements from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`tx-queue` *queue_level*

Parameters

queue_level The transmit queue. Values range from *0* to *7*.

Commands Available in tx-queue Configuration Mode

- bandwidth percent (Arad/Jericho)
- priority (Arad/Jericho)
- shape rate (Tx-queue – Arad/Jericho)

Guidelines

Arad and Jericho platform switch queues handle unicast traffic. Queues for multicast traffic are not supported.

Example

This command enters Tx-queue configuration mode for ***transmit queue 4*** of ***interface ethernet 3/3/3***.

```
switch(config)# interface ethernet 3/3/3
switch(config-if-Et3/3/3)# tx-queue 4
switch(config-if-Et3/3/3-txq-4)#
```

10.1.19.78 tx-queue (FM6000)

The **tx-queue** command places the switch in Tx-queue configuration mode to configure a transmit queue on the configuration mode interface. Tx-queue configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

FM6000 platform switches have eight queues, ***0*** through ***7***. All queues are exposed through the CLI and are user configurable.

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no tx-queue** and **default tx-queue** commands remove the configuration for the specified transmit queue by deleting the all corresponding **tx-queue** mode commands from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`tx-queue` *queue_level*

Parameter

queue_level The transmit queue. Values range from ***0*** to ***7***.

Commands Available in tx-queue Configuration Mode

- bandwidth percent (FM6000)
- priority (FM6000)
- shape rate (Tx-queue – FM6000)

Guidelines

FM6000 platform switch queues handle unicast and multicast traffic.

Example

This command enters Tx-queue configuration mode for ***transmit queue 3*** of ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# tx-queue 3
switch(config-if-Et5-txq-3)#
```

10.1.19.79 tx-queue (Helix)

The **tx-queue** command places the switch in ***tx-queue*** configuration mode to configure a transmit queue on the configuration mode interface. The ***tx-queue*** configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

Helix platform switches have eight unicast (***UC0 – UC7***) and eight multicast (***MC0 – MC7***) queues. Each UCx-MCx queue set is combined into a single queue group (L1.x), which is exposed to the CLI through this command.

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no tx-queue** and **default tx-queue** commands remove the configuration for the specified transmit queue by deleting the all corresponding **tx-queue** mode commands from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`tx-queue` *queue_level*

Parameter

queue_level Transmit queue group number. Values range from ***0*** to ***7***.

Commands Available in tx-queue Configuration Mode

- bandwidth guaranteed (Helix)
- shape rate (Tx-queue – Helix)

Guidelines

Helix platform switch queues handle unicast and multicast traffic.

Example

This command enters Tx-queue configuration mode for ***transmit queue 4*** of ***interface ethernet 17/3***.

```
switch(config)# interface ethernet 17/3
switch(config-if-Et17/3)# tx-queue 4
switch(config-if-Et17/3-txq-4)#
```

10.1.19.80 tx-queue (Petra)

The **tx-queue** command places the switch in ***tx-queue*** configuration mode to configure a transmit queue on the configuration mode interface. The ***tx-queue*** configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

Petra platform switches have eight queues, ***0*** through ***7***, and all queues are exposed through the CLI. However, ***queue 7*** is not user-configurable. ***Queue 7*** is always mapped to ***traffic class 7***, which is reserved for control traffic.

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no tx-queue** and **default tx-queue** commands remove the configuration for the specified transmit queue by deleting the all corresponding **tx-queue** mode commands from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`tx-queue` *queue_level*

Parameter

queue_level The transmit queue. Values range from ***0*** to ***7***.

Commands Available in tx-queue Configuration Mode

- bandwidth percent (Petra)
- priority (Petra)
- shape rate (Tx-queue – Petra)

Guidelines

Petra platform switch queues handle unicast traffic. Queues for multicast traffic are not supported.

Example

This command enters the ***tx-queue*** configuration mode for ***transmit queue 3*** of ***interface ethernet 3/3***.

```
switch(config)# interface ethernet 3/3
switch(config-if-Et3/3)# tx-queue 3
switch(config-if-Et3/3-txq-3)#
```

10.1.19.81 tx-queue (Trident II)

The **`tx-queue`** command places the switch in ***tx-queue*** configuration mode to configure a transmit queue on the configuration mode interface. The ***tx-queue*** configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **`exit`** command does not affect the configuration.

Trident II platform switches have eight unicast (***UC0 – UC7***) and eight multicast (***MC0 – MC7***) queues. Each UCx-MCx queue set is combined into a single queue group (L1.x), which is exposed to the CLI through this command.

The **`exit`** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **`no tx-queue`** and **`default tx-queue`** commands remove the configuration for the specified transmit queue by deleting the all corresponding **`tx-queue`** mode commands from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`tx-queue` *queue_level*

Parameter

queue_level Transmit queue group number. Values range from ***0*** to ***7***.

Commands Available in tx-queue Configuration Mode

- bandwidth guaranteed (Trident II)
- shape rate (Tx-queue – Trident II)

Trident II platform switch queues handle unicast and multicast traffic.

Example

This command enters the ***tx-queue*** configuration mode for ***transmit queue 4*** of ***interface ethernet 17/3***.

```
switch(config)# interface ethernet 17/3
switch(config-if-Et17/3)# tx-queue 4
switch(config-if-Et17/3-txq-4)#
```

10.1.19.82 uc-tx-queue

The **uc-tx-queue** command places the switch in the ***uc-tx-queue*** configuration mode to configure a unicast transmit queue on the configuration mode interface. The ***uc-tx-queue*** configuration mode is not a group change mode; ***running-config*** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

Trident and Tomahawk switches have eight unicast queues (***UC0 – UC7***) and four multicast queues (***MC0 – MC03***), categorized into two priority groups. All queues are exposed through the CLI and are user-configurable.

- **Priority Group 1:** ***UC7***, ***UC6***, ***MC3***
- **Priority Group 0:** ***UC5***, ***UC4***, ***MC2***, ***UC3***, ***UC2***, ***MC1***, ***UC1***, ***UC0***, ***MC0***

The **exit** command returns the switch to the configuration mode for the base Ethernet or port channel interface.

The **no uc-tx-queue** and **default uc-tx-queue** commands remove the configuration for the specified transmit queue by deleting the all corresponding **uc-tx-queue** mode commands from ***running-config.***

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Command Syntax

`uc-tx-queue` *queue_level*

Parameter

queue_level The multicast transmit queue number. Values range from ***0*** to ***7***.

Commands Available in uc-tx-queue Configuration Mode

- bandwidth percent (Trident and Tomahawk)
- priority (Trident and Tomahawk)
- shape rate (Tx-queue – Trident and Tomahawk)

Related Command

mc-tx-queue: Configures multicast transmit queues on Trident and Tomahawk platform switches.

Example

This command enters the ***mc-tx-queue*** configuration mode for ***multicast transmit queue 4*** of ***interface ethernet 5***.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# uc-tx-queue 4
switch(config-if-Et5-mc-txq-4)#
```

10.1.20 Chipset Mapping for QoS

To display chipset information on a platform, use the **`show platform fap`** command.

Table 61: Chipset Names by Model Number

10.2 Traffic Management

This chapter describes Traffic Management on Arista switches, including configuration instructions and command descriptions. Topics discussed by this chapter include:

- Traffic Management Conceptual Overview
- Traffic Management Configuration Trident Platform Switches
- Traffic Management Configuration Trident II Platform Switches
- Traffic Management Configuration Commands

10.2.1 Traffic Management Conceptual Overview

Traffic is managed through policy maps that apply data shaping methods to specific data streams. A policy map is a data structure that identifies specific data streams and then defines shaping parameters that modify packets within the streams. The switch defines four types of policies:

- Control Plane Policies: Control plane policy maps are applied to the control plane.
- QoS Policies: QoS policy maps are applied to Ethernet and port channel interfaces.
- Segment Routing Traffic Engineering Policy (SR-TE).
- PBR Policies: PBR policy maps are applied to Ethernet interfaces, port channel interfaces and switch virtual interfaces (SVIs).

A policy map consists of classes. Each class contains an eponymous class map and traffic resolution commands.

- A class map is a data structure that defines a data stream by specifying characteristics of data packets that comprise that stream. Each class map is typed as either QoS, control plane, or PBR and is available only to identically typed policy maps.
- Traffic resolution commands specify data handling methods for traffic that matches a class map. Traffic resolution options vary by policy map type.

Data packets that enter an entity to which a policy map is assigned are managed with traffic resolution commands of the first class that matches the packets.

10.2.1.1 Control Plane Policies

The switch defines one control plane policy map named ***copp-system-policy***. The ***copp-system-policy*** policy map always applies to the control plane and cannot be removed from the switch. Other control plane policy maps cannot be added. **Copp-system-policy** consists of preconfigured classes, each containing a static class map and traffic resolution commands. Preconfigured classes cannot be removed from ***copp-system-policy***.

The switch provides static class maps and you cannot modify or delete them. The switch uses a naming convention of static class maps as ***copp-system-*** *name*, where *name* differentiates the class maps. Static class maps have pre-defined internal conditions, not based on ACLs, and only listed in ***running-config*** as components of ***copp-system-policy***. The sequence of static class maps in the policy map is not significant. Traffic resolution commands define minimum (bandwidth) and maximum (shape) transmission rates for data streams matching the corresponding class map.

Copp-system-policy can be modified through the following steps:

1. Add classes consisting of an eponymous dynamic class map and traffic resolution commands.

   Create, edit, or delete dynamic class maps, and filter traffic with a single IPv4 ACL, and list in ***running-config***.

2. Change traffic resolution commands for a preconfigured class.

The following section describes control plane traffic policy configuration procedures:

- Configuring Control Plane Traffic Policies Trident Platform Switches

10.2.1.2 QoS Policies

QoS policy maps are user defined. The switch does not provide preconfigured QoS policy maps and in the default configuration, policy maps are not applied to any Ethernet or port channel interface. Policy maps and class maps are created and applied to interfaces through configuration commands.

A QoS policy map is composed of one or more classes. Each class contains an eponymous dynamic class map and traffic resolution commands. Dynamic class maps are user created, can be edited or deleted, filter traffic with a single IPv4 ACL, and are listed in ***running-config***.

QoS traffic resolution commands perform one of the following:

- Set the Layer 2 CoS field
- Set the DSCP value in the ToS byte
- Specify a traffic class queue

The last class in all QoS policy maps is ***class-default***, composed as follows:

- The ***class-default*** class map matches all traffic except IPv4 or IPv6 traffic and is not editable.
- By default, ***class-default*** class contains no traffic resolution commands. Traffic resolution commands can be added through configuration commands.
- Disable the ***class-default*** map, use the **`class class-default disabled`** command.

Data packets that enter an interface to which a policy map is assigned are managed with traffic resolution commands that correspond to the first class that matches the packet.

These sections describe QoS traffic policy configuration procedures:

- Configuring QoS Traffic Policies Arad Platform Switches
- Configuring QoS Traffic Policies FM6000 Platform Switches
- Configuring QoS Traffic Policies Petra Platform Switches
- Configuring QoS Traffic Policies Trident Platform Switches

10.2.1.3 Segment Routing Traffic Engineering Policy (SR-TE)

Segment Routing Traffic Engineering Policy (SR-TE) policy uses Segment Routing (SR) to enable a headend to steer traffic along any path without maintaining per flow state in every node based on the policy. Configuring SR policy for the MPLS dataplane (SR-MPLS) for Type-1 SR policy segments with BGP and locally configured policies as sources of SR policy is available on DCS-7500 and DCS-7280 family of switches.

SR Policy Overview

SR Policy Identification

The following identifies an SR policy.

- **Endpoint** - An IPv4 or IPv6 address which refers to the destination of the policy. EOS allows 0/0 and 0:: and calls these IP addresses *null endpoints*.
- **Color** - An unsigned 32-bit opaque numerical quantity. Define the semantic of a color as you prefer. It can refer to, for instance, an application or a type of traffic, such as low latency, or a geographical location.

SR Policy Constituents

The SR policy consists of *candidate paths*. Each candidate path has the following.

- **SID-lists (SLs)** - An ordered list of Segment Identifiers. Each SID provides a MPLS label in the MPLS instantiation of SR). An SL encodes one path from the headend to the destination. Each SL has an optional weight attached to it for the purpose of Unequal Cost Multipath (UCMP) traffic distribution. The default value for SL weight is ***1***.
- **Preference** - An optional, unsigned 32-bit integer used in the candidate path selection algorithm to select the *active* candidate path. The default value for preference is ***100***.
- **Binding SID (BSID)** - an optional SID.

Note: In EOS, a BSID is mandatory for each candidate path.

SR Policy Sources

A headend learns SR policies using the following methods:

- **BGP**
  - Single agent routing model (Ribd)
  - Multi-agent routing model
- **Local configuration using CLI**

- Single agent routing model (Ribd)
- Multi-agent routing model
- Openconfig YANG models

- **PCEP**

> **Note:** EOS does not support PCEP.

Identity of a Candidate Path

A candidate path within an SR policy is identified by a 3-tuple of {Protocol-Origin, Originator, Discriminator}. In EOS, for locally configured policies:

- The ASN in the Originator set to 0.
- The node address in the Originator set to ***0.0.0.0***.
- The discriminator set to the Preference configured.

> **Note:** EOS CLI allows configuring only one candidate path at a given preference and does not allow configuring the discriminator for a candidate path.

State of an SID List (SL)

The following describes the state of an SL:

- **Valid** - The top label of the SL resolves within the LFIB to the outgoing next hop(s), interface(s) and a label action.
- **Invalid** - The top label of the SL unresolvable to the outgoing next hop(s), interface(s) and a label action. An SL is also marked as invalid when the SL is resolvable, but the resolved labeled stack exceeds the platform's maximum SID depth (SID), that is, exceeds the maximum number of labels the platform can push in to the outgoing packet.

> **Note:** The state is either valid or invalid.

State of a Candidate Path

The following describes the states of a candidate path.

- **Invalid** - Not eligible to participate in the best/active candidate path selection algorithm because of one of the reasons below.
  - Invalid constituent SLs in the candidate path.

  - No Binding SID present in the candidate path.
  - Binding SIDpresent but outside SRLB range for the candidate path.
- **Valid** - At least one valid SL has lost out to some other candidate path in the best / active candidate path selection algorithm.
- **Active**: - A valid candidate path exists and wins the best / active candidate path selection algorithm. The active candidate path installs in the switch hardware and forwards traffic.

State of an SR Policy

EOS considers an SR policy as *valid* when at least one of its candidate paths is valid. Otherwise, the SR policy is *invalid*.

Resolution of an SL

An SL resolves if the top label (first SID) can be resolved in the system Labeled FIB (LFIB) to yield a nexthop and outgoing interface(s). The other labels in the SID-List do not play a part in resolution.

Best Candidate Path (Active Candidate Path) Selection Algorithm

EOS overrides selection based on discriminator by retaining the current active candidate path even when current active path has a lower discriminator value. This reduces the active path flap when a new path appears with the same significance. The following lists a summary of valid candidate paths ordering for a given policy.

1. The candidate path with higher preference selected.
2. Locally configured candidate path selected over a BGP learned path
3. Lower originator selected in the following instances:
   a. Lower AS number of Originator field selected.
   b. Lower Node address of Originator field selected.
4. Current active candidate path selected in the following instances:

The following displays the reason for not selecting a path as an active path for a specified policy.

```
switch#show traffic-engineering segment-routing policy endpoint <endpoint> color <color>
```

Binding SID

The following describes the use cases for the Binding SID:

- Stitch together multiple domains.
- Stitch together different traffic tunnels .
- Overcome label stack imposition limitation in hardware.

BSID Conflict Handling

Examples

1. **Between Policies** - If the policy (E1, C1) becomes eligible to be active first, then it installs in the LFIB and the policy (E2,C2) whose best path(CP1) conflicts with the Policy (E1, C1) and does not become active.
   - Policy(E1, C1): CP1: Binding-SID 965536 (wins best path)
   - Policy(E2, C2): CP1: Binding-SID 965536 (wins best path)
   - CP2: Binding-SID 965537
2. **with another Application**: The SR-TE policies have the lowest preference when a conflict exists with any other application in EOS using the SRLB range. The candidate paths with the same binding-SID as that of an LFIB entry by another application, for example, static adjacency segment, remains invalid.

In both the cases, when the conflict no longer exists, the candidate paths re-evaluate and may become active.

BGP as a Source of Policies

SR Policies from a BGP peer (a controller, route reflector) received for installation at the headend by EOS. It does not propagate the received policies to BGP peers nor does it originate SR Policies for transmission to BGP peers.

The following supports IPv4 or IPv6 peers which can be single hop or multi-hop iBGP or eBGP peers.

1. **SAFI 73 for AFI 1 and AFI 2**: IPv4 and IPv6 policy endpoints, with the encoding defined in section 2.1 of ***Advertising Segment Routing Policies in BGP***.

   Note: The nexthop address-family must match the AFI of the NLRI.

2. **Sub-TLVs of Tunnel Encapsulation TLV of type 15 (SR-TE Policy Type) of the Tunnel Encapsulation Path Attribute**
   a. Preference (Sub-TLV Type 12)
   b. Binding SID (Sub-TLV Type 13) of length ***2*** or ***6*** bytes
   c. Segment List (Sub-TLV Type 128). The following Segment List sub-TLVs are supported:
      1. Type 1 Segment (Sub-TLV type 1)
      2. Weight (Sub-TLV type 9)
   d. Explicit NULL Label Policy (Sub-TLV Type 14)
   e. SR Prefix SID (sub TLV 3 of TLV 149, TLV 150)
   f. SR Range - Contents of TLV 149, TLV 150 (multi-topology)

Note: EOS ignores all other sub-TLVs of the Tunnel Encapsulation TLV and Segment List sub-TLVs.

Route-Target and NO_ADVERTISE Community in SR-TE SAFI Updates

EOS implements the Acceptance and Usability checks as defined in sections 4.2.1 and 4.2.2 of the IETF draft Advertising Segment Routing Policies in BGP. However EOS skips matching the Route-Target with the router-ID of the headend if the SR-TE NLRI is tagged with **NO_ADVERTISE** community.

ECMP does not support SR-TE SAFI Paths

EOS does not support ECMP for BGP SR-TE SAFI. The BGP path selects only one best candidate path and publishes it to SR-TE Policy Agent for candidate path selection.

> **Note:** EOS supports ECMP of BGP next hops where each next hop resolves to an SR-TE policy.

Path Selection within BGP

The IETF draft **Advertising Segment Routing Policies in BGP** supports passing multiple candidate paths from a single protocol source for an SR-TE policy path selection. Therefore, it includes a field distinguisher in the NLRI which can be unique for each controller to make BGP pass through the policies. However when multiple sources use the same distinguisher, BGP performs a path selection for the tuple: Endpoint, Color and Distinguisher. The best path for that tuple publishes to the SR-TE Policy Agent for selecting an Active path. The best **bgp-best-path** selection applies to SR-TE SAFI as well.

Error Handling / Edge Cases

- **Weight 0**: The IETF draft does not limit the range of SL weight to exclude weight 0. A SID-List with weight 0 is not used for forwarding so BGP module in EOS does not pass on SID-Lists with weight 0 to the SR-TE policy agent. Such SID-Lists will be visible in **`show bgp sr-te`** commands but not in **`show traffic-engineering segment-routing policy`** commands.
- **Empty SLs**: Given the TLV encoding used to propagate SR Policies in BGP, it is possible to receive SID-Lists without SIDs. The BGP module in EOS does not pass empty SID-Lists to SR-TE policy agent. Such SID-Lists are visible in **`show bgp sr-te`** commands but not in **`show traffic-engineering segment-routing policy`** commands.
- **Non Type 1 segments**: EOS supports only Type-1 segments. When receiving a BGP update with a SID-List that has non Type-1 segments, EOS ignores the entire SID-List and sends a **`BGP-4-SRTE_IGNORED_SEGMENT_LIST_UNSUPPORTED_SEGMENTS`** syslog. Such SID-Lists are not stored locally, and **`show bgp sr-te`** command does not display them.

  > **Note:** The SID-Lists made up of all Type-1 segments pass to the SR-TE policy agent.

Steering Traffic into a Policy

Incoming label as BSID - Labelled Steering

At the headend when receiving a packet with a label stack with a BSID of an active CP of a valid SR Policy as the top label, the headend pops the label, and imposes the resolved label stack on the outgoing packet.

Example

For instance, an SR Policy with an active candidate path with BSID ***965536*** and SL with label stack [***965540***, ***900001***, ***900002***]. Assume that ***965540*** is an IS-IS SR Adjacency SID. An incoming packet has a label stack [***965536***, ***100000***] then the outgoing label stack consists of [***900001***, ***900002***, ***100000***].

Steering BGP learnt IP(v6) prefixes - IP Steering

Incoming label is BSID - Labelled Steering

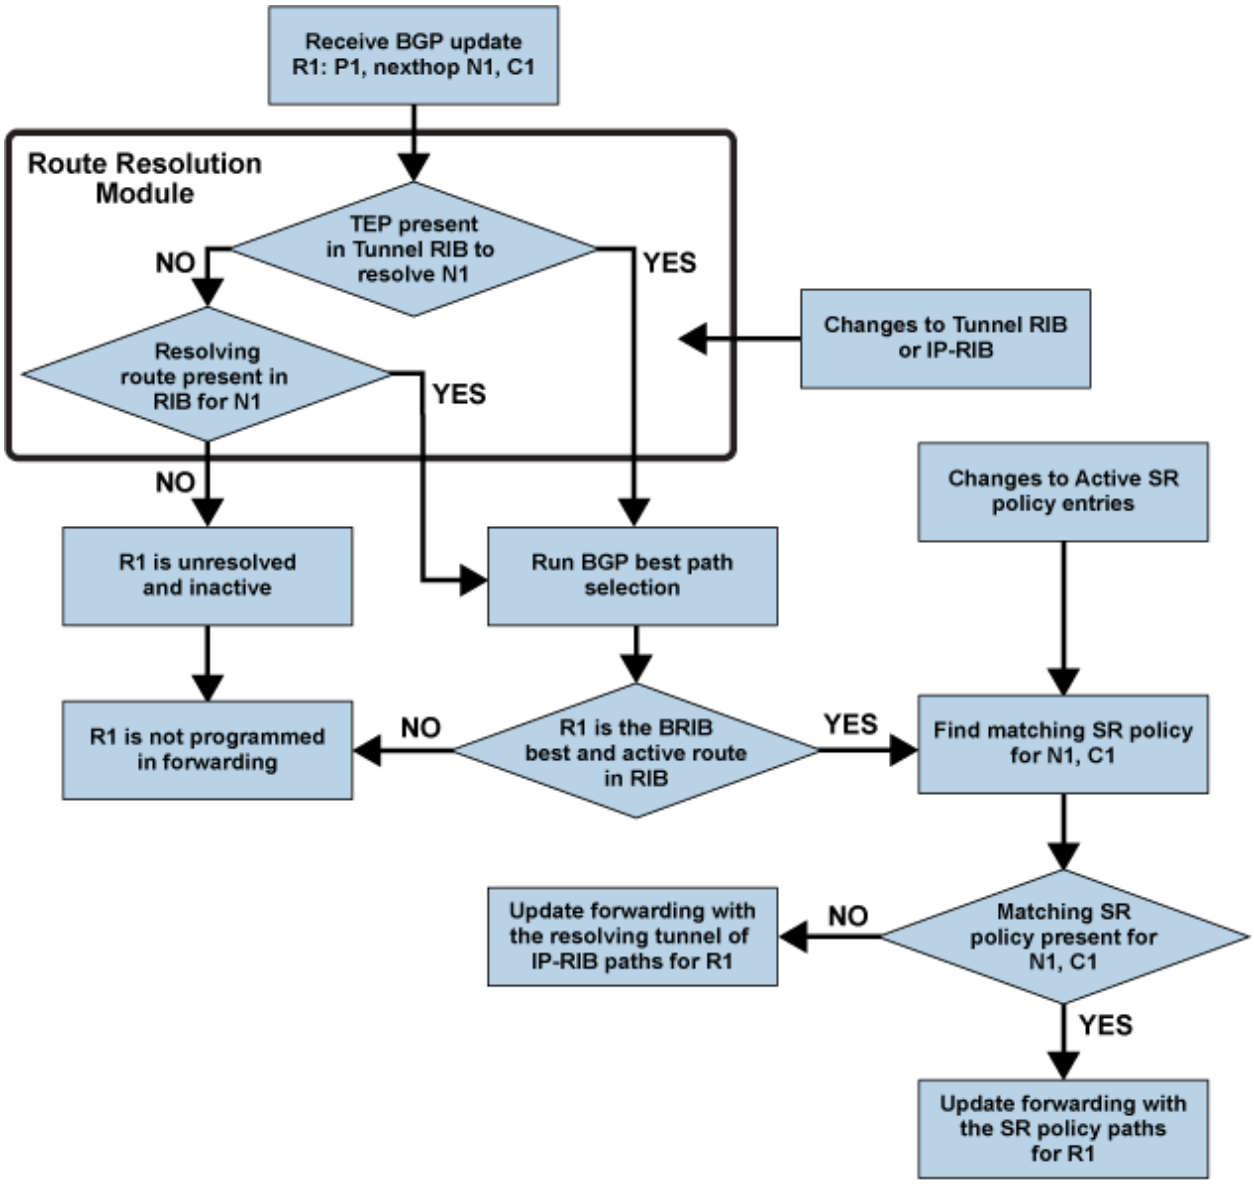
At the headend, BGP IPv4 and IPv6 routes receive one or more extended color communities and recursively resolves them through any active SR Policy that matches the BGP routes' nexthop and color. When receiving an IPv4 or IPv6 packet forwarded using this policy, the SL's resolved label stack imposes on the outgoing packet.

