# Table of Contents

Chapter 1  Overview .............................................................................................................................. 1

Chapter 2  Initial Configuration and Recovery .................................................................................... 3
  Initial Switch Access ............................................................................................................................. 3
  Connection Management ......................................................................................................................... 9
  Configure Session ................................................................................................................................. 10
  Recovery Procedures ............................................................................................................................. 14
  Session Management Commands ......................................................................................................... 18

Chapter 3  Command-Line Interface .................................................................................................... 47
  Accessing the EOS CLI ........................................................................................................................... 47
  Processing Commands ........................................................................................................................... 48
  Kernel-based Virtual Machine Commands and Configuration ............................................................ 54
  Switch Platforms ................................................................................................................................ 60
  Command Modes ................................................................................................................................ 72
  Managing Switch Configuration Settings ............................................................................................ 75
  Other Command-Line Interfaces ........................................................................................................... 78
  Common Criteria (CC) ............................................................................................................................ 79
  Directory Structure ............................................................................................................................... 80
  Command-Line Interface Commands .................................................................................................... 81

Chapter 4  AAA Configuration ............................................................................................................... 145
  Authorization, Authentication, and Accounting Overview ................................................................. 145
  Configuring the Security Services ......................................................................................................... 147
  Server Groups ..................................................................................................................................... 155
  Role Based Authorization ...................................................................................................................... 156
  Activating Security Services ................................................................................................................. 165
  TACACS+ Configuration Examples .................................................................................................... 168
  AAA Commands .................................................................................................................................. 170

Chapter 5  Administering the Switch ..................................................................................................... 227
  Managing the Switch Name .................................................................................................................... 227
  Managing the System Clock ................................................................................................................... 230
  Synchronizing the Time Settings .......................................................................................................... 232
  Managing Display Attributes ............................................................................................................... 242
  Event Monitor ..................................................................................................................................... 244
  Switch Administration Commands ....................................................................................................... 248

Chapter 6  Booting the Switch ............................................................................................................... 325
  Boot Loader – Aboot ............................................................................................................................... 325
  Configuration Files ............................................................................................................................... 326
  Supervisor Redundancy ......................................................................................................................... 330
  System Reset ....................................................................................................................................... 332
  Aboot Shell .......................................................................................................................................... 337
  Aboot Configuration Commands ......................................................................................................... 341
  Switch Booting Commands ................................................................................................................... 346

Chapter 7  Upgrades and Downgrades ................................................................................................. 365
  Upgrade/Downgrade Overview ............................................................................................................. 365
  Accelerated Software Upgrade (ASU) ................................................................................................. 366
  Leaf Smart System Upgrade (Leaf SSU) .............................................................................................. 370
  Standard Upgrades and Downgrades ................................................................................................. 377
# Table of Contents

**Upgrade/Downgrade Commands** ................................................................. 385  

**Chapter 8  Switch Environment Control** ...................................................... 389  
  Environment Control Introduction ............................................................... 389  
  Environment Control Overview ................................................................. 389  
  Configuring and Viewing Environment Settings ....................................... 391  
  Environment Commands ......................................................................... 396  

**Chapter 9  Maintenance Mode** .................................................................. 409  
  Overview .................................................................................................... 410  
  Maintenance Mode Elements .................................................................... 411  
  Maintenance Mode Features ..................................................................... 416  
  Maintenance Mode Configuration ......................................................... 417  
  Maintenance Mode Commands .............................................................. 433  

**Chapter 10  Ethernet Ports** ................................................................. 485  
  Ethernet Ports Introduction ................................................................... 485  
  Ethernet Standards .................................................................................. 485  
  Ethernet Physical Layer .......................................................................... 488  
  Interfaces ................................................................................................ 491  
  Ethernet Configuration Procedures .................................................. 494  
  Ethernet Configuration Commands .................................................. 515  

**Chapter 11  Port Channels and LACP** ....................................................... 549  
  Port Channel Introduction ...................................................................... 549  
  Port Channel Conceptual Overview ..................................................... 549  
  Port Channel Configuration Procedures ............................................ 552  
  Load Balancing Hash Algorithms ....................................................... 557  
  Port Channel and LACP Configuration Commands .......................... 562  

**Chapter 12  Multi-Chassis Link Aggregation** ............................................ 611  
  MLAG Introduction .................................................................................. 611  
  MLAG Conceptual Overview ................................................................. 612  
  MLAG Maintenance ............................................................................... 614  
  Configuring MLAG ................................................................................ 617  
  MLAG Implementation Example ......................................................... 624  
  MLAG Commands ................................................................................ 633  

**Chapter 13  802.1x Port Security** ............................................................. 651  
  802.1x Port Security Introduction ....................................................... 651  
  802.1x Port Security Description ....................................................... 652  
  Configuring 802.1x Port Security .......................................................... 657  
  Displaying 802.1x information .............................................................. 660  
  IEEE 802.1x Configuration Commands ........................................... 662  

**Chapter 14  DCBX and Flow Control** ...................................................... 675  
  Introduction .............................................................................................. 675  
  DCBX and Priority-Based Flow Control Overview ................................ 676  
  DCBX and PFC Configuration and Verification Procedures ............... 677  
  DCBX and Flow Control Configuration Commands ........................ 679  

**Chapter 15  LLDP** .................................................................................. 693  
  LLDP Introduction .................................................................................. 693  
  LLDP Overview ...................................................................................... 693  
  LLDP Configuration Procedures ........................................................ 695

Overview

Arista Networks features switches with high-density, non-blocking Ethernet ports that are controlled through an extensible, Linux-based, modular network operating system. The intended audience for this manual is network administrators who configure Arista switches. A working knowledge of network administration is assumed.

New Features
This guide may not describe the features added in the most recent EOS version. For information on undocumented features, consult the TOI documents here: https://eos.arista.com/toi/

Switch Platforms
A list of Arista switches and detailed information about each is available online here: http://www.arista.com/products/switches

Recently released switches may not appear in the list, but can be found in the most recent Release Notes (found under Active Releases here: https://www.arista.com/support/software-download).

Supported Features
For the complete supported-features list in the latest EOS release, see https://www.arista.com/en/support/product-documentation/supported-features.

For details on a specific release, please see the Release Notes (found under Active Releases here: https://www.arista.com/en/support/software-download).
Initial Configuration and Recovery

This chapter describes initial configuration and recovery tasks. Subsequent chapters provide details about features introduced in this chapter.

This chapter contains these sections:

- **Section 2.1: Initial Switch Access**
- **Section 2.2: Connection Management**
- **Section 2.3: Configure Session**
- **Section 2.4: Recovery Procedures**
- **Section 2.5: Session Management Commands**

### 2.1 Initial Switch Access

Arista Network switches provide two initial configuration methods:

- **Zero Touch Provisioning (ZTP)** configures the switch without user interaction (Section 2.1.1).
- **Manual provisioning** configures the switch through commands entered by a user through the CLI (Section 2.1.2).

#### 2.1.1 Zero Touch Provisioning

Zero Touch Provisioning (ZTP) configures a switch without user intervention by downloading a startup configuration file (`startup-config`) or a boot script from a location specified by a DHCP server. Section 6.5.2 describes network tasks required to set up ZTP.

The switch enters ZTP mode when it boots if flash memory does not contain `startup-config`. It remains in ZTP mode until a user cancels ZTP mode, or until the switch retrieves a `startup-config` or a boot script. After downloading a file through ZTP, the switch reboots again, using the retrieved file.

**Security Considerations**

The ZTP process cannot distinguish an approved DHCP server from a rogue DHCP server. For secure provisioning, you must ensure that only approved DHCP servers are able to communicate with the switch until after the ZTP process is complete. Arista also recommends validating the EOS image on your ZTP server by confirming that its MD5 checksum matches the MD5 checksum that can be found on the EOS download page of the Arista website. On a UNIX server, the `md5sum` command calculates this checksum:

```
% md5sum EOS.swi
3bac45b96bc820eb1d10c9ee33108a25  EOS.swi
```
To provision the switch through Zero Touch Provisioning:

**Step 1** Mount the switch in its permanent location.

**Step 2** Connect at least one management or Ethernet port to a network that can access the DHCP server and the configuration file.

**Step 3** Provide power to the switch.

ZTP provisioning progress can be monitored through the console port. Section 2.1.2.1 provides information for setting up the console port. Section 2.1.2.2 provides information for monitoring ZTP progress and canceling ZTP mode.

### 2.1.2 Manual Provisioning

Initial manual switch provisioning requires the cancellation of ZTP mode, the assignment of an IP address to a network port, and the establishment of an IP route to a gateway. Initial provisioning is performed through the serial console and Ethernet management ports.

- The console port is used for serial access to the switch. These conditions may require serial access:
  - management ports are not assigned IP addresses
  - the network is inoperable
  - the password to access the enable mode is not available
- The Ethernet management ports are used for out-of-band network management tasks. Before using a management port for the first time, an IP address must be assigned to that port.

#### 2.1.2.1 Console Port

The console port is a serial port located on the front of the switch. Figure 2-1 shows the console port on the DCS-7050T-64 switch. Use a serial or RS-232 cable to connect to the console port. The accessory kit also includes an RJ-45 to DB-9 adapter cable for connecting the switch.

![Figure 2-1: Switch Ports](image)

**Port Settings**

Use these settings when connecting to the console port:

- 9600 baud
- no flow control
- 1 stop bit
- no parity bits
- 8 data bits
Chapter 2: Initial Configuration and Recovery

Admin Username

The initial configuration provides one username, admin, that is not assigned a password. When using the admin username without a password, you can only log into the switch through the console port. After a password is assigned to the admin username, it can log into the switch through any port.

The username command assigns a password to the specified username.

Example

- This command assigns the password pxq123 to the admin username:
  
  switch(config)#username admin secret pxq123
  switch(config)#

New and altered passwords that are not saved to the startup configuration file are lost when the switch is rebooted.

2.1.2.2 Canceling Zero Touch Provisioning

Zero Touch Provisioning (ZTP) installs a startup-config file from a network location if flash memory does not contain a startup-config when the switch reboots. Canceling ZTP is required if the switch cannot download a startup-config or boot script file.

When the switch boots without a startup-config file, it displays the following message through the console port:

No startup-config was found.

The device is in Zero Touch Provisioning mode and is attempting to download the startup-config from a remote system. The device will not be fully functional until either a valid startup-config is downloaded from a remote system or Zero Touch Provisioning is cancelled. To cancel Zero Touch Provisioning, login as admin and type 'zerotouch cancel' at the CLI.

localhost login:
To cancel ZTP mode, log into the switch with the `admin` password, then enter the `zerotouch cancel` command. The switch immediately boots without installing a `startup-config` file.

```
localhost login: admin
admin
localhost>Apr 15 21:28:21 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21, Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9, Management1, Management2 ]
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-DHCP_QUERY_FAIL: Failed to get a valid DHCP response
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-RETRY: Retrying Zero Touch Provisioning from the beginning (attempt 1)
Apr 15 21:29:22 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21, Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9, Management1, Management2 ]
```

```
localhost>zerotouch cancel
zerotouch cancel
Apr 15 21:29:39 localhost ZeroTouch: %ZTP-5-RELOAD: Rebooting the system
Broadcast messenger: Stopping sshd: [ OK ]
watchdog is not running
SysRq : Remount R/O
Restarting system

Aboot 1.9.0-52504.EOS2.0
Press Control-C now to enter Aboot shell
```

To avoid entering ZTP mode on subsequent reboots, create a `startup-config` file as described in step 8 of Section 2.1.2.3.

### 2.1.2.3 Ethernet Management Port

Arista switches provide one or more Ethernet management ports for configuring the switch and managing the network out of band. Figure 2-1 shows the location of the Ethernet management ports on a DCS-7050T-64 switch. Only one port is required to manage the switch.

You can access the Ethernet management port(s) remotely over a common network or locally through a directly connected PC. Before you can access the switch through a remote connection, an IP address and a static route to the default gateway are required. On a modular switch with dual supervisors, a virtual IP address can also be configured to access the management port on whichever supervisor is active.

#### Assigning a Virtual IP Address to Access the Active Ethernet Management Port

On modular switches with dual supervisors, this procedure assigns a virtual IP address which will connect to the Ethernet management port of the active supervisor. (To assign a physical IP address to an individual Ethernet management port, see Assigning an IP Address to a Specific Ethernet Management Port below.)

**Step 1** Connect a PC or terminal server to the console port. Use the settings listed in Section 2.1.2.1 under Port Settings.
Step 2  Type **admin** at the login prompt to log into the switch. Initial login through the console port does not require a password.

Arista EOS
switch login: admin
Last login: Fri Apr 9 14:22:18 on Console

switch>

Step 3  Type **enable** at the command prompt to enter Privileged EXEC mode.

switch> enable
switch#

Step 4  Type **configure terminal** (or **config**) to enter global configuration mode.

switch# configure terminal
switch(config)#

Step 5  Type **interface management 0** to enter interface configuration mode for the virtual interface which accesses management port 1 on the currently active supervisor.

switch(config)# interface management 0
switch(config-if-Ma0)#

Step 6  Type **ip address**, followed by the desired address, to assign a virtual IP address for access to the active management port.

This command assigns IP address 10.0.2.5 to management port 0.

switch(config-if-Ma0)# ip address 10.0.2.5/24

Step 7  Type **end** at both the interface configuration and global configuration prompts to return to Privileged EXEC mode.

switch(config-if-Ma0)# end
switch(config)# end
switch#

Step 8  Type **write** (or **copy running-config startup-config**) to save the new configuration to the **startup-config** file.

switch# write
switch#

Assigning an IP Address to a Specific Ethernet Management Port

This procedure assigns an IP address to a specific Ethernet management port:

Step 1  Connect a PC or terminal server to the console port. Use the settings listed in Section 2.1.2.1 under Port Settings.

Step 2  Type **admin** at the login prompt to log into the switch. The initial login does not require a password.

Arista EOS
switch login: admin
Last login: Fri Apr 9 14:22:18 on Console

switch>

Step 3  Type **enable** at the command prompt to enter Privileged EXEC mode.

switch> enable
switch#
Step 4 Type `configure terminal` (or `config`) to enter global configuration mode.

```
switch#configure terminal
```

Step 5 Type `interface management 1` to enter interface configuration mode. (Any available management port can be used in place of management port 1.)

```
switch(config)#interface management 1
switch(config-if-Ma1)#
```

Step 6 Type `ip address`, followed by the desired address, to assign an IP address to the port. This command assigns the IP address 10.0.2.8 to management port 1.

```
switch(config-if-Ma1)#ip address 10.0.2.8/24
```

Step 7 Type `end` at both the interface configuration and global configuration prompts to return to Privileged EXEC mode.

```
switch(config-if-Ma1)#end
switch(config)#end
switch#
```

Step 8 Type `write` (or `copy running-config startup-config`) to save the new configuration to the `startup-config` file.

```
switch#write
switch#
```

Configuring a Default Route to the Gateway

This procedure configures a default route to a gateway located at 10.0.2.1.

Step 1 Enter global configuration mode.

```
switch>enable
switch#configure terminal
```

Step 2 Create a static route to the gateway with the IP route command.

```
switch(config)#ip route 0.0.0.0/0 10.0.2.1
```

Step 3 Save the new configuration.

```
switch#write
switch#
```
2.2 Connection Management

The switch supports three connection methods:

- console
- SSH
- Telnet

The switch always enables console and SSH. Telnet is disabled by default.

Management commands place the switch in a configuration mode for changing session connection parameters.

Examples

- The **management console** command places the switch in console management mode:

  ```
  switch(config)#management console
  switch(config-mgmt-console)#
  ```

- The **management ssh** command places the switch in SSH management mode:

  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#
  ```

- The **management telnet** command places the switch in Telnet management mode:

  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#
  ```

- The **exit** command returns the switch to global configuration mode.

  ```
  switch(config-mgmt-ssh)#exit
  switch(config)#
  ```

The **idle-timeout** commands shown below configure the idle timeout period for the connection type being configured. The idle timeout is the interval that the connection waits after a user’s most recent command before shutting down the connection. Automatic connection timeout is disabled by setting the idle-timeout to zero, which is the default setting.

Examples

- This **idle-timeout (SSH Management)** command configures an ssh idle-timeout period of three hours.

  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#idle-timeout 180
  ```

- This **idle-timeout (Telnet Management)** command disables automatic connection timeout for telnet connections.

  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#idle-timeout 0
  ```

The **shutdown (Telnet Management)** command enables and disables Telnet connections.

Examples

- These commands enable Telnet.

  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#no shutdown
  ```

- These commands disable Telnet.

  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#shutdown
  ```
2.3 Configure Session

The command `configure session` allows users to issue configuration sessions as CLIs that do not take effect immediately. Each `configure session` is saved with a unique name. A session is entered, modified and exited at any time by entering `configure session <name of session>` (e.g., `configure session routing_changes`) without impacting the currently running system configuration.

A session is defined as a collection of configuration changes that are grouped together.

When a session is committed, the configuration that was modified during the session is copied into the running configuration. A session can be aborted or removed, thereby removing the session completely and freeing up memory used by the session. The user must explicitly request that the changes in a deferred session be applied to the configuration of the router, entering a `commit` command and exiting the mode. Alternately, the user may abandon the changes, entering an `abort` command.

Configuration sessions are used to make sets of changes, after verifying there are no CLI errors. Configuration sessions allow the administrator to pre-provision a group of CLIs in a named session, thereby committing execution of each configuration session at specified times.

This chapter contains the following sections:

- Section 2.3.1: Configuration Session
- Section 2.3.2: Configure Replace

2.3.1 Configuration Session

The command `configure session` allows users to make a series of configuration changes in a temporary location and commit them to `running-config` at once by issuing the `commit` command.

- `configure session <name of session>` and `running-config` — The user enters a session (versus `configure terminal` in the case where configuration sessions are not used). If a session name is not specified, a system named session is created. A snapshot of the current `running-config` is copied into the session’s data structure as the basis of further configuration changes.
- CLI configuration commands — User can run any configuration commands inside the session.
- `rollback clean-config` — User can run `rollback` command to revert the session’s configuration to the default configuration (or clean configuration).
- `show session-config` — User can run `show session-config` to show the session’s configuration, which will be the future `running-config` once committed.
- `commit` — User issues `commit` to commit the changes, which will replace the current `running-config`.
- `abort` — To abort the session and throw away all changes.
- `exit` — User can exit from the session, and later return to the same session by running `configure session <name>` again.
- For named session — More than one CLI instance can enter the same session and make changes to the session configuration. Once the session is committed in any of the CLIs, no other CLI can commit or make any other changes in that session.

2.3.2 Configure Replace

The command `configure replace <URL>` replaces the current `running-config` with the configuration saved in `<URL>`.

`configure replace <URL> [ignore-errors]`
By default, `configure replace <URL>` will replace `running-config` only if the configuration in `<URL>` loads without errors. The `ignore-errors` flag optionally forces the operation in spite of errors.

**Note**
The command `copy <URL> running-config` was typically used to apply a saved configuration file to the system, and append that configuration to the current `running-config` (in lieu of replacing it). However, it is recommended the user uses the CLI command `configure replace <URL>` to streamline the process of deterministically restoring the system back to a known good configuration.

The normal workflow internally uses a configuration session to perform the replace.

### 2.3.3 Configuration CLI

In the CLI, execute the following configuration steps to create a configuration session.

**Step 1**  
`configure session [<name of session>]`  
Create or enter a session. If a name is not specified, it is automatically generated. The user is put in the session configuration mode and the prompt will change to show the first six characters of the session name. Designating the name of a session is optional. When `<name of session>` is not specified, a unique name is assigned.  

`no configure session <name of session>`  
Delete the specified configuration session. Designating the name of a session is required.

**Step 2**  
`commit`  
Commit the changes made in the session. This command must be issued from within the session configuration mode.  

`abort`  
Abort the session, which is the same as deleting it. This command must be issued from within the session configuration mode.

**Step 3**  
`rollback clean-config`  
Revert configuration in the session to the clean, factory-default configuration. This command must be issued from within the session configuration mode.

**Step 4**  
`service configuration session max completed <num>`  
Set a limit on the maximum number of committed sessions that are saved.

**Step 5**  
`service configuration session max pending <num>`  
Set a limit on the maximum number of uncommitted sessions that can be outstanding.

### 2.3.4 Show Commands

#### 2.3.4.1 show configuration sessions [detail]

This command displays the following information about the sessions that exist in the system:

- The name of each session and its state (completed, pending, aborted, etc.) are displayed.
- If a user has currently entered the session, the user name and the associated terminal are also shown.
- With the detail flag, the process ID of the CLI process that is using the session is also displayed.

**Note**  
An asterisk (*) indicates that the user running the show command is currently in the marked session.
Example

Arista(config-s-s2)#show configuration sessions detail
Maximum number of completed sessions: 1
Maximum number of pending sessions: 5

<table>
<thead>
<tr>
<th>Name</th>
<th>State</th>
<th>User</th>
<th>Terminal</th>
<th>PID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>completed</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>* s2</td>
<td>pending</td>
<td>user123</td>
<td>vty870</td>
<td>7729</td>
<td></td>
</tr>
</tbody>
</table>

2.3.4.2 show session-config [diff]

This command must be issued from within a session. It shows the following:

- The session configuration, including the changes made in the session.
- The diff flag shows the differences with the running-config, which helps highlight the changes made in the session.

Example 1

Arista(config-s-s2)#show session-config
! Command: show session-configuration named s2
ip dhcp smart-relay global
! transceiver qsfp default-mode 4x10G
! ip pim bsr-candidate Loopback0 224.0.0.0/4 priority 64 hashmask 30 interval 60
! hostname Arista
ip host one 1.1.1.1
! no aaa root
! spanning-tree mode mstp
! interface Ethernet1
! interface Ethernet2
! interface Ethernet3
! interface Ethernet4
! interface Ethernet5
! interface Ethernet6
! no ip routing
!
end
Example 2

Arista(config-s-s2)#show session-config diff
--- system:/running-config
+++ session:/s2
@@ -5,6 +5,7 @@

2.4 Recovery Procedures

These sections describe switch recovery procedures:

- Section 2.4.1: Removing the Enable Password from the Startup Configuration
- Section 2.4.2: Reverting the Switch to the Factory Default Startup Configuration
- Section 2.4.3: Restoring the Factory Default EOS Image and Startup Configuration
- Section 2.4.4: Restoring the Configuration and Image from a USB Flash Drive

The first three procedures require Aboot Shell access through the console port. If the console port is not accessible, use the last procedure in the list to replace the configuration file through the USB Flash Drive.

**Boot Loader – Aboot** describes the switch booting process and includes descriptions of the Aboot shell, Aboot boot loader, and required configuration files.

2.4.1 Removing the Enable Password from the Startup Configuration

The *enable password* controls access to Privileged EXEC mode. To prevent unauthorized disclosure, the switch stores the *enable password* as an encrypted string that it generates from the clear-text password. When the switch authentication mode is local and an *enable password* is configured, the CLI prompts the user to enter the clear-text password after the user types *enable* at the EXEC prompt.

The *startup-config* file stores the encrypted *enable password* to ensure that the switch loads it when rebooting. If the text version of the *enable password* is lost or forgotten, access to enable mode is restored by removing the encrypted *enable password* from the startup configuration file.

This procedure restores access to enable mode without changing any other configuration settings.

**Step 1** Access the Aboot shell:

- a. Power cycle the switch by successively removing and restoring access to its power source.
- b. Type *Ctrl-C* when prompted, early in the boot process.
- c. Enter the Aboot password, if prompted.
  
  If the Aboot password is unknown, refer to Section 2.4.3: Restoring the Factory Default EOS Image and Startup Configuration for instructions on reverting all flash directory contents to the factory default, including the startup configuration and EOS image.

**Step 2** Change the active directory to /mnt/flash directory.

```
Aboot#cd /mnt/flash
```

**Step 3** Open the startup-config file in vi.

```
Aboot#vi startup-config
```

**Step 4** Remove the enable password line.

This is an example of an enable password line:

```
enable secret 5 $1$dBXo2KpF$Pd4XYLpI0ap12aU7g1G1w/
```

**Step 5** Save the changes and exit vi.

**Step 6** Exit Aboot. This boots the switch.

```
Aboot#exit
```
Reverting the Switch to the Factory Default Startup Configuration

The *startup-config* file contains configuration parameters that the switch uses during a boot. Parameters that do not appear in *startup-config* are set to their factory defaults when the switch reloads. The process requires the Aboot password if Aboot is password protected.

This procedure reverts EOS configuration settings to the default state through bypassing the *startup-config* file during a switch boot.

**Step 1** Access the Aboot shell through the console port:

a. Type `reload` at the Privileged EXEC prompt.
b. Type `Ctrl-C` when prompted, early in the boot process.
c. Enter the Aboot password, if prompted.

If the Aboot password is unknown, refer to Section 2.4.3: Restoring the Factory Default EOS Image and Startup Configuration for instructions on reverting all flash directory contents to the factory default, including *startup-config* and EOS image.

**Step 2** Change the active directory to `/mnt/flash` directory.

```
Aboot# cd /mnt/flash
```

**Step 3** Rename the startup configuration file.

```
Aboot# mv startup-config startup-config.old
```

**Step 4** Exit Aboot. This boots the switch

```
Aboot# exit
```

**Step 5** Cancel Zero Touch Provisioning (ZTP). Refer to Section 2.1.2.2: Canceling Zero Touch Provisioning for instructions.

If ZTP is not canceled, the switch either:

- boots, using the *startup-config* file or boot script that it obtains from the network, or
- remains in ZTP mode if the switch is unable to download a *startup-config* file or boot script.

**Step 6** Configure the *admin* and *enable* passwords.

```
switch>enable
switch#configure terminal
switch(config)#enable secret xyz1
switch(config)#username admin secret abc41
```

**Step 7** Save the new *running-config* to the startup configuration file.

```
switch#write
```

**Step 8** (Optional) Delete the old startup configuration file.

```
switch#delete startup-config.old
```

After ZTP is canceled, the switch reboots, using the factory default settings. To avoid entering ZTP mode on subsequent reboots, create a *startup-config* file before the next switch reboot.

**2.4.3 Restoring the Factory Default EOS Image and Startup Configuration**

A `fullrecover` command removes all internal flash contents (including configuration files, EOS image files, and user files), then restores the factory default EOS image and *startup-config*. A subsequent installation of the current EOS image may be required if the default image is outdated. This process requires Aboot shell access through the console port.
This procedure restores the factory default EOS image and startup configuration.

**Step 1** Access the Aboot shell through the console port:

a. Type `reload` at the Privileged EXEC prompt.

b. Type `Ctrl-C` when prompted, early in the boot process.

c. Enter the Aboot password, if prompted.

   If the Aboot password is not known, enter an empty password three times, after which the CLI displays:

   ```
   Type "fullrecover" and press Enter to revert /mnt/flash to factory default state, or just press Enter to reboot:
   ```

d. Type `fullrecover` and go to step 4.

**Step 2** Type `fullrecover` at the Aboot prompt.

Aboot#`fullrecover`

Aboot displays this warning:

```
All data on /mnt/flash will be erased; type "yes" and press Enter to proceed, or just press Enter to cancel:
```

**Step 3** Type `yes` and press `Enter`.

The switch performs these actions:

- erases the contents of /mnt/flash
- writes new boot-config, startup-config, and EOS.swi files to /mnt/flash
- returns to the Aboot prompt

**Step 4** Exit Aboot. This boots the switch.

Aboot#`exit`

The serial console settings are restored to their default values (9600/N/8/1/N).

**Step 5** Reconfigure the console port if non-default settings are required.

**Step 6** Cancel Zero Touch Provisioning (ZTP). Refer to Section 2.1.2.2: Canceling Zero Touch Provisioning for instructions.

If ZTP is not canceled, the switch either:

- boots, using the `startup-config` file or boot script that it obtains from the network, or
- remains in ZTP mode if the switch is unable to download a `startup-config` file or boot script.

After ZTP is canceled, the switch reboots, using the factory default settings. To avoid entering ZTP mode on subsequent reboots, create a `startup-config` file before the next switch reboot.

### 2.4.4 Restoring the Configuration and Image from a USB Flash Drive

The USB flash drive port can be used to restore an original configuration when you cannot establish a connection to the console port. This process removes the contents of the internal flash drive, restores the factory default configuration, and installs a new EOS image from the USB flash drive.
This procedure restores the factory default configuration and installs an EOS image stored on a USB flash drive.

**Step 1** Prepare the USB flash drive:

a. Verify the drive is formatted with MS-DOS or FAT file system.

   Most USB drives are pre-formatted with a compatible file system.

b. Create a text file named `fullrecover` on the USB flash drive.

   The filename does not have an extension. The file may be empty.

c. Create a text file named `boot-config`.

   The last modified timestamp of the `boot-config` file on the USB flash must differ from the timestamp of the `boot-config` file on the switch.

d. Enter this line in the new `boot-config` file on the USB flash:

   ```
   SWI=flash:EOS.swi
   ```

   e. Copy an EOS image file to the flash drive. Rename it `EOS.swi` if it has a different file name.

   For best results, the flash drive should contain only these three files, because the procedure copies all files and directories on the USB flash drive to the switch.

   - `fullrecover`
   - `boot-config`
   - `EOS.swi`

**Step 2** Insert the USB flash drive into the USB flash port on the switch, as shown in Figure 2-1.

**Step 3** Connect a terminal to the console port and configure it with the default terminal settings (9600/N/8/1) to monitor progress messages on the console.

**Step 4** Power up or **reload** the switch.

The switch erases internal flash contents and copies the files from the USB flash drive to internal flash. The switch then boots automatically.

**Step 5** Cancel Zero Touch Provisioning (ZTP). Refer to Section 2.1.2.2: Canceling Zero Touch Provisioning for instructions.

If ZTP is not canceled, the switch either:

- boots, using the `startup-config` file or boot script that it obtains from the network, or
- remains in ZTP mode if the switch is unable to download a `startup-config` file or boot script.

After ZTP is canceled, the switch reboots using the factory default settings. To avoid entering ZTP mode on subsequent reboots, create a `startup-config` file before the next switch reboot.
2.5 Session Management Commands

**Global Configuration Commands**
- management api http-commands
- management console
- management ssh
- management telnet
- management xmpp

**Management Configuration Commands**
- domain (XMPP Management)
- idle-timeout (Console Management)
- idle-timeout (SSH Management)
- idle-timeout (Telnet Management)
- protocol http (API Management)
- protocol https (API Management)
- protocol https certificate (API Management)
- server (XMPP Management)
- session privilege (XMPP Management)
- shutdown (API Management)
- shutdown (Telnet Management)
- shutdown (XMPP Management)
- switch-group (XMPP Management)
- username (XMPP Management)
- vrf (API Management)
- vrf (XMPP Management)
- xmpp send
- xmpp session

**Display Commands**
- show inventory
- show xmpp neighbors
- show xmpp status
- show xmpp switch-group
domain (XMPP Management)

The domain command configures the switch's XMPP domain name. Only messages using a domain matching the locally configured one are accepted by the XMPP client. The switch's domain name is used if none is specified.

Management over XMPP is disabled by default. To enable it, you must provide the location of the server along with the domain, username and password for the switch.

Arista recommends configuring the XMPP domain before the username, because it will provide shortcuts for the switch-group and username so they can be configured without the domain attached to it (e.g., USERNAME instead of USERNAME@DOMAIN).

The no domain and default domain commands delete the domain name by removing the domain command from running-config.

Command Mode

Mgmt-xmpp Configuration

Command Syntax

domain string
no domain
default domain

Parameters

• string domain name (text string)

Example

• This command configures test.aristanetworks.com as the switch's domain name.

switch(config)#management xmpp
test1(config-mgmt-xmpp)#server arista-xmpp
test1(config-mgmt-xmpp)#domain test.aristanetworks.com
test1(config-mgmt-xmpp)#username test1@test.aristanetworks.com password 0 arista
test1(config-mgmt-xmpp)#no shutdown

• This command removes the domain name from the XMPP configuration.

switch(config-mgmt-xmpp)#no domain
switch(config-mgmt-xmpp)
idle-timeout (Console Management)

The *idle-timeout (Console Management)* command configures the idle timeout period for console connection sessions. The idle timeout is the interval that the connection waits after a user’s most recent command before shutting down the connection. Automatic connection timeout is disabled by setting the idle-timeout to zero, which is the default setting.

The *no idle-timeout* and *default idle-timeout* commands disables the automatic connection timeout by removing the *idle-timeout* statement from *running-config*.

**Command Mode**

Mgmt-console

**Command Syntax**

```
idle-timeout idle_period
no idle-timeout
default idle-timeout
```

**Parameters**

- *idle_period*  session idle timeout length. Options include:
  - 0  Automatic connection timeout is disabled
  - *<1 to 86400>*  Automatic timeout period (minutes).

**Example**

- These commands configure a console idle-timeout period of three hours, then return the switch to global configuration mode.
  ```
  switch(config)#management console
  switch(config-mgmt-console)#idle-timeout 180
  switch(config-mgmt-console)#exit
  switch(config)#
  ```

- These commands disable automatic connection timeout.
  ```
  switch(config)#management console
  switch(config-mgmt-console)#idle-timeout 0
  switch(config-mgmt-console)#
  ```
idle-timeout (SSH Management)

The idle-timeout (SSH Management) command configures the idle timeout period for SSH connection sessions. The idle timeout is the interval that the connection waits after a user’s most recent command before shutting down the connection. Automatic connection timeout is disabled by setting the idle-timeout to zero, which is the default setting.

The no idle-timeout and default idle-timeout commands disables the automatic connection timeout by removing the idle-timeout statement from running-config.

Command Mode
Mgmt-ssh Configuration

Command Syntax
idle-timeout idle_period
no idle-timeout
default idle-timeout

Parameters
- idle_period  session idle timeout length. Options include:
  - 0  Automatic connection timeout is disabled
  - <1 to 86400>  Automatic timeout period (minutes).

Example
- These commands configure an ssh idle-timeout period of three hours, then return the switch to global configuration mode.
  switch(config)#management ssh
  switch(config-mgmt-ssh)#idle-timeout 180
  switch(config-mgmt-ssh)#exit
  switch(config)#
- These commands disable automatic connection timeout.
  switch(config)#management ssh
  switch(config-mgmt-ssh)#idle-timeout 0
  switch(config-mgmt-ssh)#
idle-timeout (Telnet Management)

The *idle-timeout (Telnet Management)* command configures the idle timeout period for Telnet connection sessions. The idle timeout is the interval that the connection waits after a user’s most recent command before shutting down the connection. Automatic connection timeout is disabled by setting the idle-timeout to zero, which is the default setting.

The *no idle-timeout* and *default idle-timeout* commands disables the automatic connection timeout by removing the *idle-timeout* statement from *running-config*.

**Command Mode**

Mgmt-telnet

**Command Syntax**

```
idle-timeout idle_period
no idle-timeout
default idle-timeout
```

**Parameters**

- `idle_period` session idle timeout length. Options include:
  - 0 Automatic connection timeout is disabled
  - `<1 to 86400>` Automatic timeout period (minutes).

**Example**

- These commands configure a telnet idle-timeout period of three hours, then return the switch to global configuration mode.
  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#idle-timeout 180
  switch(config-mgmt-telnet)#exit
  switch(config)#
  ```

- These commands disable automatic connection timeout.
  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#idle-timeout 0
  switch(config-mgmt-telnet)#
  ```
management api http-commands

The **management api http-commands** command places the switch in mgmt-api-http-cmds configuration mode.

The **no management api http-commands** and **default management api http-commands** commands delete mgmt-api-http-command configuration mode statements from **running-config**.

Mgmt-api-http-cmds configuration mode is not a group change mode; **running-config** is changed immediately upon entering commands. Exiting mgmt-api-http-cmds configuration mode does not affect **running-config**. The **exit** command returns the switch to global configuration mode.

Command Mode

| Global Configuration |

Command Syntax

| management api http-commands |
| no management api http-commands |
| default management api http-commands |

Commands Available in Mgmt-api-http-commands Configuration Mode

- **protocol http** (API Management)
- **protocol https** (API Management)
- **protocol https certificate** (API Management)
- **shutdown** (API Management)
- **vrf** (API Management)

Example

- This command places the switch in mgmt-api-http-cmds configuration mode.
  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#
  ```

- This command returns the switch to global management mode.
  ```
  switch(config-mgmt-api-http-cmds)#exit
  switch(config)#
  ```
management console

The **management console** command places the switch in mgmt-console configuration mode to adjust the idle timeout period for console connection sessions. The idle timeout period determines the inactivity interval that terminates a connection session.

The **no management console** and **default management console** commands delete mgmt-console configuration mode statements from **running-config**.

Mgmt-console configuration mode is not a group change mode; **running-config** is changed immediately upon entering commands. Exiting mgmt-console configuration mode does not affect **running-config**. The **exit** command returns the switch to global configuration mode.

**Command Mode**
- Global Configuration

**Command Syntax**
- `management console`
- `no management console`
- `default management console`

**Commands Available in mgmt-console Configuration Mode**
- **idle-timeout (Console Management)**

**Example**
- This command places the switch in mgmt-console configuration mode:
  ```
  switch(config)#management console
  switch(config-mgmt-console)#
  ```
- This command returns the switch to global management mode:
  ```
  switch(config-mgmt-console)#exit
  switch(config)#
  ```
management ssh

The management ssh command places the switch in mgmt-ssh configuration mode to adjust SSH session connection parameters.

The no management ssh and default management ssh commands delete the mgmt-ssh configuration mode statements from running-config.

Mgmt-ssh configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting mgmt-ssh configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
management ssh
no management ssh
default management ssh

Commands Available in Mgmt-ssh Configuration Mode
- authentication mode (Management-SSH)
- cipher (Management-SSH)
- fips restrictions (Management-SSH)
- hostkey (Management-SSH)
- idle-timeout (Management-SSH)
- ip access group (Management-SSH)
- ipv6 access group (Management-SSH)
- key-exchange (Management-SSH)
- login timeout (Management-SSH)
- mac hmac (Management-SSH)
- server-port (Management-SSH)
- shutdown (Management-SSH)
- vrf (Management-SSH)

Example
- This command places the switch in mgmt-ssh configuration mode:
  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#
  ```
- This command returns the switch to global management mode:
  ```
  switch(config-mgmt-ssh)#exit
  switch(config)#
  ```
management telnet

The management telnet command places the switch in mgmt-telnet configuration mode to adjust telnet session connection parameters.

The no management telnet and default management telnet commands delete the mgmt-telnet configuration mode statements from running-config.

Mgmt-telnet configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting mgmt-telnet configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

management telnet
no management telnet
default management telnet

Commands Available in mgmt-telnet Configuration Mode

- idle-timeout (Management-Telnet)
- ip access group (Management-Telnet)
- ipv6 access group (Management-Telnet)
- shutdown (Management-Telnet)
- vrf (Management-Telnet)

Example

- This command places the switch in mgmt-telnet configuration mode:
  
  switch(config)#management telnet
  switch(config-mgmt-telnet)#
  
- This command returns the switch to global management mode:
  
  switch(config-mgmt-telnet)#exit
  switch(config)#
management xmpp

The `management xmpp` command places the switch in mgmt-xmpp configuration mode. Management over XMPP is disabled by default. To enable XMPP, you must provide the location of the XMPP server along with the username and password for the switch.

The `no management xmpp` and `default management xmpp` commands delete the mgmt-xmpp configuration mode statements from `running-config`.

Mgmt-xmpp configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting mgmt-xmpp configuration mode does not affect `running-config`. The `exit` command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
```plaintext
management xmpp
no management xmpp
default management xmpp
```

Commands Available in Mgmt-xmpp Configuration Mode
- `domain` (Management-xmpp)
- `server` (Management-xmpp)
- `session` (Management-xmpp)
- `shutdown` (Management-xmpp)
- `switch-group` (Management-xmpp)
- `username` (Management-xmpp)
- `vrf` (Management-xmpp)

Example
- This command places the switch in mgmt-xmpp configuration mode:
  ```plaintext
  switch(config)#management xmpp
  switch(config-mgmt-xmpp)#
  ```
- This command returns the switch to global management mode:
  ```plaintext
  switch(config-mgmt-xmpp)#exit
  switch(config-mgmt-xmpp)#
  ```
protocol http (API Management)

The protocol http command enables the hypertext transfer protocol (HTTP) server.
The no protocol http and default protocol http commands disable the HTTP server by removing the protocol http statement from running-config.

Command Mode
Mgmt-API Configuration

Command Syntax

```
protocol http [TCP_PORT]
no protocol http
default protocol http
```

Parameters

- **TCP_PORT**  
  *Port number to be used for the HTTP server.* Options include:
  - <no parameter>  
    *Specifies default port number 80.*
  - port <1 to 65535>  
    *Specifies HTTP server port number. Value ranges from 1 to 65535.*
  - localhost  
    *The name of the server bound on the localhost.*
  - port  
    *The number of the TCP port to serve on.*

Related Commands

- management api http-commands places the switch in Management-api configuration mode.

Examples

- These commands enables the management API for the HTTP server.

  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#
  ```
protocol https (API Management)

The `protocol https` command enables the HTTP secure server. The HTTP secure server is active by default.

The `default protocol https` command restores the default setting by removing the `no protocol https` statement from `running-config`. The `no protocol https` command disables the HTTP secure server.

**Command Mode**

Mgmt-API Configuration

**Command Syntax**

```
protocol https [TCP_PORT]
no protocol https
default protocol https
```

**Parameters**

- **TCP_PORT**  
  Port number to be used for the HTTPS server. Options include:
  - `<no parameter>`  
    Specifies default port number 443.
  - **port <1 to 65535>**  
    Specifies HTTP server port number. Value ranges from 1 to 65535.
  - **certificate**  
    The HTTPS key and certificate to use.
  - **cipher**  
    Exclusive list of cryptographic ciphers.
  - **key-exchange**  
    Exclusive list of key-exchange algorithms.
  - **mac**  
    Exclusive list of MAC algorithms.
  - **port**  
    The number of the TCP port to serve on.
  - **ssl**  
    Configure SSL options.

**Related Commands**

- `management api http-commands` places the switch in Management-api configuration mode.

**Examples**

- These commands enables service to the HTTP server. The `no shutdown` command allows access to the service.

  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#protocol https
  switch(config-mgmt-api-http-cmds)# no shutdown
  ```

- These commands specifies the port number that should be used for the HTTPS server. The `no shutdown` command allows access to the service.

  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#protocol https port 52
  switch(config-mgmt-api-http-cmds)#no shutdown
  ```
**protocol https certificate (API Management)**

The `protocol https certificate` command configures the HTTP secure server to request an X.509 certificate from the client. The client then authenticates the certificate with a public key.

The `no protocol https certificate` and `default protocol https certificate` commands restore default behavior by removing the `protocol https certificate` statement from `running-config`.

**Command Mode**

Mgmt-API Configuration

**Command Syntax**

```
protocol https certificate
no protocol https certificate
default protocol https certificate
```

**Related Commands**

- `management api http-commands` places the switch in Management-api configuration mode.

**Examples**

- These commands configure the HTTP secure server to request an X.509 certificate from the client for authentication.

  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#protocol https certificate
  switch(config-mgmt-api-http-cmds)#
  ```
server (XMPP Management)

The `server` command adds a XMPP server to `running-config`. Multiple XMPP servers can be set up for redundancy. For redundant configurations, the XMPP server location should be a DNS name and not a raw IP address. The DNS server is responsible for returning the list of available XMPP servers, which the client can go through until an accessible server is found.

User authentication is provided by the XMPP server. Command authorization can be provided by EOS local configuration or TACACS+. The XMPP server should use the same authentication source as the switches. RADIUS is not supported as an XMPP authorization mechanism.

The `no server` and `default server` commands remove the specified XMPP server from `running-config`.

Command Mode
Mgmt-xmpp Configuration

Command Syntax
```
server SERVER_NAME [SERVER_PORT]
no server
default server
```

Parameters
- `SERVER_NAME` XMPP server location. Options include:
  - `IP address` in dotted decimal notation.
  - a host name for the XMPP server.
- `SERVER_PORT` Server port. Options include:
  - `port <1 to 65535>` where `number` ranges from 1 to 65535. If no port is specified, the default port 5222 is used.

Examples
- This command configures the server hostname `arista-xmpp` to server port 1.
  ```
  switch(config)#management xmpp
  switch(config-mgmt-xmpp)#server arista-xmpp port 1
  ```
- This command removes the XMPP server.
  ```
  switch(config-mgmt-xmpp)# no server
  ```
**session privilege (XMPP Management)**

The `session privilege` command will place the user in EXEC mode. The initial privilege level is meaningless by default. However, with the configuration of roles, users can add meaning to the different privilege levels. By default, XMPP does not limit access to any command.

Level 1-15: Commands accessible from EXEC Mode.

If AAA is not configured and the switch is configured to connect to the XMPP client, any message received is executed with privilege level 1 by default.

The `no session privilege` and `default session privilege` commands revert the list contents to *none* for the specified privilege levels.

**Command Mode**

Mgmt-xmpp Configuration

**Command Syntax**

- `session privilege PRIV_LEVEL`
- `no session privilege`
- `default session privilege`

**Parameters**

- *PRIV_LEVEL* Privilege levels of the commands. Value ranges from 0 and 15.

**Examples**

- These commands authorizes configuration commands (privilege level config 5) for XMPP.

  ```
  switch(config)#(config)##management xmpp
  switch(config-mgmt-xmpp)#session privilege 5
  switch(config-mgmt-xmpp)#
  ```

- This command removes the privilege levels set for the XMPP session.

  ```
  switch(config)#management xmpp
  switch(config-mgmt-xmpp)#no session privilege
  ```
**show inventory**

The *show inventory* command displays the hardware components installed in the switch. Serial numbers and a description is also provided for each component.

**Command Mode**

EXEC

**Command Syntax**

*show inventory*

**Examples**

- This command displays the hardware installed in a DCS-7150S-52 switch.

```
switch> show inventory
System information
    Model                    Description

switch>
```
show xmpp neighbors

The **show xmpp neighbors** command displays all neighbors and their connection status. The XMPP server keeps track of all relationships between its users.

**Command Mode**
EXEC

**Command Syntax**
```
show xmpp neighbors
```

**Example**
- This command displays all the XMPP neighbors and their connection status.

```
switch#show xmpp neighbors
Neighbor                          State           Last Seen Login Time
------------------------------    --------------- -------------------------
admin@test.aristanetworks.com    present         0:01:40 ago
test1@test.aristanetworks.com    present         20:29:39 ago

Neighbor                          Status Message
------------------------------    ----------------------------------------
admin@test.aristanetworks.com
test1@test.aristanetworks.com     Arista Networks DCS-7048T-4S
switch#
```
show xmpp status

The show xmpp status command displays the current XMPP connection status to the server.

The XMPP server keeps track of all relationships between its users. In order for two users to directly communicate, this relationship must first be established and confirmed by the other party.

Switches automatically confirm requests from outside parties as long as they are a user from the same domain name, for example when you chat with your switch from your own XMPP chat client.

**Command Mode**

EXEC

**Command Syntax**

```
show xmpp status
```

**Example**

- This command displays the current XMPP connection status to the server.

```
switch# show xmpp status
XMPP Server:  port 5222
Client username: test@test.aristanetworks.com
Default domain: test.aristanetworks.com
Connection status: connected
switch#
```
show xmpp switch-group

The **show xmpp switch-group** command displays the configured and active switch groups for the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show xmpp switch-group
```

**Example**

- This command displays the configured and active switch groups.