For BGP routes received with color community to be steered via an SR policy, the route's nexthop must already be resolvable through IGP. If no resolving route exists in IGP, the route is considered unresolvable and does not program in hardware even if a matching SR policy exists for the corresponding nexthop and color.

If no matching SR policy exists for the received BGP nexthop and color, the route resolves through the IGP route in IP RIB. If an active SR policy that matches the BGP nexthop and color gets instantiated at a later time, the BGP route changes from resolving through IGP to the new active SR policy.

Note: The recursion through SR policy is only applicable for active BGP routes in RIB.

Figure 10-1: Route Resolution Module Flowchart



Color only IP steering using CO bits

It is possible to relax the requirement of an exact match of the BGP route's nexthop with the endpoint of the SR Policy using the "CO" (Color Only) bits in the color extended community. The "CO" bits are 2 reserved bits repurposed for color only steering as defined in section 3 of Advertising Segment Routing Policies in BGP. The exact match of the nexthop is done with the CO bits set to 00 or 11.

CO = 01 Steering: relaxes the nexthop to match the null endpoint of a policy. For a BGP route with nexthop N and color C, the following order is used for resolution. If there is no IGP route resolving the BGP nexthop, the route is not programmed in hardware.

1. Active SR policy with endpoint N and color C
2. Active SR policy with null endpoint (from the same AFI as the BGP route) and color C

3. Active SR policy with null endpoint from any AFI and color C
4. IGP route

CO = 10 Steering: in addition to the steps in CO = ***01*** steering, CO = ***10*** additionally relaxes the nexthop to match *any* endpoint. The following order is used for resolving a BGP route with nexthop N and color C. The behavior described is in accordance with section 8.8.1 of the IETF draft Segment Routing Policy for Traffic Engineering.

1. Active SR policy with endpoint N and color C
2. Active SR policy with null endpoint (from the same AFI as the BGP route) and color C
3. Active SR policy with null endpoint from any AFI and color C
4. Active SR policy for any endpoint from the same AFI as the BGP route and color C
5. Active SR policy for any endpoint from any AFI and color C
6. IGP route

ECMP of IPv4/IPv6 Prefixes that Resolve over SR-TE Policies

When multiple BGP paths of BGP unicast prefixes resolve through active SR policies form ECMP, the resulting FIB entry for the BGP route has an ECMP of segment list paths which is a union of all the segments-list entries present in each of the resolving SR policies for the BGP paths.

Example

The following table displays four paths for prefix ***192.1.0.0/31***, and each of the four paths resolves via SR-TE policies.

Table 62: List of Paths Resolved via SR-TE Policies

Path	Nexthop	Color	Policy EP	Policy Color	Segment Lists	Per SL Traffic Distribution
1	1.0.0.2	CO(00):1000	1.0.0.2	1000	[2500 500], Weight: 1 [2501 500], Weight: 2	8.33% 16.66%

```
B I    192.1.0.0/31 [200/0] via SR-TE Policy 1.0.4.2, color 3000
                              via SR-TE tunnel index 6, weight 1
                                 via 1.0.4.2, Ethernet1, label 2505 500
                              via SR-TE tunnel index 5, weight 1
                                 via 1.0.4.2, Ethernet1, label 2504 500
                           via SR-TE Policy 1.0.0.2, color 1000
                              via SR-TE tunnel index 2, weight 1
                                 via 1.0.0.2, Ethernet2, label 2501 500
                              via SR-TE tunnel index 1, weight 1
                                 via 1.0.0.2, Ethernet2, label 2500 500
                           via SR-TE Policy 1.0.2.2, color 2000
                              via SR-TE tunnel index 4, weight 1
                                 via 1.0.2.2, Ethernet3, label 2503 500
                              via SR-TE tunnel index 3, weight 1
                                 via 1.0.2.2, Ethernet3, label 2502 500
                           via SR-TE Policy 1.0.6.2, color 4000
                              via SR-TE tunnel index 8, weight 1
                                 via 1.0.6.2, Ethernet6, label 2507 500
                              via SR-TE tunnel index 7, weight 1
                                 via 1.0.6.2, Ethernet6, label 2506 500
```

The traffic distribution honors the weights of the SID-Lists. In the example, each of the four SR Policies will get ***25%*** of the total traffic meant for prefix ***192.1.0.0/31***. Within each policy, the distribution is based on the weights of the SID-Lists.

ECMP Group when some BGP unicast paths resolve over SR Policies and some via non SR Policy IGP paths

If some BGP paths resolve via SR Policy paths and some BGP paths resolve via non SR Policy IGP, then the ECMP group formed programmed as the active route in FIB, only considers the SR Policy paths. ECMP in the FIB is not formed between paths that resolve over SR Policy and paths that resolve via non SR Policy

IGP routes. In the example above, if SR Policy with endpoint ***1.0.6.2*** and color ***4000*** becomes inactive or is removed, the FIB path for ***192.1.0.0/31*** resolves via 3 SR Policies as shown below.

```
B I    192.1.0.0/31 [200/0] via SR-TE Policy 1.0.4.2, color 3000
                              via SR-TE tunnel index 6, weight 1
                                 via 1.0.4.2, Ethernet1, label 2505 500
                              via SR-TE tunnel index 5, weight 1
                                 via 1.0.4.2, Ethernet1, label 2504 500
                            via SR-TE Policy 1.0.0.2, color 1000
                              via SR-TE tunnel index 2, weight 1
                                 via 1.0.0.2, Ethernet2, label 2501 500
                              via SR-TE tunnel index 1, weight 1
                                 via 1.0.0.2, Ethernet2, label 2500 500
                            via SR-TE Policy 1.0.2.2, color 2000
                              via SR-TE tunnel index 4, weight 1
                                 via 1.0.2.2, Ethernet3, label 2503 500
                              via SR-TE tunnel index 3, weight 1
                                 via 1.0.2.2, Ethernet3, label 2502 500
```

Note: `show ip bgp` still shows a 4-way ECMP. The FIB paths switch to resolving via the (non SR Policy) IGP paths when there are no BGP paths in the ECMP group that resolve via an SR Policy.

UCMP of IPv4/IPv6 prefixes using LinkBandwidth (LBW) Extended Community that resolve over SR-TE policies not supported

When multiple BGP paths of BGP unicast prefixes resolve through active SR policies form ECMP, and the unicast paths also contain the LBW extended community, EOS does not form UCMP amongst the unicast paths. Only ECMP is formed at the unicast prefix level. The LBW is ignored the behavior is identical to the behavior explained in the previous section.

Resolution of BGP unicast prefixes that resolve over other BGP unicast prefixes resolved via SR Policies

A BGP unicast prefix P1, that is recursively resolved via another BGP prefix P2, such that P2 resolves via an SR Policy, then in the FIB, P1 is programmed with the resolved nexthop pointing to the non SR Policy resolution of P2. P1 does not use P2s SR Policy for forwarding.

Explicit Null Label Imposition

When the address family of the BGP unicast prefix is not the same as the address family of the endpoint of the SR Policy that the unicast prefixes resolves via, an explicit null label is automatically imposed in the outgoing label stack.

Example

If an IPv4 unicast prefix ***P1*** resolves over a policy whose endpoint ***EP1*** is an IPv6 address (this can happen due to color only CO=01/10 steering with ***P1*** having an IPv4 nexthop) and the SR Policy had a SID-List

whose resolved label stack is [***1001***, ***1002***, ***1003***], the outgoing packet is imposed with [***1001***, ***1002***, ***1003***, ***2***] where ***0*** is the IPv4 explicit null label.

If an IPv6 prefix ***P2***, resolves over a policy whose endpoint ***EP2*** is an IPv4 address (this can happen with color only CO=01/10 steering with ***P2*** having a IPv6 nexthop) and the SR Policy had a SID-List whose resolved label stack is [***1001***, ***1002***, ***1003***], the outgoing packet is imposed with [***1001***, ***1002***, ***1003***, ***2***] where ***2*** is the IPv6 explicit null label.

The following table lists the configurations which result in having explicit-null label in the resolved label stack.

Table 63: Configurations resulting in Explicit-Null Label in Resolved Label Stack

ENLP configuration for the resolving SR Policy	IPv4 Prefixes	IPv6 Prefixes
None	-	-
IPv4	IPv4 explicit null appended to the end of label stack	-
IPv6	-	IPv6 explicit null appended to the end of label stack
Both	IPv4 explicit null appended to the end of label stack	IPv6 explicit null appended to the end of label stack
No/Default config (incase of BGP learnt policies ENLP Sub-TLV is not received)	Resolving SR Policy has IPv4 Endpoint address: No explicit-null	Resolving SR Policy has IPv4 Endpoint address: IPv6 explicit null appended to the end of label stack
	Resolving SR Policy has IPv6 Endpoint address: IPv4 explicit null appended to the end of label stack	Resolving SR Policy has IPv6 Endpoint address: No explicit-null

Traffic Accounting

All egress tunnel counters (MPLS/GRE/MPLSoGRE using SR-TE/Nexthop-group/BGP-LU tunnel types) share the same hardware resource.

- **7280E/7500E systems**: Up to ***16k*** tunnels
- **7280R/7500R systems**: Up to ***8k*** tunnels

Tunnel counters are allocated on a first-come, first-served basis. Configurations using GRE/MPLSoGRE, GRE, and MPLS further limit a maximum of 4k countable egress MPLS tunnels on 7280R/7500R.

FEC Optimizations

The hardware FEC usage could be reduced as the underlying FEC is shared among different routes.

- Programming of the active candidate path of an SR-TE policy in hardware is shared between the BSID route and IP steering route.
- If all of the following conditions are met, ISIS-SR MPLS routes and tunnel entries directly point to the next hop FEC generated by the routing agent (IGP FEC).

- All the next hops of the MPLS route either point to pop or forward (i.e. swapping to the same label) label action.
- The switch is either a 7280 or a 7500 platform.

- The corresponding SR-TE policy BSID routes (and corresponding Segment List tunnels) that resolve over ISIS-SR MPLS routes, will directly point to the IGP FEC.

Configuring SR-TE

The following commands start the **SrTePolicy** agent and enter the switch into the Traffic Engineering configuration sub-mode.

```
switch(config)# router traffic-engineering
switch(config-te)# segment-routing
```

Note: The agent must be running even if the only source of policies is BGP.

Static Policy Configuration

The following commands set the policy using endpoint and color value, and define the BSID for the policy.

```
switch(config-te-sr)# policy endpoint v4Address|v6Address color color-value
switch(config-te-sr-policy)# binding-sid mpls-label
switch(config-te-sr-policy)# path-group preference value
```

The following commands enter the policy path configuration sub mode, and adds a segment list to the candidate path.

```
switch(config-te-sr-policy)# path-group preference value
switch(config-te-sr-policy-path)# segment-list label-stack label1 label2 … weight value
```

Note: The default weight value is ***1***. Adding weight is optional. Repear the configuration statement for multiple segment lists per candidate path.

The following commands configures a null label policy.

```
switch(config-te-sr-policy-path)# explicit-null [none|ipv4|ipv6|both]
```

Note: The null label policy configuration is optional.

BGP configuration for SR-TE SAFI

The following commands configures a BGP router to activate a neighbor to negotiate and accept SR-TE address-family with this peer.

```
switch(config)# router bgp <as>
switch(config-router-bgp)# address-family ipv4|ipv6 sr-te
switch(config-router-bgp-af-srte)# neighbor neighbor activate
```

The following command configures an inbound route-map to filter or modify attributes on incoming SR-TE prefixes from the peer.

```
switch(config-router-bgp-af-srte)# neighbor neighbor route-map routeMapName in
```

Configuring Egress SR-TE Traffic Accounting

The following command enables egress traffic accounting for SR policies (also known as MPLS tunnels).

```
switch(config)# hardware counter feature mpls tunnel
```

The following command displays current status of the MPLS counters.

```
switch# show hardware counter feature
Feature            Direction        Counter Resource (Engine)
------------------ ---------------- --------------------------
ACL-IPv4           out              Jericho: 2, 3
ACL                in               Jericho: 4, 5, 6, 7
MPLS tunnel        out              Jericho: 8, 9
```

The following command disables egress traffic accounting for SR policies.

```
switch(config)# no hardware counter feature mpls tunnel
```

The following command displays a summary information of SR-TE SAFI.

```
switch# show bgp sr-te summary
BGP summary information for VRF default
Router identifier 100.1.1.2, local AS number 100
Neighbor Status Codes: m - Under maintenance
  Neighbor         V  AS           MsgRcvd   MsgSent  InQ OutQ  Up/Down State  PfxRcd PfxAcc
  100.1.1.1        4  100              407       413    0    0 00:18:57 Estab  1      1
  1000::1          4  100              407       413    0    0 00:18:57 Estab  1      1
```

The following command displays a summary information of candidate paths received from neighbors which have negotiated AFI=1 for SR-TE SAFI.

```
switch# show bgp sr-te ipv4 summary
BGP summary information for VRF default
Router identifier 100.1.1.2, local AS number 100
Neighbor Status Codes: m - Under maintenance
  Neighbor    V  AS   MsgRcvd  MsgSent InQ OutQ  Up/Down  State  PfxRcd PfxAcc
```

```
  100.1.1.1   4  100  407      413     0   0     00:18:57 Estab  0      0
```

The following command displays a summary information of candidate paths received from neighbors which have negotiated AFI=2 for SR-TE SAFI.

```
switch# show bgp sr-te ipv6 summary
BGP summary information for VRF default
Router identifier 100.1.1.2, local AS number 100
Neighbor Status Codes: m - Under maintenance
  Neighbor     V  AS   MsgRcvd  MsgSent InQ OutQ  Up/Down  State  PfxRcd PfxAcc
  1000::1      4  100  407      413     0   0     00:18:57 Estab  0      0
```

The following command displays all the SR-TE candidate paths.

```
switch# show bgp sr-te
BGP routing table information for VRF default
Router identifier 100.1.1.1, local AS number 100
Policy status codes: * - valid, > - active, E - ECMP head, e - ECMP
                     c - Contributing to ECMP
Origin codes: i - IGP, e - EGP, ? - incomplete
AS Path Attributes: Or-ID - Originator ID, C-LST - Cluster List, LL Nexthop - Link Local Nexthop

     Endpoint    Color   Distinguisher   Next Hop    Metric  LocPref Weight  Path
*>   133.1.1.1   0       1               130.1.1.3   0       100     0       ?
*>   133.1.1.1   0       2               130.1.1.3   0       100     0       ?
*>   1330::1     0       1               1300::3     0       100     0       ?
*>   1330::1     0       2               1300::3     0       100     0       ?
```

The following command displays all the SR-TE candidate paths with IPv4 endpoints.

```
switch# show bgp sr-te ipv4
BGP routing table information for VRF default
Router identifier 100.1.1.1, local AS number 100
Policy status codes: * - valid, > - active, E - ECMP head, e - ECMP
                     c - Contributing to ECMP

```

```
      Rx SAFI: SR TE Policy
      Tunnel encapsulation attribute: SR Policy
         Preference: 200
         Binding SID: 965536
         Explicit null label policy: IPv4
         Segment-List: Label Stack: [ 16004 16003 ], Weight: 10
         Segment-List: Label Stack: [ 2000 3000 ]
```

10.2.1.4 PBR Policies

Policy-Based Routing (PBR) allows the operator to specify the next hop for selected incoming packets on an L3 interface, overriding the routing table. Incoming packets are filtered through a policy map referencing one or more ACLs, and matching packets are routed to the next hop specified.

A PBR policy map is composed of one or more classes and can include next-hop information for each class. It can also include single-line raw match statements, which have the appearance and function of a single line from an ACL. Each class contains an eponymous class map. Class maps are user-created, can be edited or deleted, filter traffic using IPv4 ACLs, and are listed in ***running-config***.

These sections describe PBR policy configuration procedures:

- Configuring PBR Policies Arad Platform Switches
- Configuring PBR Policies FM6000 Platform Switches
- Configuring PBR Policies Petra Platform Switches
- Configuring PBR Policies Trident Platform Switches

10.2.2 Traffic Management Configuration Arad Platform Switches

Traffic policies are implemented by policy maps, which are applied to the control plane, or to L3 interfaces for Policy-Based Routing (PBR). Policy maps contain classes, which are composed of class maps and traffic resolution commands.

Traffic Management Conceptual Overview describes traffic policies.

10.2.2.1 Configuring Control Plane Traffic Policies Arad Platform Switches

Default control plane traffic policies are implemented automatically without user intervention. These policies are modified by associating traffic resolution commands with static classes that comprise the control plane policy map.

Static Class Maps

Control plane traffic policies utilize static class maps, which are provided by the switch, are not editable, and cannot be deleted.

Editing the Policy Map

The only control plane policy map is **copp-system-policy**, which cannot be deleted. In its default form, **copp-system-policy** consists of the classes listed in class (policy-map (control-plane) Arad). Although the underlying class map of each class cannot be edited, the traffic resolution commands can be adjusted. The default classes cannot be removed from the policy map and their sequence within the policy map is not editable.

Policy maps are modified in policy-map configuration mode. The `policy-map type copp` command enters policy-map configuration mode.

Examples

This command enters policy-map configuration mode for editing copp-system-policy.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)#
```

The **`class (policy-map (control-plane) Arad)`** command enters policy-map-class configuration mode, where traffic resolution commands are modified for the configuration mode class.

Example

This command enters policy-map-class configuration mode for the copp-system-lacp static class.

```
switch(config-pmap-copp-system-policy)# class copp-system-lacp
switch(config-pmap-c-copp-system-policy-copp-system-lacp)#
```

Two traffic resolution commands determine bandwidth parameters for class traffic:

- bandwidth (policy-map-class (control-plane) Arad) specifies the minimum bandwidth.
- shape (policy-map-class (control-plane) Arad) specifies the maximum bandwidth.

Example

These commands configure a bandwidth range of ***2000*** to ***4000*** kilobits per seconds (kbps) for traffic filtered by the copp-system-lacp class map:

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# bandwidth kbps 2000
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# shape kbps 4000
switch(config-pmap-c-copp-system-policy-copp-system-lacp)#
```

Policy-map and policy-map-class configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the saved version of policy map. The **`show pending`** command displays the modified policy map.

Example

These commands exit policy-map-class configuration mode, display the pending policy-map, then exit policy-map configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class copp-system-bpdu

  class copp-system-lldp

  class copp-system-lacp
    shape kbps 4000
    bandwidth kbps 2000

  class copp-system-l3ttl1

  class copp-system-l3slowpath

switch(config-pmap-copp-system-policy)# exit
switch(config)#
```

Applying Policy Maps to the Control Plane

The **copp-system-policy** policy map is always applied to the control plane. No commands are available to add or remove this assignment.

Displaying Policy Maps

The show policy-map interface type qos command displays the configured values of the policy maps classes and the number of packets filtered and dropped as a result of the class maps.

Example

These commands exit policy-map-class configuration mode, display the pending policy-map, then exit policy-map configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy
  Hardware programming status: InProgress

  Class-map: copp-system-mlag (match-any)
       shape : 10000001 kbps
       bandwidth : 10000001 kbps
      Out Packets : 0
      Drop Packets : 0

  Class-map: copp-system-bpdu (match-any)
       shape : 2604 kbps
       bandwidth : 1302 kbps
      Out Packets : 0
      Drop Packets : 0

  Class-map: copp-system-lacp (match-any)
       shape : 4230 kbps
       bandwidth : 2115 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# exit
```

10.2.2.2 Configuring QoS Traffic Policies Arad Platform Switches

QoS traffic policies are implemented by creating class maps and policy maps, then applying the policy maps to Ethernet and port channel interfaces.

Creating Class Maps

QoS traffic policies utilize dynamic class maps that are created and modified in class-map configuration mode. The `class-map type qos` command enters class-map configuration mode.

Example

This command enters class-map configuration mode to create QoS class map named ***Q-CMap_1***.

```
switch(config)# class-map type qos match-any Q-CMap_1
switch(config-cmap-Q-CMap_1)#
```

A class map contains one IPv4 access control list (ACL). The **`match ip access-group`** command assigns an ACL to the class map. Subsequent **`match`** commands replace the existing **`match`** command. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded.

Example

This command adds the IPv4 ACL named ***ACL_1*** to the class map.

```
switch(config-cmap-Q-CMap_1)# match ip access-group ACL_1
switch(config-cmap-Q-CMap_1)#
```

Class-map configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **`show active`** command displays the saved version of class map. The **`show pending`** command displays the unsaved class map.

Example

The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***. The **`show pending`** command displays the class map to be stored upon exiting class-map configuration mode.

```
switch(config-cmap-Q-CMap_1)# show active
switch(config-cmap-Q-CMap_1)# show pending
class-map type qos match-any Q-CMap_1
   match ip access-group ACL_1

switch(config-cmap-Q-CMap_1)#
```

The **exit** command returns the switch to global configuration mode and saves pending class map changes. The **abort** command returns the switch to global configuration mode and discards pending changes.

Example

This command exits class-map configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-CP-CMAP_1)# exit
switch(config)# show class-map type control-plane CP-CMAP_1
  Class-map: CP-CMAP_1 (match-any)
    Match: ip access-group name ACLv4_1
switch(config)#
```

Creating Policy Maps

Policy maps are created and modified in policy-map configuration mode. The `policy-map type quality-of-service` command enters policy-map configuration mode.

Example

This command places the switch in policy-map configuration mode and creates a QoS policy map named ***Q-PMAP_1***.

```
switch(config)# policy-map type quality-of-service Q-PMAP_1
switch(config-pmap-Q-PMAP_1)#
```

Policy map are edited by adding or removing classes. A class automatically contains its eponymous class map; traffic resolution commands are added or edited in ***policy-map-class*** configuration mode. The **below** command adds a class to the configuration mode policy map and places the switch in ***policy-map-class*** configuration mode, where traffic resolution commands are added to the class.

Example

This command adds the ***Q-CMap_1*** class to the ***Q-PMAP_1*** policy map and places the switch in ***policy-map-class*** configuration mode.

```
switch(config-pmap-Q-PMAP_1)# class Q-CMap_1
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

The **set cos** commands configure traffic resolution methods for data that passes the class map:

- **set cos** sets the Layer 2 CoS field.
- **set dscp** sets the DSCP value in the ToS byte.
- **set traffic class** specifies a traffic class queue.

Example

These commands configure the policy map to set the ***CoS field 7*** on packets filtered by the class map, then assigns those packets to ***traffic class 4***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set cos 7
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set traffic-class 4
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

Policy-map and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** and ***show pending*** commands display the saved and modified policy map versions, respectively.