```
switch#show xmpp switch-group
testroom@conference.test.aristanetworks.com
switch#
```
shutdown (API Management)

The `shutdown` command, in Mgmt-API mode, disables or enables management over API on the switch. API is disabled by default.

The `no shutdown` command, in Mgmt-API mode, re-enables the management API access.

The `default shutdown` command, in Mgmt-API mode, disables the management API access and removes the command from the from `running-config`.

**Command Mode**

Mgmt-API Configuration

**Command Syntax**

- `shutdown`
- `no shutdown`
- `default shutdown`

**Related Commands**

- `management api http-commands` places the switch in Management-API configuration mode.

**Example**

- These commands disables API access to the HTTP server.
  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)# shutdown
  switch(config-mgmt-api-http-cmds)#
  ```

- These commands enables API access to the HTTP server.
  ```
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)# no shutdown
  switch(config-mgmt-api-http-cmds)#
  ```
shutdown (Telnet Management)

The **shutdown** command, in management-telnet mode, disables or enables Telnet on the switch. Telnet is disabled by default. The **management telnet** command places the switch in management-telnet mode.

- To enable Telnet, enter **no shutdown** at the management-telnet prompt.
- To disable Telnet, enter **shutdown** at the management-telnet prompt.

**Command Mode**

Management-Telnet Configuration

**Command Syntax**

```
shutdown
no shutdown
```

**Example**

- These commands enable Telnet, then return the switch to global configuration mode.
  
  ```
  switch(config)#management telnet
  switch(config-mgmt-telnet)#no shutdown
  switch(config-mgmt-telnet)#exit
  switch(config)#
  ```

- This command disables Telnet.
  
  ```
  switch(config-mgmt-telnet)#shutdown
  ```
**shutdown (XMPP Management)**

The `shutdown` command, in mgmt-xmpp mode, disables or enables management over XMPP on the switch. XMPP is disabled by default.

The `no shutdown` and `default shutdown` commands re-enable XMPP by removing the `shutdown` command from `running-config`.

**Command Mode**

Mgmt-xmpp Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Example**

- These commands enable management over XMPP, then return the switch to global configuration mode.

  ```
  switch(config-mgmt-xmpp)#no shutdown
  switch(config-mgmt-xmpp)#exit
  switch(config)#
  ```

- This command disables management over XMPP.

  ```
  switch(config-mgmt-xmpp)#shutdown
  switch(config-mgmt-xmpp)#
  ```
switch-group (XMPP Management)

The switch-group command allows you to configure each switch to join specified chat rooms on startup. In order for the switch to participate in a chat group, the switch has to be configured to belong to the specified chat room.

The no username and default username commands delete the specified username by removing the corresponding username statement from running-config.

Command Mode
Mgmt-xmpp Configuration

Command Syntax
```
switch-group name SECURITY
no switch-group
default switch-group
```

Parameters
- **name** Group name text that the user enters at the login prompt to access the CLI.
  Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:
  $$@#$%^&*-=+;<>.,~|$$

- **SECURITY** password assignment.
  - **password** pwd_txt name is protected by specified password. pwd_txt is a clear-text string.
  - **password 0** pwd_txt name is protected by specified password. pwd_txt is a clear-text string.
  - **password 7** pwd_txt name is protected by specified password. pwd_txt is encrypted string.

Guidelines
- A switch group is an arbitrary grouping of switches within the network which belong to one chat group.
- In order to belong to one or more switch groups, the switch has to be manually assigned to it.
- Switch groups are defined dynamically based on the configuration of all of the switches in the network.
- As per the multi-user chat XMPP standard (XEP-0045), switch groups have a full name of GROUPNAME@conference.DOMAIN
- All CLI commands allow either the full group name or the short name, which are appended the @conference.DOMAIN
- If the switch belongs to multiple chat rooms, you must configure each group with a separate command.

Examples
- These commands configures the switch-group to be part of the chat room.
  ```
  switch (config)#management xmpp
  switch (config-mgmt-xmpp)# switch-group
testroom@conference.test.aristanetworks.com password 0 arista
  ```
- Use the show xmpp switch-group to verify the active switch-group for the switch.
  ```
  switch# show xmpp switch-group
testroom@conference.test.aristanetworks.com
  ```
username (XMPP Management)

The `username` command configures the switch’s username and password on the XMPP server. The `no username` and `default username` commands delete the specified username by removing the corresponding `username` statement from `running-config`.

**Command Mode**

Mgmt-xmpp Configuration

**Command Syntax**

```
username name SECURITY
no username
default username
```

**Parameters**

- `name` username text that defines the XMPP username and password.
  - Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:
    `@ # $ % ^ & * ( ) _ - = + { } [ ] ; < > , . ~ |`

- `SECURITY` password assignment.
  - `password pwd_txt name` specifies and unencrypted shared key. `pwd_txt` is a clear-text string.
  - `password 0 pwd_txt name` specifies and unencrypted key. `pwd_txt` is a clear-text string.
  - `password 7 pwd_txt name` specifies a hidden key. `pwd_txt` is encrypted string.

**Guidelines**

Encrypted strings entered through this parameter are generated elsewhere. The `password 7` option (SECURITY) is typically used to enter a list of username-passwords from a script.

**Examples**

- These commands create the username and assigns it a password. The password is entered in clear text because the parameter is set to 0.
  ```
  switch(config)#management xmpp
  switch(config-mgmt-xmpp)#server arista-xmpp
  switch(config-mgmt-xmpp)#domain test.aristanetworks.com
  switch(config-mgmt-xmpp)#username test1@test.aristanetworks.com password 0
  switch(config-mgmt-xmpp)#
  ```

- This command removes all usernames from the XMPP server.
  ```
  switch(config-mgmt-xmpp)#no username
  switch(config-mgmt-xmpp)#
  ```
vrf (API Management)

The vrf command places the switch in VRF configuration mode for the server. If the named VRF does not already exist, this command creates it.

Command Mode
Mgmt-API Configuration

Command Syntax
vrf VRF_INSTANCE

Parameters
- **VRF_INSTANCE** specifies the VRF instance.
  - **default** Instance is created in the default VRF.
  - **vrf_name** Instance is created in the specified user-defined VRF.

Related Commands
- **management api http-commands** places the switch in Management-api configuration mode.

Example
- This command creates a VRF named management-vrf and places the switch in VRF configuration mode for the server.
  switch(config)#management api http-commands
  switch(config-mgmt-api-http-cmds)#vrf management-vrf
  switch(config-mgmt-api-http-cmds-vrf-management-vrf)#
vrf (XMPP Management)

The `vrf` command places the switch in VRF configuration mode for the XMPP server. If the named VRF does not already exist, this command creates it.

The VRF configuration for the client is for the entire XMPP service, rather than per server. All servers resolving on a particular hostname must be reachable in the same VRF.

**Command Mode**

Mgmt-xmpp Configuration

**Command Syntax**

```
 vrf [VRF_INSTANCE]
```

**Parameters**

- `VRF_INSTANCE` specifies the VRF instance.
  - `default` Instance is created in the default VRF.
  - `vrf_name` Instance is created in the specified user-defined VRF.

**Example**

- This command creates a VRF named `management-vrf` and places the switch in VRF configuration mode for the server.

```
 switch(config)#management xmpp
 switch(config-mgmt-xmpp)#vrf management-vrf
 switch(config-mgmt-xmpp)
```
**xmpp send**

The `xmpp send` command can be used to connect to the XMPP server and send messages to switches or switch groups within the network.

Before switches can send messages to each other, they must friend each other. An easy way to have them auto friend each other is to have them join the same chat room. The friendship between switches can be verified by using the `show xmpp neighbor` command.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
xmpp send to neighbor XMIT_TYPE content
```

**Parameters**

- `neighbor` Options include switches or switch groups within the network that are connected as friends in a chat room.
- `XMIT_TYPE` Transmission type. Valid options include:
  - `command` Sends an XMPP command.
  - `message` Sends an XMPP message.
- `content` The command you want the friends within the chat room to display or execute.

**Configuration Restrictions**

- Only enable-mode commands are allowed within the multi-switch CLI.
- Changing into a different CLI mode and running several commands in that mode is not supported (e.g., into configuration mode)
- An external XMPP client (for example Adium) can be used to send multiple lines within a single message. By sending multiple lines, it is possible to change into another CLI mode. After the message is processed, the switch automatically return to the enable mode.
- Commands that prompt for a response (like reload) are not supported.
- Long commands, such as image file copies, may cause the switch XMPP client to momentarily stop responding and disconnect. The switch should reconnect and the long command should complete.
- Many command outputs display in a specific table format. To achieve the same visual feel as through a terminal, use a monospaced font, such as Courier, for the incoming messages.

**Example**

- This command sends the switch in the chat room the request to execute the `show version` command.

```
switch# xmpp send test2 command show version
message from user: test2@test.aristanetworks.com
--------------------------------------------------
Hardware version:    04.40
Serial number:       JFL08432083
System MAC address:  001c.7301.7d69
Software image version: 4.12.3
Architecture:           i386
Internal build version: 4.12.3
Internal build ID:      f5ab5f57-9c26-4fe4-acaa-fb60fa55d01d
Uptime:                 2 hours and 38 minutes
Total memory:           1197548 kB
Free memory:            182452 kB
```
xmpp session

The **xmpp session** command is similar to running SSH from the switch. The user is required to input their username (default is to USER@DEFAULTDOMAIN) and password in order to connect to the XMPP server. This command allows you to interact in the enable mode with a switch or switch group over XMPP using the standard CLI, with access to help and tab completion. All commands are then executed remotely and only the non-empty results are displayed on the screen.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
xmpp session switchgroup
```

**Parameters**
- **switchgroup** The option includes the switch group within the network that is connected as friends in a chat room.

**Configuration Restrictions**
- Only enable-mode commands are allowed within the multi-switch CLI.
- Changing into a different CLI mode and running several commands in that mode is not supported (e.g., into configuration mode)
- An external XMPP client (for example Adium) can be used to send multiple lines within a single message. By sending multiple lines, it is possible to change into another CLI mode. After the message is processed, the switch automatically return to the enable mode.
- Commands that prompt for a response (like reload) are not supported.
- Long commands, such as image file copies, may cause the switch XMPP client to momentarily stop responding and disconnect. The switch should reconnect and the long command should complete.
- Many command outputs display in a specific table format. To achieve the same visual feel as through a terminal, use a monospaced font, such as Courier, for the incoming messages.

**Example**
- This command displays the status of Ethernet 3 from *test1*, which is a member of the switch group chat room.

```
switch# xmpp session all@test.aristanetworks.com
xmpp-all# show int Eth3 status

response from: test1@test.aristanetworks.com
-----------------------------------------------
Port  Name  Status     Vlan     Duplex  Speed   Type
Et3   bs3   connected  in Po3   a-full  a-1000  10GBASE-SR
switch#
```

Chapter 3

Command-Line Interface

The command-line interface (CLI) is one tool for controlling the switch and displaying information about its status and configuration. This chapter describes the use of the CLI.

This chapter includes these sections:

- Section 3.1: Accessing the EOS CLI
- Section 3.2: Processing Commands
- Section 3.3: Kernel-based Virtual Machine Commands and Configuration
- Section 3.4: Switch Platforms
- Section 3.5: Command Modes
- Section 3.6: Managing Switch Configuration Settings
- Section 3.7: Other Command-Line Interfaces
- Section 3.8: Common Criteria (CC)
- Section 3.9: Directory Structure
- Section 3.10: Command-Line Interface Commands

3.1 Accessing the EOS CLI

You can open an EOS CLI session through these connections:

- Ethernet management ports
- console port
- Telnet connections
- Secure Shell (SSH)
Processing Commands

3.2 Command Execution

Command keywords are not case-sensitive. The CLI also accepts truncated keywords that uniquely correspond to one command.

- The command abbreviation `con` does not execute a command in Privileged EXEC mode because the names of two commands begin with these letters: `configure` and `connect`.
  
  ```
  switch#con
  % Ambiguous command
  ```

- The command abbreviation `conf` executes `configure` in Privileged EXEC mode because no other command name begins with `conf`.
  
  ```
  switch#conf
  switch(config)#
  ```
3.2.2 Alias

The alias command creates an alias for a CLI command. Entering the alias in the CLI executes the corresponding command.

Example
- This command makes *srie* an alias for the command *show running-config interface ethernet 1-5*.

```
switch(config)#alias srie show running-config interface ethernet 1-5
switch(config)#srie
interface Ethernet1
  switchport access vlan 33
  storm-control broadcast level 1
  spanning-tree portfast
  spanning-tree bpduguard enable
interface Ethernet2
  switchport access vlan 33
  spanning-tree portfast
interface Ethernet3
  switchport access vlan 33
  spanning-tree portfast
  spanning-tree bpduguard enable
interface Ethernet4
interface Ethernet5
  shutdown
```

3.2.3 Cursor Movement Keystrokes

EOS supports these cursor movement keystrokes:
- **Ctrl-B** or the Left Arrow key: moves cursor to the left.
- **Ctrl-F** or the Right Arrow key: moves cursor to the right.
- **Ctrl-A**: moves cursor to beginning of line.
- **Ctrl-E**: moves cursor to end of line.
- **Esc-B**: moves cursor left one word.
- **Esc-F**: moves cursor right one word.

3.2.4 History Substitution Keystrokes

The history buffer retains the last 20 commands entered. History substitution keystrokes that access previously entered commands include:
- **Ctrl-P** or the Up Arrow key: Recalls the most recent buffered commands. Repeat to recall older commands.
- **Ctrl-N** or the Down Arrow key: Recalls more recent commands after using the Ctrl-P or the Up Arrow. Repeat to recall newer commands.

The *show history* command in Privileged EXEC mode displays the history buffer contents.

```
switch#show history
  en
  config
  exit
  show history
```
3.2.5 Command Lists and Syntax Assistance

EOS CLI uses widely followed conventions for providing command lists and syntax assistance. These conventions are available in all command modes.

- To display all commands available at this level, type a question mark (?):

  switchName>?
  clear   Reset functions
  connect Open a terminal connection
  disable Turn off privileged commands
  enable  Turn on privileged commands
  exit    Exit from the EXEC
  help    Description of the interactive help system
  logout  Exit from the EXEC
  no      Negate a command or set its defaults
  ping    Send echo messages
  show    Show running system information
  telnet  Open a telnet connection
  terminal Configure the terminal
  traceroute Trace route to destination

- To display a list of commands beginning with a specific character sequence, type the sequence followed by a question mark.

  switch#di?
  diagnostic diff dir disable

- To display a command’s keywords or arguments, type a question mark as an argument.

  switch>ping ?
  WORD  Ping destination address or hostname

- The switch accepts an address-mask or CIDR notation (address-prefix) in commands that require an IP address and mask. For example, these commands are processed identically:

  switch(config)#ip route 0.0.0.0 255.255.255.255 10.1.1.254

  switch(config)#ip route 0.0.0.0/32 10.1.1.254

- The switch accepts an address-wildcard or CIDR notation in commands requiring an IP address and wildcard. Wildcards use zeros to mask portions of the IP address and are found in some protocol configuration statements, including OSPF. The switch processes these commands identically:

  switch:network 10.255.255.1 0.0.0.255 area 15

  switch:network 10.255.255.1/24 area 15

3.2.6 Regular Expressions

A regular expression is pattern of symbols, letters, and numbers that represent an input string for matching an input string entered as a CLI parameter. The switch uses regular expression pattern matching in several BGP commands.

Regular expressions use the following operands:

- **.(period)** matches any single character.
  
  Example 1.3 matches 123, 133, and 1c3.

- **\ (backslash)** matches character or special character following the backslash.

  Example 15\.\. matches 15.5.10.10 it does not match 15.52.10.10

  Example \. matches . (period)
51

^ (caret)  matches the character or null string at the beginning of a string.

Example  ^read matches reader  ^read does not match bread.

* (asterisk)  matches zero or more sequences of characters preceding the asterisk.

Example  12* matches 167, 1267, or 12267  it does not match 267

+ (plus sign)  matches one or more sequences of characters preceding the plus sign.

Example  46+ matches 2467 or 24667  it does not match 247

$ (dollar sign)  dollar sign matches the character or null string at the end of an input string.

Example  read$ matches bread  but not reads

[ ] (brackets)  matches characters or a character range separated by a hyphen.

Example  [0137abcr-y] matches 0, 1, 3, v  it does not match 2, 9, m, z

? (question mark)  pattern matches zero or one instance. Entering Ctrl-V prior to the question mark prevents the CLI from interpreting ? as a help command.

Example  x1?x matches xx and x1x

I (pipe)  pattern matches character patterns on either side of bar.

Example  B(E|A)D matches BED and BAD. It does not match BD, BEAD, BEED, or EAD

() (parenthesis)  nests characters for matching. Endpoints of a range are separated with a dash (-).

Example  6(45)+ matches 645454523  it does not match 6443

Example  ([A-Za-z][0-9])+ matches C4 or x9

_ (underscore)  Pattern replaces a long regular expression list by matching a comma (,) a space, or the beginning or end of the input string.

Example  _rxy_ matches any of the following:

^rxy$  
^rxy  23  21  rxy  ,rxy,  rxy  ,rxy.

3.2.7 Scheduling CLI Commands

The schedule command facilitates the periodic execution of a specified CLI command. Command parameters configure the interval between consecutive execution instances and the maximum number of files that can be created when the command requires log files. By default, periodic execution of the following show tech-support command is enabled:

```
schedule tech-support interval 60 max-log-files 100 command show tech-support
```

Examples

- This command schedules the execution of a script file once every 12 hours. The log file option is set to zero because the command does not generate output to std-out.

```
switch# schedule ms_1 interval 720 max-log-files 0 command bash /mnt/flash/myscript.sh
```
The **show schedule summary** command displays the commands that are scheduled for periodic execution.

```
switch(config)#show schedule summary
Name       Last time  Interval  Max log files  Log file location
---------------- ----- -------- --------  -----------------  
tech-support  16:13    60     100       flash:/schedule/tech-support
ms_1        16:28    720      10       flash:/schedule/ms_1
```

- **This command stores** running-config **contents to a log file once each hour, creating up to 24 log files.**

```
switch#schedule backup-test interval 60 max-log-files 24 command show running-config
```

### 3.2.8 Running Bash Shell Commands Automatically with Event Handlers

Event handlers execute a Linux Bash shell command in response to a specific system event. An event handler consists of a Bash command, a trigger and a delay; when the trigger event occurs, the action is scheduled to run after delay seconds.

To create an event handler, use the **event-handler** command. This creates a new event handler and places the CLI in event handler configuration mode for that handler. Use the **action bash** command to configure a Bash command to run when the handler is triggered, and the **trigger** command to specify the trigger. Event handlers can be triggered by various events, including:

- system booting
- a change in a specified interface’s operational status or IP address
- a change in the startup-config file
- a state change in a virtual machine monitored by VM Tracer

To change the delay period between the trigger and the action, use the **delay** command.

When an action is run, certain information is passed to it through environment variables. For the **boot** trigger, no variables are set. For the **interface** triggers, the following variables are set and passed to the action:

- **$INTF** interface name
- **$OPERSTATE** current operational status of the specified interface
- **$IP-PRIMARY** current primary IP address of the specified interface

To execute more than one Bash command in response to a trigger, create a script containing the desired commands and enter the file path to the script as the argument of the **action bash** command.

To display information about all event handlers or about a specific event handler, use the **show event-handler** command.

The **no event-handler** command deletes an event handler.
Examples

- These commands create an event handler named “eth_4” which will send email to a specified address when there is a change in the operational status of Ethernet interface 4:

  ```
  switch(config)#event-handler eth_4
  switch(config-event-eth_4)#action bash email x@yz.com -s "Et4 $OPERSTATE"
  switch(config-event-eth_4)#trigger onintf ethernet 4 operstatus
  switch(config-event-eth_4)#delay 60
  switch(config-event-eth_4)#exit
  switch(config)#
  ```

  The above handler uses the $OPERSTATE variable to include the current operational state (“linkup” or “linkdown”) in the subject of the email. Note that the action will only function if email has been configured on the switch.

- These commands create an event handler named “onStartup” which will execute a user-defined script 60 seconds after the system boots.

  ```
  switch(config)#event-handler onStartup
  switch(config-event-onStartup)#action bash /mnt/flash/startupScript1
  switch(config-event-onStartup)#trigger onboot
  switch(config-event-onStartup)#delay 60
  switch(config-event-onStartup)#exit
  switch(config)#
  ```

  The above handler will also be executed on exiting from event-handler configuration mode.

- This command displays information about all event handlers configured on the system.

  ```
  switch#show event-handler
  Event-handler onStartup
  Trigger: onBoot delay 60 seconds
  Action: /mnt/flash/startupScript1
  Last Trigger Activation Time: 1 minutes 51 seconds ago
  Total Trigger Activations: 1
  Last Action Time: 51 seconds ago
  Total Actions: 1
  ```

- This command deletes the event handler named “onStartup”.

  ```
  switch(config)#no event-handler onStartup
  switch(config)#
  ```
3.3 Kernel-based Virtual Machine Commands and Configuration

Arista’s EOS has leveraged its unmodified Linux kernel, and embraced open source standards-based technology that has brought operating system virtualization to Ethernet switching, utilizing the kernel-based virtual machine (KVM) as follows:

- The hypervisor is the Linux kernel.
- The core virtualization infrastructure is provided by the kernel module.
- The CPU-specific implementation is provided by the processor-specific module (Intel or AMD).
- The generic machine emulator and virtualizer KVM is provided by a Modified Quick Emulator (QEMU), which transforms the Linux kernel into the hypervisor.

The standard Linux kernel is the hypervisor, resulting in changes to the standard kernel (such as memory support and scheduler). Optimizations to these Linux components (such as a new scheduler in the 2.6 kernel) benefit both the hypervisor (host operating system) and Linux guest operating systems. With the kernel acting as the hypervisor, the switch can run other operating systems, such as Windows or Linux.

All components required are pre-installed with the Arista EOS software image, requiring only the download of the image. A few additional configuration steps get the KVM fully operational.

This chapter contains the following sections:

- Section 3.3.1: KVM Commands
- Section 3.3.2: KVM Configuration

3.3.1 KVM Commands

The following table covers KVM commands used throughout the configuration.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>Up to 240 character comment for this mode.</td>
</tr>
<tr>
<td>config-file</td>
<td>VM’s libvirt configuration file (overrides other settings).</td>
</tr>
<tr>
<td>default</td>
<td>Set a command to its defaults.</td>
</tr>
<tr>
<td>disk-image</td>
<td>Add Virtual Machine disk image.</td>
</tr>
<tr>
<td>enable</td>
<td>Enable VM.</td>
</tr>
<tr>
<td>exit</td>
<td>Exit from Virtual Machine configuration mode.</td>
</tr>
<tr>
<td>help</td>
<td>Description of the interactive help system.</td>
</tr>
<tr>
<td>memory-size</td>
<td>Set memory size.</td>
</tr>
<tr>
<td>no</td>
<td>Negate a command or set its defaults.</td>
</tr>
<tr>
<td>show</td>
<td>Show running system information.</td>
</tr>
<tr>
<td>virtual-nic</td>
<td>Add virtual NIC.</td>
</tr>
<tr>
<td>vnc-port</td>
<td>Set VNC server port.</td>
</tr>
<tr>
<td>! !</td>
<td>Append to comment</td>
</tr>
</tbody>
</table>

3.3.1.1 CLI Commands

The following KVN CLI commands are used throughout the configuration.
vm

In config mode, the vm CLI command creates or deletes a KVM configuration, or enters config-vm mode. A newly created KVM will have an empty config file path and is disabled.

The CLI command syntax is as follows:

[no] vm NAME

Note Deleting an enabled KVM first disables it, using the same process as the no enabled command in the config-vm mode.

cfg-file

In config-vm mode, the cfg-file CLI command sets the path of the libvirt config file, using standard file syntax (e.g. flash:vm/NetscalerVPX.xml or sata:vm/NetscalerVPX.xml or /mnt/sata1/vm/NetscalerVPX.xml). Changing this value does not affect the state of a currently enabled KVM. To use the new file, the user must disable and then reenable the KVM.

The CLI command syntax is as follows:

cfg-file [PATH]

Note If the file does not exist, a warning is printed and the new value is stored.

enabled

In config-vm mode, the enabled CLI command allows enabling a currently disabled VM, causing it to start up immediately. If a VM is enabled in the startup-config, it starts up automatically when EOS boots (or when VirtAgent starts).

The CLI command syntax is as follows:

[no] enabled

Disabling a currently enabled VM initiates a shutdown process in the following sequence:

- Attempt to shut down the VM politely if the guest OS supports ACPI.
- If the VM is still running after 30 seconds, terminate it.

show vm

In enable mode, the show vm CLI command prints information about the configuration and status of a KVM, or of all KVMs if NAME is omitted, as follows:

- Configuration: Name, config file path, and enabled.
- Status: PID, log file path, and serial console pty path.
- Current resource usage: RES, CPU%
- (Detailed only) contents of the config file.
- (Detailed only) contents of the log file.

The CLI command syntax is as follows:

show vm [detailed] [NAME]
attach vm
In enable mode, the attach vm CLI command connects to a KVM's serial console pty (using virsh console).

Note
Press Ctrl-\] to exit to the CLI.

The CLI command syntax is as follows:

```
attach vm [NAME]
```

show tech-support
The CLI command syntax is as follows:

```
show tech-support [detailed] [NAME]
```

reload
In enable mode, the reload CLI command is executed before restarting the system, and will shut down currently enabled KVMs using the same process as the no enabled command in config-vm mode.

The CLI command syntax is as follows:

```
reload
```

### 3.3.2 KVM Configuration

Arista EOS enables kernel-based virtual machine (KVM) instances by running KVM on the control-plane CPU of the switch. KVM instances can be defined from the CLI.

To configure a KVM, you must download the virtual machine image and configure the EOS.

This section contains the following topics:
- Section 3.3.2.1: Configuring a KVM
- Section 3.3.2.2: Configuring a Guest KVM

#### 3.3.2.1 Configuring a KVM

To configure a KVM, perform the following steps:

**Step 1** Download the Virtual Machine Image to /mnt/flash

**Step 2** Name the virtual machine:

```
switch(config)#virtual-machine [kvm_name]
```

Example:

```
switch(config)#virtual-machine foo
```

**Step 3** Provide a pointer to the image:

```
switch(config-vm-foo)#disk-image [file:[path] image-format [format]
```

Example:

```
disk-image file:/mnt/flash/fedora.img image-format qcow2
```

**Step 4** Define the amount of memory allocated:

```
switch(config-vm-foo)#memory-size [size in bytes]
```

**Step 5** Bind the virtual NIC to an SVI (or management interface):

```
switch(config-vm-foo)#virtual-nic 1 vlan [1-4]
switch(config-vm-foo)#virtual-nic 1 management [1-4]
```
Step 6  Create the VNC server's tcp port (display):
  switch(config-vm-foo)#vnc-port [vnc-port number]

Step 7  Enable the virtual machine:
  switch(config-vm-foo)#enable

Optionally attach to the virtual machine via VNC client pointed to the switch’s IP address. However, if Kernel hair-pinning is currently not enabled, preventing communication directly with the local switch, all traffic must have a destination on another networked device (such as a router, switch, or server).

For specifics about KVM please visit http://www.linux-kvm.org/.

Note  In the Real VNC Viewer for Options, Expert, and ColorLevel, if the default value is pal8, establishing a session may fail. If this occurs, set this value to full and reconnect.

Example

  switch#copy http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-openstack-sda.qcow2 (http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-openstack-sda.qcow2) flash:
  ...
  switch(config)#virtual-machine foo
  switch(config-vm-foo)#disk-image file:/mnt/flash/fedora.img image-format qcow2
  switch(config-vm-foo)#memory-size 512
  switch(config-vm-foo)#virtual-nic 1 vlan 1
  switch(config-vm-foo)#virtual-nic 2 management 1
  switch(config-vm-foo)#vnc-port 5900
  switch(config-vm-foo)#enable

3.3.2.2  Configuring a Guest KVM

To configure a guest KVM, perform the following steps:

Step 1  Download the Virtual Machine Image to /mnt/flash

Step 2  Name the virtual machine:
  switch(config)#virtual-machine [guest_name]
  Example:
  switch(config)#virtual-machine guest123

Step 3  Provide a pointer to the image:
  switch(config-vm-guest123)#disk-image [file:[path] image-format [format]
  Example:
  switch(config-vm-guest123)#disk-image flash:f16-x86_64-openstack-sda.qcow2 image-format ?
  iso iso image format
  qcow qcow image format
  qcow2 qcow2 image format
  raw raw image format
  vmdk vmdk image format
  switch(config-vm-guest123)#disk-image flash:f16-x86_64-openstack-sda.qcow2 image-format qcow2

Step 4  Define the amount of memory allocated:
  switch(config-vm-guest123)#memory-size [size in bytes]
Step 5  Bind the virtual NIC to an SVI (or management interface):
switch(config-vm-guest123)#virtual-nic 1 vlan [1-4]
switch(config-vm-guest123)#virtual-nic 2 management [1-4]

Step 6  Create the VNC server's tcp port (display):
switch(config-vm-guest123)#vnc-port [vnc-port number]

Step 7  Enable the virtual machine:
switch(config-vm-guest123)#enable
Example

```
switch#copy http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-openstack-sda.qcow2
(http://berrange.fedorapeople.org/images/2012-02-29/f16-x86_64-openstack-sda.qcow2) flash:
...  
switch#config terminal
switch(config)#virtual-machine ?
  WORD Virtual Machine name
switch(config)#virtual-machine foo
switch(config-vm-foo)#disk-image flash:f16-x86_64-openstack-sda.qcow2
image-format ?
  iso   iso image format
  qcow  qcow image format
  qcow2 qcow2 image format
  raw   raw image format
  vmdk  vmdk image format
switch(config-vm-foo)#disk-image flash:f16-x86_64-openstack-sda.qcow2
image-format qcow2
switch(config-vm-foo)#memory-size 1024
switch(config-vm-foo)#virtual-nic ?
  <1-4> Virtual NIC Id
switch(config-vm-foo)#virtual-nic 1
  Management Management interface
  Vlan    Vlan interface
switch(config-vm-foo)#virtual-nic 1 vlan 1
switch(config-vm-foo)#virtual-nic 2 management 1
switch(config-vm-foo)#enable
switch(config-vm-foo)#
switch(config-vm-foo)#write mem
switch(config-vm-foo)#^Z
switch#write mem
switch#show virtual-machine detail
Virtual Machine: foo
  Enabled: Yes
  State: Running
  Disk Image: /mnt/flash/f16-x86_64-openstack-sda.qcow2
  Disk Image Format: qcow2
  Memory Size: 1024MB
  VNC port: 5900
  Virtual Nic: vnic1
    Mac Address: 52:54:00:ee:11:c9
    Device: Vlan1
    Model Type: e1000
  Virtual Nic: vnic2
    Mac Address: 52:54:00:df:2a:e1
    Device: Management1
    Model Type: e1000
```

Note

Once a Guest KVM has its configuration setup correctly, it can have virtual NIC connections in VLANs (inband), or on out-of-band management interfaces.
3.4 Switch Platforms

Features and CLI commands vary by switch platform. CLI options may also vary by switch platform for commands that are available on all platforms. Command descriptions in this manual describe feature availability and command parameters on the basis of switch platform, noting exceptions that exist among models that use a common platform.

These sections describe the following topics:

- **Section 3.4.1: Viewing the Model Number**
- **Section 3.4.2: Determining a Switch’s Operating Platform**
- **Section 3.4.3: Modular System Platforms – 7500 and 7500E Series Switches**
- **Section 3.4.4: Viewing Modules on 7300 Series Modular Switches**
- **Section 3.4.5: Multi-Chip Devices**

### 3.4.1 Viewing the Model Number

To view the switch’s model number through the CLI, enter `show version`.

**Example**

- This command displays the model number, serial number, system MAC address, and manufacturing information of a DCS-7150S-64 switch.

```
switch>show version
Arista DCS-7150S-64-CL-F
Hardware version: 01.01
Serial number: JPE13120819
System MAC address: 001c.7326.fd0c

Software image version: 4.13.2F
Architecture: i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID: eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime: 16 hours and 39 minutes
Total memory: 4017088 kB
Free memory: 1348228 kB
```

### 3.4.2 Determining a Switch’s Operating Platform

**FM6000 Platforms**

To determine the operating platform on switch, display `platform` command options from Global Configuration command mode.
Chapter 3: Command-Line Interface

Switch Platforms

- This command displays the operating platform of a switch operating on the FM6000 platform (7150 Series switches).

  switch(config)#platform ?
  fm6000  FM6000 chip

  switch(config)#platform

Arad and Petra Platforms

The `platform ?` command displays the same options on Arad and Petra platform switches. Refer to Section 3.4.1 to determine the switch’s model number.

- Fixed system switches (DCS-7048 Series) operate on the Petra platform.
- Modular switches (DCS-7500 Series) operate on Arad and Petra platforms. Section 3.4.3: Modular System Platforms – 7500 and 7500E Series Switches describe platform usage on these switches.

Arad and Petra platform switch typically utilize multiple chips. Section 3.4.5 describe methods of determining the port distribution on multi-chip platforms.

Example

- These commands display platform options of a switch operating on either Petra or Arad platforms.

  switch(config)#platform ?
  arad    Arad switch chip
  fe1600  Fe1600 chip
  fe600   Fe600 fabric chip
  petraA  PetraA switch chip
  ptp     Precision Time Protocol
  sand    Sand platform

  switch(config)#platform

Trident and Trident-II Platforms

The `platform ?` command returns `trident` on switches that operate on Trident or Trident-II platforms. Trident-II platform switches include options that configure the forwarding and routing tables. To determine the Trident platform that a switch uses, display `platform trident` options.

- These commands indicate that the switch is operating on the Trident-II platform:

  switch(config)#platform ?
  ptp     Precision Time Protocol
  trident Trident chip

  switch(config)#platform trident ?
  fabric            Fabric configuration
  forwarding-table  Forwarding table configuration
  mmu               Trident MMU configuration
  routing-table     Routing table configuration

  switch(config)#platform trident

Fixed and Modular switches are available that operate on the Trident-II platform. Refer to Section 3.4.1 to determine the switch’s model number. Section 3.4.4: Viewing Modules on 7300 Series Modular Switches displays the modules on a Trident-II platform modular switch.

Trident-II platform switches typically utilize multiple chips. Section 3.4.5 describe methods of determining port distribution on multi-chip platforms.
3.4.3 Modular System Platforms – 7500 and 7500E Series Switches

Modular switch platforms depend on their installed modules along with the fabric and forwarding software modes. The `show module` command displays the fabric modules in the switch. System performance in switches containing both module types is based on first-generation fabric capabilities. Best practice is to avoid switch configurations with mixed fabric modules.

These sections describe modular switch components and software modes that program their capacities.

3.4.3.1 Fabric Modules and Fabric Mode – 7500 and 7500E Series Switches

Each modular switch fabric module is categorized as first-generation or E-Series:

- First-generation fabric modules support all basic switch functions.
- E-Series fabric modules support faster fabric link speeds, greater internal table capacities, and advanced encoding formatting.

Fabric mode determines the switch’s fabric performance capabilities. This mode must match the fabric modules in the switch. Fabric mode settings include:

E-series fabric modules can operate in `fe600` mode, but are limited to first-generation fabric performance. First-generation modules cannot operate in `fe1600` mode. Switches containing both types of modules must be set to `fe600` mode. Best practice is to avoid switch configurations with mixed fabric modules.

When a switch reloads, fabric mode is determined by the following (in order of precedence):

**Step 1** Switches reloading in `petraA` forwarding compatibility mode (Section 3.4.3.2) also reload in `fe600` fabric mode.

**Step 2** As specified by the `platform sand fabric mode (7500 and 7500E Series)` statement in `running-config`.

**Step 3** The first fabric module that becomes operational as the switch reloads.

In switches with a homogeneous module set, the fabric mode matches its fabric modules. Switches with a mixed set of modules are typically reloaded in `fe600` mode because first generation modules are usually operational before E-Series modules. However, the fabric mode in mixed module switches that are reloading cannot be guaranteed in the absence of the first two conditions.

**Example**

- This command configures the switch to reload in `fe1600` fabric mode to support E-series fabric modules. After issuing this command, the switch should be reset only after exchanging all switch fabric modules to E-series modules.

```
switch(config)#platform sand fabric mode fe1600
switch(config)#exit
switch#show platform sand compatibility

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>Status</td>
</tr>
<tr>
<td>Forwarding mode</td>
<td>None</td>
</tr>
<tr>
<td>Fabric mode</td>
<td>Fe1600</td>
</tr>
</tbody>
</table>
switch#  ```
3.4.3.2 Linecard Modules and Forwarding Compatibility Mode – 7500 and 7500E Series

Each modular switch linecard module is categorized as first-generation or E-Series:

- First-generation linecard modules support all basic switch functions.
- E-Series linecard modules support provide faster data processing, greater internal table capacities, and advanced encoding formatting.

The forwarding compatibility mode determines the switch’s performance capabilities when forwarding data between linecard interfaces. Forwarding compatibility mode settings include:

- **PetraA**: Supports first-generation linecard modules.
- **Arad**: Supports E-Series linecard modules.

Forwarding compatibility mode determines the operational capacity of installed linecards. Table 3-2 lists the affect of the forwarding compatibility mode on linecard module types.

Table 3-2 Linecard Module and Forwarding Mode Performance

<table>
<thead>
<tr>
<th>Linecard Module Type</th>
<th>Forwarding Compatibility Mode</th>
<th>Linecard Operating Capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>First-generation</td>
<td>petraA</td>
<td>First-generation performance capacity.</td>
</tr>
<tr>
<td>First-generation</td>
<td>arad</td>
<td>Linecard is powered-down.</td>
</tr>
<tr>
<td>E-Series</td>
<td>petraA</td>
<td>First-generation performance capacity.</td>
</tr>
<tr>
<td>E-Series</td>
<td>arad</td>
<td>E-series performance capacity.</td>
</tr>
</tbody>
</table>

**Important!** Switches must contain E-Series fabric modules to operate at E-Series performance capacities.

The forwarding compatibility mode is configured by the `platform sand forwarding mode (7500 and 7500E Series)` command. This command may be required after exchanging a linecard for a different module type or in switches containing first-generation and E-series linecards.

Without a `platform sand forwarding mode` command, forwarding compatibility mode is determined by the first linecard that is operational after reloading the switch. In a switch that is reloaded with a homogeneous module set, forwarding compatibility mode matches its linecards. Switches with a mixed set of modules are typically reloaded in **PetraA** mode because first generation modules are usually operational before E-Series modules. However, forwarding compatibility mode in mixed module switches that are reloading is not guaranteed without a `platform sand forwarding mode` command.

**Example**

- This command changes the forwarding software mode to support E-series linecard modules. This command should be run only after exchanging all linecards to E-series modules.

  ```
  switch(config)#platform sand forwarding mode arad
  switch(config)#
  ```

3.4.3.3 Viewing Modules – 7500 and 7500E Series

The **show module** command displays the model number of all installed modules.
This command displays the modules of a 7504 switch that contains first-generation modules.

```plaintext
switch> show module

<table>
<thead>
<tr>

Multi-Chip Devices
Trident-II, Petra, and Arad platform switches and linecards utilize multiple chips, with Ethernet ports
evenly distributed among the chips. Creating multi-port data structures (including port channels) that
include ports from multiple chips protects against the failure of an individual chip on a device.
The following sections describe methods of determining port distribution on various switch platforms
Petra Fixed Switches
7048-Series switches are Petra platform devices that distribute ports among two PetraA chips. The
show platform petraA port-info routing command displays the ports that are controlled by each chip.
Example
•

This command displays the following Ethernet port distribution on a DCS-7048-T switch:
•

66

Petra0 chip controls Ethernet 1 through Ethernet 32


**Petra1 chip controls Ethernet 33 through Ethernt 52**

```bash
switch#show platform petraA port-info routing
Petra0 Port Routing Information:

```

Petra Modular Switches

Linecards on 7500-Series modular switches distribute Ethernet ports among multiple petraA chips. The `show platform petraA port-info routing` command displays the ports that are controlled by each chip on all PetraA linecards or on a single linecard.

**Example**

- This command displays the following Ethernet port distribution on linecard 4 of a DCS-7504 switch:
  - Petra4/0 chip controls Ethernet 4/1 through Ethernet 4/8
  - Petra4/1 chip controls Ethernet 4/9 through Ethernet 4/16
  - Petra4/2 chip controls Ethernet 4/17 through Ethernet 4/24
  - Petra4/3 chip controls Ethernet 4/25 through Ethernet 4/32
  - Petra4/4 chip controls Ethernet 4/33 through Ethernet 4/40
 Petra4/5 chip controls Ethernet 4/41 through Ethernet 4/48

```
switch(s1)# show platform petra module 4 port-info routing

**Arad Modular Switches**

7500-E Series linecards distribute Ethernet ports among multiple Arad chips. The `show platform arad port-info routing` command displays the ports that are controlled by each chip on all Arad linecards.

**Example**

- This command displays the following Ethernet port distribution on the 7500E-72S-LC linecard that is inserted as module 3 in a DCS-7508E switch:

```
switch#show platform arad mapping

Trident-II Fixed Switches

Trident-II platform devices distribute their ports among multiple Trident II chips. The \texttt{show platform trident system port} command displays the ports that are controlled by each chip.

Example

- This command displays the following Ethernet port distribution on a DCS-7250QX-64-F switch:
  - Trident 0 chip controls Ethernet 1/1 through Ethernet 16/4
  - Trident 1 chip controls Ethernet 17/1 through Ethernet 32/4
  - Trident 2 chip controls Ethernet 33/1 through Ethernet 48/4
  - Trident 3 chip controls Ethernet 49/1 through Ethernet 64/4

\begin{verbatim}
switch# show platform trident system port

Trident-II Modular Switches

Linecards on 7300-Series modular switches distribute Ethernet ports among multiple Trident II chips. The \texttt{show platform trident system port} command can display the ports that are controlled by each chip on all linecards or on a single chip.

- This command displays the following Ethernet port distribution on DCS-7304-F switch that contains a 7300X-32Q-LC linecard as module 3:
  - Trident 0 chip controls Ethernet 1/1 through Ethernet 16/4 (on module 3)
- Trident 1 chip controls Ethernet 17/1 through Ethernet 32/4 (on module 3)

```bash
switch# show platform trident system port

<table>
<thead>
<tr>
<th>Port</th>
<th>Intf</th>
<th>Chip</th>
<th>ModId</th>
<th>Logical</th>
<th>Physical</th>
<th>MMU</th>
</tr>
</thead>
<tbody>

```

switch#
3.5 Command Modes

Command modes define the user interface state. Each mode is associated with commands that perform a specific set of network configuration and monitoring tasks.

- **Section 3.5.1: Mode Types** lists the available modes.
- **Section 3.5.2: Navigating Through Command Modes** lists mode entry and exit commands.
- **Section 3.5.3: Command Mode Hierarchy** describes the mode structure.
- **Section 3.5.4: Group-Change Configuration Modes** describes editing aspects of these modes.

### 3.5.1 Mode Types

The switch includes these command modes:

- **EXEC**: EXEC mode commands display system information, perform basic tests, connect to remote devices, and change terminal settings. When logging into EOS, you enter EXEC mode.
  
  EXEC mode prompt: `switch>`

- **Privileged EXEC**: Privileged EXEC mode commands configure operating and global parameters. The list of Privileged EXEC commands is a superset of the EXEC command set. You can configure EOS to require password access to enter Privileged EXEC from EXEC mode.
  
  Privileged EXEC mode prompt: `switch#`

- **Global Configuration**: Global Configuration mode commands configure features that affect the entire system, such as system time or the switch name.
  
  Global Configuration mode prompt: `switch(config)#`

- **Interface Configuration**: Interface configuration mode commands configure or enable Ethernet, VLAN, and Port-Channel interface features.
  
  Interface Configuration mode prompt: `switch(config-if-Et24)#`

- **Protocol specific mode**: Protocol specific mode commands modify global protocol settings. Protocol specific mode examples include **ACL Configuration** and **Router BGP Configuration**.
  
  The prompt indicates the active command mode. For example, the Router BGP command prompt is `switch(config-router-bgp)#`

### 3.5.2 Navigating Through Command Modes

To change the active command mode, perform one of these actions:

- To enter EXEC mode, log into the switch.
- To enter Privileged EXEC mode from EXEC, type `enable` (or `en`) followed, if prompted, by the enable password:
  
  switch>en
  Password:
  switch#

- To enter Global Configuration mode from Privileged EXEC, type `configure` (or `config`):
  
  switch#config
  switch(config)#

**Note** EOS supports `copy <url> running-config` in place of the `configure network` command.
• To enter Interface Configuration mode from Global Configuration, type `interface` and the name of
  the interface to be modified:
  switch(config)#`interface Et24`
  switch(config-if-Et24)#

• To enter a protocol specific configuration mode from Global Configuration, type the required
  command for the desired mode.
  switch(config)#`router bgp 100`
  switch(config-router-bgp)#

• To return one level from any configuration mode, type `exit`.
  switch(config)#`exit`
  switch#

• To return to Privileged EXEC mode from any configuration mode, type `end` or `Ctrl-Z`.
  switch(config-if-Et24)#`<Ctrl-z>`
  switch#

• To return to EXEC mode from Privileged EXEC mode, type `disable` (or `dis`).
  switch#`dis`
  switch>

• To exit EOS and log out of the CLI, type `exit` from EXEC mode or Privileged EXEC mode.
  switch#`exit`
  login:

3.5.3 Command Mode Hierarchy

Command modes are hierarchical. The parent mode of a specified command mode is the mode that
contains the command that enters the specified mode.

Example

• EXEC mode contains the `enable` command, which enters Privileged EXEC mode. Therefore,
  EXEC is the parent mode of Privileged EXEC.

Commands that are executable in a specified command mode include all commands available in the
specified mode plus all commands executable from its parent mode.

Example

• EXEC mode includes the `ping` command. EXEC mode is the parent mode of Privileged EXEC
  mode. Therefore, Privileged EXEC mode includes `ping`.

  Additionally, Privileged EXEC is the parent mode of Global Configuration mode. Therefore, Global
  Configuration mode also includes `ping`.

Executing a configuration mode command from a child mode may change the active command mode.

Example

• Global Configuration mode contains `interface ethernet` and `ip access-list` commands, which
  enter Interface Configuration and Access Control List (ACL) Configuration modes, respectively.
  When the switch is in Interface Configuration mode, the `ip access-list` command is available and
  changes the active mode to ACL Configuration.
  switch(config)#`interface ethernet 1`
  switch(config-if-Et1)#`ip access-list master-list`
  switch(config-acl-master-list)#
The **exit** command changes the active command mode to its parent mode. When executed from Privileged EXEC or EXEC modes, the exit command terminates the session.

**Example**

- This command exits Global Configuration mode to Privileged EXEC mode.
  
  ```
  switch(config)#exit
  switch#
  ```

- This command terminates the user session.
  
  ```
  switch#exit
  ```

### 3.5.4 Group-Change Configuration Modes

Group-change modes apply all changes made during an edit session only after exiting the mode. Changes are stored when the user exits the mode, either through an **exit** or **end** command or through a command that enters a different configuration mode.

The **abort** command discards all changes not previously applied.