Example

These commands exit policy-map-class configuration mode, display the pending policy-map, then exit policy-map configuration mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# exit
switch(config-pmap-Q-PMAP_1)# show pending
policy-map type quality-of-service Q-PMAP_1
  class Q-CMap_1
    set cos 7
    set traffic-class 4

  class class-default

switch(config-pmap-Q-PMAP_1)# exit
switch(config)#
```

The last class in all QoS policy maps is ***class-default***. The ***class-default*** class map matches all traffic except IPv4 or IPv6 traffic and provides no traffic resolution commands. The ***class-default*** class map is not editable; traffic resolution commands can be added to the ***class-default*** class.

To modify traffic resolution commands for the ***class-default*** class, enter ***policy-map-class*** configuration mode for the class, then enter the desired **`set`** commands.

Example

These commands enter ***policy-map-class*** configuration mode for ***class-default***, configures the stream to enter ***traffic class 2***, and saves the altered policy map to ***running-config***.

```
switch(config)# policy-map type quality-of-service Q-PMap_1
switch(config-pmap-Q-PMap_1)# class class-default
switch(config-pmap-c-Q-PMap_1-class-default)# set traffic-class 2
switch(config-pmap-c-Q-PMap_1-class-default)# exit
switch(config-pmap-Q-PMap_1)# exit
switch(config)# show policy-map type qos Q-PMap_1
Service-policy Q-PMap_1

  Class-map: Q-CMap_1 (match-any)
    Match: ipv6 access-group name ACLv6_1
       set cos 7
```

```
       set traffic-class 4

  Class-map: class-default (match-any)
       set traffic-class 2

switch(config)#
```

Applying Policy Maps to an Interface

The service-policy type qos (Interface mode) command applies a specified policy map to the configuration mode interface.

These commands apply ***PMAP-1*** policy map to ***interfaceEthernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# show active
switch(config-if-Et8)# service-policy input PMAP-1
switch(config-if-Et8)# show active
interface Ethernet8
   service-policy type qos input PMAP-1
switch(config-if-Et8)#
```

10.2.2.3 Configuring PBR Policies Arad Platform Switches

Policy-Based Routing (PBR) is implemented by creating class maps and policy maps, then applying the policy maps to Ethernet interfaces, port channel interfaces or switch virtual interfaces (SVIs).

Creating PBR Class Maps

PBR policies utilize class maps that are created and modified in the ***class-map*** configuration mode. The class-map type pbr command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode to create a PBR class map named CMAP1.

```
switch(config)# class-map type pbr match-any CMAP1
switch(config-cmap-PBR-CMAP1)#
```

A class map contains one or more access control lists (ACLs). The match (policy-map (pbr)) command assigns an ACL to the class map. Subsequent **match** commands add additional ACLs to the class map. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded; if a class map includes ACLs with deny rules, the configuration reverts to its previous state.

Example

This command adds the ACL named ***ACL1*** to the class map.

```
switch(config-cmap-PBR-CMAP1)# match ip access-group ACL1
switch(config-cmap-PBR-CMAP1)#
```

The ***class-map*** configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **`show active`** command displays the saved version of class map.

The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***.

```
switch(config-cmap-PBR-CMAP1)# show active
switch(config-cmap-PBR-CMAP1)#
```

The **`exit`** command returns the switch to the ***global*** configuration mode and saves pending class map changes. The **`abort`** command returns the switch to the ***global*** configuration mode and discards pending changes.

Example

This command exits class-map configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-PBR-CMAP1)# exit
switch(config)# show class-map type pbr CMAP1
class-map type pbr match-any CMAP1
   10 match ip access-group ACL1
switch(config)#
```

Creating PBR Policy Maps

Policy maps are created and modified in policy-map configuration mode. The policy-map type pbr command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for creating a PBR policy map named ***PMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)#
```

Policy map are edited by adding or removing classes. A class automatically contains its eponymous class map; next-hop commands are added or edited in the ***policy-map-class*** configuration mode. The class (policy-map (pbr)) command adds a class to the configuration mode policy map and places the switch in the ***policy-map-class*** configuration mode, where next-hop commands are added to the class.

Examples

- This command adds the *CMAP1* class to the policy map and places the switch into the ***policy-map-class*** configuration mode.

  ```
  switch(config-pmap-PMAP1)# class CMAP1
  ```

```
switch(config-pmap-c-PMAP1-CMAP1)#
```

The set nexthop (policy-map-class pbr) command configures the next hop for data that passes the class map.

- This command configures the policy map to set the next hop to ***10.12.0.5*** on packets filtered by the class map.

```
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop 10.12.0.5
switch(config-pmap-c-PMAP1-CMAP1)#
```

The set nexthop-group (policy-map-class(pbr) Arad) command configures a nexthop group as the next hop for data that passes the class map.

- These commands configure the policy map ***PMAP1*** to set the next hop to a nexthop group named ***GROUP1*** for traffic defined by class map ***CMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# class CMAP1
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop-group GROUP1
switch(config-pmap-c-PMAP1-CMAP1)#
```

The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the currently saved map version.

- These commands exits the ***policy-map-class*** configuration mode, then exits the ***policy-map*** configuration mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-PMAP1-CMAP1)# exit
switch(config-pmap-PMAP1)# exit
switch(config)#
```

Applying a PBR Policy Map to an Interface

The service-policy type pbr (Interface mode) command applies the specified PBR policy map to the configuration mode interface. Only one PBR service policy is supported per interface.

These commands apply the PMAP1 PBR policy map to ***interface ethernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# service-policy type pbr input PMAP1
switch(config-if-Et8)#
```

Hardware Decapsulation

When hardware decapsulation takes place, PBR policy maps on Arad platform switches match on outer packet headers (i.e., they match based on the attributes of the packet before it is decapsulated).

10.2.3 Traffic Management Configuration FM6000 Platform Switches

Traffic policies are implemented by policy maps, which are applied to the control plane or an interface. Policy maps contain classes, which are composed of class maps and traffic resolution commands. Traffic Management Conceptual Overview describes traffic policies.

FM6000 platform switches support the following traffic policies:

- Control plane policies manage control plane traffic.
- QoS traffic policies manage traffic on Ethernet and port channel interfaces.

These sections describe the construction and application of policy maps on FM6000 platform switches:

- Configuring Control Plane Traffic Policies FM6000 Platform Switches
- Configuring QoS Traffic Policies FM6000 Platform Switches
- Configuring PBR Policies FM6000 Platform Switches

10.2.3.1 Configuring Control Plane Traffic Policies FM6000 Platform Switches

Default control plane traffic policies are implemented automatically without user intervention. These policies are modified by associating traffic resolution commands with static classes that comprise the control plane policy map.

Static Class Maps

Control plane traffic policies utilize static class maps, which are provided by the switch, are not editable, and cannot be deleted.

Editing the Policy Map

The only control plane policy map is **copp-system-policy**, which cannot be deleted. In its default form, **copp-system-policy** consists of the classes listed in copp-system-policy default classes: FM6000 Platform Switches. Although the underlying class map of each class cannot be edited, the traffic resolution commands can be adjusted. The default classes cannot be removed from the policy map and their sequence within the policy map is not editable.

Table 64: Copp-system-policy Default Classes: FM6000 Platform Switches

Class Name	shape (pps)	bandwidth (pps)
copp-system-arp	10000	1000
copp-system-default	8000	1000
copp-system-ipmcrsvd	10000	1000
copp-system-ipmcmiss	10000	1000
copp-system-igmp	10000	1000
copp-system-l2rsvd	10000	10000
copp-system-l3slowpath	10000	1000
copp-system-pim-ptp	10000	1000
copp-system-ospf-isis	10000	1000
copp-system-selfip	5000	5000
copp-system-selfip-tc6to7	5000	5000
copp-system-sflow	25000	1000

Policy maps are modified in the ***policy-map*** configuration mode. The `policy-map type copp` command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for editing ***copp-system-policy***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)#
```

The `class (policy-map (control-plane) FM6000)` command enters the ***policy-map-class*** configuration mode, where traffic resolution commands are modified for the configuration mode class.

Example

This command enters the ***policy-map-class*** configuration mode for the copp-system-arp static class.

```
switch(config-pmap-copp-system-policy)# class copp-system-arp
switch(config-pmap-c-copp-system-policy-copp-system-arp)#
```

Two traffic resolution commands determine bandwidth parameters for class traffic:

- bandwidth (policy-map-class (control-plane) FM6000)
- shape (policy-map-class (control-plane) FM6000)

Example

These commands configure a bandwidth range of ***2000*** to ***4000*** packets per seconds (pps) for traffic filtered by the copp-system-arp class map:

```
switch(config-pmap-c-copp-system-policy-copp-system-arp)# bandwidth pps 2000
switch(config-pmap-c-copp-system-policy-copp-system-arp)# shape pps 4000
switch(config-pmap-c-copp-system-policy-copp-system-arp)#
```

The policy-map and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the saved version of policy map. The **`show pending`** command displays the modified policy map.

Example

These commands exit the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the ***policy-map*** configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class CP-CMAP_1
    shape pps 4000
    bandwidth pps 2000

  class copp-system-bpdu

  class copp-system-lldp

  class copp-system-lacp

  class copp-system-arp

  class copp-system-arpresolver

  class copp-system-default

switch(config-pmap-copp-system-policy)#exit
switch(config)#
```

Applying Policy Maps to the Control Plane

The **copp-system-policy** policy map is always applied to the control plane. No commands are available to add or remove this assignment.

10.2.3.2 Configuring QoS Traffic Policies FM6000 Platform Switches

QoS traffic policies are implemented by creating class maps and policy maps, then applying the policy maps to Ethernet and port channel interfaces.

Creating Class Maps

QoS traffic policies utilize dynamic class maps that are created and modified in the ***class-map*** configuration mode. The `class-map type qos` command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode to create QoS class map named ***Q-CMap_1***.

```
switch(config)# class-map type qos match-any Q-CMap_1
switch(config-cmap-Q-CMap_1)#
```

A class map contains one IPv4 access control list (ACL). The `match (class-map (qos) FM6000)` command assigns an ACL to the class map. Subsequent **`match`** commands replace the existing **`match`** command. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded.

Example

This command adds the IPv4 ACL named ***ACL_1*** to the class map.

```
switch(config-cmap-Q-CMap_1)# match ip access-group ACL_1
switch(config-cmap-Q-CMap_1)#
```

The ***class-map*** configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **`show active`** command displays the saved version of class map. The **`show pending`** command displays the unsaved class map.

Example

The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***. The **`show pending`** command displays the class map to be stored upon exiting the ***class-map*** configuration mode.

```
switch(config-cmap-Q-CMap_1)# show active
switch(config-cmap-Q-CMap_1)# show pending
class-map type qos match-any Q-CMap_1
   match ip access-group ACL_1

switch(config-cmap-Q-CMap_1)#
```

The **`exit`** command returns the switch to the ***global*** configuration mode and saves pending class map changes. The **`abort`** command returns the switch to the ***global*** configuration mode and discards pending changes.

Example

This command exits the ***class-map*** configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-CP-CMAP_1)# exit
switch(config)# show class-map type control-plane CP-CMAP_1
  Class-map: CP-CMAP_1 (match-any)
    Match: ip access-group name ACLv4_1
```

```
switch(config)#
```

Creating Policy Maps

Policy maps are created and modified in the ***policy-map*** configuration mode. The `policy-map type quality-of-service` command enters the ***policy-map*** configuration mode.

Example

This command places the switch in the ***policy-map*** configuration mode and creates a QoS policy map named ***Q-PMAP_1***.

```
switch(config)# policy-map type quality-of-service Q-PMAP_1
switch(config-pmap-Q-PMAP_1)#
```

Policy map are edited by adding or removing classes. A class automatically contains its eponymous class map; traffic resolution commands are added or edited in the ***policy-map-class*** configuration mode. The `class (policy-map (qos) FM6000)` command adds a class to the configuration mode policy map and places the switch in the *policy-map-class* configuration mode, where traffic resolution commands are added to the class.

Example

This command adds the ***Q-CMap_1*** class to the ***Q-PMAP_1*** policy map and places the switch in the ***policy-map-class*** configuration mode.

```
switch(config-pmap-Q-PMAP_1)# class Q-CMap_1
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

`set (policy-map-class (qos) FM6000)` commands configure traffic resolution methods for data that passes the class map:

- **`set cos`** sets the Layer 2 CoS field.
- **`set dscp`** sets the DSCP value in the ToS byte.
- **`set traffic class`** specifies a traffic class queue.

Example

These commands configure the policy map to set the ***CoS field 7*** on packets filtered by the class map, then assigns those packets to ***traffic class 4***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set cos 7
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set traffic-class 4
```

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** and **`show pending`** commands display the saved and modified policy map versions, respectively.

Example

These commands exit the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the ***policy-map*** configuration mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# exit
switch(config-pmap-Q-PMAP_1)# show pending
policy-map type quality-of-service Q-PMAP_1
  class Q-CMap_1
    set cos 7
    set traffic-class 4

  class class-default

switch(config-pmap-Q-PMAP_1)# exit
switch(config)#
```

The last class in all QoS policy maps is ***class-default***. The ***class-default*** class map matches all traffic except IPv4 or IPv6 traffic and provides no traffic resolution commands. The ***class-default*** class map is not editable; traffic resolution commands can be added to the ***class-default*** class.

To modify traffic resolution commands for the ***class-default*** class, enter the ***policy-map-class*** configuration mode for the class, then enter the desired **`set`** commands.

Example

These commands enter the ***policy-map-class*** configuration mode for ***class-default***, configures the stream to enter ***traffic class 2***, and saves the altered policy map to ***running-config***.

```
switch(config)# policy-map type quality-of-service Q-PMap_1
switch(config-pmap-Q-PMap_1) #class class-default
switch(config-pmap-c-Q-PMap_1-class-default)# set traffic-class 2
switch(config-pmap-c-Q-PMap_1-class-default)# exit
switch(config-pmap-Q-PMap_1)# exit
switch(config)# show policy-map type qos Q-PMap_1
Service-policy Q-PMap_1

  Class-map: Q-CMap_1 (match-any)
    Match: ipv6 access-group name ACLv6_1
       set cos 7
       set traffic-class 4

  Class-map: class-default (match-any)
       set traffic-class 2

switch(config)#
```

Applying Policy Maps to an Interface

The service-policy type qos (Interface mode) command applies a specified policy map to the configuration mode interface.

These commands apply ***PMAP-1*** policy map to ***interface ethernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# show active
switch(config-if-Et8)# service-policy input PMAP-1
switch(config-if-Et8)# show active
interface Ethernet8
   service-policy type qos input PMAP-1
switch(config-if-Et8)#
```

10.2.3.3 Configuring PBR Policies FM6000 Platform Switches

Policy-Based Routing (PBR) is implemented by creating class maps and policy maps, then applying the policy maps to Ethernet interfaces, port channel interfaces or Switch Virtual Interfaces (SVIs).

Creating PBR Class Maps

PBR policies utilize class maps that are created and modified in the ***class-map*** configuration mode. The `class-map type pbr` command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode to create a PBR class map named ***CMAP1***.

```
switch(config)# class-map type pbr match-any CMAP1
switch(config-cmap-PBR-CMAP1)#
```

A class map contains one or more IPv4 access control lists (ACLs). The `match (policy-map (pbr))` command assigns an ACL to the class map. Subsequent **`match`** commands add additional ACLs to the class map. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded; if a class map includes ACLs with deny rules, the configuration reverts to its previous state.

On FM6000 platform switches, counters are not supported, so a `counters per-entry (ACL configuration modes)` command in an ACL is ignored.

Example

This command adds the IPv4 ACL named ***ACL1*** to the class map.

```
switch(config-cmap-PBR-CMAP1)# match ip access-group ACL1
switch(config-cmap-PBR-CMAP1)#
```

The ***class-map*** configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **`show active`** command displays the saved version of class map.

The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***.

```
switch(config-cmap-PBR-CMAP1)# show active
switch(config-cmap-PBR-CMAP1)#
```

The **`exit`** command returns the switch to ***global*** configuration mode and saves pending class map changes. The **`abort`** command returns the switch to ***global*** configuration mode and discards pending changes.

Example

This command exits the ***class-map*** configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-PBR-CMAP1)# exit
switch(config)# show class-map type pbr CMAP1
class-map type pbr match-any CMAP1
   10 match ip access-group ACL1
switch(config)#
```

Creating PBR Policy Maps

Policy maps are created and modified in the ***policy-map*** configuration mode. The `policy-map type pbr` command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for creating a PBR policy map named ***PMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)#
```

Policy map are edited by adding or removing classes. A class automatically contains its eponymous class map; next-hop commands are added or edited in the ***policy-map-class*** configuration mode. The `class (policy-map (pbr))` command adds a class to the configuration mode policy map and places the switch in the ***policy-map-class*** configuration mode, where next-hop commands are added to the class.

Examples

- This command adds the ***CMAP1*** class to the policy map and places the switch in the ***policy-map-class*** configuration mode.

  ```
  switch(config-pmap-PMAP1)# class CMAP1
  switch(config-pmap-c-PMAP1-CMAP1)#
  ```

The `set nexthop (policy-map-class pbr)` command configures the next hop for data that passes the class map.

- This command configures the policy map to set the next hop to ***10.12.0.5*** on packets filtered by the class map.

```
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop 10.12.0.5
switch(config-pmap-c-PMAP1-CMAP1)#
```

The ***policy-map*** and ***policy-map-clas***s configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the currently saved map version.

Example

These commands exits the ***policy-map-class*** configuration mode, then exits the ***policy-map configuration*** mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-PMAP1-CMAP1)# exit
switch(config-pmap-PMAP1)# exit
switch(config)#
```

Applying a PBR Policy Map to an Interface

The `service-policy type pbr (Interface mode)` command applies the specified PBR policy map to the configuration mode interface. Only one PBR service policy is supported per interface.

These commands apply the ***PMAP1*** PBR policy map to ***interface ethernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# service-policy type pbr input PMAP1
switch(config-if-Et8)#
```

Hardware Decapsulation

When hardware decapsulation takes place, PBR policy maps on FM6000 platform switches match on outer packet headers (i.e., they match based on the attributes of the packet before it is decapsulated).

10.2.4 Traffic Management Configuration Petra Platform Switches

Traffic policies are implemented by policy maps, which are applied to the control plane. Policy maps contain classes, which are composed of class maps and traffic resolution commands. QoS traffic policies are not supported on 7500 Series switches.

Traffic Management Conceptual Overview describes traffic policies.

10.2.4.1 Configuring Control Plane Traffic Policies Petra Platform Switches

Default control plane traffic policies are implemented automatically without user intervention. These policies are modified by associating traffic resolution commands with static classes that comprise the control plane policy map.

Static Class Maps

Control plane traffic policies utilize static class maps, which are provided by the switch, are not editable, and cannot be deleted.

Editing the Policy Map

The only control plane policy map is **copp-system-policy**, which cannot be deleted. In its default form, **copp-system-policy** consists of the classes listed in copp-system-policy default classes: Petra Platform Switches. Although the underlying class map of each class cannot be edited, the traffic resolution commands can be adjusted. The default classes cannot be removed from the policy map and their sequence within the policy map is not editable.

Table 65: copp-system-policy default classes: Petra Platform Switches

Class Name	shape (kbps)	bandwidth (kbps)
copp-system-bpdu	2500	1250
copp-system-default	2500	250
copp-system-igmp	2500	250
copp-system-ipbroadcast	2500	250
copp-system-ipmc	2500	250
copp-system-ipmcmiss	2500	250
copp-system-ipmcrsvd	2500	250
copp-system-ipunicast	NO LIMIT	250
copp-system-l3destmiss	2500	250
copp-system-l3slowpath	2500	250
copp-system-l3ttl0	2500	250
copp-system-l3ttl1	2500	250
copp-system-lacp	2500	1250
copp-system-lldp	2500	250
copp-system-unicast-arp	2500	250

Policy maps are modified in the ***policy-map*** configuration mode. The `policy-map type copp` command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for editing **copp-system-policy**.

```
switch(config)# policy-map type copp copp-system-policy
```

```
switch(config-pmap-copp-system-policy)#
```

The `class (policy-map (control-plane) Petra)` command enters the ***policy-map-class*** configuration mode, where traffic resolution commands are modified for the configuration mode class.

Example

- This command enters the ***policy-map-class*** configuration mode for the **copp-system-lldp** static class.

```
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

Two traffic resolution commands determine bandwidth parameters for class traffic:

- `bandwidth (policy-map-class (control-plane) Petra)` specifies the minimum bandwidth.
- `shape (policy-map-class (control-plane) Petra)` specifies the maximum bandwidth.

Example

These commands configure a bandwidth range of ***2000*** to ***4000*** kilobits per seconds (kbps) for traffic filtered by the **copp-system-arp** class map:

```
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# bandwidth kbps 2000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# shape kbps 4000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the saved version of policy map. The **`show pending`** command displays the configured policy map.

Petra platform switches do not support all discrete rate values. When a **`bandwidth`** or **`shape`** command specifies a value that is not supported, the switch converts the rate to the next highest discrete value that it supports. The show policy-map interface type qos command displays the converted rate and not the user configured rate.

Example

These commands exits the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the ***policy-map*** configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class copp-system-bpdu

  class copp-system-lldp
    shape kbps 4000
    bandwidth kbps 2000
```

```
  class copp-system-lacp

switch(config-pmap-copp-system-policy)# exit
switch(config)#
```

Changes are saved with the **exit** command or discarded with the **abort** command. The **show active** command displays the saved version of policy map. The **show pending** command displays the modified policy map.

Displaying Policy Maps

The show policy-map interface type qos command displays the traffic resolution rates of the policy maps classes and the number of packets filtered and dropped as a result of the class maps. The shape and bandwidth rates may differ from configured values, because the switch does not support all discrete rate values.

Example

These commands exits the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the *policy-map* configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy
  Hardware programming status: InProgress

  Class-map: copp-system-mlag (match-any)
       shape : 10000001 kbps
       bandwidth : 10000001 kbps
      Out Packets : 0
      Drop Packets : 0

  Class-map: copp-system-lacp (match-any)
       shape : 2604 kbps
       bandwidth : 1302 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

Applying Policy Maps to the Control Plane

The **copp-system-policy** policy map is always applied to the control plane. No commands are available to add or remove this assignment.

10.2.4.2 Configuring QoS Traffic Policies Petra Platform Switches

QoS traffic policies are not supported on Petra platform switches.

10.2.4.3 Configuring PBR Policies Petra Platform Switches

PBR policies are not supported on Petra platform switches.

10.2.5 Traffic Management Configuration Trident Platform Switches

Traffic policies are implemented by policy maps, which are applied to the control plane or an interface. Policy maps contain classes, which are composed of class maps and traffic resolution commands. Traffic Management Conceptual Overview describes traffic policies.

Trident platform switches support the following traffic policies:

- Control plane policies manage control plane traffic.
- QoS traffic policies manage traffic on Ethernet and port channel interfaces.

These sections describe the construction and application of policy maps:

- Configuring Control Plane Traffic Policies Trident Platform Switches
- Configuring QoS Traffic Policies Trident Platform Switches
- Configuring PBR Policies Trident Platform Switches

10.2.5.1 Configuring Control Plane Traffic Policies Trident Platform Switches

Default control plane traffic policies are implemented automatically without user intervention. These policies are modified by creating class maps and editing the policy map to include the new class maps.

Creating Class Maps

Control plane traffic policies utilize static and dynamic class maps. Static class maps are provided by the switch, are not editable, and cannot be deleted. Dynamic class maps are created and modified in the ***class-map*** configuration mode. The `class-map type copp` command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode for creating or editing a control plane dynamic class map named ***CP-CMAP_1***.

```
switch(config)# class-map type copp match-any CP-CMAP_1
switch(config-cmap-CP-CMAP_1)#
```

Class maps contain one IPv4 or IPv6 access control list (ACL). The match (class-map (control-plane) Trident) command assigns an ACL to the class map. Subsequent **`match`** commands replace the existing **`match`** command. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded.

Example

This command assigns the IPv4 ACL named ***ACLv4_1*** to the class map.

```
switch(config-cmap-CP-CMAP_1)# match ip access-group ACLv4_1
```

```
switch(config-cmap-CP-CMAP_1)#
```

The ***class-map*** configuration mode is a group-change mode. Changes are saved by exiting the mode. The **`show active`** command displays the saved version of class map. The **`show pending`** command displays the unsaved class map.

Example

The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***. The **`show pending`** command displays the class map to be stored upon exiting the ***class-map*** configuration mode.