Access Control List (ACL) and Multiple Spanning Tree (MST) configuration modes are examples of group-change modes.
3.6 Managing Switch Configuration Settings

3.6.1 Verifying the Running Configuration Settings

*running-config* is the virtual file that stores the operating configuration. The *show running-config* command displays the *running-config*. The command is supported in Privileged EXEC mode.

**Example**

- Type *show running-config* in Privileged EXEC mode. The response in the example is truncated to display only the ip route configured.

```
switch#show running-config
! Command: show running-config
  <--------OUTPUT OMITTED FROM EXAMPLE---------->
  !
ip route 0.0.0.0/0 192.0.2.1
!  <--------OUTPUT OMITTED FROM EXAMPLE---------->
end
switch#
```

3.6.2 Verifying Settings for the Current Mode

To display only the lines of *running-config* that affect the current mode, use the *active* option of the *show (various configuration modes)* command. This command option is available in all configuration modes except global configuration.

**Example**

- Type *show active* to display the content of *running-config* that affects the current mode. To include default settings in the display, type *show active all*.

```
switch(config-router-ospf3)#show active all
ipv6 router ospf 9
    router-id 0.0.0.0
    default-metric 10
    distance ospf intra-area 10
    area 0.0.0.200 default-cost 10
    area 0.0.0.200
    no log-adjacency-changes
    timers spf 5
switch(config-router-ospf3)#
```

To display any comments associated with the current mode, use the *comment* option of the *show (various configuration modes)* command.

**Example**

- Type *show comment* to display any comments attached to the current mode.

```
switch(config-router-ospf3)#show comment
Comment for router-ospf3:
    Consult Thomas Morton before making changes to the OSPF configuration.
switch(config-router-ospf3)#
```
3.6.3 Adding a Comment to a Configuration Mode

To add a comment to most switch configuration modes, use the `comment (various configuration modes)` command. Comments cannot be modified, but can be replaced by entering the `comment` command again and entering new text. Comments cannot be added to global configuration mode.

To append to an existing comment, enter `!` followed by additional comment text. To display comments for the active mode, use the `comment` option of the `show (various configuration modes)` command. The `no comment` and `default comment` commands remove the comment from `running-config`.

**Examples**

- To add a comment to the active configuration mode, enter `comment`, then type the comment text. To end comment editing, type EOF on a separate line (case sensitive) and press `enter`.
  
  ```
  switch(config-router-ospf3)#comment
  Enter TEXT message. Type 'EOF' on its own line to end.
  Consult Thomas Morton before making changes to the OSPF configuration.
  EOF
  switch(config-router-ospf3)#
  ```

- To append to an existing comment, enter `!` followed by additional comment text.
  
  ```
  switch(config-router-ospf3)#!x2735
  switch(config-router-ospf3)#show comment
  Comment for router-ospf3:
  Consult Thomas Morton before making changes to the OSPF configuration.
  x2735
  switch(config-router-ospf3)#
  ```

3.6.4 Saving the Running Configuration Settings

`startup-config` is the file, stored in internal flash memory, that the switch loads when it boots. Configuration changes that are not saved to `startup-config` are lost the next time the switch is booted.

The `write` and `copy running-config startup-config` commands store the operating configuration to `startup-config`. Both commands are supported in Privileged EXEC mode.

**Example**

- These equivalent commands save the current operating configure to the startup-config file.
  
  ```
  switch#write
  ```

The `show startup-config` command displays the startup configuration file. The command is supported in Privileged EXEC mode.
Example

- Type `show startup-config` to display the startup configuration file. The response in the example is truncated to display only the `ip route` configured in Admin Username.

```
switch#show startup-config
! Command: show startup-config
! Startup-config last modified at  Wed Feb 19 08:34:31 2014 by admin
!

<--------OUTPUT OMITTED FROM EXAMPLE-------->
!
ip route 0.0.0.0/0 192.0.2.1
!
<--------OUTPUT OMITTED FROM EXAMPLE-------->
end
switch#
```
3.7 Other Command-Line Interfaces

EOS can access other CLIs that provide switch commands, files, and services.

- Section 3.7.1: Aboot Command-Line Interface describes the boot-loader CLI
- Section 3.7.2: Bash Shell describes the Bash shell CLI.

3.7.1 Aboot Command-Line Interface

Aboot is the switch boot loader. It reads a configuration file from the internal flash or a USB flash drive and attempts to boot a software image. The switch opens an Aboot shell if the switch does not find a software image, the configuration is corrupted, or the user terminates the boot process. The Aboot shell provides a CLI for manually booting a software image, recovering the internal flash to its default factory state, running hardware diagnostics, and managing files.

3.7.2 Bash Shell

The switch provides a Linux Bash shell for accessing the underlying Linux operating system and extensions. The Bash shell is accessible in all command modes except EXEC. Section 3.5.1: Mode Types describes EOC command modes.

- To enter the Bash, type `bash` at the prompt.

    switch#bash

    Arista Networks EOS shell

    [admin@Switch ~]$ 

- To exit the Bash, type `logout`, `exit`, or `Ctrl-D` at the Bash prompt.

    [admin@Switch ~]$ logout
    switch#
3.8 Common Criteria (CC)

EOS firmware supports U.S. Federal Information Processing Standards (FIPS) and Common Criteria (CC) security requirements. These are enhanced security options for some Arista models.

CC consists of specifications and guidelines for the evaluation of information security products. It is used internationally to ensure that these products meet the security standards necessary for government deployments.

The primary elements of CC are Protection Profiles and Evaluation Assurance Levels. Protection Profiles define the standard security requirements for a product type. Evaluation Assurance Levels describe the thoroughness of the testing done to evaluate the product on a scale of 1-7, with one being the least thorough evaluation and seven being the most thorough. A higher Evaluation Assurance Level indicates that the product has undergone more testing, but does not necessarily correlate to a higher level of security.

United States non-military governmental security requirements for computer systems are detailed in Federal Information Processing Standards (FIPS).

Refer to the Arista Networks website for additional information at:

http://www.arista.com
3.9 Directory Structure

EOS operates from a flash drive root mounted as the `/mnt/flash` directory on the switch. The EOS CLI supports these file and directory commands:

- **delete**: Delete a file or directory tree.
- **copy**: Copy a file.
- **more**: Display the file contents.
- **diff**: Compares the contents of files located at specified URLs.
- **rename**: Rename a file
- **cd**: Change the current working directory.
- **dir**: Lists directory contents, including files and subdirectories.
- **mkdir**: Create a directory.
- **rmdir**: Remove a directory.
- **pwd**: Display the current working directory.

Verify flash memory space before copying a file. When a file is copied to flash, it is first written to a temporary file and then renamed to the destination rather than directly overwriting the destination file. This protects the integrity of the existing file if the `copy` command is interrupted, but requires more free space to complete the process.

Switch directory files are accessible through the Bash shell and Aboot. When entering the Bash shell from the switch, the working directory is located in `/home` and has the name of the user name from which Bash was entered.

**Example**

- These commands were entered from the user name john:

  ```
  switch#bash
  [john@switch ~]$ pwd
  /home/john
  [john@switch ~]$ 
  
  In this instance, the working directory is `/home/john`
  ```

When a flash drive is inserted in the USB flash port, flash drive contents are accessible through `/mnt/usb1`.

When entering Aboot, the working directory is the root directory of the boot.
3.10 Command-Line Interface Commands

Mode Navigation Commands
- alias
- bash
- configure (configure terminal)
- configure network
- daemon
- disable
- enable
- end
- exit

File Transfer Commands
- ip ftp client source-interface
- ip http client source-interface
- ip ssh client source-interface
- ip tftp client source-interface

File Management Commands
- copy running-config
- dir
- pwd

Modular Switch Platform Commands
- platform arad lag mode
- platform arad lag mode
- platform sand fabric mode (7500 and 7500E Series)
- platform sand forwarding mode (7500 and 7500E Series)
- show platform sand compatibility

CLI Scheduling Commands
- schedule
- show schedule
- show schedule summary

Common Criteria Commands
- boot test memory
- entropy source hardware
- fips restrictions (SSH Management)
- hostkey client strict-checking (SSH Management)
- known-hosts (SSH Management)
- local (SSH Management-Tunnel)
- logging host
- logging source-interface
- logging trap system
- log-level (SSH Management)
- management security
- remote (SSH Management-Tunnel)
- secret hash
- send log message
- server-alive count-max (SSH Management-Tunnel)
- server-alive interval (SSH Management-Tunnel)
- show management ssh hostkey
- shutdown (SSH Management-Tunnel)
- ssh
- tunnel (SSH Management)

**Event Handler Commands**
- action bash
- delay
- event-handler
- show event-handler
- trigger

**Terminal Parameter Commands**
- terminal length
- terminal monitor

**Display and Comment Commands**
- comment (various configuration modes)
- show (various configuration modes)
- show module
- show version
The `action bash` command specifies a Bash shell command to be run when an event handler is triggered. When an event handler is triggered, execution of the associated shell command is delayed by a configurable period set by the `delay` command. Only a single Bash command may be configured for an event handler, but the command may have multiple arguments. If more than one Bash command must be executed in response to a trigger, create a script containing the desired commands and enter the file path to the script as the argument of the `action bash` command.

To specify the event that will trigger the action, use the `trigger` command. If the event handler uses an `onIntf` trigger, the following environment variables are passed to the action and can be used as arguments to the Bash command:

- `$INTF` interface name.
- `$OPERSTATE` current operational status of the specified interface.
- `$IP-PRIMARY` current primary IP address of the specified interface.

### Command Mode
Event-Handler Configuration

### Command Syntax

```
action bash command
```

### Parameters
- `command` Bash shell command to be executed when the event handler is triggered.

### Example
- This command configures the event handler “onStartup” to run a script on the flash drive.

```
switch(config-handler-onStartup)# action bash /mnt/flash/myScript1
```

- This command configures the event handler “eth_4” to send email to the specified address when there is a change in the operational status of Ethernet interface 4.

```
switch(config-event-eth_4)# action bash email x@yz.com -s "Et4 $OPERSTATE"
```

The above action uses the `OPERSTATE` variable to include the current operational state ("linkup" or "linkdown") in the subject of the email. Note that the action will only function if email has been configured on the switch.
alias

The `alias` command creates an alias for a CLI command. Entering the alias in the CLI executes the corresponding command. Once created, an alias is accessible in all modes and all user sessions, but is subject to all the restrictions of the original command.

When using a command alias, no tokens may precede the alias except the `no` and `default` keywords. However, an alias can incorporate positional parameters.

In online help, aliases are preceded by an asterisk (*) in this format:

```
*alias_name=command_name
```

The `no alias` and `default alias` commands remove the specified alias.

**Command Mode**

Global Configuration

**Command Syntax**

```
alias alias_name command_name
no alias alias_name
default alias alias_name
```

**Parameters**

- `alias_name` the string which is to be substituted for the original command. The string can include letters, numbers, and punctuation, but no spaces. If the `alias_name` string is identical to an existing command, the alias will supersede the original command.

- `command_name` the command which is to be executed when the alias is entered in the CLI. If the original command requires additional parameters, they must be included in the `command_name` string in the following manner:

  Positional parameters are of the form "%n" and must be whitespace-delimited. The first parameter is represented by "%1" and any additional parameters must be numbered sequentially. When executing the alias a value must be entered for each parameter or the CLI will display the error "% incomplete command".

**Examples**

- This command makes `e` an alias for the command `enable`.

  ```
  switch(config)#alias e enable
  ```

- This command makes `srie` an alias for the command `show running-config interface ethernet 1-6`.

  ```
  switch(config)#alias srie show running-config interface ethernet 1-6
  ```

- These commands make `ss` an alias for the command `show interfaces ethernet <range> status` with a positional parameter for the port range, then use the alias to display the status of ports 4/1-4/5.

  ```
  switch(config)#alias ss show interfaces ethernet %1 status
  switch(config)#ss 4/1-4/5
  ```

<table>

<td>10000</td>
<td>10GBASE-SRL</td>
</tr>
</tbody>
</table>
bash

The `bash` command starts the Linux Bash shell. The Bash shell gives you access to the underlying Linux operating system and system extensions.

To exit the Bash, type `logout`, `exit`, or Ctrl-D at the Bash prompt.

**Command Mode**
- Privileged EXEC

**Command Syntax**

```
bash
```

**Examples**

- This command starts the Bash shell.
  ```
  switch#bash
  Arista Networks EOS shell
  [admin@switch ~]$ 
  ```

- This command, executed within Bash, exits the Bash shell.
  ```
  [admin@switch ~]$ logout
  switch#
  ```
**boot test memory**

The `boot test memory` command enables the user to set the number of iterations for a boot memory test.

In order to ensure proper operation of the switch, software and hardware checks are run continuously on and by the switch. By default the cryptographic libraries run tests to verify that they are operating correctly, EOS software processes are continually monitored and hardware health is monitored for proper functionality. Additionally, a check must be enabled for an in-kernel memory check of the Linux subsystem.

The `no boot test memory` and `default boot test memory` commands revert to the default setting by removing the corresponding `boot test memory` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
boot test memory iterations
no boot test memory
default boot test memory
```

**Parameters**

- **iterations** Specified number of times until a condition is met. Two iterations of the memory test are the minimum for Common Criteria mode operation. Value ranges from 1 to 17.

**Examples**

- This command enables two iterations of the memory test that are required for common criteria mode operation.

```
switch(config)#boot test memory 2
switch(config)#
```
comment (various configuration modes)

The `comment` command adds a comment for the active configuration mode to `running-config`. Comments cannot be modified, but can be replaced by entering the `comment` command again and entering new text. To append to an existing comment, enter `!` followed by additional comment text. To display comments, use the `comment` option of the `show (various configuration modes)` command.

The `no comment` and `default comment` commands remove the comment from `running-config`. Comments cannot be added to the global configuration mode through the EOS.

**Command Mode**

All configuration modes except Global Configuration

**Command Syntax**

```
comment comment_text EOF
no comment
default comment
! comment_text
```

**Parameters**

- `comment_text` To create a comment, enter a message when prompted. The message may span multiple lines.
- `EOF` To append to an existing comment, enter `!` followed by additional comment text. To end comment editing, type `EOF` on its own line (case sensitive) and press `enter`.

**Example**

- This command adds a comment to the active configuration mode.
  
  ```
  switch(config-sg-radius-RAD-SV1)#comment
  Enter TEXT message. Type 'EOF' on its own line to end.
  Consult Thomas Morton before making changes to the RADIUS configuration.
  EOF
  switch(config-sg-radius-RAD-SV1)#
  ```

- This command appends a line to the comment for the active configuration mode.
  
  ```
  switch(config-sg-radius-RAD-SV1)#! x3452
  switch(config-sg-radius-RAD-SV1)#
  ```
configure (configure terminal)

The `configure` command places the switch in Global Configuration mode to configure features that affect the entire system. This mode also provides access to Interface Configuration mode and protocol-specific modes. The command may also be entered as `configure terminal`.

The `configure network` command refers the user to Arista's `copy <url> running-config` command for configuring the switch from a local file or network location.

**Command Mode**
- Privileged EXEC

**Command Syntax**
```
configure
configure terminal
```

**Example**
- These commands place the switch in Global Configuration mode.
  ```
switch>enable
switch#configure
switch(config)#
```
configure network

The `configure network` command refers the user to Arista's `copy <url> running-config` command for configuring the switch from a local file or network location.

**Command Mode**

Privileged EXEC

**Command Syntax**

`configure network`

**Example**

* This is the output of the `configure network` command.

```
switch# configure network
%% Please use copy <url> running-config
switch#
```
copy running-config

The current operating configuration of the switch is stored in a virtual file called *running-config*. The *copy running-config* command saves the contents of the *running-config* virtual file to a new location.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
copy running-config DESTINATION
```

**Parameters**

- `DESTINATION` destination for the contents of the *running-config* file. Values include:
  - `startup-config` the configuration file that the switch loads when it boots.
  - `file:` a file in the switch file directory.
  - `flash:` a file in flash memory.
  - `url:` any valid URL.

  The *copy running-config startup-config* and *write* commands are equivalent.

**Examples**

- This command copies *running-config* to the *startup-config* file.
  ```
  switch#copy running-config startup-config
  switch#
  ```

- This command copies *running-config* to a file called rc20110617 in the dev subdirectory of the switch directory.
  ```
  switch#copy running-config file:dev/rc20110617
  switch#
  ```
daemon

The `daemon` command accesses daemon configuration mode for adding or removing external daemons and scripts, which are then managed by ProcMgr.

The `no daemon` and `default daemon` commands delete the daemon by removing the corresponding `daemon` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
daemon daemon_name
no daemon daemon_name
default daemon daemon_name
```

**Parameters**
- `daemon_name` label that references the daemon configuration mode.

**Examples**
- These commands enters daemon configuration mode and initiates the daemon script.

```
switch(config)#daemon process1
switch(config-daemon-process1)#command process-script -i -m
switch(config-daemon-process1)#
```
delay

The `delay` command specifies the time in seconds the system will delay between a triggering event and the execution of an event handler action. The default delay is 20 seconds.

**Command Mode**

Event-Handler Configuration

**Command Syntax**

```
delay seconds
```

**Parameters**

- `seconds` number of seconds to delay before executing the action. The default is 20.

**Example**

- This command configures the event handler Eth5 to delay 10 seconds before executing.

```
switch(config-handler-Eth5)#delay 10
switch(config-handler-Eth5)#
```
**dir**

The `dir` command displays a list of files on a file system.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
dir [SCOPE][FILE TYPE]
```

**Parameters**

- **SCOPE** the files to display. Options include
  - `<no parameter>` lists normal files in current directory.
  - `/all` list all files, including hidden files
  - `/recursive` list files recursively
- **FILE TYPE** The options include:
  - `<no parameter>` lists undeleted files
  - `all_filesystems` list files on all filesystems including deleted files, undeleted files, and files with errors
  - `extensions` directory or file name
  - `file` directory or file name
  - `flash` directory or file name
  - `supervisor-peer` directory or file name
  - `system` directory or file name
  - `usb1` directory or file name

**Example**

- This command displays the flash directory.

```
switch# dir flash:
Directory of flash:/
-rwx 293409892 Oct 23 08:55 EOS-4.11.0.swi
-rwx 221274543 Sep 6 13:37 EOS-4.7.5.swi
-rwx 271453650 Sep 4 19:13 EOS_4.10.1-SSO.swi
-rwx 135168 Dec 31 1979 FSCK0000.REC
-rwx 26 Oct 23 13:51 boot-config

-rwx 5642 Sep 20 10:35 config.reset
drwx 4096 Oct 23 13:59 debug
drwx 12 Oct 23 13:56 kernel-params
drwx 4096 Oct 23 14:59 persist
drwx 4096 Sep 6 14:50 schedule
-rwx 5970 Oct 23 13:53 startup-config
```

```
switch#
```
disable

The disable command exchanges the session’s current command mode with the specified privilege level.

Command Mode
Privileged EXEC

Command Syntax
\texttt{disable [PRIVILEGE\_LEVEL]}

Parameters
\begin{itemize}
  \item \texttt{PRIVILEGE\_LEVEL} Session’s new privilege level. Value ranges from 0 to 15. Levels 2 through 15 place the switch in Privileged EXEC mode. Values of 0 or 1 leave the switch in EXEC mode.
  \item \texttt{<no parameter>} Session is assigned default level of 1.
  \item \texttt{<0 to 15>} Specifies session level.
\end{itemize}

Restrictions
New privilege level must be less than the session’s current level.

Examples
\begin{itemize}
  \item This command exits Privileged EXEC mode level of 15 to enter EXEC mode level 1.
    \begin{verbatim}
    switch\# disable
    switch>
    \end{verbatim}
\end{itemize}
enable

The `enable` command places the switch in Privileged EXEC mode. If an `enable` password is set, the CLI displays a password prompt when a user enters the `enable` command. If the user enters an incorrect password three times, the CLI displays the EXEC mode prompt.

To set a local `enable` password, use the `enable secret` command.

Command Mode

EXEC

Command Syntax

`enable [PRIVILEGE_LEVEL]`

Parameters

- `PRIVILEGE_LEVEL`  Session’s privilege level. Values range from 0 to 15. Values of 0 or 1 places the switch in EXEC mode. Any level above 1 leaves the switch in Privileged EXEC mode.
  - `<no parameter>`  Session is assigned default level of 15.
  - `<0 to 15>`  Specifies session level.

Example

- This command places the switch in Privileged EXEC mode with the default privilege level of 15.

```
switch>enable
switch>
```
end

The `end` command exits to Privileged Exec mode from any Configuration mode. If the switch is in a group-change mode (such as ACL-Configuration mode or MST-Configuration mode), the `end` command also saves all pending changes made in that mode to `running-config`.

**Command Mode**

All configuration modes

**Command Syntax**

`end`

**Example**

- This command exits to Privileged Exec mode.

  ```
  switch(config-if-Et25)#end
  switch#
  ```
survey source hardware

The **entropy source hardware** command specifies that the switch must use its hardware-based random number generator from a physical process.

Entropy is a measure of randomness in a system. An entropy source is a device that gathers quantum randomness from a physical system.

The **no entropy source hardware** and **default entropy source hardware** commands disable the hardware-based random number generator.

**Command Mode**

Mgmt-security Configuration

**Command Syntax**

```
memory source hardware
no memory source hardware
default memory source hardware
```

**Examples**

- This command enables the hardware random number generator.

  ```
  switch(config)#management security
  switch(config-mgmt-security)#entropy source hardware
  ```

- Use the following command to verify that entropy generation is enabled.

  ```
  switch#show management security
  CPU Version: 03.02
  Hardware Version: 04.00
  Security Chip Version: R5H30211
  Hardware Entropy Generation is enabled
  ```
event-handler

An event handler executes a Linux Bash shell command in response to a specific system event. An event handler consists of a Bash command, a trigger and a delay; when the trigger event occurs, the action is scheduled to run after *delay* seconds.

The `event-handler` command places the switch in event-handler configuration mode for the specified event handler. If the named event handler does not already exist, this command creates it.

Event-handler configuration mode is a group change mode that configures event handlers.

Changes made in a group change mode are saved by leaving the mode through the `exit` command or by entering another configuration mode.

These commands are available in event-handler configuration mode:

- `action bash`
- `delay`
- `trigger`

The `no event-handler` and `default event-handler` commands delete the specified event handler by removing it from *running config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
event-handler name
no event-handler name
default event-handler name
```

**Parameters**

- `name` name of the event handler to be configured. If the named event handler does not already exist, this command will create it.

**Example**

- This command places the switch in event-handler configuration mode for an event handler called “Eth_5”.

  switch (config)#event-handler Eth_5
  switch (config-handler-Eth_5)#
exit

The exit command places the switch in the parent of the command mode from which the exit command was entered.

- When used in Global configuration, the switch enters Privileged EXEC mode.
- When used in EXEC or Privileged EXEC mode, the exit command terminates the user session.
- When the command is used in a group-change mode (such as ACL-Configuration mode or MST-Configuration mode), the exit command also applies all pending changes made in that mode.

Command Mode
All modes

Command Syntax
exit

Example
- This command exits Global Configuration mode to Privileged EXEC mode.
  switch(config)#exit
  switch#
- This command terminates the user session.
  switch#exit
fips restrictions (SSH Management)

The `fips restrictions` command enables the switch to use FIPS-validated encryption algorithms to fulfill Common Criteria requirements.

The `no fips restrictions` and `default fips restrictions` commands restore default behavior by removing the `fips restrictions` statement from `running-config`.

Command Mode

Mgmt-ssh Configuration

Command Syntax

- `fips restrictions`
- `no fips restrictions`
- `default fips restrictions`

Examples

- These commands configure the switch to use FIPS-validated encryption algorithms to fulfill the Common Criteria requirements.

```
switch(config)#management ssh
switch(config-mgmt-ssh)#fips restrictions
```
hostkey client strict-checking (SSH Management)

The **hostkey client strict-checking** command specifies how host keys are checked during the connection and authentication phase. By default strict host key checking is disabled. When disabled the SSH client verifies the incoming host key against the keys in the known hosts list. If the host key does not match an existing known host entry for the remote server, the connection is rejected. If the known host list does not contain a host key for the remote server, the SSH client automatically accepts the host and adds its host key to the known host list.

When strict host key checking is enabled, the SSH client connects only to known hosts with valid SSH host keys that are stored in the known hosts list. Host keys not listed in the known host list are rejected.

The **no hostkey client strict-checking** and **default hostkey client strict-checking** commands revert to its default by removing the corresponding **hostkey client strict-checking** command from **running-config**.

**Command Mode**

- Mgmt-ssh Configuration

**Command Syntax**

- `hostkey client strict-checking`
- `no hostkey client strict-checking`
- `default hostkey client strict-checking`

**Examples**

- These commands specify how host keys are checked during the connection and authentication phase.

  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)# hostkey client strict-checking
  ```
ip ftp client source-interface

By default, the FTP (File Transfer Protocol) source IP address is selected by the switch (the IP address of the source interface if one is assigned). The **ip ftp client source-interface** command allows the user to override the default FTP source address.

The **ip ftp client source-interface** and **ip ftp source-interface** commands are functionally equivalent. In each case, **ip ftp client source-interface** is stored in **running-config**.

The **no ip ftp client source-interface** and **default ip ftp client source-interface** commands restore default behavior by removing the **ip ftp client source-interface** statement from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
ip ftp [client] source-interface INTERFACE
no ip ftp [client] source-interface
default ip ftp [client] source-interface
```

**Parameters**

- **client** Parameter has no functional effect.
- **INTERFACE** Interface providing the IP address. Options include:
  - **ethernet e_num** Ethernet interface specified by **e_num**.
  - **loopback l_num** Loopback interface specified by **l_num**.
  - **management m_num** Management interface specified by **m_num**.
  - **port-channel p_num** Port-channel interface specified by **p_num**.
  - **vlan v_num** VLAN interface specified by **v_num**.

**Examples**

- These commands configure the 10.10.121.15 as the source IP address the switch uses when communicating with FTP servers.
  ```plaintext
  switch(config)#interface ethernet 17
  switch(config-if-Et17)#ip address 10.10.121.15/24
  ! IP configuration will be ignored while interface Ethernet17 is not a routed port.
  switch(config-if-Et17)#ip ftp client source-interface ethernet 17
  switch(config-if-Et17)#
  ```
ip http client source-interface

The `ip http client source-interface` command specifies the source IP address for hypertext transfer protocol (HTTP) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The `no ip http client source-interface` and `default ip http client source-interface` commands restore default behavior by removing the `ip http client source-interface` statement from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip http client source-interface INTERFACE
no ip http client source-interface
default ip http client source-interface
```

**Parameters**
- `INTERFACE` Interface providing the IP address. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.

**Examples**
- These commands configure the 10.15.17.9 as the source IP address the switch uses when communicating with http servers.

```
switch(config)#interface vlan 10
switch(config-if-Vl10)#ip address 10.15.17.9/24
switch(config-if-Vl10)#ip http client source-interface vlan 10
switch(config)#
```
**ip ssh client source-interface**

The `ip ssh client source-interface` command specifies the source IP address for secure shell (SSH) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The `ip ssh client source-interface` and `ip ssh source-interface` commands are functionally equivalent. In each case, `ip ssh client source-interface` is stored in `running-config`.

The `no ip ssh client source-interface` and `default ip ssh client source-interface` commands restore default behavior by removing the `ip ssh client source-interface` statement from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip ssh [client] source-interface INTERFACE
no ip ssh [client] source-interface
default ip ssh [client] source-interface
```

**Parameters**

- `client` Parameter has no functional effect.
- `INTERFACE` Interface providing the IP address. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.

**Examples**

- These commands configure the 10.17.17.9 as the source IP address the switch uses when communicating with ssh servers.

  ```
  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.15.17.9/24
  switch(config-if-Vl10)#ip ssh client source-interface vlan 10
  switch(config)#
  ```
The `ip tftp client source-interface` command specifies the source IP address for Trivial File Transfer Protocol (TFTP) connections. By default, the source IP address is selected by the switch when this command is not configured or when the specified interface is not assigned an IP address.

The `ip tftp client source-interface` and `ip tftp source-interface` commands are functionally equivalent. In each case, `ip tftp client source-interface` is stored in `running-config`.

The `no ip tftp client source-interface` and `default ip tftp client source-interface` commands restore default behavior by removing the `ip tftp client source-interface` statement from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**
- `ip tftp [client] source-interface INTERFACE`
- `no ip tftp [client] source-interface`
- `default ip tftp [client] source-interface`

**Parameters**
- `client` Parameter has no functional effect.
- `INTERFACE` Interface providing the IP address. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.

**Examples**
- These commands configure the 10.15.17.9 as the source IP address the switch uses when communicating with tftp servers.

```plaintext
switch(config)#interface vlan 10
switch(config-if-Vl10)#ip address 10.15.17.9/24
switch(config-if-Vl10)#ip tftp client source-interface vlan 10
switch(config)#
```
known-hosts (SSH Management)

The known-hosts command configures the MD5 fingerprint of the SSH server’s host key. The local SSH client uses this fingerprint to authenticate the server, which should return a matching fingerprint.

**Note**

Note: the fingerprint must be re-entered after a system reboot.

The no known-hosts and default known-hosts commands revert the specified list configuration to its default by removing the corresponding known-hosts command from running-config. By default, there is no fingerprint configured and the SSH server will not be authenticated.

**Command Mode**

Mgmt-ssh Configuration

**Command Syntax**

```
known-hosts SERVER ALGORITHM key_string
no known-hosts
default known-hosts
```

**Parameters**

- **SERVER** Location of SSH server. Options include:
  - *ip_address* IP address of the SSH server
  - *hostname* Hostname of the SSH server
- **ALGORITHM** connection type of sessions for which authentication list is used
  - *dsa* Fingerprint was created using DSA (Digital Signature Algorithm).
  - *rsa* Fingerprint was created using RSA encryption.
- **key_string** MD5 fingerprint string (Base-64).

**Examples**

- This command configures an entry for a server called “tacplus” that is connected to by an SSH tunnel:

```
switch(config-mgmt-ssh)#known-hosts tacplus rsa
AAAAB3NzaC1yc2EAAAADAQABAAABAQABABADQBxABBbatWBM7ubC7TQMECNcHVqxhTEo4kRl8cbw8dAtVUtQ0lhBjJRu18cqTv61Vn7R15+05kuROGHDVNx3mbXwxyWBVhgorw7RvNEwW46SW280xAlNccCCJM42sJk+xO6qAIR3L7WhobDU05HR9JrrmKZsBxR5VTKL0a7zOM22V0i/Uf6fJ1m0NktxDL1JQJnogdxupc5fxqodAURLtup5H+pRyPEXrBzTk1007eNg62hMgT8ijISSNR48dM0WRXjc+6loVpAqDvdkDa4kDmsRb9RuzNPiXYrhzQXf+nD1bdzVta77oPuwbb5M350StFFaUB4/nlCs3
switch(config-mgmt-ssh)#
```
local (SSH Management-Tunnel)

The `local` command specifies the local binding on the switch for an SSH Tunnel. The `no local` and `default local` commands remove the `local` command from the configuration.

**Command Mode**

Mgmt-SSH-Tunnel

**Command Syntax**

```
local port port_number
no local
default local
```

**Parameters**

- `port_number` port number. Value ranges from 1 to 32767.

**Example**

- This command enables a tunnel named “test”. This tunnel will bind to local port 49 on the switch.
  
  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#
  switch(config-mgmt-ssh)#tunnel test
  switch(config-mgmt-ssh-tunnel-Test)#local port 49
  ```
logging host

The `logging host` command specifies a remote host to receive syslog messages generated by the switch. `Running-config` can contain multiple logging host statements.

A Common Criteria compliant switch must connect to a syslog audit server to record syslog messages generated. The syslog server being connected to must implement RFC 5424 to be considered capable of using the syslog protocol.

The default port for syslog is 514. The host must be localhost and the protocol TCP for SSH Tunneling.

The `no logging host` and `default logging host` commands clear the specified method list by removing the corresponding `logging host` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
logging [VRF_INSTANCE] host syslog_host [PORT] [PROT_TYPE]
no logging [VRF_INSTANCE] host syslog_host
default logging [VRF_INSTANCE] host syslog_host
```

**Parameters**

- `VRF_INSTANCE` specifies the VRF instance being modified.
  - `<no parameter>` changes are made to the default VRF.
  - `vrf vrf_name` changes are made to the specified user-defined VRF.
- `syslog_host` remote syslog server location. Valid formats include hostname or IPv4 address.
- `PORT` Remote syslog server port that handles syslog traffic. Options include:
  - `<no parameter>` Default port number 514.
  - `<1 to 65535>` Port number.
- `PROT_TYPE` Specifies the transport protocol for packets. Options include:
  - `<no parameter>` Packets transported by User Datagram Protocol (UDP).
  - `protocol tcp` Packets transported by TCP.
  - `protocol udp` Packets transported by User Datagram Protocol (UDP).

**Examples**

- This command logs system messages to a host with an IP address of 172.1.1.63.

  ```
  switch(config)#logging host 172.1.1.63
  switch(config)#
  ```

- A Common Criteria compliant switch must connect to a syslog audit server to record syslog messages generated. The syslog server on the switch should be configured as follows:

  ```
  switch(config)#logging host localhost protocol tcp
  switch(config)#logging trap informational
  switch(config)#logging trap system tag ntpd contain clock_step
  switch(config)#logging trap system tag sshd
  switch(config)#
  ```
logging source-interface

The **logging source-interface** command specifies a local interface as the source for UDP packets sent to a syslog server (a process known as “source spoofing”).

**Important!** Source spoofing cannot be used with TCP, and is therefore incompatible with all TCP syslog usage including Common Criteria remote logging.

The **no logging source-interface** and **default logging source-interface** commands restore the default source address for syslog packets by removing the corresponding **logging source-interface** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
logging source-interface INTERFACE
no logging source-interface
default logging source-interface
```

**Parameters**

- **INTERFACE** Interface providing the source address of outgoing UDP packets sent to the logging server. Values include:
  - *ethernet interface* Ethernet interface specified by `interface`.
  - *loopback interface* Loopback interface specified by `interface`.
  - *management interface* Management interface specified by `interface`.
  - *port-channel interface* Port-channel interface specified by `interface`.
  - *vlan interface* VLAN interface specified by `interface`.

**Related Commands**

- The **logging host** command specifies the transport protocol used to communicate with the remote syslog server. Source spoofing is only supported when communicating with the syslog server using UDP; to use source spoofing, use the **logging host** command to specify UDP as the transport protocol.

**Example**

- These commands configure packets sent to a syslog server at 198.162.3.5 to use the IP address of Ethernet port 5 as their source address.

```
switch(config)#logging host 198.162.3.5 protocol udp
switch(config)#logging source-interface ethernet 5
switch(config)#
```
**logging trap system**

The **logging trap system** command configures remote logging of system messages. Specifying a severity level logs only those messages with a severity at or above that level to the remote server. To configure the IP address of the remote syslog server, use the **logging host** command; to enable logging, use the **logging on** command.

The **no logging trap system** and **default logging trap system** commands restore remote logging defaults by removing the corresponding **logging trap system** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
logging trap system [FACILITY] [SEVERITY] [PROGRAM] [TEXT]
no logging trap system [FACILITY] [SEVERITY] [PROGRAM] [TEXT]
default logging trap system [FACILITY] [SEVERITY] [PROGRAM] [TEXT]
```

The **TEXT** parameter, when present, is always last. All other parameters can be placed in any order.

**Parameters**

- **FACILITY** Defines the appropriate facility.
  - <no parameter> Specifies default facility.
  - `facility <facility-name>` Specifies named facility.
- **SEVERITY** Specifies minimum severity level to be logged. Options include:
  - <no parameter> Specifies default severity level.
  - `severity <level>` Minimum severity level for remote logging.

Valid **level** options include:

- 0 or **emergencies** System is unusable
- 1 or **alerts** Immediate action needed
- 2 or **critical** Critical conditions
- 3 or **errors** Error conditions
- 4 or **warnings** Warning conditions
- 5 or **notifications** Normal but significant conditions
- 6 or **informational** Informational messages
- 7 or **debugging** Debugging messages

- **PROGRAM** Filters packets based on program name. Options include:
  - <no parameter> All tags or program names.
  - `tag program-name` Specific tag or program name.
- **TEXT** Specifies log message text. Options include:
  - <no parameter> Specify text contained in log message.
  - `contain reg-expression` Specify text contained in log message.
Examples

- This command enables the logging of system informational messages to a remote server.
  
  ```
  switch(config)#logging trap informational
  switch(config)#
  ```
log-level (SSH Management)

The `log-level` command configures the verbosity level that is used when logging messages from SSH. The `no log-level` and `default log-level` commands revert the verbosity level to its default by removing the corresponding `log-level` command from `running-config`.

**Command Mode**

Mgmt-ssh Configuration

**Command Syntax**

```
log-level MESSAGE_LEVEL
no log-level
default log-level
```

**Parameters**

- **MESSAGE_LEVEL** Specifies level of detail in debug messages. The higher the number, the more detail that is logged. Higher levels include all lower levels.
  - `debug` production logging levels
  - `debug1` informational logging levels
  - `debug2` higher logging levels
  - `debug3` extended higher logging levels
  - `error` non-fatal errors
  - `fatal` severe errors likely to terminate SSH
  - `info` informational messages
  - `quiet` only fatal errors
  - `verbose` debugging messages about the progress of SSH

**Examples**

- This command configures the switch to log SSH messages of level “error.”

```
switch(config)#management ssh
switch(config-mgmt-ssh)#log-level error
switch(config-mgmt-ssh)#
```
management security

The management security command places the switch in mgmt-security configuration mode.

The no management security and default management security commands delete all mgmt-security configuration mode statements from running-config.

Mgmt-security configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting mgmt-security configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
   Global Configuration

Command Syntax
   management security
   no management security
   default management security

Example
   • This command places the switch in mgmt-security configuration mode:
     switch(config)#management security
     switch(config-mgmt-security)#
   • This command returns the switch to global management mode:
     switch(config-mgmt-security)#exit
     switch(config)#
platform arad lag mode

The `platform arad lag mode` command allows configuration of LAGs with more than 16 members.

**Command Mode**

Global Configuration

**Command Syntax**

`platform arad lag mode [1024x16 | 256x64 | 512x32]`

**Examples**

- This command configures 1024 LAGs with 16 members each.
  
  switch(config)# `platform arad lag mode 1024x16`
  
  ! Change will take effect only after switch reboot.
  
  switch(config)#

- This command configures 256 LAGs with 64 members each.
  
  switch(config)# `platform arad lag mode 256x64`
  
  ! Change will take effect only after switch reboot.
  
  switch(config)#

- This command configures 512 LAGs with 32 members each.
  
  switch(config)# `platform arad lag mode 512x32`
  
  ! Change will take effect only after switch reboot.
  
  switch(config)#
platform sand fabric mode (7500 and 7500E Series)

The platform sand fabric mode command specifies the fabric mode under which the switch operates after the next system reload. The command has no operational effect until the switch reloads.

The fabric mode determines the modular switch’s fabric performance capabilities and must be compatible with the installed fabric modules. Fabric mode settings include:

- **fe600**: Supports first-generation fabric modules.
- **fe1600**: Supports E-Series fabric modules.

**Important!** Switches that reload in petraA forwarding compatibility mode (platform sand forwarding mode (7500 and 7500E Series)) also reload in fe600 fabric mode regardless of the presence of a platform sand fabric mode statement in running-config.

The switch’s fabric mode setting must match the capabilities of its installed fabric modules. Reloading the switch in a different mode may be required after exchanging fabric modules for a different module type. The show module command displays the fabric modules in the switch.

Each fabric module is categorized as first-generation or E-Series:

- First-generation fabric modules support all basic switch functions.
- E-Series fabric modules support faster fabric link speeds, greater internal table capacities, and advanced encoding formatting.

E-series fabric modules can operate in fe600 mode, but are limited to first-generation fabric performance. First-generation modules cannot operate in fe1600 mode. Switches containing both types of modules must be set to fe600 mode. Best practice is to avoid switch configurations with mixed fabric modules.

When a switch reloads, fabric mode is determined by the following (in order of precedence):

**Step 1** Switches reloading in petraA forwarding compatibility mode also reload in fe600 fabric mode.

**Step 2** As specified by the platform sand fabric mode statement in running-config.

**Step 3** The first fabric module that becomes operational as the switch reloads.

In switches with a homogeneous module set, the fabric mode matches its fabric modules. Switches with a mixed set of modules are typically reloaded in fe600 mode because first generation modules are usually operational before E-Series modules. However, the fabric mode in mixed module switches that are reloading cannot be guaranteed in the absence of the first two conditions.

The no platform sand fabric mode and default platform sand fabric mode commands remove the platform sand fabric mode command from running-config.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
platform sand fabric mode [MODE_SETTING]
no platform sand fabric mode
default platform sand fabric mode
```

**Parameters**

- **MODE_SETTING** Specifies the switch’s fabric mode. Options include:
  - **fe1600**: E-Series fabric mode.
  - **fe600**: First-generation fabric mode.
Examples

- This command configures the switch to reload in **fe1600** fabric mode to support E-series fabric modules. After issuing this command, the switch should be reset only after exchanging all switch fabric modules to E-series modules.

  ```
  switch(config)#platform sand fabric mode fe1600
  switch(config)#exit
  switch#show platform sand compatibility
  Configuration       Status

  Fabric mode         Fe1600   Fe600
  switch#
  ```
platform sand forwarding mode (7500 and 7500E Series)

The **platform sand forwarding mode** command specifies the forwarding compatibility mode under which the switch operates after the next system reload. The command has no operational effect until the switch reloads.

Forwarding compatibility mode specifies switch forwarding capabilities and configures performance capacity of installed linecards. Forwarding compatibility modes settings include:

- **petraA**: Supports first-generation fabric modules.
- **arad**: Supports E-Series fabric modules.

**Important!** Switches that reload in **petraA** forwarding compatibility mode also reload in **fe600** fabric mode regardless of the presence of a **platform sand fabric mode (7500 and 7500E Series)** statement in **running-config**.

This command may be required after exchanging a linecard for a different module type or in switches containing first-generation and E-series linecards. The **show module** command displays the linecard modules in the switch.

Each modular switch linecard module is categorized as first-generation or E-Series:

- First-generation linecards support all basic switch functions.
- E-Series linecards support provide faster data processing, greater internal table capacities, and advanced encoding formatting.

The forwarding compatibility mode determines the operational capacity of installed linecards. **Table 3-3** lists the affect of the forwarding compatibility mode on all linecard module types.

**Table 3-3** Linecard Module and Forwarding Mode Performance

<table>
<thead>
<tr>
<th>Linecard Module Type</th>
<th>Forwarding Software Mode</th>
<th>Linecard Operating Capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>First-generation</td>
<td>petraA</td>
<td>Linecard performs at first-generation performance capacity.</td>
</tr>
<tr>
<td>First-generation</td>
<td>arad</td>
<td>Linecard is powered-down.</td>
</tr>
<tr>
<td>E-Series</td>
<td>petraA</td>
<td>Linecard performs at first-generation performance capacity.</td>
</tr>
<tr>
<td>E-Series</td>
<td>arad</td>
<td>Linecard performs at E-series performance capacity.</td>
</tr>
</tbody>
</table>

**Important!** Linecards operate at E-Series performance capacities only on switches that contain E-Series fabric modules and have a fabric mode setting of **fe1600** fabric mode (**platform sand fabric mode (7500 and 7500E Series)**).

Without a **platform sand forwarding mode** command, forward compatibility mode is determined by the first linecard that becomes operational after reloading the switch. In a switch that is reloaded with a homogeneous module set, forwarding compatibility mode matches its linecards. Switches with a mixed set of modules are typically reloaded in **petraA** mode because first generation modules are usually operational before E-Series modules. However, forwarding compatibility mode in mixed module switches that are reloading is not guaranteed without a **platform sand forwarding mode** command.

The **no platform sand forwarding mode** and **default platform sand forwarding mode** commands restore the **platform sand forwarding mode** command from **running-config**.

**Command Mode**

Global Configuration
Command Syntax

platform sand forwarding mode [MODE_SETTING]
no platform sand forwarding mode
default platform sand forwarding mode

Parameters

•  **MODE_SETTING**  Specifies the switch's software forwarding mode. Options include:
  •  **arad**  the switch supports E-Series linecard capabilities.
  •  **petraA**  the switch supports first-generation linecard capabilities.

Examples

•  This command changes the forwarding software mode to support E-series linecard modules. This command should be run only after exchanging all linecards to E-series modules.

  switch(config)#platform sand forwarding mode arad
  switch(config)#
pwd

The `pwd` command displays the working directory.

**Command Mode**
Privileged EXEC

**Command Syntax**
`pwd`

**Examples**
- This command shows that the working is Flash.
  ```
  switch# pwd
  flash:/
  switch#
  ```
remote (SSH Management-Tunnel)

The `remote` command provides a SSH tunneling feature to transparently secure TCP connections to remote servers. This feature can accept any TCP connection that goes to the CPU on the switch and establish a standard SSH tunnel to a remote host. This has a twofold advantage:

- TCP based services do not need to perform any encryption within their own protocol.
- The connection is secure against replay attacks, manipulation and eavesdropping via SSHv2 Common Criteria compliant encryption.

In order to support this the server the switch will connect on will need to support the following:

- The SSH Server will need to have TCP forwarding allowed for the user account the SSH Tunnel will connect to. On OpenSSH’s sshd implementation this is the “AllowTcpForwarding” option.
- Public key login for users. The SSH Tunneling feature does not support password based login and uses the switch’s SSH keys instead to perform authentication.
- As an additional Common Criteria requirement the switch needs to know the hostkey it is connecting to in advance to prevent attacks where the connection is intercepted. To do this, enter the hostkey in either the management ssh mode for the main vrf or a vrf submode. (Refer to `hostkey client strict-checking (SSH Management)` and `known-hosts (SSH Management)` commands for further information.)

The `no remote` and `default remote` commands remove the `remote` command from the configuration.

Command Mode

Mgmt-SSH-Tunnel

Command Syntax

```
remote host_addr host_port
no remote
default remote
```

Parameters

- `host_addr` IP address or host name.
- `host_port` port number. Value ranges from 1 to 32767.

Example

- The following commands will configure and enable a tunnel named “bar”. This tunnel will bind to local port 49 on the switch. The tunnel will then connect to a server named “tacplus” with a SSH server listening on the standard port 22. The user account on tacplus that the tunnel connects to will be called “authuser”. From that connection the tunnel will bind to port 49 on the tacplus server.

```
switch(config-mgmt-ssh)#tunnel bar
switch(config-mgmt-ssh-tunnel-bar)#local port 49
switch(config-mgmt-ssh-tunnel-bar)#ssh-server tacplus user authuser port 22
switch(config-mgmt-ssh-tunnel-bar)#remote host localhost port 49
```
schedule

The schedule command facilitates the periodic execution of a specified CLI command. Command parameters configure the start time of periodic execution, the interval between consecutive execution instances, and the maximum number of files that can be created. By default, periodic execution of the following show tech-support command is enabled:

    schedule tech-support interval 60 max-log-files 100 command show tech-support

Text that the CLI normally displays as a result of executing the scheduled command through the CLI is stored in log files at flash:/schedule/<sched_name>. Empty log files are created for commands that do not generate CLI text.

The no schedule and default schedule commands disable execution of the specified command by removing the corresponding schedule statement from running-config.