```
switch(config-cmap-CP-CMAP_1)# show active
switch(config-cmap-CP-CMAP_1)# show pending
class-map type copp match-any CP-CMAP_1
   match ip access-group ACLv4_1

switch(config-cmap-CP-CMAP_1)#
```

The **`exit`** command returns the switch to the ***global*** configuration mode and saves pending class map changes. The **`abort`** command returns the switch to the ***global*** configuration mode and discards pending class map changes.

Example

This command exits the ***class-map*** configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-CP-CMAP_1)# exit
switch(config)# show class-map type control-plane CP-CMAP_1
  Class-map: CP-CMAP_1 (match-any)
    Match: ip access-group name ACLv4_1
switch(config)#
```

Editing the Policy Map

The only control plane policy map is **copp-system-policy**, which cannot be deleted. In its default form, **copp-system-policy** consists of the classes listed in copp-system-policy default classes: Trident Platform Switches. Although the underlying class map of each class cannot be edited, the traffic resolution commands can be adjusted. The default classes cannot be removed from the policy map and their sequence within the policy map is not editable.

Table 66: copp-system-policy default classes: Trident Platform Switches

Class Name	shape (pps)	bandwidth (pps)
copp-system-bpdu	5000	5000
copp-system-lacp	5000	5000
copp-system-selfip-tc6to7	5000	5000
copp-system-selfip	5000	5000
copp-system-tc6to7	10000	1000
copp-system-lldp	10000	1000
copp-system-ipmcrsvd	10000	1000
copp-system-igmp	10000	1000
copp-system-ipmcmiss	10000	1000
copp-system-glean	10000	1000
copp-system-tc3to5	10000	1000
copp-system-arp	10000	1000
copp-system-arpresolver	10000	1000
copp-system-l3destmiss	10000	1000
copp-system-l3slowpath	10000	1000
copp-system-l3ttl1	10000	1000
copp-system-default	8000	1000
copp-system-acllog	10000	1000
copp-system-sflow	25000	0

Policy maps are modified in the ***policy-map*** configuration mode. The `policy-map type copp` command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for editing **copp-system-policy**.

```
switch(config)#policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)#
```

Dynamic classes are inserted in front of the static classes. Classes automatically contain their eponymous class map; traffic resolution commands are created or edited in the ***policy-map-class*** configuration mode. The class (policy-map (control-plane) Trident) command adds a class to the policy map and places the switch in the ***policy-map-class*** configuration mode, where traffic resolution commands are added to the class.

Example

This command adds the ***CP-CMAP_1*** class to the copp-system-policy policy map and places the switch in the ***policy-map-class*** configuration mode.

```
switch(config-pmap-copp-system-policy)# class CP-CMAP_1
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)#
```

Two traffic resolution commands determine bandwidth parameters for class traffic:

- bandwidth (policy-map-class (control-plane) Trident) specifies the minimum bandwidth.
- shape (policy-map-class (control-plane) Trident) specifies the maximum bandwidth.

Example

These commands configure a bandwidth range of ***2000*** to ***4000*** packets per seconds (pps) for traffic filtered by the ***CP-CMAP_1*** class map:

```
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)# bandwidth pps 2000
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)# shape pps 4000
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)#
```

The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the saved version of policy map. The **`show pending`** command displays the modified policy map.

Example

These commands exits the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the ***policy-map*** configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config-pmap-c-copp-system-policy-CP-CMAP_1)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class CP-CMAP_1
    shape pps 4000
    bandwidth pps 2000

  class copp-system-bpdu

  class copp-system-lldp

  class copp-system-lacp

  class copp-system-arp

  class copp-system-arpresolver

  class copp-system-default

switch(config-pmap-copp-system-policy)# exit
switch(config)#
```

To modify traffic resolution commands for a static class, enter the ***policy-map-class*** configuration mode for the class, then enter the desired **bandwidth** and **shape** commands.

Example

These commands enters the ***policy-map-class*** configuration mode for **copp-system-bpdu** class, change the bandwidth range for the class, then save the altered policy map to ***running-config***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-bpdu
switch(config-pmap-c-copp-system-policy-copp-system-bpdu)# shape pps 200
switch(config-pmap-c-copp-system-policy-copp-system-bpdu)# bandwidth pps 100
switch(config-pmap-c-copp-system-policy-copp-system-bpdu)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class CP-CMAP_1
    shape pps 4000
    bandwidth pps 2000

  class copp-system-bpdu
    shape pps 200
    bandwidth pps 100

  class copp-system-lldp

switch(config-pmap-copp-system-policy)# exit
switch(config)#
```

Applying Policy Maps to the Control Plane

The **copp-system-policy** policy map is always applied to the control plane. No commands are available to add or remove this assignment.

10.2.5.2 Configuring QoS Traffic Policies Trident Platform Switches

QoS traffic policies are implemented by creating class maps and policy maps, then applying the policy maps to Ethernet and port channel interfaces.

Creating Class Maps

QoS traffic policies utilize dynamic class maps that are created and modified in the ***class-map*** configuration mode. The `class-map type qos` command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode to create QoS class map named ***Q-CMap_1***.

```
switch(config)# class-map type qos match-any Q-CMap_1
switch(config-cmap-Q-CMap_1)#
```

A class map contains one IPv4 or IPv6 Access Control List (ACL). The `match (class-map (qos) Trident)` command assigns an ACL to the class map. Subsequent **match** commands replace the existing **match** command. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded.

Example

This command adds the IPv6 ACL named **ACLv6_1** to the class map.

```
switch(config-cmap-Q-CMap_1)# match ipv6 access-group ACLv6_1
switch(config-cmap-Q-CMap_1)#
```

The ***class-map*** configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **show active** command displays the saved version of class map. The **show pending** command displays the unsaved class map.

Example

The **show active** command indicates that the configuration mode class map is not stored in ***running-config***. The **show pending** command displays the class map to be stored upon exiting the ***class-map*** configuration mode.

```
switch(config-cmap-Q-CMap_1)# show active
switch(config-cmap-Q-CMap_1)# show pending
class-map type qos match-any Q-CMap_1
   match ipv6 access-group ACLv6_1

switch(config-cmap-Q-CMap_1)#
```

The **exit** command returns the switch to ***global*** configuration mode and saves pending class map changes. The **abort** command returns the switch to ***global*** configuration mode and discards pending class map changes.

Example

This command exits the ***class-map*** configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-CP-CMAP_1)# exit
switch(config)# show class-map type control-plane CP-CMAP_1
  Class-map: CP-CMAP_1 (match-any)
    Match: ip access-group name ACLv4_1
switch(config)#
```

Creating Policy Maps

Policy maps are created and modified in the ***policy-map*** configuration mode. The `policy-map type quality-of-service` command enters the ***policy-map*** configuration mode.

Example

This command enters the ***policy-map*** configuration mode for creating a QoS policy map named ***Q-PMAP_1***.

```
switch(config)# policy-map type quality-of-service Q-PMAP_1
switch(config-pmap-Q-PMAP_1)#
```

Policy maps are edited by adding or removing classes. A class automatically contains its eponymous class map; traffic resolution commands are added or edited in the ***policy-map-class*** configuration mode. The `class (policy-map (qos) Trident)` command adds a class to the configuration mode policy map and places the switch in the ***policy-map-class*** configuration mode, where traffic resolution commands are added to the class.

Example

This command adds the ***Q-CMap_1*** class to the ***Q-PMAP_1*** policy map and places the switch in the ***policy-map-class*** configuration mode.

```
switch(config-pmap-Q-PMAP_1)# class Q-CMap_1
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

The `set (policy-map-class (qos) Trident)` command configures traffic resolution methods for data that passes the class map:

- **set cos** sets the layer 2 CoS field.
- **set dscp** sets the DSCP value in the ToS byte.
- **set traffic class** specifies a traffic class queue.

Example

These commands configure the policy map to set ***CoS field 7*** on packets filtered by the class map, then assigns those packets to ***traffic class 4***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set cos 7
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# set traffic-class 4
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)#
```

The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **exit** command or discarded with the **`abort`** command. The **`show active`** and **`show pending`** commands display the saved and modified policy map versions, respectively.

Example

These commands exit the ***policy-map-class*** configuration mode, display the pending policy-map, then exits the ***policy-map*** configuration mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-Q-PMAP_1-Q-CMap_1)# exit
switch(config-pmap-Q-PMAP_1)# show pending
policy-map type quality-of-service Q-PMAP_1
  class Q-CMap_1
    set cos 7
    set traffic-class 4

  class class-default

switch(config-pmap-Q-PMAP_1)# exit
switch(config)#
```

The last class in all QoS policy maps is ***class-default***. The ***class-default*** class map matches all traffic except IPv4 or IPv6 traffic and provides no traffic resolution commands. The ***class-default*** class map is not editable; traffic resolution commands can be added to the ***class-default*** class.

To modify traffic resolution commands for the ***class-default*** class, enter the ***policy-map-class*** configuration mode for the class, then enter the desired **`set`** commands.

Example

These commands enters the ***policy-map-class*** configuration mode for ***class-default***, configures the stream to enter ***traffic class 2***, and saves the altered policy map to ***running-config***.

```
switch(config)# policy-map type quality-of-service Q-PMap_1
switch(config-pmap-Q-PMap_1)# class class-default
switch(config-pmap-c-Q-PMap_1-class-default)# set traffic-class 2
switch(config-pmap-c-Q-PMap_1-class-default)# exit
switch(config-pmap-Q-PMap_1)# exit
switch(config)# show policy-map type qos Q-PMap_1
Service-policy Q-PMap_1

  Class-map: Q-CMap_1 (match-any)
    Match: ipv6 access-group name ACLv6_1
       set cos 7
       set traffic-class 4

  Class-map: class-default (match-any)
       set traffic-class 2

switch(config)#
```

Applying Policy Maps to an Interface

The `service-policy type qos (Interface mode)` command applies a specified policy map to the configuration mode interface.

Example

These commands apply ***PMAP-1*** policy map to ***interface ethernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# show active
switch(config-if-Et8)# service-policy input PMAP-1
```

```
switch(config-if-Et8)# show active
interface Ethernet8
   service-policy type qos input PMAP-1
switch(config-if-Et8)#
```

10.2.5.3 Configuring PBR Policies Trident Platform Switches

Policy-Based Routing (PBR) is implemented by creating class maps and policy maps, then applying the policy maps to Ethernet interfaces, port channel interfaces or Switch Virtual Interfaces (SVIs).

Creating PBR Class Maps

PBR policies utilize class maps that are created and modified in the ***class-map*** configuration mode. The `class-map type pbr` command enters the ***class-map*** configuration mode.

Example

This command enters the ***class-map*** configuration mode to create a PBR class map named ***CMAP1***.

```
switch(config)# class-map type pbr match-any CMAP1
switch(config-cmap-PBR-CMAP1)#
```

A class map contains one or more Access Control Lists (ACLs). The `match (policy-map (pbr))` command assigns an ACL to the class map. Subsequent **`match`** commands add additional ACLs to the class map. Class maps filter traffic only on ACL permit rules. Deny ACL rules are disregarded; if a class map includes ACLs with deny rules, the configuration reverts to its previous state.

Examples

- This command adds the ACL named ***ACL1*** to the class map.

  ```
  switch(config-cmap-PBR-CMAP1)# match ip access-group ACL1
  switch(config-cmap-PBR-CMAP1)#
  ```

  The ***class-map*** configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The **`show active`** command displays the saved version of class map.

- The **`show active`** command indicates that the configuration mode class map is not stored in ***running-config***.

  ```
  switch(config-cmap-PBR-CMAP1)# show active
  switch(config-cmap-PBR-CMAP1)#
  ```

- The **`exit`** command returns the switch to ***global*** configuration mode and saves pending class map changes. The **`abort`** command returns the switch to ***global*** configuration mode and discards pending changes.

- This command exits the ***class-map*** configuration mode and stores pending changes to ***running-config***.

```
switch(config-cmap-PBR-CMAP1)# exit
switch(config)# show class-map type pbr CMAP1
class-map type pbr match-any CMAP1
   10 match ip access-group ACL1
switch(config)#
```

Creating PBR Policy Maps

Policy maps are created and modified in the ***policy-map*** configuration mode. The `policy-map type pbr` command enters policy-map configuration mode.

Examples

- This command enters the ***policy-map*** configuration mode for creating a PBR policy map named ***PMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)#
```

Policy map are edited by adding or removing classes. A class automatically contains its eponymous class map; next-hop commands are added or edited in the ***policy-map-class*** configuration mode. The `class (policy-map (pbr))` command adds a class to the configuration mode policy map and places the switch in the ***policy-map-class*** configuration mode, where next-hop commands are added to the class.

- This command adds the ***CMAP1*** class to the policy map and places the switch in the ***policy-map-class*** configuration mode.

```
switch(config-pmap-PMAP1)# class CMAP1
switch(config-pmap-c-PMAP1-CMAP1)#
```

- The set nexthop (policy-map-class pbr) command configures the next hop for data that passes the class map.This command configures the policy map to set the next hop to ***10.12.0.5*** on packets filtered by the class map.

```
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop 10.12.0.5
switch(config-pmap-c-PMAP1-CMAP1)#
```

- The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the currently saved map version. These commands exits the ***policy-map-class*** configuration mode, then exits the ***policy-map*** configuration mode to save the altered policy map to ***running-config***.

```
switch(config-pmap-c-PMAP1-CMAP1)# exit
switch(config-pmap-PMAP1)# exit
switch(config)#
```

Applying a PBR Policy Map to an Interface

The service-policy type pbr (Interface mode) command applies the specified PBR policy map to the configuration mode interface. Only one PBR service policy is supported per interface.

- These commands apply the ***PMAP1*** PBR policy map to ***interface ethernet 8***.

```
switch(config)# interface ethernet 8
switch(config-if-Et8)# service-policy type pbr input PMAP1
switch(config-if-Et8)#
```

Hardware Decapsulation

When hardware decapsulation takes place, PBR policy maps on Trident platform switches match on inner packet headers (i.e., they match based on the attributes of the decapsulated packet).

10.2.6 Traffic Management Configuration Trident II Platform Switches

Traffic policies are implemented by policy maps, which are applied to the control plane or an interface. Policy maps contain classes, which are composed of class maps and traffic resolution commands. Traffic Management Conceptual Overview describes traffic policies.

Trident platform switches support the following traffic policies:

- Control plane policies manage control plane traffic.
- QoS traffic policies manage traffic on Ethernet and port channel interfaces.

10.2.6.1 Configuring Control Plane Traffic Policies Trident II Platform Switches

Default control plane traffic policies are implemented automatically without user intervention. These policies are modified by associating traffic resolution commands with static classes that comprise the control plane policy map.

Static Class Maps

Control plane traffic policies utilize static class maps, which are provided by the switch, are not editable, and cannot be deleted.

Editing the Policy Map

The only control plane policy map is **copp-system-policy**, which cannot be deleted. In its default form, **copp-system-policy** consists of the classes listed in copp-system-policy default classes: Trident II Platform Switches. Although the underlying class map of each class cannot be edited, the traffic resolution commands can be adjusted. The default classes cannot be removed from the policy map and their sequence within the policy map is not editable.

Table 67: copp-system-policy default classes: Trident II Platform Switches

Class Name	shape (pps)	bandwidth (pps)
copp-system-acllog	1000	10000
copp-system-arp	1000	10000
copp-system-arpresolver	1000	10000
copp-system-bfd	5000	10000
copp-system-bgp	5000	5000
copp-system-bpdu	5000	5000
copp-system-default	1000	8000
copp-system-glean	1000	10000
copp-system-igmp	1000	10000
copp-system-ipmcmiss	1000	10000
copp-system-ipmcrsvd	1000	10000
copp-system-l3destmiss	1000	10000
copp-system-l3slowpath	1000	10000
copp-system-l3ttl1	1000	10000
copp-system-lacp	5000	5000
copp-system-lldp	1000	10000
copp-system-mlag	5000	5000
copp-system-selfip	5000	5000
copp-system-selfip-tc6to7	5000	5000
copp-system-sflow	0	25024
copp-system-tc3to5	1000	10000
copp-system-tc6to7	1000	10000
copp-system-urm	1000	10000

Policy maps are modified in the ***policy-map*** configuration mode. The policy-map type copp command enters the ***policy-map*** configuration mode.

Examples

- This command enters the ***policy-map*** configuration mode for editing **copp-system-policy**.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)#
```

- The class (policy-map (control-plane) Trident II) command enters the ***policy-map-class*** configuration mode, where traffic resolution commands are modified for the configuration mode class.

- This command enters the ***policy-map-class*** configuration mode for the **`copp-system-lacp static`** class.

```
switch(config-pmap-copp-system-policy)# class copp-system-lacp
switch(config-pmap-c-copp-system-policy-copp-system-lacp)#
```

Two traffic resolution commands determine bandwidth parameters for class traffic:

- bandwidth (policy-map-class (control-plane) Trident II) specifies the minimum bandwidth.
- shape (policy-map-class (control-plane) Trident II) specifies the maximum bandwidth.

Examples

- These commands configure a bandwidth range of ***2000*** to ***4000*** packets per seconds (pps) for traffic filtered by the **copp-system-lacp** class map:

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# bandwidth pps 2000
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# shape pps 4000
switch(config-pmap-c-copp-system-policy-copp-system-lacp)#
```

- The ***policy-map*** and ***policy-map-class*** configuration modes are group-change modes. Changes are saved with the **`exit`** command or discarded with the **`abort`** command. The **`show active`** command displays the saved version of policy map. The **`show pending`** command displays the modified policy map.

- These commands exits the ***policy-map-class*** configuration mode, display the pending ***policy-map***, then exit ***policy-map*** configuration mode, which saves the altered policy map to ***running-config***.

```
switch(config-pmap-c-copp-system-policy-copp-system-lacp)# exit
switch(config-pmap-copp-system-policy)# show pending
policy-map type copp copp-system-policy
  class copp-system-bpdu

  class copp-system-lldp

  class copp-system-lacp
    shape pps 4000
    bandwidth pps 2000

  class copp-system-arp

switch(config-pmap-copp-system-policy)# exit
switch(config)#
```

Applying Policy Maps to the Control Plane

The **copp-system-policy** policy map is always applied to the control plane. No commands are available to add or remove this assignment.

10.2.7 Traffic Management Configuration Commands

Traffic Policy (Control Plane) Configuration Commands

- bandwidth (policy-map-class (control-plane) Arad)
- bandwidth (policy-map-class (control-plane) FM6000)
- bandwidth (policy-map-class (control-plane) Helix)
- bandwidth (policy-map-class (control-plane) Petra)
- bandwidth (policy-map-class (control-plane) Trident)
- bandwidth (policy-map-class (control-plane) Trident II)
- class-map type copp
- class (policy-map (control-plane) Arad)
- class (policy-map (control-plane) FM6000)
- class (policy-map (control-plane) Helix)
- class (policy-map (control-plane) Petra)
- class (policy-map (control-plane) Trident)
- class (policy-map (control-plane) Trident II)
- match (class-map (control-plane) Helix)
- match (class-map (control-plane) Trident)
- match (class-map (control-plane) Trident II)
- policy-map type copp
- shape (policy-map-class (control-plane) Arad)
- shape (policy-map-class (control-plane) FM6000)
- shape (policy-map-class (control-plane) Helix)
- shape (policy-map-class (control-plane) Petra)
- shape (policy-map-class (control-plane) Trident)
- shape (policy-map-class (control-plane) Trident II)

Traffic Policy (PBR) Configuration Commands

- action set-ttl
- class (policy-map (pbr))
- class-map type pbr
- feature pbr

- match (class-map (pbr))
- match (policy-map (pbr))
- platform arad tcam counters feature
- policy-map type pbr
- resequence (class-map (pbr))
- resequence (policy-map (pbr))
- service-policy type pbr (Interface mode)
- set nexthop (policy-map-class pbr)
- set nexthop-group (policy-map-class(pbr) Arad)

CPU Traffic Policy Command

- feature traffic-policy cpu
- feature traffic-policy port

Traffic Policy (QoS) Configuration Commands

- class-map type qos
- class (policy-map (qos) FM6000)
- class (policy-map (qos) Helix)
- class (policy-map (qos) Trident)
- class (policy-map (qos) Trident II)
- match (class-map (qos) FM6000)
- match (class-map (qos) Helix)
- match (class-map (qos) Trident)
- match (class-map (qos) Trident II)
- policy-map type quality-of-service
- policy-map type quality-of-service policer
- service-policy type qos (Interface mode)
- set (policy-map-class (qos) FM6000)
- set (policy-map-class (qos) Helix)
- set (policy-map-class (qos) Trident)
- set (policy-map-class (qos) Trident II)

Traffic Policy Display and Utility Commands

- clear policy-map counters
- show class-map type control-plane
- show class-map type pbr
- show class-map type qos
- show policy-map type copp
- show policy-map type pbr
- show policy-map type qos
- show policy-map type qos counters
- show policy-map copp
- show policy-map interface type qos
- show policy-map interface type qos counters
- show traffic-policy

10.2.7.1 action set-ttl

The TTL action is effective only when it is configured along with a set nexthop or nexthop-group action. The TCAM profile has the set-ttl-3b or set-ttl action in the pbr ip and pbr ipv6 features, such as in the tc-counters system profile.

Command Mode

For IP

TCAM feature PBR IP configuration mode.

For IPv6

TCAM feature PBR IPv6 configuration mode.

Command Syntax

`action set-time` [set-ttl | set-ttl-3b]

`no action set-time` [set-ttl | set-ttl-3b]

`default action set-time` [set-ttl | set-ttl-3b]

Parameters

- **set-ttl** Set time to live.
- **set-ttl-3b** Set 3-bit time to live.

Examples

- In the following example, for IP, the action sets the time to live for the next hop.

```
(config)# hardware tcam
(config-tcam)# profile pbr-set-ttl copy default
(config-tcam-profile-pbr-set-ttl)# feature pbr ip
(config-tcam-feature-pbr-ip)# action set-ttl
```

- In the following example, for IPv6, the action sets the time to live for the next hop group.

```
config)# hardware tcam
(config-tcam)# profile pbr-set-ttl copy default
(config-tcam-profile-pbr-set-ttl)# feature pbr ip
(config-tcam-feature-pbr-ip)# feature pbr ipv6
(config-tcam-feature-pbr-ipv6)# action set-ttl
```

10.2.7.2 bandwidth (policy-map-class (control-plane) Arad)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) Arad)**

Command Syntax

`bandwidth kbps` *kilobits*

`no bandwidth`

`default bandwidth`

Parameters

kilobits Minimum data rate in kilobits per second. Value ranges from ***1*** to ***10000000***.

Related Commands

- class (policy-map (control-plane) Arad) places the switch in the ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) Arad) specifies the maximum bandwidth for traffic defined by the associated class map in its configuration mode policy map class.

Static Classes Default Bandwidth

Arad platform switches define these default bandwidths for control plane static classes:

- copp-system-bgp 250 copp-system-l3lpmoverflow 250
- copp-system-bpdu 1250 copp-system-l3slowpath 250
- copp-system-default 250 copp-system-l3ttl1 250
- copp-system-ipbroadcast 250 copp-system-lacp 1250

- copp-system-ipmc 250 copp-system-linklocal 250
- copp-system-ipmcmiss 250 copp-system-lldp 250
- copp-system-ipunicast 250 copp-system-mlag 250
- copp-system-l2broadcast 250 copp-system-multicastsnoop 250
- copp-system-l2unicast 250 copp-system-OspfIsis 250
- copp-system-l3destmiss 250 copp-system-sflow 250

Example

These commands configure the minimum bandwidth of ***500*** kbps for data traffic specified by the class map **copp-system-lldp** of the default ***control-plane*** policy map.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# bandwidth kbps 500
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy
  Hardware programming status: InProgress

  Class-map: copp-system-lldp (match-any)
       shape : 2500 kbps
       bandwidth : 500 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

10.2.7.3 bandwidth (policy-map-class (control-plane) FM6000)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) FM6000)**

Command Syntax

```
bandwidth pps packets

no bandwidth

default bandwidth
```

Parameters

packets Minimum data rate in packets per second. Value ranges from ***1*** to ***100000***.

Related Commands

- class (policy-map (control-plane) FM6000) places the switch in ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) FM6000) specifies the maximum bandwidth for traffic defined by the associated class map in its configuration mode policy map class.

Static Classes Default Bandwidth

FM6000 platform switches define these default bandwidths for control plane static classes:

- copp-system-arp 1000 copp-system-l3slowpath 1000
- copp-system-default 1000 copp-system-pim-ptp 1000
- copp-system-ipmcrsvd 1000 copp-system-ospf-isis 1000
- copp-system-ipmcmiss 1000 copp-system-selfip 5000
- copp-system-igmp 1000 copp-system-selfip-tc6to7 5000

- copp-system-l2rsvd 10000 copp-system-sflow 1000

Example

These commands configure the minimum bandwidth of ***1000*** packets per second for data traffic specified by the class map ***PMAP-1*** in the policy map named **copp-system-policy**.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class PMAP-1
switch(config-pmap-c-copp-system-policy-PMAP-1)# bandwidth pps 1000
switch(config-pmap-c-copp-system-policy-PMAP-1)#
```

10.2.7.4 bandwidth (policy-map-class (control-plane) Helix)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) Helix)**

Command Syntax

```
bandwidth pps packets

no bandwidth

default bandwidth
```

Parameter

packets Minimum data rate in packets per second. Value ranges from ***1*** to ***100000***.

Related Commands

- class (policy-map (control-plane) Helix) places the switch in ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) Helix) specifies the maximum bandwidth for traffic defined by the associated class map in its configuration mode policy map class.

Static Classes Default Bandwidth

Helix platform switches define these default bandwidths for control plane static classes:

- copp-system-acllog 1000 copp-system-l3ttl1 1000
- copp-system-arp 1000 copp-system-lacp 5000
- copp-system-arpresolver 1000 copp-system-lldp 1000
- copp-system-bfd 5000 copp-system-mlag 5000

- copp-system-bgp 5000 copp-system-OspfIsis 5000
- copp-system-bpdu 5000 copp-system-selfip 5000
- copp-system-default 1000 copp-system-selfip-tc6to7 5000
- copp-system-glean 1000 copp-system-sflow 0
- copp-system-igmp 1000 copp-system-tc3to5 1000
- copp-system-ipmcmiss 1000 copp-system-tc6to7 1000
- copp-system-ipmcrsvd 1000 copp-system-urm 1000
- copp-system-l3destmiss 1000 copp-system-vrrp 1000
- copp-system-l3slowpath 1000

Example

These commands configure the minimum bandwidth of ***500*** packets per second for data traffic specified by the class map **copp-system-lldp**.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# bandwidth pps 500
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map interface control-plan copp-system-policy
Service-policy input: copp-system-policy
  Number of units programmed: 4
  Hardware programming status: Successful

  Class-map: copp-system-lldp (match-any)
       shape : 10000 pps
       bandwidth : 500 pps
      Out Packets : 304996
      Drop Packets : 0

switch(config)#
```

10.2.7.5 bandwidth (policy-map-class (control-plane) Petra)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) Petra)**

Command Syntax

```
bandwidth kbps kilobits

no bandwidth

default bandwidth
```

Parameter

kbits Minimum data rate in kilobits per second. Value ranges from ***1*** to ***10000000***.

Related Commands

- class (policy-map (control-plane) Petra) places the switch in ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) Petra) specifies the maximum bandwidth for traffic defined by the associated class map in its ***policy map class*** configuration mode .

Static Classes Default Bandwidth

Petra platform switches define these default bandwidths for control plane static classes:

- copp-system-bpdu 1250 copp-system-l3destmiss 250
- copp-system-default 250 copp-system-l3slowpath 250
- copp-system-igmp 250 copp-system-l3ttl0 250
- copp-system-ipbroadcast 250 copp-system-l3ttl1 250

- copp-system-ipmc 250 copp-system-lacp 1250
- copp-system-ipmcmiss 250 copp-system-lldp 250
- copp-system-ipmcrsvd 250 copp-system-unicast-arp 250
- copp-system-ipunicast 250

Guidelines

Petra does not support all discrete rate values. When a specified discrete value is not supported, the switch converts the rate to the next highest discrete value that it supports. The **show** command displays the converted rate and not the user-configured rate.

Example

These commands configure a minimum bandwidth of ***500*** kbps for data traffic specified by the class map ***copp-system-lldp*** of the default ***control-plane*** policy map. Because the switch does not support the discrete value of ***500*** kbps, it converts the bandwidth up to ***651*** kbps.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# bandwidth kbps 500
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy
  Hardware programming status: InProgress

  Class-map: copp-system-lldp (match-any)
       shape : 2766 kbps
       bandwidth : 651 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

10.2.7.6 bandwidth (policy-map-class (control-plane) Trident II)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) Trident II)**.

Command Syntax

```
bandwidth pps packets

no bandwidth

default bandwidth
```

Parameter

packets Minimum data rate in packets per second. Value ranges from *1* to ***100000***.

Related Commands

- class (policy-map (control-plane) Trident II) places the switch in ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) Trident II) specifies the maximum bandwidth for traffic defined by the associated class map in its configuration mode policy map class.

Static Classes Default Bandwidth

Trident II platform switches define these default bandwidths for control plane static classes:

- copp-system-acllog 1000 copp-system-l3slowpath 1000
- copp-system-arp 1000 copp-system-l3ttl1 1000
- copp-system-arpresolver 1000 copp-system-lacp 5000
- copp-system-bfd 5000 copp-system-lldp 1000

- copp-system-bgp 5000 copp-system-mlag 5000
- copp-system-bpdu 5000 copp-system-selfip 5000
- copp-system-default 1000 copp-system-selfip-tc6to7 5000
- copp-system-glean 1000 copp-system-sflow 0
- copp-system-igmp 1000 copp-system-tc3to5 1000
- copp-system-ipmcmiss 1000 copp-system-tc6to7 1000
- copp-system-ipmcrsvd 1000 copp-system-urm 1000
- copp-system-l3destmiss 1000

Example

These commands configure the minimum bandwidth of ***500*** packets per second for data traffic specified by the class map **copp-system-lldp**.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# bandwidth pps 500
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map interface control-plan copp-system-policy
Service-policy input: copp-system-policy
  Number of units programmed: 4
  Hardware programming status: Successful

  Class-map: copp-system-lldp (match-any)
       shape : 10000 pps
       bandwidth : 500 pps
      Out Packets : 304996
      Drop Packets : 0

switch(config)#
```

10.2.7.7 bandwidth (policy-map-class (control-plane) Trident)

The **bandwidth** command specifies the minimum bandwidth for traffic filtered by the configuration mode policy map class.

The **no bandwidth** and **default bandwidth** commands remove the minimum bandwidth guarantee for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration

accessed through **class (policy-map (control-plane) Trident)**.

Command Syntax

```
bandwidth pps packets

no bandwidth

default bandwidth
```

Parameter

packets Minimum data rate in packets per second. Value ranges from ***1*** to ***100000***.

Related Commands

- class (policy-map (control-plane) Trident) places the switch in ***policy-map-class*** (control plane) configuration mode.
- shape (policy-map-class (control-plane) Trident) specifies the maximum bandwidth for traffic defined by the associated class map in its configuration mode policy map class.

Static Classes Default Bandwidth

Trident platform switches define these default bandwidths for control plane static classes:

- copp-system-arp 1000 copp-system-lldp 1000
- copp-system-arpresolver 1000 copp-system-l3destmiss 1000
- copp-system-bpdu 5000 copp-system-l3slowpath 1000
- copp-system-default 1000 copp-system-l3ttl1 1000

- copp-system-glean 1000 copp-system-selfip 5000
- copp-system-igmp 1000 copp-system-selfip-tc6to7 5000
- copp-system-ipmcmiss 1000 copp-system-sflow 0
- copp-system-ipmcrsvd 1000 copp-system-tc6to7 1000
- copp-system-lacp 5000 copp-system-tc3to5 1000

Example

These commands configure the minimum bandwidth of ***1000*** packets per second for data traffic specified by the class map ***PMAP-1*** in the policy map named ***copp-system-policy***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class PMAP-1
switch(config-pmap-c-copp-system-policy-PMAP-1)# bandwidth pps 1000
switch(config-pmap-c-copp-system-policy-PMAP-1)#
```

10.2.7.8 class (policy-map (control-plane) Arad)

The **class** command places the switch in policy-map-class (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The control plane policy map contains ***20*** static classes. Each class contains an eponymous class map and may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content. Dynamic classes are not supported for control plane policing on Arad platform switches.

Each class corresponds to a transmission queue. Queue scheduling is round-robin until ***bandwidth*** rate for a queue is exceeded. Scheduling becomes strict-priority with CPU queue number determining priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to policy-map configuration mode. Saving policy-map-class changes also require an exit from policy-map mode, which saves pending policy-map-class and policy-map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove **policy-map-class** commands for the specified class assignment from the policy map.

Command Mode

Policy-Map (control plane) configuration accessed through **policy-map type copp** command.

Command Syntax

`class` *class_name*

`no class` *class_name*

`default class` *class_name*

Parameter

class_name name of the class.

Static Classes

Arad platform switches provide the following static control plane classes:

- copp-system-bgp copp-system-l2broadcast copp-system-linklocal
- copp-system-bpdu copp-system-l2unicast copp-system-lldp
- copp-system-default copp-system-l3destmiss copp-system-mlag
- copp-system-ipbroadcast copp-system-l3lpmoverflow copp-system-multicastsnoop
- copp-system-ipmc copp-system-l3slowpath copp-system-OspfIsis
- copp-system-ipmcmiss copp-system-l3ttl1 copp-system-sflow
- copp-system-ipunicast copp-system-lacp

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) Arad)
- shape (policy-map-class (control-plane) Arad)
- **`exit`** saves pending class map changes, then returns the switch to global configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to global configuration mode.

Related Commands

policy-map type copp places switch in ***policy-map*** (control plane) configuration mode.

Example

These commands enters ***policy-map-class*** configuration mode to modify the shape, bandwidth parameters associated with the static class named ***copp-system-lldp***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

10.2.7.9 class (policy-map (control-plane) FM6000)

The **class** command places the switch in ***policy-map-class*** (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The control plane policy map contains ***12*** static classes. Each class contains an eponymous class map and may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content. Dynamic classes are not supported for control plane policing on FM6000 platform switches.

Each class corresponds to a transmission queue. Queue scheduling is round-robin until ***bandwidth*** rate for a queue is exceeded. Scheduling becomes strict-priority with CPU queue number determining priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to policy-map configuration mode. Saving policy-map-class changes also require an exit from policy-map mode, which saves pending policy-map-class and policy-map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove **policy-map-class** commands for the specified class assignment from the policy map. The class is removed from the policy map if it is a dynamic class.

Command Mode

Policy-Map (control plane) configuration accessed through **policy-map type copp** command.

Command Syntax

`class` *class_name*

`no class` *class_name*

`default class` *class_name*

Parameter

class_name name of the class.

Static Classes

FM6000 platform switches provide the following static control plane classes:

- copp-system-arp copp-system-igmp copp-system-PimPtp
- copp-system-default copp-system-l2rsvd copp-system-selfip
- copp-system-ipmcmiss copp-system-l3slowpath copp-system-selfip-tc6to7
- copp-system-ipmcrsvd copp-system-OspfIsis copp-system-sflow

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) FM6000)
- shape (policy-map-class (control-plane) FM6000)
- **`exit`** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.

Related Commands

policy-map type copp places switch in ***policy-map*** (control plane) configuration mode.

Example

These commands enters ***policy-map-class*** configuration mode to modify the shape, bandwidth parameters associated with the static class named ***copp-system-arp***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-arp
switch(config-pmap-c-copp-system-policy-copp-system-arp)#
```

10.2.7.10 class (policy-map (control-plane) Helix)

The **class** command places the switch in ***policy-map-class*** (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The **control plane** policy map contains *23* static classes. Each class contains an eponymous class map and may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content. Dynamic classes are not supported for control plane policing on Helix platform switches.

Each class corresponds to a transmission queue. Queue scheduling is strict-priority; CPU queue number determines priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to ***policy-map*** configuration mode. Saving policy-map-class changes also require an exit from ***policy-map*** mode, which saves the pending ***policy-map-class*** and ***policy-map*** changes to ***running-config*** and returns the switch to global configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the ***policy-map-class*** commands for the specified class assignment from the policy map.

Command Mode

Policy-Map (control plane) configuration accessed through **policy-map type copp** command.

Command Syntax

`class` *class_name*

`no class` *class_name*

`default class` *class_name*

Parameter

class_name name of the class.

Static Classes

Helix platform switches provide the following static control plane classes:

- copp-system-acllog copp-system-ipmcmiss copp-system-OspfIsis
- copp-system-arp copp-system-ipmcrsvd copp-system-selfip
- copp-system-arpresolver copp-system-l3destmiss copp-system-selfip-tc6to7
- copp-system-bfd copp-system-l3slowpath copp-system-sflow
- copp-system-bgp copp-system-l3ttl1 copp-system-tc3to5
- copp-system-bpdu copp-system-lacp copp-system-tc6to7
- copp-system-default copp-system-lldp copp-system-urm
- copp-system-glean copp-system-lldp copp-system-vrrp
- copp-system-igmp copp-system-lldp

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) Helix)
- shape (policy-map-class (control-plane) Helix)
- **`exit`** saves pending class map changes, then returns the switch to the *global* configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.

Related Commands

policy-map type copp places switch in ***policy-map*** (control plane) configuration mode.

Example

These commands enters ***policy-map-class*** configuration mode to modify the shape, bandwidth parameters associated with the static class named ***copp-system-arp***.

```
switch(config)# policy-map
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

10.2.7.11 class (policy-map (control-plane) Petra)

The **class** command places the switch in policy-map-class (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The control plane policy map contains 15 static classes. Each class contains an eponymous class map and may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content. Dynamic classes are not supported for control plane policing on Petra platform switches.

Each class corresponds to a transmission queue. Queue scheduling is round-robin until ***bandwidth*** rate for a queue is exceeded. Scheduling becomes strict-priority with CPU queue number determining priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to ***policy-map*** configuration mode. Saving the ***policy-map-class*** changes also require an exit from ***policy-map*** mode, which saves the pending ***policy-map-class*** and ***policy-map*** changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the **policy-map-class** commands for the specified class assignment from the policy map.

Command Mode

Policy-Map (control plane) configuration accessed through policy-map type copp command.

Command Syntax

`class` *class_name*

`no class` *class_name*

`default class` *class_name*

Parameter

class_name name of the class.

Static Classes

Petra platform switches provide the following static control plane classes:

- copp-system-bpdu copp-system-ipmcmiss copp-system-l3ttl0
- copp-system-default copp-system-ipmcrsvd copp-system-l3ttl1
- copp-system-igmp copp-system-ipunicast copp-system-lacp
- copp-system-ipbroadcast copp-system-l3destmiss copp-system-lldp
- copp-system-ipmc copp-system-l3slowpath copp-system-unicast-arp

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) Petra)
- shape (policy-map-class (control-plane) Petra)
- **`exit`** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.

Related Commands

policy-map type copp places switch in ***policy-map*** (control plane) configuration mode.

Example

These commands enters ***policy-map-class*** configuration mode to modify the shape, bandwidth parameters associated with the static class named ***copp-system-lldp***.

```
switch(config)# policy-map
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

10.2.7.12 class (policy-map (control-plane) Trident II)

The **class** command places the switch in ***policy-map-clas***s (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The control plane policy map contains ***23*** static classes. Each class contains an eponymous class map and may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content. Dynamic classes are not supported for control plane policing on Trident II platform switches.

Each class corresponds to a transmission queue. Queue scheduling is strict-priority; CPU queue number determines priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to the ***policy-map*** configuration mode. Saving the ***policy-map-class*** changes also require an exit from the ***policy-map*** mode, which saves the pending ***policy-map-class*** and ***policy-map*** changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the ***policy-map-class*** commands for the specified class assignment from the policy map.

Command Mode

Policy-Map (control plane) configuration accessed through **policy-map type copp** command.

Command Syntax

`class` *class_name*

`no class` *class_name*

`default class` *class_name*

Parameter

class_name name of the class.

Static Classes

Trident II platform switches provide the following static control plane classes:

- copp-system-acllog copp-system-igmp copp-system-mlag
- copp-system-arp copp-system-ipmcmiss copp-system-selfip
- copp-system-arpresolver copp-system-ipmcrsvd copp-system-selfip-tc6to7
- copp-system-bfd copp-system-l3destmiss copp-system-sflow
- copp-system-bgp copp-system-l3slowpath copp-system-tc3to5
- copp-system-bpdu copp-system-l3ttl1 copp-system-tc6to7
- copp-system-default copp-system-lacp copp-system-urm
- copp-system-glean copp-system-lldp

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) Trident II)
- shape (policy-map-class (control-plane) Trident II)
- **`exit`** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.

Related Commands

policy-map type copp places switch in ***policy-map (control plane)*** configuration mode.

Example

These commands enters the ***policy-map-class*** configuration mode to modify the shape, bandwidth parameters associated with the static class named ***copp-system-arp***.

```
switch(config)# policy-map
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)#
```

10.2.7.13 class (policy-map (control-plane) Trident)

The **class** command places the switch in ***policy-map-class*** (control plane) configuration mode, which is a group change mode for changing bandwidth and shape parameters associated with a specified class. The command adds the specified class to the policy map if it was not previously included. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. The control plane policy map contains 18 static classes and up to *30* dynamic classes. Dynamic classes contain an eponymous class map. All classes may contain **bandwidth** and **shape** commands.

- The class map identifies a data stream.
- **bandwidth** command defines the streams minimum transmission rate through the control plane.
- **shape** command defines the streams maximum transmission rate through the control plane.

Dynamic class maps identify a data stream with an ACL assigned by **match (class-map (control-plane) Trident)**. Static class maps identify a data stream by definition. Each data packet is managed by commands of the first class whose map matches the packets content.

Static classes are provided with the switch and cannot be removed from the policy map or modified by the **class** command. Dynamic classes are user defined and added to the policy map by this command. Dynamic classes are always placed in front of the static classes. Bandwidth and shape parameters are editable for all classes.

Each class corresponds to a transmission queue. Queue scheduling is round-robin until ***bandwidth*** rate for a queue is exceeded. Scheduling becomes strict-priority with CPU queue number determining priority until the ***shape*** rate is reached. Packets are dropped after the shape rate is exceeded.

The **exit** command returns the switch to policy-map configuration mode. Saving the ***policy-map-class*** changes also require an exit from ***policy-map*** mode, which saves the pending ***policy-map-class*** and ***policy-map*** changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the ***policy-map-class*** commands for the specified class assignment from the policy map. The class is removed from the policy map if it is a dynamic class.

Command Mode

Policy-Map (control plane) configuration accessed through **policy-map type copp** command.

Command Syntax

`class` *class_name* [**PLACEMENT**]

`no class` *class_name* [**PLACEMENT**]

`default class` *class_name* [**PLACEMENT**]

Parameters

- ***class_name*** name of the class.
- **PLACEMENT** Specifies the classs map placement. Configurable only for dynamic classes.
  - **no parameter** New classes are placed between the dynamic and static classes. Previously defined classes retain their current policy map placement.
  - **insert-before *dynamic_class*** Class is inserted in front of the specified dynamic class.

Static Classes

Trident switches provide the following static control plane classes:

- copp-system-acllog copp-system-ipmcmiss copp-system-lldp
- copp-system-arp copp-system-ipmcrsvd copp-system-selfip
- copp-system-arpresolver copp-system-l3destmiss copp-system-selfip-tc6to7
- copp-system-bpdu copp-system-l3slowpath copp-system-sflow
- copp-system-glean copp-system-l3ttl1 copp-system-tc3to5
- copp-system-igmp copp-system-lacp copp-system-tc6to7

Commands Available in Policy-map-class (control plane) Configuration Mode

- bandwidth (policy-map-class (control-plane) Trident)
- shape (policy-map-class (control-plane) Trident)
- **`exit`** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.

Related Commands

- class-map type copp places switch in the ***class-map*** (control-plane) configuration mode.
- policy-map type copp places switch in the ***policy-map*** (control plane) configuration mode.

Example

These commands add ***CM-1*** class to the ***copp-system-policy*** policy map.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class CM-1
switch(config-pmap-c-copp-system-policy-CM-1)#
```

10.2.7.14 class (policy-map (pbr)

The **class (policy-map (pbr)** command places the switch in ***policy-map-class (pbr)*** configuration mode, which is a group change mode that modifies the specified class of the configuration mode Policy-Based Routing (PBR) policy map. The command adds the class to the policy map if it was not previously included in the policy map. All changes in a group change mode edit session are pending until the mode is exited, and can be canceled by using the **abort** command.

A PBR policy map is an ordered list of classes. Each class contains an eponymous class map and can contain set commands to specify next hop. Classes without set commands translate to no action being performed on that class of packets.

- The class map identifies a data stream through ACLs. Class maps are configured in the ***class-map*** (pbr) configuration mode.

- **Set** commands can be used to specify the next hop for a given class. **Set** commands are configured in ***policy-map-class*** (pbr) configuration mode.

PBR policy maps can also contain one or more raw match statements which filter incoming traffic without using ACLs. Data packets are managed by commands of the first class or raw match statement matching the packets contents.

The **exit** command returns the switch to the ***policy-map*** (pbr) configuration mode. However, saving the policy-map-class changes also requires an exit from ***policy-map*** (pbr) configuration mode. This saves all the pending policy map and policy-map-class changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the class assignment from the configuration mode policy map by deleting the corresponding **class** configuration from ***running-config***.

Command Mode

Policy-Map (pbr) Configuration accessed through **policy-map type pbr**.

Command Syntax

[*sequence_number*] `class` *class_name*

`no` [*sequence_number*] `class` *class_name*

`default` [*sequence_number*] `class` *class_name*

`no` [*sequence_number*]

`default` [*sequence_number*]

Parameters

- ***sequence_number*** Sequence number (***1*** to ***4294967295***) assigned to the rule. If no number is entered, the number is derived by adding ***10*** to the number of the policy maps last numbered line. To increase the distance between existing entries, use the **`resequence`** command.
- ***class_name*** name of the class.

Commands Available in Policy-map-class (pbr) Configuration Mode

- set nexthop (policy-map-class pbr) sets next hop for the class.
- **`exit`** saves pending class changes and returns switch to ***policy-map (pbr)*** configuration mode.
- **`abort`** discards pending class changes and returns switch to ***policy-map (pbr)*** configuration mode.

Related Commands

- class-map type pbr places switch in the ***class-map*** (pbr) configuration mode.
- policy-map type pbr places switch in the ***policy-map (pbr)*** configuration mode.