Command Mode
Global Configuration

Command Syntax

    schedule sched_name interval PERIOD max-log-files num_files command cli_name
    no schedule sched_name
    default schedule sched_name

Parameters

- sched_name    label associated with the scheduled command.
- PERIOD        start time for execution and interval between consecutive execution instances. Options include:
  - at hh:mm:ss interval <1 to 1440>    The command is executed at the next hh:mm:ss and repeated every interval minutes.
  - at hh:mm:ss once                     The command is executed at the next hh:mm:ss and not repeated.
  - at hh:mm:ss mm/dd/yyyy interval <1 to 1440> The command is executed at hh:mm:ss on mm/dd/yyyy and repeated every interval minutes.
  - at hh:mm:ss mm/dd/yyyy once          The command is executed at hh:mm:ss on mm/dd/yyyy and not repeated.
  - at hh:mm:ss yyyy-mm-dd interval <1 to 1440> The command is executed at hh:mm:ss on yyyy-mm-dd and repeated every interval minutes.
  - at hh:mm:ss yyyy-mm-dd once          The command is executed at hh:mm:ss on yyyy-mm-dd and not repeated.
  - interval <1 to 1440>                 The command is executed immediately and repeated every interval minutes.
  - now interval <1 to 1440>             The command is executed immediately and repeated every interval minutes.
- num_files     maximum number of log files command generates for command output. Range is 1 to 10000.
- cli_name      name of the CLI command.

Guidelines
Log files created by the command are stored in the flash:/schedule/<sched_name>/ directory.
Examples

- This command schedules the execution of a script file once every 12 hours, beginning at noon. The log file option is set to the option minimum of one because the command does not generate output to the CLI.

  switch(config)# schedule ms_1 at 12:00:00 interval 720 max-log-files 1 command bash /mnt/flash/myscript.sh

  The **show schedule summary** command displays the commands that are scheduled for periodic execution.

  switch(config)# show schedule summary

  Name             Last   Interval Max log     Log file location
  time   (mins)   files
  ---------------- -----  -------- --------  -----------------
  tech-support     16:13   60      100       flash:/schedule/tech-support
  ms_1             16:28   720     1         flash:/schedule/ms_1

- This command stores **running-config** contents to a log file once each hour, beginning immediately, and creating up to 24 log files.

  switch(config)# schedule backup-test interval 60 max-log-files 24 command show running-config
secret hash

The secret hash command enables the default hash function used for encrypting passwords.

The no secret hash and default secret hash commands reverts the default hash setting to its default value of MD5 by deleting the secret hash command from running-config.

Command Mode

Mgmt-Defaults

Command Syntax

secret hash ENCRYPT_TYPE
no secret hash
default secret hash

Parameters

•  **ENCRYPT_TYPE** encryption level of the password parameter. Settings include:
  •  **md5** the password is entered as an MD5-encrypted string.
  •  **sha512** the password is entered as an SHA-512-encrypted string.

Example

• These commands enable SHA-512 as the default hash function used for encrypting passwords.

  switch(config)# management defaults
  switch(config-mgmt-defaults)# secret hash sha512
send log message

The send log message command allows the user to manually send a syslog message with an optional severity level attribute. This feature is usually used for debugging purposes.

Command Mode
Privileged EXEC

Command Syntax

```
send log [CONDITION] message message_text
```

Parameters
- **CONDITION**  The severity of level value. Options include:
  - **level condition_name**  Severity level to be included in the message. Values include:
    - alerts  Immediate action needed (severity level = 1)
    - critical  Critical conditions (severity level = 2)
    - debugging  Debugging messages (severity level = 7)
    - emergencies  System is unusable (severity level = 0)
    - errors  Error conditions (severity level = 3)
    - informational  Informational messages (severity level = 6)
    - notifications  Normal but significant conditions (severity level = 5)
    - warnings  Warning conditions (severity level = 4)
    - <0 to 7>  Severity level value
- **message_text**  The description of the event log message.

Example
- This command generates an alerts-level syslog message reading “test message from console.”

```
switch# send log level alerts message test message from console
switch# show logging level alerts
Dec 23 16:52:56 switch Cli: %SYS-1-LOGMSG_ALERT: Message from admin on con0 (0.0.0.0): test message from console
switch#
```
server-alive count-max (SSH Management-Tunnel)

The `server-alive count-max` command sets the maximum number of server-alive messages that can be lost before the server is declared dead. Note: These packets are sent inside the tunnel and have the same properties of not being replayable or readable.

The `no server-alive count-max` and `default server-alive count-max` commands remove the `server-alive count-max` command from `running-config`.

Command Mode

  Mgmt-SSH-Tunnel

Command Syntax

  `server-alive count-max max_packet_lost`
  `no server-alive count-max`
  `default server-alive count-max`

Parameters

  - `max_packet_lost` the maximum number of keep-alive messages that are sent to the Secure Shell server. Value ranges from 1 to 1000; default value is 3.

Example

  - This command sets the rate to 600 keep-alive packets that can be lost before the connection is declared dead.

    ```
    switch(config)#management ssh
    switch(config-mgmt-ssh-tunnel)test
    switch(config-mgmt-ssh-tunnel-test)#server-alive count-max 10
    switch(config-mgmt-ssh-tunnel-test)#
    ```
server-alive interval (SSH Management-Tunnel)

The server-alive interval command specifies an interval for sending keepalive messages to the Secure Shell server. The time value is given in seconds.

The no server-alive interval and default server-alive interval commands remove the server-alive interval command from running-config.

Command Mode
Mgmt-SSH-Tunnel

Command Syntax
server-alive interval keep_alive_period
no server-alive interval
default server-alive interval

Parameters
- keep_alive_period  keepalive period (seconds). Value ranges from 1 to 1000. Default value is 10.

Example
- These commands set the server-alive interval to 15 and the server-alive maximum count to 3. If the server becomes unresponsive, SSH will disconnect after approximately 45 seconds.

```
switch(config)#management ssh
switch(config-mgmt-ssh-tunnel)test
switch(config-mgmt-ssh-tunnel-test)#server-alive count-max 3
switch(config-mgmt-ssh-tunnel-test)#server-alive interval 15
switch(config-mgmt-ssh-tunnel-test)#
```
show (various configuration modes)

The show command, when executed within a configuration mode, can display data in `running-config` for the active configuration mode.

**Command Mode**
All configuration modes except Global Configuration

**Command Syntax**
```
show [DATA_TYPE]
```

**Parameters**
- `DATA_TYPE` Specifies display contents. Values include:
  - `active` Displays `running-config` settings for the configuration mode.
  - `active all` Displays `running-config` plus defaults for the configuration mode.
  - `active all detail` Displays `running-config` plus defaults for the configuration mode.
  - `comment` Displays comment entered for the configuration mode.

**Related Commands**
The `show` commands in ACL-configuration mode and MST-configuration mode include the `active` and `comment` options along with additional mode-specific options.

**Example**
- This command shows the server-group-TACACS+ configuration commands in `running-config`.
  ```
  switch(config-sg-tacacs+-TAC-GR)#show active
  server TAC-1
  server 10.1.4.14
  switch(config-sg-tacacs+-TAC-GR)#
  ```
**show event-handler**

The `show event-handler` command displays the contents and activation history of a specified event handler or all event handlers.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
show event-handler [handler_name]
```

**Parameters**
- `handler_name` optional name of an event handler to display. If no parameter is entered, the command displays information for all event handlers configured on the system.

**Example**
- This command displays information about an event handler called “eth_5”.

```
switch#show event-handler eth_5
Event-handler eth_5
  Trigger: onIntf Ethernet5 on operstatus delay 20 seconds
  Action: /mnt/flash/myScript1
  Last Trigger Activation Time: Never
  Total Trigger Activations: 0
  Last Action Time: Never
  Total Actions: 0
switch#
```
**show management ssh hostkey**

The `show management ssh hostkey` command to display the public key authentication.

**Command Mode**

EXEC

**Command Syntax**

```
show management ssh hostkey ALGORITHM
```

**Parameters**

- **ALGORITHM** the public key in a public/private keypair is used.
  - `dsa public` the default authentication list. Note: It is a violation of Common Criteria policy to use the DSA algorithm.
  - `rsa public` the authentication list for SSH logins.

**Example**

- After a switch is configured to a hardware source of entropy and FIPS algorithms, the RSA key pair used on the switch for SSH access must be regenerated. Regeneration of the key will securely zeroize the old key pair and generate a new one. This command regenerates the key pair.

  switch#reset ssh hostkey rsa

  This command displays the new public key.

  switch#show management ssh hostkey rsa public
  ssh-rsa AAAAB3NzaC1yc2EAAAABIwAAAQEAwGXvEQ40NMSGpNqQ44mzFc6STteWp3FmAK+19TJYsK9

switch#
show module

The show module command displays information that identifies the supervisor, fabric, and linecard modules in a modular switch, including model number, serial number, hardware version number, software version (supervisors only), MAC address (supervisors and linecards), and operational status.

Command Mode
EXEC

Command Syntax
show module [MODULE_NAME]

Parameters
- **MODULE_NAME** Specifies modules for which data is displayed. Options include:
  - <no parameter> All modules (identical to all option).
  - linecard line_num Linecard module. Number range varies with switch model.
  - supervisor super_num Supervisor module. Number range varies with switch model.
  - mod_num Supervisor (1 to 2) or linecard (3 to 18) module.
  - all All modules.

Related Commands
- show version displays model and serial numbers of modular system components.
Example

This command displays information about all installed modules on a DCS-7504 switch.

```
switch# show module
Module          Ports Card Type                             Model       Serial No.
1              2     DCS-7500 Series Supervisor Module    7500-SUP     JSH11440327
2              1     Standby supervisor                   Unknown     Unknown
3              48    48-port SFP+ 10GigE Linecard          7548S-LC     JSH10315938
4              48    48-port SFP+ 10GigE Linecard          7548S-LC     JSH11665247
5              48    48-port SFP+ 10GigE Linecard          7548S-LC     JSH11834614
6              48    48-port SFP+ 10GigE Linecard          7548S-LC     JSH11060688

switch#
show platform sand compatibility

The **show sand platform compatibility** command displays the fabric and forwarding modes. These modes determine switch forwarding capabilities and programs performance capacity of installed linecards.

The information that identifies the supervisor, fabric, and linecard modules in the modular switch, including model number, serial number, hardware version number, software version (supervisors only), MAC address (supervisors and linecards), and operational status.

**Command Mode**
- Privileged EXEC

**Command Syntax**
```
show platform sand compatibility
```

**Related Commands**
- **platform sand fabric mode (7500 and 7500E Series)** specifies the fabric software mode.
- **platform sand forwarding mode (7500 and 7500E Series)** specifies the forwarding software mode.

**Example**
- This command indicates that the switch is in Fe600 fabric mode and PetraA forwarding mode.

```
switch#show platform sand compatibility
  Configuration        Status
  Forwarding mode      None                 PetraA
  Fabric mode          None                 Fe600
switch#
```
**show schedule**

The *show schedule* command displays logging output on the terminal during the current terminal session. This command affects only the local monitor. The *no terminal monitor* command disables direct monitor display of logging output for the current terminal session.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show schedule schedule_name
```

**Parameters**

- *schedule_name*  
  label associated with the scheduled command.

**Example**

- This command displays logging to the local monitor during the current terminal session.

  ```
  switch#show schedule tech-support
  CLI command "show tech-support" is scheduled, interval is 60 minutes
  Maximum of 100 log files will be stored
  100 log files currently stored in flash:/schedule/tech-support
  
  Start Time    Size    Filename

  ```
show schedule summary

The `show schedule summary` command displays the list of active scheduled commands.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show schedule summary
```

**Example**
- This command displays the list of active scheduled commands.

```
switch# show schedule summary
Name           Last   Interval Max log   Log file location
------------- ------  -------  --------  ----------------------------------
tech-support   00:00    60     100       flash:/schedule/tech-support
Et45-counters  00:05     5     100       flash:/schedule/Et45-counters
Memfree       00:10    10     100       flash:/schedule/Memfree
```
**show version**

The `show version` command displays information that identifies the switch, including its model number, serial number, and system MAC address. The command also provides hardware and software manufacturing information, along with the available memory and elapsed time from the most recent reload procedure.

**Command Mode**

EXEC

**Command Syntax**

```
show version [INFO_LEVEL]
```

**Parameters**

- **INFO_LEVEL** Specifies information the command displays. Options include
  - `<no parameter>` Model and serial numbers, manufacturing data, uptime, and memory.
  - **detail** Data listed `<no parameter>` option plus version numbers of internal components.

**Related Commands**

- **show module** displays model and serial numbers of modular system components.

**Examples**

- This command displays the switch’s model number, serial number, hardware and software manufacturing information, uptime, and memory capacity,

  ```
  switch>show version
  Arista DCS-7150S-64-CL-F
  Hardware version: 01.01
  Serial number: JPE13120819
  System MAC address: 001c.7326.fd0c
  
  Software image version: 4.13.2F
  Architecture: i386
  Internal build version: 4.13.2F-1649184.4132F.2
  Internal build ID: eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1
  
  Uptime: 1 hour and 36 minutes
  Total memory: 4017088 kB
  Free memory: 1473280 kB
  
  switch>
  ```
shutdown (SSH Management-Tunnel)

The `shutdown` command, in Mgmt-SSH-Tunnel mode, disables or enables management SSH on the switch. Management SSH is disabled by default.

The `no shutdown` command, in Mgmt-SSH-Tunnel mode, re-enables the management SSH access.

The `default shutdown` command, in Mgmt-SSH-Tunnel mode, disables the management SSH access and removes the corresponding `no shutdown` command from the from `running-config`.

**Command Mode**

Mgmt-SSH-Tunnel

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Example**

- These commands disables the SSH management access.

  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)# shutdown
  switch(config-mgmt-ssh)#
  ```

- These commands enables the SSH management access.

  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)# no shutdown
  switch(config-mgmt-ssh)#
  ```
**ssh**

The *ssh* command establishes an SSH connection to an IPv4 server and optionally specifies additional parameters for the connection.

**Command Mode**

EXEC

**Command Syntax**

```bash
ssh \[\[VRF\_INST]\] \[\[CIPHER\]\] \[\[LOG\_NAME\]\] \[\[MAC\_CRYPT\]\] \[\[KEX\]\] \[\[KEY\]\] \[\[PORT\]\] \[\[VERSION\]\] \[\[SERVER\]\]
```

The *VRF\_INST* parameter, when present, is always first. The *SERVER* parameter is always last. All other parameters can be placed in any order.

**Parameters**

- **VRF\_INST** specifies the VRF instance.
  - *<no parameter>* changes are made to the default VRF.
  - *vrf vrf\_name* changes are made to the specified user-defined VRF.
- **CIPHER** Cipher specification for encryption. Options include:
  - *-c cipher\_1  cipher\_2  ...  cipher\_n*
    - **3des** Specifies the encryption algorithm 3des(v1)
    - **3des-cbc** Specifies triple DES (112 bit)
    - **aes128-cbc** Specifies advanced Encryption Standard (128 bit, CBC mode)
    - **aes128-ctr** Specifies advanced Encryption Standard (128 bit, counter mode)
    - **aes192-cbc** Specifies advanced Encryption Standard (192 bit, CBC mode)
    - **aes192-ctr** Specifies advanced Encryption Standard (192 bit, counter mode)
    - **aes256-cbc** Specifies advanced Encryption Standard (256 bit, CBC mode)
    - **aes256-ctr** Specifies advanced Encryption Standard (256 bit, counter mode)
    - **arcfour** Specifies arcfour stream cipher (RC4 like)
    - **arcfour128** Specifies arcfour stream cipher (RFC 4345, 128 bit)
    - **arcfour256** Specifies arcfour stream cipher (RFC 4345, 256 bit)
    - **blowfish** Specifies blowfish block cipher (64 bit)
    - **blowfish-cbc** Specifies blowfish block cipher (128 bit, CBC mode)
    - **cast128-cbc** Specifies CAST-128 (RFC 2144, 128 bit, CBC mode)
    - **des** Specifies the encryption algorithm des(v1)
- **LOG\_NAME** Login name. Options include:
  - *-l login* Name of a user during login
- **MAC\_CRYPT** MAC specification for encryption. Options include:
  - *-m mac\_crypt\_1  mac\_crypt\_2  ...  crypt\_n*
    - **hmac-md5** Hash Message Authentication Code MD5
    - **hmac-md5-96** Hash Message Authentication Code MD5 for use in ESP and AH
    - **hmac-ripemd160** Hash Message Authentication Code RIPEMD-160
    - **hmac-sha1** Hash Message Authentication Code SHA-1
    - **hmac-sha1-96** Hash Message Authentication Code SHA-1 for use in ESP and AH
• **KEX** Limits the message authentication codes from all of the available options to the set specified.
  - `-o KexAlgorithms kex_1 kex_2 ... kex_n`
    - `diffie-hellman-group-exchange-sha1` Negotiated Group Exchange with SHA-1
    - `diffie-hellman-group-exchange-sha256` Negotiated Group Exchange with SHA-256
    - `diffie-hellman-group1-sha1` Oakley Group 1 with SHA-1
    - `diffie-hellman-group14-sha1` Oakley Group 14 with SHA-1

• **KEY** Limits the key-exchange methods from all of the available options to the set specified. Options include:
  - `-o StrictHostKeyChecking yes` Specifies that SSH will automatically check remote servers hostkey before connecting.
  - `-o StrictHostKeyChecking no` Specifies that SSH will ignore remote servers hostkey.

• **PORT** Options include:
  - `-p <1 to 65535>` Specifies the port number of the server.

• **VERSION** Protocol version to force. Options include:
  - `-v <1 to 2>` When the SSH supports SSH1, the protocol version is 1.99. Otherwise, the protocol version is 2.

• **SERVER** Options include:
  - `ip_address` Specifies the IPv4 address of the server.
  - `hostname` Specifies the host name of the server

**Example**
- This command instructs the server to use the Oakley Group 14 Diffie-Hellman method with an SHA-1 hash for key exchange.
  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#key-exchange diffie-hellman-group14-sha1
  ```

**For Common Criteria**
- The following set of commands will put the SSH server and SSH Tunnels on the switch into a Common Criteria approved mode:
  ```
  switch(config)#management ssh
  switch(config-mgmt-ssh)#cipher aes128-cbc aes256-cbc
  switch(config-mgmt-ssh)#key-exchange diffie-hellman-group14-sha1
  switch(config-mgmt-ssh)#mac hmac-sha1
  switch(config-mgmt-ssh)#hostkey server rsa
  switch(config-mgmt-ssh)#hostkey client strict-checking
  switch(config-mgmt-ssh)#log-level verbose
  ```
**terminal length**

The **terminal length** command overrides automatic pagination and sets pagination length for all show commands on a terminal. If the output of a show command is longer than the configured terminal length, the output will be paused after each screenful of output, prompting the user to continue.

To disable pagination for an SSH session, set **terminal length** to 0. By default, all console sessions have pagination disabled.

The **no terminal length** and **default terminal length** commands restore automatic pagination by removing the **terminal length** command from **running-config**.

The pagination setting is persistent if configured from Global Configuration mode. If configured from EXEC mode, the setting applies only to the current CLI session. Pagination settings may also be overridden when you adjust the size of the SSH terminal window, but can be reconfigured by running the **terminal length** command again.

**Command Mode**

EXEC

**Command Syntax**

```
terminal length lines
no terminal length
default terminal length
```

**Parameters**

- **lines**  number of lines to be displayed at a time. Values range from 0 through 32767. A value of 0 disables pagination.

**Example**

- This command sets the pagination length for the current terminal session to 10 lines.

  ```
  switch#terminal length 10
  Pagination set to 10 lines.
  ```

- This command configures the switch to paginate terminal output automatically based on screen size for the current terminal session.

  ```
  switch#no terminal length
  ```

- These commands disable pagination globally.

  ```
  switch#configure
  switch(config)#terminal length 0
  Pagination disabled.
  ```
terminal monitor

The **terminal monitor** command enables the display of logging output on the terminal during the current terminal session. This command affects only the local monitor. The **no terminal monitor** command disables direct monitor display of logging output for the current terminal session.

**Command Mode**
Privileged EXEC

**Command Syntax**
- `terminal monitor`
- `no terminal monitor`
- `default terminal monitor`

**Example**
- This command enables the display of logging to the local monitor during the current terminal session.
  ```
  switch#terminal monitor
  switch#
  ```
trigger

The `trigger` command specifies what event will trigger the event handler. Handlers can be triggered either by the system booting or by a change in a specified interface’s IP address or operational status.

To specify the action to be taken when the handler is triggered, use the `action bash` command.

**Command Mode**

Event-Handler Configuration

**Command Syntax**

```
trigger EVENT
```

**Parameters**

- **EVENT** event which will trigger the configuration mode event handler. Values include:
  - `onboot` triggers when the system reboots, or when you exit event-handler configuration mode. This option takes no further arguments, and passes no environment variables to the action triggered.
  - `onintf INTERFACE CHANGE` triggers when a change is made to the specified interface.
  - `on-startup-config` triggers when a change is made to the `startup-config` file.
  - `vm-tracer vm` triggers when a virtual machine monitored by VM Tracer changes state.

- **INTERFACE** the triggering interface. Values include:
  - `ethernet number` Ethernet interface specified by `number`.
  - `loopback number` loopback interface specified by `number`.
  - `management number` management interface specified by `number`.
  - `port-channel number` channel group interface specified by `number`.
  - `vlan number` VLAN interface specified by `number`.

- **CHANGE** the change being watched for in the triggering interface. Values include:
  - `ip` triggers when the IPv4 address of the specified interface is changed.
  - `ip6` triggers when the IPv6 address of the specified interface is changed.
  - `operstatus` triggers when the operational status of the specified interface changes.

**Examples**

- This command configures the event handler “Eth5” to be triggered when there is a change in the operational status or IP address of Ethernet interface 5.
  ```
  switch(config-handler-Eth5)#trigger onIntf Ethernet 5 operstatus ip
  switch(config-handler-Eth5)#
  ```

- This command configures the event handler “onStartup” to be triggered when the system boots, or on exiting event-handler configuration mode.
  ```
  switch(config-handler-onStartup)#trigger onboot
  switch(config-handler-onStartup)#
  ```
tunnel (SSH Management)

The `tunnel` command places the switch in SSH tunnel configuration mode. EOS provides a SSH Tunneling feature to transparently secure TCP connections to remote servers. This feature can accept any TCP connection that goes to the CPU on the switch and establish a standard SSH tunnel to a remote host. This has a twofold advantage:

- TCP based services do not need to perform any encryption within their own protocol.
- The connection is secure against replay attacks, manipulation and eavesdropping via SSHv2 Common Criteria compliant encryption.

The `no tunnel` and `default tunnel` commands disable Management-ssh-tunnel mode on the switch by removing all Management-ssh-tunnel configuration mode commands from `running-config`.

Management-ssh-tunnel configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting SSH configuration mode does not affect `running-config`. The `exit` command returns the switch to global configuration mode.

Command Mode

Mgmt-ssh Configuration

Command Syntax

```
tunnel tunnel_name
no tunnel
default tunnel
```

Parameters

- `tunnel_name` SSH Tunnel or SSH VRF name.

Commands Available in Management-ssh-tunnel Configuration Mode

- `local` (SSH Management-Tunnel)
- `remote` (SSH Management-Tunnel)
- `server-alive count-max` (SSH Management-Tunnel)
- `server-alive interval` (SSH Management-Tunnel)
- `shutdown` (SSH Management-Tunnel)
- `ssh-server user` (SSH Management-Tunnel)

Example

- These commands place the switch in management-ssh-tunnel mode and create a management SSH tunnel called “foo”.