Example

These commands add the ***CMAP1*** class map to the ***PMAP1*** policy map, then place the switch in ***policy-map-class*** configuration mode where the next hops can be assigned to the class. Changes will not take effect until both modes are exited.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# class CMAP1
switch(config-pmap-c-PMAP1-CMAP1)#
```

10.2.7.15 class (policy-map (qos) FM6000)

The **class** command places the switch in ***policy-map-class*** (qos) configuration mode, which is a group change mode that modifies the specified class of the configuration mode policy map. The command adds the class to the policy map if it was not previously included in the policy map. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. Each class contains an eponymous class map and at least one set command:

- The class map identifies a data stream through an ACL. Class maps are configured in the ***class-map*** (qos) configuration mode.

- **Set** commands either modify a packets content (CoS or DSCP fields) or assigns it to a traffic class queue. **Set** commands are configured in the ***policy-map-class*** (qos) configuration mode.

  Data packets are managed by commands of the first class whose map matches the packets content.

The **exit** command returns the switch to the ***policy-map*** configuration mode. However, saving policy-map-class changes also require an exit from the ***policy-map*** mode. This saves all pending policy map and policy-map-class changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the class assignment from the configuration mode policy map by deleting the corresponding **class** configuration from ***running-config***.

Command Mode

Policy-Map (qos) Configuration accessed through **policy-map type quality-of-service**.

Command Syntax

`class` *class_name* [**PLACEMENT**]

`no class` *class_name* [**PLACEMENT**]

`default class` *class_name* [**PLACEMENT**]

Parameters

- ***class_name*** name of the class.
- **PLACEMENT** Specifies the map placement within the list of class maps.
  - **no parameter** Class is placed at the top of the list.
  - **insert-before *existing_class*** Class is inserted in front of the specified class.

Commands Available in Policy-map-class (qos) Configuration Mode

- set (policy-map-class (qos) FM6000)
- **exit** saves pending class changes and returns switch to ***policy-map (qos)*** configuration mode.
- **abort** discards pending class changes and returns switch to ***policy-map (qos)*** configuration mode.

Related Commands

- class-map type qos places switch in the ***class-map*** (QoS) configuration mode.
- policy-map type quality-of-service places switch in the ***policy-map*** (QoS) configuration mode

Example

These commands add the ***CMAP_1*** class map to the ***PMAP_1*** policy map, then places the switch in the ***policy-map-class*** configuration mode.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.16 class (policy-map (qos) Helix)

The **class** command places the switch in the ***policy-map-class*** (QoS) configuration mode, which is a group change mode that modifies the specified class of the configuration mode policy map. The command adds the class to the policy map if it was not previously included in the policy map. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. Each class contains an eponymous class map and at least one set command:

- The class map identifies a data stream through an ACL. Class maps are configured in the ***class-map*** (qos) configuration mode.

- **Set** commands either modify a packets content (CoS or DSCP fields) or assigns it to a traffic class queue. **Set** commands are configured in the ***policy-map-class*** (qos) configuration mode.

  Data packets are managed by commands of the first class whose map matches the packets content.

The **exit** command returns the switch to the ***policy-map*** configuration mode. However, saving policy-map-class changes also require an exit from the ***policy-map*** mode. This saves all the pending policy map and policy-map-class changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the class assignment from the configuration mode policy map by deleting the corresponding **class** configuration from ***running-config***.

Command Mode

Policy-Map (qos) Configuration accessed through **policy-map type quality-of-service** command.

Command Syntax

`class` *class_name* [**PLACEMENT**]

`no class` *class_name* [**PLACEMENT**]

`default class` *class_name* [**PLACEMENT**]

Parameters

- ***class_name*** name of the class.
- **PLACEMENT** Specifies the map placement within the list of class maps.
  - ***no parameter*** Class is placed at the top of the list.
  - **insert-before *existing_class*** Class is inserted in front of the specified class.

Commands Available in Policy-map-class (QoS) Configuration Mode

- set (policy-map-class (qos) Helix)
- **exit** saves pending class changes and returns switch to ***policy-map (qos)*** configuration mode.
- **abort** discards pending class changes and returns switch to ***policy-map (qos)*** configuration mode.

Related Commands

- class-map type qos places switch in the ***class-map*** (qos) configuration mode.
- policy-map type quality-of-service places switch in the ***policy-map*** (QoS) configuration mode.

Example

These commands add the ***CMAP_1*** class map to the ***PMAP_1*** policy map, then places the switch in ***policy-map-class*** configuration mode.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.17 class (policy-map (qos) Trident II)

The **class** command places the switch in the ***policy-map-class*** (QoS) configuration mode, which is a group change mode that modifies the specified class of the configuration mode policy map. The command adds the class to the policy map if it was not previously included in the policy map. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. Each class contains an eponymous class map and at least one set command:

- The class map identifies a data stream through an ACL. Class maps are configured in ***class-map (qos)*** configuration mode.
- **Set** commands either modify a packets content (CoS or DSCP fields) or assigns it to a traffic class queue. **Set** commands are configured in ***policy-map-class (qos)*** configuration mode.

Data packets are managed by commands of the first class whose map matches the packets content.

The **exit** command returns the switch to the ***policy-map*** configuration mode. However, saving the policy-map-class changes also require an exit from the ***policy-map*** mode. This saves all the pending policy map and policy-map-class changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the class assignment from the configuration mode policy map by deleting the corresponding **class** configuration from ***running-config***.

Command Mode

Policy-Map (qos) Configuration accessed through **policy-map type quality-of-service** command.

Command Syntax

`class` *class_name* [**PLACEMENT**]

`no class` *class_name* [**PLACEMENT**]

`default class` *class_name* [**PLACEMENT**]

Parameters

- ***class_name*** name of the class.
- **PLACEMENT** Specifies the map placement within the list of class maps.
  - ***no parameter*** Class is placed at the top of the list.
  - **insert-before *existing_class*** Class is inserted in front of the specified class.

Commands Available in Policy-map-class (qos) Configuration Mode

- set (policy-map-class (qos) Trident II)
- **exit** saves pending class changes and returns switch to ***policy-map (qos)*** configuration mode.
- **abort** discards pending class changes and returns switch to ***policy-map (qos)*** configuration mode.

Related Commands

- class-map type qos places switch in ***class-map (qos)*** configuration mode.
- policy-map type quality-of-service places switch in ***policy-map (qos)*** configuration mode.

Example

These commands add the ***CMAP_1*** class map to the ***PMAP_1*** policy map, then places the switch in ***policy-map-class*** configuration mode.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.18 class (policy-map (qos) Trident)

The **class** command places the switch in ***policy-map-class (qos)*** configuration mode, which is a group change mode that modifies the specified class of the configuration mode policy map. The command adds the class to the policy map if it was not previously included in the policy map. All changes in a group change mode edit session are pending until the end of the session.

A policy map is an ordered list of classes. Each class contains an eponymous class map and at least one set command:

- The class map identifies a data stream through an ACL. Class maps are configured in ***class-map (qos)*** configuration mode.
- **Set** commands either modify a packets content (CoS or DSCP fields) or assigns it to a traffic class queue. **Set** commands are configured in ***policy-map-class (qos)*** configuration mode.

  Data packets are managed by commands of the first class whose map matches the packets content.

The **exit** command returns the switch to ***policy-map*** configuration mode. However, saving policy-map-class changes also require an exit from ***policy-map*** mode. This saves all the pending policy map and policy-map-class changes to ***running-config*** and returns the switch to the ***global*** configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no class** and **default class** commands remove the class assignment from the configuration mode policy map by deleting the corresponding **class** configuration from ***running-config***.

Command Mode

Policy-Map (qos) Configuration accessed through **policy-map type quality-of-service** command.

Command Syntax

`class` *class_name* [**PLACEMENT**]

`no class` *class_name* [**PLACEMENT**]

`default class` *class_name* [**PLACEMENT**]

Parameters

- ***class_name*** name of the class.
- **PLACEMENT** Specifies the map placement within the list of class maps.
  - **no parameter** Class is placed at the top of the list.
  - **insert-before *existing_class*** Class is inserted in front of the specified class.

Commands Available in Policy-map-class (qos) Configuration Mode

- set (policy-map-class (qos) Trident)
- **exit** saves pending class changes and returns switch to ***policy-map (qos)*** configuration mode.
- **abort** discards pending class changes and returns switch to ***policy-map (qos)*** configuration mode.

Related Commands

- class-map type qos places switch in ***class-map (qos)*** configuration mode.
- policy-map type quality-of-service places switch in ***policy-map (qos)*** configuration mode.

Example

These commands add the ***CMAP_1*** class map to the ***PMAP_1*** policy map, then places the switch in ***policy-map-class*** configuration mode.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.19 class-map type copp

The **`class-map type copp`** command places the switch in ***Class-Map*** (control plane) configuration mode, which is a group change mode that modifies a control-plane dynamic class map. A dynamic class map is a data structure that uses Access Control Lists (ACLs) to define a data stream by specifying characteristics of data packets that comprise that stream. Control-plane policy maps use class maps to specify which control plane traffic is controlled by policy map criteria.

The **`exit`** command saves pending class map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. Class map changes are also saved by entering a different configuration mode. The **`abort`** command discards pending changes and returns the switch to the ***global*** configuration mode.

The **`no class-map type copp`** and **`default class-map type copp`** commands delete the specified class map by removing the corresponding **`class-map type copp`** command and its associated configuration.

Command Mode

Global Configuration

Command Syntax

`class-map type copp match-any` *class_name*

`no class-map type copp [match-any]` *class_name*

`default class-map type copp [match-any]` *class_name*

Parameter

class_name Name of class map.

Commands Available in Class-Map (Control Plane) Configuration Mode

match (class-map (control-plane) Trident)

Related Commands

- policy-map type copp
- class (policy-map (control-plane) Trident)
- class-map type qos

Example

This command creates the control plane class map named ***CP-MAP-1*** and places the switch in ***class-map*** configuration mode.

```
switch(config)# class-map type copp match-any CP-CMAP-1
switch(config-cmap-CP-CMAP-1)#
```

10.2.7.20 class-map type pbr

The **`class-map type pbr`** command places the switch in the ***class-map*** (pbr) configuration mode for the specified class map, and creates the class map if one does not already exist. The ***class-map*** (PBR) configuration mode is a group change mode that modifies a class map for Policy-Based Routing (PBR). PBR class maps contain one or more **match** statements which filter incoming traffic using ACLs. PBRs can then use these class maps to set next-hop IP addresses for the traffic that matches them. (Classes without set commands translate to no action being performed on that class of packets.)

The **`exit`** command saves pending class map changes to ***running-config***, then returns the switch to the ***global*** configuration mode. Class map changes are also saved by directly entering a different configuration mode. The **`abort`** command discards pending changes and returns the switch to the ***global*** configuration mode.

The **`no class-map type pbr`** and **`default class-map type pbr`** commands delete the specified class map by removing the corresponding **`class-map type pbr`** command and its associated configuration.

Command Mode

Global Configuration

Command Syntax

`class-map type pbr match-any` *map_name*

`no class-map type pbr match-any` *map_name*

`default class-map type pbr match-any` *map_name*

Parameter

map_name Name of class map.

Commands Available in Class-Map (PBR) configuration mode

- match (class-map (pbr))
- resequence (class-map (pbr))

Related Commands

- policy-map type pbr
- class (policy-map (pbr))

Example

This command creates the PBR class map named ***MAP1*** and places the switch in ***class-map (pbr)*** configuration mode where match criteria can be configured for the class.

```
switch(config)# class-map type pbrmatch-any MAP1
switch(config-cmap-MAP1)#
```

10.2.7.21 class-map type qos

The **`class-map type qos`** command places the switch in the ***class-map*** (QoS) configuration mode, which is a group change mode that modifies a QoS dynamic class map. A dynamic class map is a data structure that uses Access Control Lists (ACLs) to define a data stream by specifying characteristics of data packets that comprise that stream. QoS policy maps use class maps to specify the traffic (to which the policy map is assigned) that is transformed by policy map criteria.

The **`exit`** command saves pending class map changes to ***running-config***, then returns the switch to the ***global*** configuration mode. Class map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes and returns the switch to the ***global*** configuration mode.

The **`no class-map type qos`** and **`default class-map type qos`** commands delete the specified class map by removing the corresponding **`class-map type qos`** command and its associated configuration. The **`class-map`** and **`class-map type qos`** commands are equivalent.

Command Mode

Global Configuration

Command Syntax

`class-map type qos` match-any *class_name*

`no class-map type qos` match-any *class_name*

`default class-map type qos` match-any *class_name*

Parameters

class_name Name of class map.

Commands Available in Class-Map (QoS) Configuration Mode

- match (class-map (qos) FM6000)
- match (class-map (qos) Trident)

Conditions

class-map *map_name* and **class-map type qos *map_name*** are identical commands.

Related Commands

- policy-map type quality-of-service

- class (policy-map (qos) FM6000)
- class (policy-map (qos) Trident)

Example

This command creates the QoS class map named ***MAP-1*** and places the switch in ***class-map*** configuration mode.

```
switch(config)# class-map type qos match-any MAP-1
switch(config-cmap-MAP-1)#
```

10.2.7.22 clear policy-map counters

The **`clear policy-map`** command resets the specified policy map counters to zero. Policy map counters record the quantity of packets that are filtered by the ACLs that comprise a specified policy map.

Command Mode

Privileged EXEC

Command Syntax

`clear policy-map` **INTERFACE_NAME** `counters` **MAP_NAME**

Parameters

- **INTERFACE_NAME** Interface for which command clears table counters. Options include:
  - **interface control-plane** Control plane.
- **MAP_NAME** Policy map for which command clears counters. Options include:
  - ***copp-system-policy*** Name of only policy map supported for the control plane.

10.2.7.23 feature pbr

Policy-Based Routing (PBR) is a feature that is applied on IPv4 or IPv6 routable ports, to preferentially route packets. Forwarding is based on a policy that is enforced at the ingress of the applied interface and overrides normal routing decisions. In addition to matches on regular ACLs, PBR policy-maps can also include “raw match” statements that look like a single entry of an ACL as a convenience for users.

Configuration Mode

For IP:

TCAM PBR profile set TTL configuration mode.

For IPv6:

TCAM feature PBR IP configuration mode.

Command Syntax

For IP:

`feature pbr` ip [copy]

`no feature pbr` ip [copy]

`default feature pbr` ip [copy]

For IPv6:

`feature pbr` ipv6 [copy | bank]

`no feature pbr` ipv6 [copy | bank]

`default featue pbr` ipv6 [copy | bank]

Parameters

For IP:

copy Copy a feature from a TCAM profile.

For IPv6:

- **copy** Copy a feature from a TCAM profile.

- **bank** TCAM banks to reserve.

Examples

- In the following example, the PBR is configured on an IP routable port.

```
(config)# hardware tcam
(config-tcam)# profile pbr-set-ttl copy default
(config-tcam-profile-pbr-set-ttl)# feature pbr ip
```

- In the following example, the PBR is configured on an IPv6 routable port.

```
(config)# hardware tcam
(config-tcam)# profile pbr-set-ttl copy default
(config-tcam-profile-pbr-set-ttl)# feature pbr ip
(config-tcam-feature-pbr-ip)# feature pbr ipv6
```

10.2.7.24 feature traffic-policy cpu

The **feature traffic-policy cpu** command configures the CPU traffic policy features for the IPv4 and IPv6 traffic in user-defined TCAM profile.

The **no feature traffic-policy cpu** and **default feature traffic-policy cpu** commands remove the CPU policy configurations from ***running-config***.

Command Mode

Hardware TCAM

Command Syntax

`feature traffic-policy cpu` [ipv4 | ipv6]

`no feature traffic-policy cpu` [ipv4 | ipv6]

`default feature traffic-policy cpu` [ipv4 | ipv6]

Parameters

- **ipv4** CPU traffic policy for IPv4 traffic.
- **ipv6** CPU traffic policy for IPv6 traffic.

Example

These commands places the switch in the hardware TCAM profile mode and configures the CPU traffic policy features for IPv4 traffic in the TCAM profile test.

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile test
switch(config-hw-tcam-profile-test)# feature traffic-policy cpu ipv4
```

10.2.7.25 feature traffic-policy port

The **`feature traffic-policy port`** command configures the port-related traffic policy features for the IPv4 and IPv6 traffic in user-defined TCAM profile.

The **`no feature traffic-policy port`** and **`default feature traffic-policy port`** commands remove the CPU policy configurations from ***running-config***.

Command Mode

Hardware TCAM

Command Syntax

`feature traffic-policy port` [ipv4 | ipv6]

`no feature traffic-policy port` [ipv4 | ipv6]

`default feature traffic-policy port` [ipv4 | ipv6]

Parameters

- **ipv4** port traffic policy for IPv4 traffic.
- **ipv6** port traffic policy for IPv6 traffic.

Example

These commands places the switch in the hardware TCAM profile mode and configures the port traffic policy features for IPv4 traffic in the TCAM profile test.

```
switch(config)# hardware tcam
switch(config-hw-tcam)# profile test
switch(config-hw-tcam-profile-test)# feature traffic-policy port ipv4
```

10.2.7.26 match (class-map (control-plane) Helix)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4 and IPv4 standard ACLs.

A class map is assigned to a policy map by the **class (policy-map (control-plane) Helix)** command.

The ***class map*** (control plane) configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-Map (control plane) configuration accessed through **class-map type copp** command.

Command Syntax

`match ip access-group` *list_name*

`no match ip access-group` *list_name*

`default match ip access-group` *list_name*

Parameters

list_name name of ACL assigned to class map.

Related Commands

- class-map type copp places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (control-plane) Helix) assigns a ***class map*** to a ***policy map***.

Guidelines

Static class maps cannot be modified by this command.

Match statements are saved to ***running-config*** only upon exiting ***class-map (control plane)*** configuration mode.

Example

These commands add the IP ACL ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type copp map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.27 match (class-map (control-plane) Trident II)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4 and IPv4 standard ACLs.

A class map is assigned to a policy map by the **class (policy-map (control-plane) Trident II)** command.

The ***class map*** (control plane) configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-Map (control plane) configuration accessed through **class-map type copp** command.

Command Syntax

list_name

list_name

list_name

Parameter

list_name name of ACL assigned to class map.

Related Commands

- class-map type copp places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (control-plane) Trident II) assigns a class map to a ***policy map***.

Guidelines

Static class maps cannot be modified by this command.

Match statements are saved to ***running-config*** only upon exiting ***class-map (control plane)*** configuration mode.

Example

These commands add the IP ACL ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type copp map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.28 match (class-map (control-plane) Trident)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4, IPv6, IPv4 standard, and IPv6 standard ACLs.

A class map is assigned to a policy map by the **class (policy-map (control-plane) Trident)** command.

Class map (control plane) configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-Map (control plane) configuration accessed through **class-map type copp** command

Command Syntax

`match` **IP_VERSION** `access-group` *list_name*

`no match` **IP_VERSION** `access-group` *list_name*

`default match` **IP_VERSION** `access-group` *list_name*

Parameters

- **IP_VERSION** IP version of the specified ACL. Options include:
  - **ipv4** IPv4.
  - **ipv6** IPv6.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type copp places the switch in ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (control-plane) Trident) assigns a class map to a policy map.

Guidelines

Static class maps cannot be modified by this command.

`Match` statements are saved to ***running-config*** only upon exiting ***class-map (control plane)*** configuration mode.

Example

These commands add the IPv4 ACL names ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type copp map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.29 match (class-map (pbr))

The **match** command assigns ACLs to the configuration mode Policy-Based Routing (PBR) class map. The command accepts IPv4, IPv4 standard, IPv6 and IPv6 standard ACLs.

Class map (pbr) configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Note: PBR ACLs use only permit rules to filter data; if there are deny rules in an ACL used by PBR, the configuration will be reverted.

Command Mode

Class-map (pbr) configuration accessed through **class-map type pbr** command.

Command Syntax

[*sequence_number*] `match` [ip | ipv6] `access-group` *list_name*

`no` [*sequence_number*] `match` [ip | ipv6] `access-group` *list_name*

`default` [*sequence_number*] [ip | ipv6] `access-group` *list_name*

`no` [*sequence_number*]

`default` [*sequence_number*]

Parameters

- ***sequence_number*** Sequence number (***1*** to ***4294967295***) assigned to the rule. If no number is entered, the number is derived by adding ***10*** to the number of the class maps last numbered line. To increase the distance between existing entries, use the **resequence** command.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type pbr places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.

- **`abort`** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (pbr)) assigns a class map to a policy map.

Example

These commands add the IPv4 ACL named ***list1*** to the ***map1*** class map, then save the change by exiting ***class-map*** mode.

```
switch(config)# class-map type pbr map1
switch(config-cmap-map1)# match ip access-group list1
switch(config-cmap-map1)# exit
switch(config)#
```

10.2.7.30 match (class-map (qos) FM6000)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4 and IPv4 standard ACLs.

The ***class map (qos)*** configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-map (qos) configuration accessed through **class-map type qos** command.

Command Syntax

`match` **IP_VERSION** `access-group` *list_name*

`no match` **IP_VERSION** `access-group` *list_name*

`default match` **IP_VERSION** `access-group` *list_name*

Parameters

- **IP_VERSION** IP version of the specified ACL. Options include:
  - **ipv4** IPv4.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type qos places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (qos) FM6000) assigns a ***class map*** to a ***policy map***.

Example

These commands add the IPv4 ACL named ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type qos map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.31 match (class-map (qos) Helix)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4, IPv4 standard, IPv6, and IPv6 standard ACLs.

the ***class map (QoS)*** configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-Map (QoS) configuration accessed through **class-map type qos** command.

Command Syntax

`match` **IP_VERSION** `access-group` *list_name*

`no match` **IP_VERSION** `access-group` *list_name*

`default match` **IP_VERSION** `access-group` *list_name*

Parameters

- **IP_VERSION** IP version of the specified ACL. Options include:
  - **ipv4** IPv4.
  - **ipv6** IPv6.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type qos places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (qos) Helix) assigns a class map to a policy map.

Example

These commands add the IPv4 ACL named ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type qos map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.32 match (class-map (qos) Trident II)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4, IPv4 standard, IPv6, and IPv6 standard ACLs.

The ***class map (QoS)*** configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

The ***class-map (qos)*** configuration accessed through **class-map type qos** command.

Command Syntax

IP_VERSION *list_name*

IP_VERSION *list_name*

IP_VERSION *list_name*

Parameters

- **IP_VERSION** IP version of the specified ACL. Options include:
  - **ipv4** IPv4.
  - **ipv6** IPv6.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type qos places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (qos) Trident) assigns a class map to a policy map.

Example

These commands add the IPv4 ACL named ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type qos map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.33 match (class-map (qos) Trident)

The **match** command assigns an ACL to the configuration mode class map. A class map can contain only one ACL. Class maps only use permit rules to filter data; deny rules are ignored. The command accepts IPv4, IPv4 standard, IPv6, and IPv6 standard ACLs.

Class map (QoS) configuration mode is a group change mode. **Match** statements are not saved to ***running-config*** until the edit session is completed by exiting the mode.

The **no match** and **default match** commands remove the **match** statement from the configuration mode class map by deleting the corresponding command from ***running-config***.

Command Mode

Class-Map (qos) configuration accessed through **class-map type qos** command.

Command Syntax

`match` **IP_VERSION** `access-group` *list_name*

`no match` **IP_VERSION** `access-group` *list_name*

`default match` **IP_VERSION** `access-group` *list_name*

Parameters

- **IP_VERSION** IP version of the specified ACL. Options include:
  - **ipv4** IPv4.
  - **ipv6** IPv6.
- ***list_name*** name of ACL assigned to class map.

Related Commands

- class-map type qos places the switch in the ***class-map*** configuration mode.
- **exit** saves pending class map changes, then returns the switch to the ***global*** configuration mode.
- **abort** discards pending class map changes, then returns the switch to the ***global*** configuration mode.
- class (policy-map (qos) Trident) assigns a ***class map*** to a ***policy map***.

Example

These commands add the IPv4 ACL named ***list_1*** to the ***map_1*** class map, then saves the command by exiting ***class-map*** mode.

```
switch(config)# class-map type qos map_1
switch(config-cmap-map_1)# match ip access-group list_1
switch(config-cmap-map_1)# exit
switch(config)#
```

10.2.7.34 match (policy-map (pbr))

The **match** command creates a policy map clause entry that specifies one filtering condition. When a packet matches the filtering criteria, its next hop is set as specified. When a packets properties do not equal the statement parameters, the packet is evaluated against the next clause or class map in the policy map, as determined by sequence number. If all clauses fail to set a next hop for the packet, the packet is routed according to the FIB.

The **no match** and **default match** commands remove the **match** statement from the configuration mode policy map by deleting the corresponding command from ***running-config***.

Command Mode

Policy-Map (pbr) Configuration accessed through `policy-map type pbr` command.

Command Syntax

[*sequence_number*] `match ip` **SOURCE_ADDR DEST_ADDR** [`set nexthop [recursive]` *NH-addr_1* [*NH-addr_2*] ... [*NH-addr_n*]]

`no match ip` **SOURCE_ADDR DEST_ADDR** [`set nexthop [recursive]` *NH-addr_1* [*NH-addr_2*] ... [*NH-addr_n*]]

`default match match ip` **SOURCE_ADDR DEST_ADDR** [`set nexthop [recursive]` *NH-addr_1* [*NH-addr_2*] ... [*NH-addr_n*]]

`no` **SEQ_NUM**

`default` **SEQ_NUM**

Parameters

- ***sequence_number*** Sequence number assigned to the rule. If no number is entered, the number is derived by adding ***10*** to the number of the policy maps last numbered line. To increase the distance between existing entries, use the **resequence** command.
- **SOURCE_ADDR** and **DEST_ADDR** source and destination address filters. Options include:
  - ***network_addr*** subnet address (CIDR or address-mask).
  - **any** packets from or to all addresses are matched.
  - **host *ip_addr*** IP address (dotted decimal notation).

    Source and destination subnet addresses support discontiguous masks.
- **recursive** enables recursive next hop resolution.
- ***NH_addr*** IP address of next hop. If multiple addresses are entered, they are treated as an ECMP group.

Related Commands

- policy-map type pbr enters the policy-map (PBR) configuration mode.
- show policy-map type pbr displays the PBR policy maps.

Example

These commands create a match rule in policy map ***PMAP1*** which sets the next hop to ***192.168.3.5*** for packets received from ***172.16.0.0/12*** regardless of their destination, then exit the mode to save the changes.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# match ip 172.16.0.0/12 any set nexthop 192.163.3.5
switch(config-pmap-PMAP1)# exit
switch(config)#
```

10.2.7.35 platform arad tcam counters feature

The **platform arad tcam counters feature** command enables incrementing PBR hardware counters corresponding to ACL. If counters for PBR are enabled, then counters for ACL will be automatically disabled in all cases. If counters for ACL are enabled, then counters for PBR will be automatically disabled in all cases.

The **no platform arad tcam counters feature** command disables PBR/ACL counters selection. The **default platform arad tcam counters feature** commands resets the default behavior.

Command Mode

Global Configuration

Command Syntax

`platform arad tcam counters feature` [*OPTIONS*]

`no platform arad tcam counters feature` [*OPTIONS*]

`default platform arad tcam counters feature` [*OPTIONS*]

Parameters

OPTIONS Assign the TCAM counters feature. Options include:

- **pbr** assign the TCAM counters feature PBR hardware counters.
- **acl** assign the TCAM counters feature ACL hardware counters.

Examples

- This command enables incrementing ACL hardware counters selection.

```
switch(config)# platform arad tcam counters feature acl
switch(config)#
```

- This command disables incrementing ACL hardware counters selection.

```
switch(config)# no platform arad tcam counters feature acl
switch(config)#
```

10.2.7.36 policy-map type copp

The **policy-map type copp** command places the switch in the ***policy-map*** (control plane) configuration mode, which is a group change mode that modifies a ***control-plane*** policy map. A policy map is a data structure that consists of class maps that identify a specific data stream and specify bandwidth and shaping parameters that controls its transmission. Control plane policy maps are applied to the control plane to manage traffic.

The ***copp-system-policy*** policy map is supplied with the switch and is always applied to the control plane. The ***copp-system-policy*** is the only valid control plane policy map.

The **exit** command saves pending policy map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. Policy map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no policy-map type copp** and **default policy-map type copp** commands delete the specified policy map by removing the corresponding **policy-map type copp** command and its associated configuration.

Command Mode

Global Configuration

Command Syntax

```
policy-map type copp copp-system-policy

no policy-map type copp copp-system-policy

default policy-map type copp copp-system-policy
```

The ***copp-system-policy*** is supplied with the switch and is the only valid control plane policy map.

Commands Available in Policy-Map Configuration Mode

- class (policy-map (control-plane) FM6000)
- class (policy-map (control-plane) Trident)

Related Commands

class-map type copp enters the ***control-plane class-map*** configuration mode for modifying a control-plane dynamic class map.

Only Helix and Trident platform switches support dynamic classes for control plane policing.

Example

This command places the switch in the ***policy-map*** configuration mode to edit the ***copp-system-policy*** policy map.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)#
```

10.2.7.37 policy-map type pbr

The **policy-map type pbr** command places the switch in ***policy-map (pbr)*** configuration mode, which is a group change mode that modifies a Policy-Based Routing (PBR) policy map. The command also creates the specified policy map if it does not already exist. A PBR policy map is a data structure that consists of class maps that identify specific packets and the next hops for those packets. Policy maps are applied to Ethernet or port channel interfaces to manage traffic.

The **exit** command saves pending policy map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. Policy map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no policy-map type pbr** and **default policy-map type pbr** commands delete the specified policy map by removing the corresponding **policy-map type pbr** command and its associated configuration.

Command Mode

Global Configuration

Command Syntax

`policy-map type pbr` *map_name*

`no policy-map type pbr` *map_name*

`default policy-map type pbr` *map_name*

Parameter

map_name Name of policy map.

Commands Available in Policy-Map Configuration Mode

- class (policy-map (pbr))
- match (policy-map (pbr))

Related Commands

- class-map type pbr
- service-policy type pbr (Interface mode)

Example

This command creates the PBR policy map named ***PMAP1*** and places the switch in ***policy-map*** configuration mode.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)#
```

10.2.7.38 policy-map type quality-of-service

The **policy-map type quality-of-service** command places the switch in the ***policy-map (QoS)*** configuration mode, which is a group change mode that modifies a QoS policy map. A policy map is a data structure that consists of class maps that identify a specific data stream and shaping parameters that controls its transmission. Policy maps are applied to Ethernet or port channel interfaces to manage traffic.

The **exit** command saves pending policy map changes to ***running-config*** and returns the switch to the ***global*** configuration mode. Policy map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes, returning the switch to the ***global*** configuration mode.

The **no policy-map type quality-of-service** and **default policy-map type quality-of-service** commands delete the specified policy map by removing the corresponding **policy-map type quality-of-service** command and its associated configuration. The **policy-map** and **policy-map type quality-of-service** commands are equivalent.

Command Mode

Global Configuration

Command Syntax

`policy-map type quality-of-service` *map_name*

`no policy-map type quality-of-service` *map_name*

`default policy-map type quality-of-service` *map_name*

Parameter

map_name Name of policy map.

Commands Available in Policy-Map Configuration Mode

- class (policy-map (qos) FM6000)
- class (policy-map (qos) Trident)

Conditions

policy-map ***map_name*** and **policy-map type quality-of-service** ***map_name*** are identical commands.

Related Commands

- class-map type qos
- service-policy type qos (Interface mode)

Example

This command creates the QoS policy map named ***PMAP-1*** and places the switch in the ***policy-map*** configuration mode.

```
switch(config)# policy-map PMAP-1
switch(config-pmap-PMAP-1)#
```

10.2.7.39 policy-map type quality-of-service counter

The **policy-map type quality-of-service counter** command in the Global Configuration Mode configures per interface counters for policy map and class map matches.

The **no | default** versions of the command disables the feature and removes it from the ***running-config***.

Command Mode

Global Configuration

Command Syntax

policy-map type quality-of-service counter per-interface

no policy-map type quality-of-service counter per-interface

default policy-map type quality-of-service counter per-interface

Parameters

- **policy-map type quality-of-service** - Specify the Policy Map as Quality of Service (QoS).
- **counter** - Change the counter settings.
- **per-interface - Specify using per-interface counters.**

Example

Use the following command to enable QoS per-interface counters:

```
switch(config)# policy-map type quality-of-service counter per-interface
```

10.2.7.40 policy-map type quality-of-service policer

The **policy-map type quality-of-service policer copy** command is used to copy an existing QoS policy map to the policy map ***policer***.

The **policy-map type quality-of-service policer drop counter** command is used to enable drop counters for the QoS policy map ***policer***.

The **no policy-map type quality-of-service policer** and **default policy-map type quality-of-service policer** commands delete the policy map ***policer*** by removing the corresponding **policy-map type quality-of-service policer** command and its associated configuration.

The **no policy-map type quality-of-service policer drop counter** and **default policy-map type quality-of-service policer drop counter** commands disable drop counters for the policy map ***policer***.

Command Mode

Global Configuration

Command Syntax

```
policy-map type quality-of-service policer copy map_name

policy-map type quality-of-service policer drop counter

no policy-map type quality-of-service policer

default policy-map type quality-of-service policer
```

Parameter

map_name Name of policy map to copy.

Related Commands

- class-map type qos
- service-policy type qos (Interface mode)

Examples

- This command copies the QoS policy map named ***PMAP-1*** to the policy map ***policer***.

```
switch(config)#policy-map type quality-of-service policer copy PMAP-1
switch(config-pmap-PMAP-1)#
```

- This command enables drop counters for the QoS policy map ***policer***.

```
switch(config)#policy-map type quality-of-service policer drop counter
switch(config)#
```

10.2.7.41 resequence (class-map (pbr))

The **resequence** command assigns sequence numbers to rules in the configuration mode class map. Command parameters specify the number of the first rule and the numeric interval between consecutive rules. Once changed, rule numbers persist unless changed again using the **resequence** command, but the interval used for numbering new rules reverts to ***10*** on the exiting ***class-map (pbr)*** configuration mode.

Maximum rule sequence number is ***4294967295***.

Command Mode

Class-Map (PBR) Configuration accessed through **class-map type pbr** command.

Command Syntax

`resequence` [*start_num* [*inc_num*]]

Parameters

- ***start_num*** sequence number assigned to the first rule. Default is ***10***.
- ***inc_num*** numeric interval between consecutive rules. Default is ***10***.

Example

The **resequence** command renumbers the rules in ***CMAP1***, starting the first command at number ***100*** and incrementing subsequent lines by ***20***.

```
switch(config)# class-map type pbr match-any CMAP1
switch(config-cmap-CMAP1)# show active
class-map type pbr match-any CMAP1
10 match ip access-group group1
20 match ip access-group group2
30 match ip access-group group3
switch(config-cmap-CMAP1)# resequence 100 20
switch(config-cmap-CMAP1)# exit
switch(config)# class-map type pbr match-any CMAP1
switch(config-cmap-CMAP1)# show active
class-map type pbr match-any CMAP1
100 match ip access-group group1
120 match ip access-group group2
140 match ip access-group group3
```

10.2.7.42 resequence (policy-map (pbr))

The **resequence** command assigns sequence numbers to rules in the configuration mode policy map. Command parameters specify the number of the first rule and the numeric interval between consecutive rules. Once changed, rule numbers persist unless changed again using the **resequence** command, but the interval used for numbering new rules reverts to ***10*** on the exiting ***policy-map (pbr)*** configuration mode.

Maximum rule sequence number is ***4294967295***.

Command Mode

Policy-Map (PBR) Configuration accessed through **policy-map type pbr** command

Command Syntax

resequence [*start_num* [*inc_num*]]

Parameters

- ***start_num*** sequence number assigned to the first rule. Default is ***10***.
- ***inc_num*** numeric interval between consecutive rules. Default is ***10***.

Example

The **resequence** command renumbers the rules in ***PMAP1***, starting the first command at number ***100*** and incrementing subsequent lines by ***20***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# show active
policy-map type pbr PMAP1
10 class CMAP1
set nexthop 172.16.1.1
20 class CMAP2
set nexthop 172.16.2.2
30 class CMAP3
set nexthop 172.16.3.3
switch(config-pmap-PMAP1)# resequence 100 20
switch(config-pmap-PMAP1)# exit
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# show active
class-map type pbr PMAP1
100 class CMAP1
set nexthop 172.16.1.1
120 class CMAP2
set nexthop 172.16.2.2
140 class CMAP3
set nexthop 172.16.3.3
switch(config-pmap-PMAP1)#
```

10.2.7.43 service-policy type pbr (Interface mode)

The **`service-policy pbr`** command applies the specified Policy-Based Routing (PBR) policy map to the configuration mode interface. A PBR policy map is a data structure that consists of class maps that identify specific packets and the next hops for those packets. Policy maps are applied to Ethernet or port channel interfaces to manage traffic. Only one service policy is supported per interface.

The **`no service-policy pbr`** and **`default service-policy pbr`** commands remove the service policy assignment from the configuration mode interface by deleting the corresponding **`service-policy pbr`** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

Command Syntax

`service-policy type pbr` **TRAFFIC_DIRECTION** *map_name*

`no service-policy type pbr` **TRAFFIC_DIRECTION** *map_name*

`default service-policy type pbr` **TRAFFIC_DIRECTION** *map_name*

Parameters

- **TRAFFIC_DIRECTION** IP address or peer group name. Values include:
  - **input** Policy map applies to inbound packet streams.
- ***map_name*** Name of policy map.

Guidelines

A policy map that is attached to a port channel interface takes precedence for member interfaces of the port channel over their individual interface Ethernet configuration. Members that are removed from a port channel revert to the policy map implementation specified by its interface Ethernet configuration.

Related Commands

policy-map type pbr

Example

This command applies the PBR policy map ***PMAP1*** to ***interface Ethernet 8***.

```
switch# config
switch(config)# interface ethernet 8
switch(config-if-Et8)# service-policy type pbr input PMAP1
switch(config-if-Et8)#
```

10.2.7.44 service-policy type qos (Interface mode)

The **service-policy** command applies a specified policy map to the configuration mode interface. A policy map is a data structure that identifies data traffic through class maps, then specifies actions to classify the traffic (by setting the traffic class), mark the traffic (by setting the cos and dscp values), and police the traffic (by setting the police rate) through data packet field modifications.

The **no service-policy** and **default service-policy** commands remove the service policy assignment from the configuration mode interface by deleting the corresponding **service-policy** command from ***running-config***.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

Command Syntax

`service-policy [type qos]` **TRAFFIC_DIRECTION** *map_name*

`no service-policy [type qos]` **TRAFFIC_DIRECTION** *map_name*

`default service-policy [type qos]` **TRAFFIC_DIRECTION** *map_name*

Parameters

- **type qos** Parameter has no functional effect.
- **TRAFFIC_DIRECTION** Direction of data stream to which command applies. Options include:
  - **input** Policy map applies to inbound packet streams.
  - ***map_name*** Name of policy map.

Guidelines

A policy map that is attached to a port channel interface takes precedence for member interfaces of the port channel over their individual interface Ethernet configuration. Members that are removed from a port channel revert to the policy map implementation specified by its interface Ethernet configuration.

DCS-7500E and DCS-7280E limitations:

- A maximum of ***31*** QoS service policies per chip may be applied on L3 interfaces.

- Applying different QoS service policies to an SVI and its member interfaces causes unpredictable behavior.
- When an SVI on which QoS service policies are applied experiences partial failure due to limited hardware resources, a forwarding agent restart causes unpredictable behavior.
- Policy-map programming may fail when QoS service policies are applied on two SVIs if an event causes a member interface to switch membership from one to the other. To change the VLAN membership of an interface in this case, remove the interface from one VLAN before adding it to the other.
- Outgoing COS rewrite is not supported.
- QoS policy-map counters are not supported.

DCS-7010, DCS-7050, DCS-7050X, DCS-7250X, and DCS-7300X limitations:

- When the same policy map is applied to multiple SVIs, TCAM resources are not shared.
- A policy map applied to an SVI results in TCAM allocation on all chips whether SVI members are present or not.
- Applying different QoS service policies to an SVI and its member interfaces causes unpredictable behavior.

Related Commands

policy-map type quality-of-service

Example

This command applies the ***PMAP-1*** policy map to ***interface ethernet 8***.

```
switch# config
switch(config)# interface ethernet 8
switch(config-if-Et8)# show active
switch(config-if-Et8)# service-policy input PMAP-1
switch(config-if-Et8)# show active
interface Ethernet8
   service-policy type qos input PMAP-1
switch(config-if-Et8)#
```

10.2.7.45 set (policy-map-class (qos) FM6000)

The **set** command specifies traffic resolution methods for traffic defined by its associated class map in its configuration mode policy map class. Three set statements are available for each class:

- **cos** Sets the Layer 2 class of service field.
- **dscp** Sets the differentiated services code point value in the type of service (ToS) byte.
- **traffic-class** Sets the traffic class queue for data packets.

Each type of set command can be assigned to a class, allowing for the simultaneous modification of both (cos, dscp) fields and assignment to a traffic class.

The **no set** and **default set** commands remove the specified data action from the class map by deleting the associated **set** command from ***running-config***.

Command Mode

Policy-map-class (qos) configuration

accessed through **class (policy-map (qos) FM6000)** command.

Command Syntax

`set` **QOS_TYPE** *value*

`no set` **QOS_TYPE**

`default set` **QOS_TYPE**

Parameters

- **QOS_TYPE** Specifies the data stream resolution method. Valid options include:
  - **cos** Layer 2 class of service field of outbound packet is modified.
  - **dscp** Differentiated services code point value in the ToS byte is modified.
  - **traffic-class** Data stream is assigned to a traffic class queue.
- ***value*** Specifies the data field value or traffic class queue. Valid data range depends on **QOS_TYPE**.
  - **QOS_TYPE** is **cos** Value ranges from ***0*** to ***7***.
  - **QOS_TYPE** is **dscp** Value ranges from ***0*** to ***63***.
  - **QOS_TYPE** is **traffic-class** Value ranges from ***0*** to ***7***.

Related Commands

- policy-map type quality-of-service
- class (policy-map (qos) FM6000)

Example

These commands configure the policy map to set ***CoS field 7*** to data traffic specified by the class map ***CMAP-1***, then assigns that data to traffic class ***queue 4***.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)# set cos 7
switch(config-pmap-c-PMAP-1-CMAP-1)# set traffic-class 4
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.46 set (policy-map-class (qos) Helix)

The **set** command specifies traffic resolution methods for traffic defined by its associated class map in its configuration mode policy map class. Three set statements are available for each class:

- **cos** Sets the Layer 2 class of service field.
- **dscp** Sets the differentiated services code point value in the type of service (ToS) byte.
- **traffic-class** Sets the traffic class queue for data packets.

Each type of set command can be assigned to a class, allowing for the simultaneous modification of both (**cos**, **dscp**) fields and assignment to a traffic class.

The **no set** and **default set** commands remove the specified data action from the class map by deleting the associated **set** command from ***running-config***.

Command Mode

Policy-map-class (qos) configuration accessed through **class (policy-map (qos) Helix)** command.

Command Syntax

`set` **QOS_TYPE** *value*

`no set` **QOS_TYPE**

`default set` **QOS_TYPE**

Parameters

- **QOS_TYPE** Specifies the data stream resolution method. Valid options include:
  - **cos** Layer 2 class of service field of outbound packet is modified.
  - **dscp** Differentiated services code point value in the ToS byte is modified.
  - **traffic-class** Data stream is assigned to a traffic class queue.
- ***value*** Specifies the data field value or traffic class queue. Valid data range depends on QOS type.
  - **QOS_TYPE** is **cos** Value ranges from ***0*** to ***7***.
  - **QOS_TYPE** is **dscp** Value ranges from ***0*** to ***63***.
  - **QOS_TYPE** is **traffic-class** Value ranges from ***0*** to ***7***.

Related Commands

- policy-map type quality-of-service
- class (policy-map (qos) Helix)

Example

These commands configure the policy map to set ***CoS field 7*** to data traffic specified by the class map ***CMAP-1***, then assigns that data to ***traffic class queue 4***.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)# set cos 7
switch(config-pmap-c-PMAP-1-CMAP-1)# set traffic-class 4
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.47 set (policy-map-class (qos) Trident II)

The **set** command specifies traffic resolution methods for traffic defined by its associated class map in its configuration mode policy map class. Three set statements are available for each class:

- **cos** Sets the Layer 2 class of service field.
- **dscp** Sets the differentiated services code point value in the type of service (ToS) byte.
- **traffic-class** Sets the traffic class queue for data packets.

Each type of set command can be assigned to a class, allowing for the simultaneous modification of both (cos, dscp) fields and assignment to a traffic class.

The **no set** and **default set** commands remove the specified data action from the class map by deleting the associated **set** command from ***running-config***.

Command Mode

Policy-map-class (qos) configuration accessed through **class (policy-map (qos) Trident)** command.

Command Syntax

`set` **QOS_TYPE** *value*

`no set` **QOS_TYPE**

`default set` **QOS_TYPE**

Parameters

- **QOS_TYPE** Specifies the data stream resolution method. Valid options include:
  - **cos** Layer 2 class of service field of outbound packet is modified.
  - **dscp** Differentiated services code point value in the ToS byte is modified.
  - **traffic-class** Data stream is assigned to a traffic class queue.
- ***value*** Specifies the data field value or traffic class queue. Valid data range depends on QOS type.
  - **QOS_TYPE** is **cos** Value ranges from ***0*** to ***7***.
  - **QOS_TYPE** is **dscp** Value ranges from ***0*** to ***63***.
  - **QOS_TYPE** is **traffic-class** Value ranges from ***0*** to ***7***.

Related Commands

- policy-map type quality-of-service
- class (policy-map (qos) Trident)

Example

These commands configure the policy map to set ***CoS field 7*** to data traffic specified by the class map ***CMAP-1***, then assigns that data to ***traffic class queue 4***.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)# set cos 7
switch(config-pmap-c-PMAP-1-CMAP-1)# set traffic-class 4
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.48 set (policy-map-class (qos) Trident)

The **set** command specifies traffic resolution methods for traffic defined by its associated class map in its configuration mode policy map class. Three set statements are available for each class:

- **cos** Sets the Layer 2 class of service field.
- **dscp** Sets the differentiated services code point value in the type of service (ToS) byte.
- **traffic-class** Sets the traffic class queue for data packets.

Each type of set command can be assigned to a class, allowing for the simultaneous modification of both (cos, dscp) fields and assignment to a traffic class.

The **no set** and **default set** commands remove the specified data action from the class map by deleting the associated **set** command from ***running-config***.

Command Mode

Policy-map-class (qos) configuration accessed through **class (policy-map (qos) Trident)** command.

Command Syntax

`set` **QOS_TYPE** *value*

`no set` **QOS_TYPE**

`default set` **QOS_TYPE**

Parameters

- **QOS_TYPE** Specifies the data stream resolution method. Valid options include:
  - **cos** Layer 2 class of service field of outbound packet is modified.
  - **dscp** Differentiated services code point value in the ToS byte is modified.
  - **traffic-class** Data stream is assigned to a traffic class queue.
- ***value*** Specifies the data field value or traffic class queue. Valid data range depends on QOS type.
  - **QOS_TYPE** is **cos** Value ranges from ***0*** to ***7***.
  - **QOS_TYPE** is **dscp** Value ranges from ***0*** to ***63***.
  - **QOS_TYPE** is **traffic-class** Value ranges from ***0*** to ***7***.

Related Commands

- policy-map type quality-of-service
- class (policy-map (qos) Trident)

Example

These commands configure the policy map to set ***CoS field 7*** to data traffic specified by the ***class map CMAP-1***, then assigns that data to ***traffic class queue 4***.

```
switch(config)# policy-map type quality-of-service PMAP-1
switch(config-pmap-PMAP-1)# class CMAP-1
switch(config-pmap-c-PMAP-1-CMAP-1)# set cos 7
switch(config-pmap-c-PMAP-1-CMAP-1)# set traffic-class 4
switch(config-pmap-c-PMAP-1-CMAP-1)#
```

10.2.7.49 set nexthop (policy-map-class pbr)

The **set nexthop** command specifies the next hop for traffic defined by its associated class map in its configuration mode policy map class.

The **no set nexthop** and **default set nexthop** commands remove the specified action from the class map by deleting the associated **set nexthop** command from ***running-config***.

Command Mode

Policy-map-class (pbr) configuration accessed through **class (policy-map (pbr))** command.

Command Syntax

`set nexthop` [recursive] *NH-addr_1* [*NH-addr_2*] ... [*NH-addr_n*]

`no set nexthop` [recursive]

`default set nexthop` [recursive]

Parameters

- **recursive** enables recursive next hop resolution.
- ***NH_addr*** IP address of next hop. If multiple addresses are entered, they are treated as an ECMP group.

Related Commands

- policy-map type pbr
- class (policy-map (pbr))

Example

These ***192.168.5.3*** commands configure the policy map ***PMAP1*** to set the next hop to for traffic defined by class map ***CMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# class CMAP1
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop 192.168.5.3
switch(config-pmap-c-PMAP1-CMAP1)#
```

10.2.7.50 set nexthop-group (policy-map-class(pbr) Arad)

The **`set nexthop-group`** command specifies a nexthop group as the next hop for traffic defined by its associated class map in its configuration mode policy map class.

The **`no set nexthop-group`** and **`default set nexthop-group`** commands remove the specified action from the class map by deleting the associated **`set nexthop-group`** command from ***running-config***.

Command Mode

Policy-map-class (pbr) configuration accessed through **`class (policy-map (pbr))`** command.

Command Syntax

`set nexthop-group` *group_name*

`no set nexthop-group` *group_name*

`default set nexthop-group` *group_name*

Parameters

group_name name of ECMP group to use as next hop.

Related Commands

- policy-map type pbr
- class (policy-map (pbr))

Example

These commands configure the policy map ***PMAP1*** to set the next hop to a nexthop group named ***GROUP1*** for traffic defined by class map ***CMAP1***.

```
switch(config)# policy-map type pbr PMAP1
switch(config-pmap-PMAP1)# class CMAP1
switch(config-pmap-c-PMAP1-CMAP1)# set nexthop-group GROUP1
switch(config-pmap-c-PMAP1-CMAP1)#
```

10.2.7.51 shape (policy-map-class (control-plane) Arad)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through **class (policy-map (control-plane) Arad)**

Command Syntax

Parameter

kilobits Maximum data rate in kilobits per second. Value ranges from 1 to 10000000.

Related Commands

- class (policy-map (control-plane) Arad) places the switch in the ***policy-map-class (control plane)*** configuration mode.
- bandwidth (policy-map-class (control-plane) Arad) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Static Classes Default Shape

Arad platform switches define these default shapes for static classes:

- copp-system-bgp 2500 copp-system-l3lpmoverflow 2500
- copp-system-bpdu 2500 copp-system-l3slowpath 2500
- copp-system-default 2500 copp-system-l3ttl1 2500
- copp-system-ipbroadcast 2500 copp-system-lacp 2500
- copp-system-ipmc 2500 copp-system-linklocal 2500
- copp-system-ipmcmiss 2500 copp-system-lldp 2500

- copp-system-ipunicast NO LIMIT copp-system-mlag 2500
- copp-system-l2broadcast 2500 copp-system-multicastsnoop 2500
- copp-system-l2unicast NO LIMIT copp-system-OspfIsis 2500
- copp-system-l3destmiss 2500 copp-system-sflow 2500

Example

These commands configure the maximum bandwidth of ***2000*** kbps for data traffic specified by the class map ***copp-system-lldp*** of the default ***control-plane policy map***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# shape kbps 2000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy

  Class-map: copp-system-lldp (match-any)
       shape : 2000 kbps
       bandwidth : 250 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

10.2.7.52 shape (policy-map-class (control-plane) FM6000)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through `class (policy-map (control-plane) FM6000)`.

Command Syntax

shape pps ***packets***

no shape

default shape

Parameters

packets Maximum data rate in packets per second. Value ranges from 1 to 100000.

Related Commands

- class (policy-map (control-plane) FM6000) places the switch in the ***policy-map-class (control plane)*** configuration mode.
- bandwidth (policy-map-class (control-plane) FM6000) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Static Classes Default Shape

FM6000 platform switches define these default shapes for static classes:

- copp-system-arp 10000 copp-system-l3slowpath 10000
- copp-system-default 8000 copp-system-pim-ptp 10000
- copp-system-ipmcrsvd 10000 copp-system-ospf-isis 10000
- copp-system-ipmcmiss 10000 copp-system-selfip 5000
- copp-system-igmp 10000 copp-system-selfip-tc6to7 5000

- copp-system-l2rsvd 10000 copp-system-sflow 25000

Example

These commands configure a maximum bandwidth of ***5000*** packets per second for data traffic specified by the class map ***PMAP-1*** in the policy map named ***copp-system-policy***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class PMAP-1
switch(config-pmap-c-copp-system-policy-PMAP-1)# shape pps 5000
switch(config-pmap-c-copp-system-policy-PMAP-1)#
```

10.2.7.53 shape (policy-map-class (control-plane) Helix)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through **class (policy-map (control-plane) Helix)**.

Command Syntax

```
shape pps packets

no shape

default shape
```

Parameters

packets Maximum data rate in packets per second. Value ranges from ***1*** to ***100000***.

Static Classes Default Shape

Trident platform switches define these default shapes for static classes:

- copp-system-acllog 10000 copp-system-l3ttl1 10000
- copp-system-arp 10000 copp-system-lacp 5000
- copp-system-arpresolver 10000 copp-system-lldp 10000
- copp-system-bfd 10000 copp-system-mlag 5000
- copp-system-bgp 5000 copp-system-OspfIsis 10000
- copp-system-bpdu 5000 copp-system-selfip 5000
- copp-system-default 8000 copp-system-selfip-tc6to7 5000
- copp-system-glean 10000 copp-system-sflow 25024
- copp-system-igmp 10000 copp-system-tc3to5 10000
- copp-system-ipmcmiss 10000 copp-system-tc6to7 10000

- copp-system-ipmcrsvd 10000 copp-system-urm 10000
- copp-system-l3destmiss 10000 copp-system-vrrp 5000
- copp-system-l3slowpath 10000

Related Commands

- class (policy-map (control-plane) Helix) places the switch in the ***policy-map-class (control plane)*** configuration mode.
- bandwidth (policy-map-class (control-plane) Helix) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Example

These commands configure a maximum bandwidth of ***5000*** packets per second for data traffic specified by the ***copp-system-lldp*** of the default control-plane policy map.

```
switch(config)# policy-map type control-plan copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# shape pps 5000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy

  Class-map: copp-system-lldp (match-any)
       shape : 5000 pps
       bandwidth : 500 pps
      Out Packets : 305961
      Drop Packets : 0

switch(config)#
```

10.2.7.54 shape (policy-map-class (control-plane) Petra)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through **class (policy-map (control-plane) Petra)**

Command Syntax

`shape kbps` *kilobits*

`no shape`

`default shape`

Parameter

kilobits Maximum data rate in kilobits per second. Value ranges from ***1*** to ***10000000***.

Related Commands

- class (policy-map (control-plane) Petra) places the switch in policy-map-class (control plane) configuration mode.
- bandwidth (policy-map-class (control-plane) Petra) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Static Classes Default Shape

Petra platform switches define these default shapes for static classes:

- copp-system-bpdu 2500 copp-system-l3destmiss 2500
- copp-system-default 2500 copp-system-l3slowpath 2500
- copp-system-igmp 2500 copp-system-l3ttl0 2500
- copp-system-ipbroadcast 2500 copp-system-l3ttl1 2500
- copp-system-ipmc 2500 copp-system-lacp 2500

- copp-system-ipmcmiss 2500 copp-system-lldp 2500
- copp-system-ipmcrsvd 2500 copp-system-unicast-arp 2500
- copp-system-ipunicast No Limit

Guidelines

Petra does not support all discrete rate values. When a specified discrete value is not supported, the switch converts the rate to the next highest discrete value that it supports. The **show** command displays the converted rate and not the user-configured rate.

Example

These commands configure the maximum bandwidth of ***2000*** kbps for data traffic specified by the class map ***copp-system-lldp*** of the ***default control-plane*** policy map. Because the switch does not support the discrete value of ***2000*** kbps, it converts the bandwidth up to ***2115*** kbps.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# shape kbps 2000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy

  Class-map: copp-system-lldp (match-any)
       shape : 2115 kbps
       bandwidth : 325 kbps
      Out Packets : 0
      Drop Packets : 0

switch(config)#
```

10.2.7.55 shape (policy-map-class (control-plane) Trident II)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through **class (policy-map (control-plane) Trident II)**.

Command Syntax

```
shape pps packets

no shape

default shape
```

Parameter

packets Maximum data rate in packets per second. Value ranges from ***1*** to ***100000***.

Static Classes Default Shape

Trident II platform switches define these default shapes for static classes:

- copp-system-acllog 10000 copp-system-l3slowpath 10000
- copp-system-arp 10000 copp-system-l3ttl1 10000
- copp-system-arpresolver 10000 copp-system-lacp 5000
- copp-system-bfd 10000 copp-system-lldp 10000
- copp-system-bgp 5000 copp-system-mlag 5000
- copp-system-bpdu 5000 copp-system-selfip 5000
- copp-system-default 8000 copp-system-selfip-tc6to7 5000
- copp-system-glean 10000 copp-system-sflow 25024
- copp-system-igmp 10000 copp-system-tc3to5 10000
- copp-system-ipmcmiss 10000 copp-system-tc6to7 10000

- copp-system-ipmcrsvd 10000 copp-system-urm 10000

Related Commands

- class (policy-map (control-plane) Trident II) places the switch in ***policy-map-class (control plane)*** configuration mode.
- bandwidth (policy-map-class (control-plane) Trident II) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Example

These commands configure a maximum bandwidth of ***5000*** packets per second for data traffic specified by the ***copp-system-lldp*** of the ***default control-plane policy*** map.

```
switch(config)# policy-map type control-plan copp-system-policy
switch(config-pmap-copp-system-policy)# class copp-system-lldp
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# shape pps 5000
switch(config-pmap-c-copp-system-policy-copp-system-lldp)# exit
switch(config-pmap-copp-system-policy)# exit
switch(config)# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy

  Class-map: copp-system-lldp (match-any)
       shape : 5000 pps
       bandwidth : 500 pps
      Out Packets : 305961
      Drop Packets : 0

switch(config)#
```

10.2.7.56 shape (policy-map-class (control-plane) Trident)

The **shape** command specifies the maximum bandwidth for traffic filtered by the configuration mode policy map class.

The **no shape** and **default shape** commands remove the maximum bandwidth restriction for the configuration mode class by deleting the corresponding **bandwidth** command from ***running-config***.

Command Mode

Policy-map-class (control plane) configuration accessed through **class (policy-map (control-plane) Trident)**.

Command Syntax

```
shape pps packets

no shape

default shape
```

Parameters

packets Maximum data rate in packets per second. Value ranges from 1 to 100000.

Static Classes Default Shape

Trident platform switches define these default shapes for static classes:

- copp-system-arp 10000 copp-system-lldp 10000
- copp-system-arpresolver 10000 copp-system-l3destmiss 10000
- copp-system-bpdu 5000 copp-system-l3slowpath 10000
- copp-system-default 8000 copp-system-l3ttl1 10000
- copp-system-glean 10000 copp-system-selfip 5000
- copp-system-igmp 10000 copp-system-selfip-tc6to7 5000
- copp-system-ipmcmiss 10000 copp-system-sflow 25000
- copp-system-ipmcrsvd 10000 copp-system-tc3to5 10000
- copp-system-lacp 5000 copp-system-tc6to7 10000

Related Commands

- class (policy-map (control-plane) Trident) places the switch in the ***policy-map-class (control plane)*** configuration mode.
- bandwidth (policy-map-class (control-plane) Trident) specifies the minimum bandwidth for traffic defined by its associated class map in its configuration mode policy map class.

Example

These commands configure a maximum bandwidth of ***5000*** packets per second for data traffic specified by the class map ***PMAP-1*** in the policy map named ***copp-system-policy***.

```
switch(config)# policy-map type copp copp-system-policy
switch(config-pmap-copp-system-policy)# class PMAP-1
switch(config-pmap-c-copp-system-policy-PMAP-1)# shape pps 5000
switch(config-pmap-c-copp-system-policy-PMAP-1)
```

10.2.7.57 show class-map type control-plane

The **show class-map** command displays contents of available control-plane class maps. **Control-plane** class maps can be added to the ***copp-system-policy*** policy map. ***Control-plane*** class maps can be static class maps defined by the system or dynamic maps created in ***class-map*** configuration mode.

Dynamic class maps are composed of statements that match IPv4 access control lists. Static class maps are defined by the switch and cannot be altered.

Command Mode

EXEC

Command Syntax

show class-map type control-plane [MAP_NAME]

Parameters

MAP_NAME Name of class map displayed by the command. Options include:

- ***no parameter*** Command displays all control plane class maps.
- ***name_text*** Command displays specified control-plane class maps.

Related Command

- **show class-map** command displays QoS class maps.
- show class-map type qos displays control plane class maps.

Example

This command displays the available control plane class maps.

```
switch# show class-map type control-plane
  Class-map: CM-CP1 (match-any)
    Match: ip access-group name LIST-CP1
  Class-map: copp-system-acllog (match-any)
  Class-map: copp-system-arp (match-any)
  Class-map: copp-system-arpresolver (match-any)
  Class-map: copp-system-bpdu (match-any)
  Class-map: copp-system-glean (match-any)
  Class-map: copp-system-igmp (match-any)
  Class-map: copp-system-ipmcmiss (match-any)
  Class-map: copp-system-ipmcrsvd (match-any)
  Class-map: copp-system-l3destmiss (match-any)
  Class-map: copp-system-l3slowpath (match-any)
  Class-map: copp-system-l3ttl1 (match-any)
  Class-map: copp-system-lacp (match-any)
  Class-map: copp-system-lldp (match-any)
  Class-map: copp-system-selfip (match-any)
```

```
  Class-map: copp-system-selfip-tc6to7 (match-any)
  Class-map: copp-system-sflow (match-any)
  Class-map: copp-system-tc3to5 (match-any)
  Class-map: copp-system-tc6to7 (match-any)
switch>
```

10.2.7.58 show class-map type pbr

The **`show class-map`** command displays contents of all available Policy-Based Routing (PBR) class maps, or of a specified PBR class map. PBR class maps are used by PBR policy maps. PBR class maps are dynamic maps that are created in class-map-configuration mode. Dynamic class maps are composed of statements that match IPv4 or IPv6 access control lists.

Command Mode

EXEC

Command Syntax

`show class-map type pbr` [*map_name*]

Parameters

map_name Name of class map displayed by the command. If no parameter is entered, command show all available PBR class maps.

Related Command

show policy-map type pbr displays PBR policy maps.

Example

This command displays the contents of the PBR class map ***CMAP1***.

```
switch# show class-map type pbr CMAP1
  Class-map: CMAP1 (match-any)
    Match: 10 ip access-group PBRgroup1
    Match: 20 ip access-group PBRgroup2
    Match: 30 ip access-group PBRgroup3 switch>
```

10.2.7.59 show class-map type qos

The **show class-map**command displays contents of all available QoS class maps. QoS class maps are used by QoS policy maps. QoS class maps are dynamic maps that are created in ***class-map*** configuration mode. Dynamic class maps are composed of statements that match IPv4 or IPv6 access control lists.

Command Mode

EXEC

Command Syntax

`show class-map type qos` [**MAP_NAME**]

Parameters

MAP_NAME Name of class map displayed by the command.

- **no parameter** Command displays all QoS class maps.
- ***name_text*** Command displays specified QoS class maps.

show class-map and **show class-map type qos** are identical commands.

Related Command

show class-map type control-plane displays control plane class maps.

Example

This command displays the available QoS class maps.

```
switch# show class-map type qos
  Class-map: CM-Q1 (match-any)
    Match: ipv6 access-group name LIST-1
  Class-map: CM-Q2 (match-any)
    Match: ip access-group name LIST-2
```

10.2.7.60 show policy-map copp

The **show policy-map copp** command displays contents of the control-plane policy map. Control-plane policy maps are applied to the control plane, and copp-system-policy is the only supported policy map.

Command Mode

EXEC

Command Syntax

show policy-map copp copp-system-policy

Example

This command displays the contents and throughput of the policy map applied to the control plane.

```
switch# show policy-map copp copp-system-policy
Service-policy input: copp-system-policy
  Number of units programmed: 1
  Hardware programming status: Successful

  Class-map: copp-system-bpdu (match-any)
       shape : 5000 pps
       bandwidth : 5000 pps
      Out Packets : 2
      Drop Packets : 0

  Class-map: copp-system-lacp (match-any)
       shape : 5000 pps
       bandwidth : 5000 pps
      Out Packets : 0
      Drop Packets : 0 switch>
```

10.2.7.61 show policy-map interface type qos counters

The **show policy-map interface** command displays the quantity of packets that are filtered by ACLs applied to a interface.

Command Mode

EXEC

Command Syntax

`show policy-map` [**INTERFACE_NAME**][`type qos`][**TRAFFIC**] `counters`

Parameters

- **INTERFACE_NAME** Filters policy map list by interfaces. Options include:
  - **no parameter** Displays data for all configured interfaces.
  - **interface ethernet *e_range*** Ethernet ports for which command displays policy maps.
  - **interface port-channel *p_range*** Port channels for which command displays policy maps.
- **TRAFFIC** Filters policy maps by the traffic they manage. Options include:
  - **no parameter** Policy maps that manage interfaces ingress traffic (same as **input** option).
  - **input** Policy maps that manage interfaces ingress traffic.

Example

This command displays the policy maps applied to interfaces Ethernet ***7*** and ***8***.

```
switch# show policy-map interface ethernet 7-8
Service-policy input: PMAP-1
  Hardware programming status: Successful

  Class-map: cmap-1 (match-any)
    Match: ip access-group name LIST-2
       set cos 6

  Class-map: class-default (match-any)

Service-policy input: PMAP-2
  Hardware programming status: Successful

  Class-map: cmap-2 (match-any)
    Match: ip access-group name LIST-2
       set dscp 10

  Class-map: class-default (match-any)
```

10.2.7.62 show policy-map interface type qos

The **show policy-map interface** command displays contents of the policy maps applied to specified interfaces or to the control plane.

Command Mode

EXEC

Command Syntax

`show policy-map interface` **INTERFACE_NAME** [`type qos`] [**TRAFFIC**]

Parameters

- **INTERFACE_NAME** Filters policy map list by interfaces. Options include:
  - **ethernet *e_range*** Ethernet ports for which command displays policy maps.
  - **port-channel *p_range*** Port channels for which command displays policy maps.
- **TRAFFIC** Filters policy maps by the traffic they manage. Options include:
  - **no parameter** Policy maps that manage interfaces ingress traffic (same as **input** option).
  - **input** Policy maps that manage interfaces ingress traffic.

Example

This command displays the policy maps applied to interfaces Ethernet ***7*** and ***8***.

```
switch# show policy-map interface ethernet 7-8
Service-policy input: PMAP-1
  Hardware programming status: Successful

  Class-map: cmap-1 (match-any)
    Match: ip access-group name LIST-2
       set cos 6

  Class-map: class-default (match-any)

Service-policy input: PMAP-2
  Hardware programming status: Successful

  Class-map: cmap-2 (match-any)
    Match: ip access-group name LIST-2
       set dscp 10

  Class-map: class-default (match-any)
```

10.2.7.63 show policy-map type copp

The **`show policy-map type copp`** command displays contents of control plane policy maps. Control-plane policy maps are applied to the control plane; copp-system-policy is the only supported policy map.

Command options filter the output to display contents of all policy maps, contents of a specified policy map, or contents of a single class map within a specified policy map.

Command Mode

EXEC

Command Syntax

`show policy-map type` copp copp-system-policy [**CMAP_NAME**]

Parameters

CMAP_NAME Name of class map displayed by the command.

- **no parameter** Command displays all class maps in specified policy map.
- ***class_name*** Command displays specified class map.

Example

This command displays the contents of the copp-system-bpdu class map in the copp-system-policy policy maps.

```
switch# show policy-map type copp copp-system-policy class copp-system-bpdu
  Class-map: copp-system-bpdu (match-any)
       shape : 5000 pps
       bandwidth : 5000 pps
```

10.2.7.64 show policy-map type pbr

The **show policy-map pbr** command displays contents of Policy-Based Routing (PBR) policy maps. PBR policy maps are applied to Ethernet interfaces, port channel interfaces or switch virtual interfaces (SVIs).

Command options filter the output to either display contents of all policy maps, contents of a specified policy map, or summary contents of all or a specified policy map.

Command Mode

EXEC

Command Syntax

`show policy-map type pbr` [**PMAP_NAME**][**DATA_LEVEL**]

Parameters

- **PMAP_NAME** Name of policy map displayed by the command.
  - **no parameter** Command displays all policy maps.
  - ***policy_map*** Command displays specified policy map.
- **DATA_LEVEL** Type of information the command displays. Values include:
  - **no parameter** Command displays all class maps in specified policy map.
  - **summary** Command displays summary data for the specified policy map.

Example

This command displays the contents of all PBR policy maps in ***running-config***.

```
switch# show policy-map type pbr
Service policy PMAP1
Configured on:
Applied on:
10: Class-map: CMAP1 (match-any)
Match: 10 ip access-group PBRgroup1
Match: 20 ip access-group PBRgroup2
Match: 30 ip access-group PBRgroup3
Configured actions: set nexthop 172.16.10.12
20: Class-map: CMAP2 (match-any)
Match: 10 ip access-group PBRgroup1
Match: 10 ip access-group PBRgroup4
Match: 20 ip access-group PBRgroup5
Configured actions: set nexthop 192.168.15.15
```

10.2.7.65 show policy-map type qos counters

The **show policy-map counters** command displays the quantity of packets that are filtered by the ACLs that comprise a specified QoS policy map.

Command Mode

EXEC

Command Syntax

`show policy-map type qos` *pmap_name* [**TRAFFIC**] `counters` [**INFO_LEVEL**]

Parameters

- ***pmap_name*** Name of policy map displayed by the command.
- **TRAFFIC** Filters policy maps by the traffic they manage. Options include:
  - **no parameter** Policy maps that manage interfaces ingress traffic (same as **input** option).
  - **input** Policy maps that manage interfaces ingress traffic.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - **no parameter** displays summarized information about the policy map.
  - **detail** displays detailed policy map information.

Example

Use the following command to display counters for policy map, *p1*, enabled for per-interface counters:

```
switch# show policy-map p1 counters
Service-policy input: p1
  Hardware programming status: Successful

  Class-map: c1 (match-any)
    Match: vlan 100 0xfff
       set dscp 7
      Matched Packets: 7
        Interface: Ethernet1/1
          Matched Packets: 1
        Interface: Ethernet2/1
          Matched Packets: 2
        Interface: Ethernet3/1
          Matched Packets: 4

  Class-map: c2 (match-any)
    Match: ip access-group name acl1
       set cos 6
      Matched Packets: 6
        Interface: Ethernet1/1
          Matched Packets: 2
        Interface: Ethernet2/1
```

```
          Matched Packets: 0
        Interface: Ethernet3/1
          Matched Packets: 4

  Class-map: class-default (match-any)
      Matched Packets: 0
        Interface: Ethernet1/1
          Matched Packets: 0
        Interface: Ethernet2/1
          Matched Packets: 0
        Interface: Ethernet3/1
          Matched Packets: 0
```

10.2.7.66 show policy-map type qos

The **show policy-map qos** command displays contents of QoS policy maps. QoS policy maps are applied to Ethernet or port channel interfaces.

Command options filter the output to either display contents of all policy maps, contents of a specified policy map, or contents of a single class map within a specified policy map.

Command Mode

EXEC

Command Syntax

`show policy-map` [`type qos`][**PMAP_NAME** [**CMAP_NAME**]]

Parameters

- **PMAP_NAME** Name of policy map displayed by the command.
  - **no parameter** Command displays all policy maps.
  - ***policy_map*** Command displays specified policy map.
- **CMAP_NAME** Name of class map displayed by the command. This option is available only when the command includes a policy map name.
  - **no parameter** Command displays all class maps in specified policy map.
  - ***class_name*** Command displays specified class map.

Example

This command displays the contents of all QoS policy maps in ***running-config***.

```
switch# show policy-map type qos
Service-policy input: PMAP-1
  Hardware programming status: Successful

  Class-map: xeter (match-any)
    Match: ip access-group name LIST-1
       set cos 6

  Class-map: class-default (match-any)

Service-policy PMAP-2

  Class-map: class-default (match-any)
```

10.2.7.67 show traffic-policy

The **`show traffic-policy`** command displays traffic policy information on the interface.

Command Mode

EXEC

Command Syntax

`show traffic-policy` **NAME** interface

`show traffic-policy` interface [**DETAILS**]

Parameters

DETAILS Details requested. Options include:

- **summary** Display summary information about the policy.
  - **errors** Display all configured remote grantees, associated profile name and latest update.
  - **details** Display all interfaces on which the policy has been configured.

Examples

- This command displays the summary information configured on the switch interfaces.

```
switch(config-traffic-policies)# show traffic-policy interface summary
Traffic policy samplePolicy
   Configured on interfaces: Ethernet1/1, Ethernet2/1, Ethernet3/1, ...
   Applied on interfaces for IPv4 traffic: Ethernet1/1, Ethernet2/1, Ethernet3/1, ...
   Applied on interfaces for IPv6 traffic:
   Total number of rules configured: 3
      match SIMPLE ipv4
      match ipv4-all-default ipv4
      match ipv6-all-default ipv6
```

- This command displays information about the traffic policy named ***samplePolicy***.

```
switch(config-traffic-policies)# show traffic-policy samplePolicy interface
Traffic policy samplePolicy
   Configured on interfaces: Ethernet1/1, Ethernet2/1, Ethernet3/1, ...