```
switch(config)#management ssh
switch(config-mgmt-ssh)#tunnel foo
switch(config-mgmt-ssh)#
```
This chapter describes authentication, authorization, and accounting configuration tasks and contains these sections:

- Section 4.1: Authorization, Authentication, and Accounting Overview
- Section 4.2: Configuring the Security Services
- Section 4.3: Server Groups
- Section 4.4: Role Based Authorization
- Section 4.5: Activating Security Services
- Section 4.6: TACACS+ Configuration Examples
- Section 4.7: AAA Commands

### 4.1 Authorization, Authentication, and Accounting Overview

#### 4.1.1 Methods

The switch controls access to EOS commands by authenticating user identity and verifying user authorization. Authentication, authorization, and accounting activities are conducted through three data services – a local security database, TACACS+ servers, and RADIUS servers. Section 4.2: Configuring the Security Services describes these services.

#### 4.1.2 Configuration Statements

Switch security requires two steps:

**Step 1** Configuring security service parameters.

The switch provides configuration commands for each security service:

- A local file supports authentication through `username` and `enable secret` commands.
- TACACS+ servers provide security services through `tacacs-server` commands.
- RADIUS servers provide security services through `radius-server` commands.

Section 4.2: Configuring the Security Services describes security service configuration commands.

**Step 2** Activating authentication, authorization, and accounting services.

EOS provides `aaa authorization`, `aaa authentication`, and `aaa accounting` commands to select the primary and backup services. Section 4.5: Activating Security Services provides information on implementing a security environment.
4.1.3 Encryption

The switch uses clear-text passwords and server access keys to authenticate users and communicate with security systems. To prevent accidental disclosure of passwords and keys, `running-config` stores their corresponding encrypted strings. The encryption method depends on the type of password or key.

Commands that configure passwords or keys can accept the clear-text password or an encrypted string that was generated by the specified encryption algorithm with the clear-text password as the seed.
4.2 Configuring the Security Services

The switch can access three security data services to authenticate users and authorize switch tasks: a local file, TACACS+ servers, and RADIUS Servers.

4.2.1 Local Security File

The local file uses passwords to provide these authentication services:

- authenticate users as they log into the switch
- control access to configuration commands
- control access to the switch root login

The local file contains username-password combinations to authenticate users. Passwords also authorize access to configuration commands and the switch root login.

4.2.1.1 Passwords

The switch recognizes passwords as clear text and encrypted strings.

- **clear-text** passwords are the text that a user enters to access the CLI, configuration commands, or the switch root login.
- **Encrypted strings** are MD5-encrypted strings generated with the clear text as the seed. The local file stores passwords in this format to avoid unauthorized disclosure. When a user enters the clear-text password, the switch generates the corresponding secure hash and compares it to the stored version. **The switch cannot recover the clear text from which an encrypted string is generated.**

Valid passwords contain the characters A-Z, a-z, 0-9 and any of these punctuation characters:

```
! @ # $ % ^ & * ( ) _ - = + { } [ ] ; : < > , . ~ | `'
```

4.2.1.2 Usernames

Usernames control access to the EOS and all switch commands. The switch is typically accessed through an SSH login, using a previously defined username-password combination. To create a new username or modify an existing username, use the `username` command.

Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:

```
@ # $ % ^ & * - _ = + < > , . ~ |`
```

The default username is `admin`, which is described in Admin Username.

Examples

- These equivalent commands create the username `john` and assign it the password `x245`. The password is entered in clear text because the encrypt-type parameter is omitted or zero.
  ```
  switch(config)#username john secret x245
  switch(config)#username john secret 0 x245
  ```
- This command creates the username `john` and assigns it to the text password that corresponds to the encrypted string `$1$SsU.7htpc$TsJ1qslCL7ZYVbyXNG1wg1`. The string was generated by an MD5-encryption program using x245 as the seed.
  ```
  switch(config)#username john secret 5 $1$SsU.7htpc$TsJ1qslCL7ZYVbyXNG1wg1
  ```
The username is authenticated by entering `x245` when the CLI prompts for a password.

- This command creates the username `jane` without securing it with a password. It also removes a password if the `jane` username exists.
  
  ```
  switch(config)#username jane nopassword
  ```

- This command removes the username `william` from the local file.
  
  ```
  switch(config)#no username william
  ```

### 4.2.1.3 Logins by Unprotected Usernames

The default switch configuration allows usernames that are not password protected to log in only from the console. The `aaa authentication policy local` command configures the switch to allow unprotected usernames to log in from any port. To reverse this setting to the default state, use `no aaa authentication policy local allow-nopassword-remote-login`.

**Warning**

Allowing remote access to accounts without passwords is a severe security risk. Arista Networks recommends assigning strong passwords to all usernames.

**Examples**

- This command configures the switch to allow unprotected usernames to log in from any port.
  
  ```
  switch(config)#aaa authentication policy local allow-nopassword-remote-login
  ```

- This command configures the switch to allow unprotected usernames to log in only from the console port.
  
  ```
  switch(config)#no aaa authentication policy local allow-nopassword-remote-login
  ```

### 4.2.1.4 Enable Command Authorization

The `enable` command controls access to Privileged EXEC and all configuration command modes. The enable password authorizes users to execute the `enable` command. When the enable password is set, the CLI displays a password prompt when a user attempts to enter Privileged EXEC mode.

```
main-host>enable
Password:
main-host#
```

If an incorrect password is entered three times in a row, the CLI displays the EXEC mode prompt.

If no enable password is set, the CLI does not prompt for a password when a user attempts to enter Privileged EXEC mode.

To set the enable password, use the `enable secret` command.

**Examples**

- These equivalent commands assign `xyrt1` as the enable password.
  
  ```
  switch(config)#enable secret xyrt1
  switch(config)#enable secret 0 xyrt1
  ```

- This command assigns the enable password to the clear text (12345) corresponding to the encrypted string `$1$8bPBrJnd$Z8wbKLPkgEd7d4tc5Z/6h/`. The string was generated by an MD5-encryption program using 12345 as the seed.
  
  ```
  switch(config)#enable secret 5 $1$8bPBrJnd$Z8wbKLPkgEd7d4tc5Z/6h/
  ```
This command deletes the enable password.

```
switch(config)#no enable secret
```

### 4.2.1.5 Root Account Password

The root account accesses the root directory in the underlying Linux shell. When it is not password protected, you can log into the root account only through the console port. After you assign a password to the root account, you can log into it through any port.

To set the password for the root account, use the `aaa root` command.

**Examples**

- These equivalent commands assign `f4980` as the root account password.
  ```
  switch(config)#aaa root secret f4980
  switch(config)#aaa root secret 0 f4980
  ```
- This command assigns the text `(ab234)` that corresponds to the encrypted string of `$1$HW05LEY8$QEVw6Jq9D9VqDfh.08r.b` as the root password.
  ```
  switch(config)#aaa root secret 5 $1$HW05LEY8$QEVw6Jq9D9VqDfh.08r.b
  ```
- This command removes the password from the root account.
  ```
  switch(config)#aaa root nopassword
  ```
- This command disables the root login.
  ```
  switch(config)#no aaa root
  ```

### 4.2.2 TACACS+

Terminal Access Controller Access-Control System Plus (TACACS+), derived from the TACACS protocol defined in RFC 1492, is a network protocol that provides centralized user validation services. TACACS+ information is maintained on a remote database. EOS support of TACACS+ services requires access to a TACACS+ server.

TACACS+ manages multiple network access points from a single server. The switch defines a TACACS+ server connection by its address and port, allowing the switch to conduct multiple data streams to a single server by addressing different ports on the server.

These sections describe steps that configure access to TACACS+ servers. Configuring TACACS+ access is most efficiently performed when TACACS+ is functioning prior to configuring switch parameters.

#### 4.2.2.1 Configuring TACACS+ Parameters

TACACS+ parameters define settings for the switch to communicate with TACACS+ servers. A set of values can be configured for individual TACACS+ servers that the switch accesses. Global parameters define settings for communicating with servers for which parameters are not individually configured.

The switch supports these TACACS+ parameters:

**Encryption key**

The encryption key is code that the switch and the TACACS+ server share to facilitate communications.

- The `tacacs-server host` command defines the encryption key for a specified server.
- The `tacacs-server key` command defines the global encryption key.
Examples

- This command configures the switch to communicate with the TACACS+ server assigned the host name `TAC_1` using the encryption key `rp31E2v`.
  ```bash
  switch(config)#tacacs-server host TAC_1 key rp31E2v
  ```
- This command configures `cv90jr1` as the global encryption key.
  ```bash
  switch(config)#tacacs-server key 0 cv90jr1
  ```
- This command assigns `cv90jr1` as the global key, using the corresponding encrypted string.
  ```bash
  switch(config)#tacacs-server key 7 020512025B0C1D70
  ```

Session Multiplexing

The switch supports multiplexing sessions on a single TCP connection.

- The `tacacs-server host` command configures the multiplexing option for a specified server.
- There is no global multiplexing setting.

Example

- This command configures the switch to communicate with the TACACS+ server at `10.12.7.9` and indicates the server supports session multiplexing on a TCP connection.
  ```bash
  switch(config)#tacacs-server host 10.12.7.9 single-connection
  ```

Timeout

The timeout is the period the switch waits for a successful connection to, or response from, the TACACS+ server. The default is 5 seconds.

- The `tacacs-server host` command defines the timeout for a specified server.
- The `tacacs-server timeout` command defines the global timeout.

Examples

- This command configures the switch to communicate with the TACACS+ server assigned the host name `TAC_1` and configures the timeout period as **20 seconds**.
  ```bash
  switch(config)#tacacs-server host TAC_1 timeout 20
  ```
- This command configures **40 seconds** as the period that the server waits for a response from a TACACS+ server before issuing an error.
  ```bash
  switch(config)#tacacs-server timeout 40
  ```

Port

The port specifies the port number through which the switch and the servers send information. The TACACS+ default port is 49.

- The `tacacs-server host` command specifies the port number for an individual TACACS+ server.
- The global TACACS+ port number cannot be changed from the default value of 49.

Example

- This command configures the switch to communicate with the TACACS+ server at `10.12.7.9` through port 54.
  ```bash
  switch(config)#tacacs-server host 10.12.7.9 port 54
  ```
4.2.2.2 TACACS+ Status

To display the TACACS+ servers and their interactions with the switch, use the `show tacacs` command.

**Example**

- This command lists the configured TACACS+ servers.

```
switch(config)#show tacacs
```

```
server1: 10.1.1.45
Connection opens: 15
Connection closes: 6
Connection disconnects: 6
Connection failures: 0
Connection timeouts: 2
Messages sent: 45
Messages received: 14
Receive errors: 2
Receive timeouts: 2
Send timeouts: 3

Last time counters were cleared: 0:07:02 ago
```

To reset the TACACS+ status counters, use the `clear aaa counters tacacs` command.

**Example**

- This command clears all TACACS+ status counters.

```
switch(config)#clear aaa counters tacacs
```

4.2.3 RADIUS

Remote Authentication Dial In User Service (RADIUS) is a networking protocol that provides centralized authentication, authorization, and accounting services for computers connecting to and using network resources. RADIUS is used to manage access to the Internet, internal networks, wireless networks, and integrated email services.

These sections describe steps that configure RADIUS server access. Configuring RADIUS parameters is most efficiently performed when RADIUS is functioning prior to configuring switch parameters.

4.2.3.1 RADIUS Vendor-Specific Attribute-Value Pairs

RADIUS servers and client companies extend basic RADIUS functionality through vendor specific attributes. A dictionary file includes a list of RADIUS attribute-value pairs that Arista switches use to perform AAA operations through the RADIUS server.

Arista switches use the following attribute values:

- Arista Vendor number: 30065
- Attribute: Arista-AVPair 1 string

Acceptable string values for Arista-AVPair include:

- "shell:priv-lvl=<privilege level of a user, 0-15>"
- "shell:roles=<list of roles for a user>"
Example

- This is a sample dictionary file that identifies Arista RADIUS vendor-specific attribute value pairs.

```
# dictionary.arista
# Standard Attribute
VENDOR Arista 30065
BEGIN-VENDOR Arista
ATTRIBUTE Arista-AVFair 1 string
END-VENDOR Arista
```

4.2.3.2 Configuring RADIUS Defaults

RADIUS policies specify settings for the switch to communicate with RADIUS servers. A set of values can be configured for individual RADIUS servers that the switch accesses. Global parameters define settings for communicating with servers for which parameters are not individually configured.

The switch defines these RADIUS parameters:

Encryption key

The encryption key is the key shared by the switch and RADIUS servers to facilitate communications.

- The `radius-server host` command defines the encryption key for a specified server.
- The `radius-server key` command specifies the global encryption key.

Examples

- This command configures the switch to communicate with the RADIUS server assigned the host name `RAD-1` using the encryption key `rp31E2v`.
  
  ```
  switch(config)#radius-server host RAD-1 key rp31E2v
  ```

- This command configures `cv90jr1` as the global encryption key.
  
  ```
  switch(config)#radius-server key 0 cv90jr1
  ```

- This command assigns `cv90jr1` as the key by specifying the corresponding encrypted string.
  
  ```
  switch(config)#radius-server key 7 020512025B0C1D70
  ```

Timeout

The timeout is the period that the switch waits for a successful connection to, or response from, a RADIUS server. The default period is 5 seconds.

- The `radius-server host` command defines the timeout for a specified server.
- The `radius-server timeout` command defines the global timeout.

Examples

- This command configures the switch to communicate with the RADIUS server assigned the host name `RAD-1` and configures the timeout period as **20 seconds**.
  
  ```
  switch(config)#radius-server host RAD-1 timeout 20
  ```

- This command configures **50 seconds** as the period that the server waits for a response from a RADIUS server before issuing an error.
  
  ```
  switch(config)#radius-server timeout 50
  ```
Retransmit
Retransmit is the number of times the switch attempts to access the RADIUS server after the first server timeout expiry. The default value is 3 times.

- The `radius-server host` command defines the retransmit for a specified server.
- The `radius-server retransmit` command defines the global retransmit value.

Examples
- This command configures the switch to communicate with the RADIUS server assigned the host name `RAD-1` and configures the retransmit value as 2.
  ```
  switch(config)#radius-server host RAD-1 retransmit 2
  ```
- This command configures the switch to attempt five RADIUS server contacts after the initial timeout. If the timeout parameter is set to `50 seconds`, then the total period that the switch waits for a response is `((5+1)*50) = 300 seconds`.
  ```
  switch(config)#radius-server retransmit 5
  ```

Deadtime
Deadtime is the period when the switch ignores a non-responsive RADIUS server, or a server that does not answer retransmit attempts after timeout expiry. Deadtime is disabled if a value is not specified.

- The `radius-server host` command defines the deadtime for a specified server.
- The `radius-server deadtime` command defines the global deadtime setting.

Examples
- This command configures the switch to communicate with the RADIUS server assigned the host name `RAD-1` and configures the deadtime period as 90 minutes.
  ```
  switch(config)#radius-server host RAD-1 deadtime 90
  ```
- This command programs the switch to ignore a server for two hours if the server does not respond to a request during the timeout-retransmit period.
  ```
  switch(config)#radius-server deadtime 120
  ```

Port
The port specifies the port number through which the switch and servers send information.

- The `radius-server host` command specifies the port numbers for an individual RADIUS server.
- The global RADIUS port numbers cannot be changed from the default values of 1812 for an authorization port and 1813 for an accounting port.

Example
- These commands configure the switch to communicate with the RADIUS server named `RAD-1` through port number 1850 for authorization and port number 1851 for accounting.
  ```
  switch(config)#radius-server host RAD-1 auth-port 1850
  switch(config)#radius-server host RAD-1 acct-port 1851
  ```
  To remove the configuration for this server, use `no radius-server host` command and specify the hostname or IP address with both the authorization and accounting port numbers.

4.2.3.3 RADIUS Status
The `show radius` command displays configured RADIUS servers and their interactions with the switch.
Example

- This command lists the configured RADIUS servers.

  switch(config)#show radius

  server1: 10.1.1.45
  Messages sent: 24
  Messages received: 20
  Requests accepted: 14
  Requests rejected: 8
  Requests timeout: 2
  Requests retransmitted: 1
  Bad responses: 1
  Last time counters were cleared: 0:07:02 ago

To reset the RADIUS status counters, use the `clear aaa counters radius` command.

Example

- This command clears all RADIUS status counters.

  switch(config)#clear aaa counters radius
4.3 **Server Groups**

A server group is a collection of servers that are associated with a single label. Subsequent authorization and authentication commands access all servers in a group by invoking the group name. The switch supports TACACS+ and RADIUS server groups.

The `aaa group server` commands create server groups and place the switch in server group mode to assign servers to the group. Commands that reference an existing group place the switch in group server mode to modify the group.

These commands create named server groups and enter the appropriate command mode for the specified group:

- `aaa group server radius`
- `aaa group server tacacs+`

The `server` (server-group-RADIUS configuration mode) and `server` (server-group-RADIUS configuration mode) commands add servers to the configuration mode server group. Servers must be previously configured with a `radius-server host` or `tacacs-server host` command before they are added to a group.

**Examples**

- This command creates the TACACS+ server group named TAC-GR and enters server group configuration mode for the new group.

  ```
  switch(config)#aaa group server tacacs+ TAC-GR
  switch(config-sg-tacacs+-TAC-GR)#
  ```

- These commands add two servers to the TAC-GR server group. To add servers to this group, the switch must be in sg-tacacs+-TAC-GR configuration mode.

  The CLI remains in server group configuration mode after adding the TAC-1 server (port 49) and the server located at 10.1.4.14 (port 151) to the group.

  ```
  switch(config-sg-tacacs+-TAC-GR)#server TAC-1
  switch(config-sg-tacacs+-TAC-GR)#server 10.1.4.14 port 151
  ```

- This command exits server group mode.

  ```
  switch(config-sg-tacacs+-TAC-GR)#exit
  switch(config)#
  ```

- This command creates the RADIUS server group named RAD-SV1 and enters server group configuration mode for the new group.

  ```
  switch(config)#aaa group server radius RAD-SV1
  switch(config-sg-radius-RAD-SV1)#
  ```

- These commands add two servers to the RAD-SV1 server group. To add servers to this group, the switch must be in sg-radius-RAD-SV1 configuration mode.

  The CLI remains in server group configuration mode after adding the RAC-1 server (authorization port 1812, accounting port 1813) and the server located at 10.1.5.14 (authorization port 1812, accounting port 1850) to the group.

  ```
  switch(config-sg-radius-RAD-SV1)#server RAC-1
  switch(config-sg-radius-RAD-SV1)#server 10.1.5.14 acct-port 1850
  ```
4.4 Role Based Authorization

Role based authorization is a method of restricting access to CLI command through the assignment of profiles, called roles, to user accounts. Each role consists of rules that permit or deny access to a set of commands within specified command modes.

All roles are accessible to the local security file through a username parameter and to remote users through RADIUS servers. Each role can be applied to multiple user accounts. Only one role may be applied to a user.

4.4.1 Role Types

The switch defines two types of roles: user-defined and built-in:

- User-defined roles are created and edited through CLI commands.
- Built-in roles are supplied with the switch and are not user-editable.

Built-in roles supplied by the switch are network-operator and network-admin.

4.4.2 Role Structure

A role is an ordered list of rules that restricts access to specified commands from users on whom it is applied. Roles consist of deny and permit rules. Each rule references a set of command modes and contains a regular expression that specifies one or more CLI commands. Commands are compared sequentially to the rules within a role until a rule’s regular expression matches the command.

- Commands that match a regular expression in a permit rule are executed.
- Commands that match a regular expression in a deny rule are disregarded.
- Commands that do not match a regular expression are evaluated against the next rule in the role.

Upon its entry on the CLI, a command is compared to the first rule of the role. Commands that match the rule are executed (permit rule) or disregarded (deny rule). Commands that do not match the rule are compared to the next rule. This process continues until the command either matches a rule or the rule list is exhausted. The switch disregards commands not matching any rule.

4.4.3 Role Rules

Role rules consist of four components: sequence number, filter type, mode expression, and command expression:

**Sequence number**

The sequence number designates a rule’s placement in the role. Sequence numbers range in value from 1 to 256. Rule commands that do not include a sequence number append the rule at the end of the list, deriving its sequence number by adding 10 to the sequence number of the last rule in the list.

**Example**

- These rules have sequence numbers 10 and 20.

  10 deny mode exec command reload
  20 deny mode config command (no |default )?router

**Filter type**

The filter type specifies the disposition of matching commands. Filter types are permit and deny. Commands matching permit rules are executed. Commands matching deny rules are disregarded.
Example

- These rules are deny and permit rules, respectively.

```
10 deny mode exec command reload
20 permit mode config command interface
```

Mode expression

The mode expression specifies the command mode under which the command expression is effective. The mode expression may be a regular expression or a designated keyword. Rules support the following mode expressions:

- `exec` EXEC and Privileged EXEC modes.
- `config` Global configuration mode.
- `config-all` All configuration modes, including global configuration mode.
- `short_name` Short key name of a command mode (exact match).
- `long_name` Long key name of a command mode (regular expression match of one or more modes).
- `<no parameter>` All command modes.

The `prompt` command parameters configures the CLI to display a configuration mode’s key name:

- `%P` long key name.
- `%p` short key name.

Example

These commands use the prompt command to display short key name (`if`) and long key name (`if-Et1`) for interface-ethernet 1.

```
switch(config)#prompt switch%p
switch(config)#interface ethernet 1
switch(config-if)#exit
switch(config)#prompt switch%P
switch(config)#interface ethernet 1
switch(config-if-Et1)#
```

The command supports the use of regular expressions to reference multiple command modes.

Example

These regular expressions correspond to the listed command modes:

- `if-Vlan(1|2)` matches interface-Vlan 1 or interface-Vlan 2.
- `if` matches all interface modes.
- `acl-text1` matches ACL configuration mode for text1 ACL.

Command Expression

The command expression is a regular expression that corresponds to one or more CLI commands.

Examples

These regular expressions correspond to the specified commands:

- `reload` reload command
- `(no |default )?router` commands that enter routing protocol configuration modes.
- `(no |default )?(ip|mac) access-list` commands that enter ACL configuration modes
Role Based Authorization

Chapter 4: AAA Configuration

• *(no |default )?(ip|mac) access-group* commands that bind ACLs to interfaces.
• *lacp|spanning-tree* LACP and STP commands
• .* all commands

4.4.4 Creating and Modifying Roles

4.4.4.1 Built-in Role

The switch provides the following two built-in roles:
• *network-operator* Allows all commands in EXEC (Privileged) modes. Commands in all other modes are denied.
• *network-admin* Allows all CLI commands in all modes.

The **network-admin** is typically assigned to the **admin** user to allow it to run any command.

Built-in roles are not editable.

Examples

• These show role commands display the contents of the built-in roles.

  ```
  switch(config)#show role network-operator
  The default role is network-operator
  role: network-operator
  10 deny mode exec command bash|
  20 permit mode exec command .* 
  switch(config)#show role network-admin
  The default role is network-operator
  role: network-admin
  10 permit command .* 
  ```

4.4.4.2 Managing Roles

Creating and Opening a Role

Roles are created and modified in role configuration mode. To create a role, enter the `role` command with the role’s name. The switch enters role configuration mode. If the command is followed by the name of an existing role, subsequent commands edit that role.

Example

• This command places the switch in role configuration mode to create a role named `sysuser`.

  ```
  switch(config)#role sysuser
  switch(config)#role sysuser
  ```

Saving Role Changes

Role configuration mode is a group-change mode; changes are saved by exiting the mode.
Examples

- These commands create a role, then adds a deny rule to the role. Because the changes are not yet saved, the role remains empty, as shown by show role.

  ```
  switch(config)#role sysuser
  switch(config-role-sysuser)#deny mode exec command reload
  switch(config-role-sysuser)#show role sysuser
  The default role is network-operator
  ```

  switch(config)#

  To save all current changes to the role and exit role configuration mode, type exit.

  ```
  switch(config-role-sysuser)#exit
  switch(config)#show role sysuser
  The default role is network-operator
  ```

  role: sysuser
  10 deny mode exec command reload
  switch(config)#

Important! After exiting role mode, running-config must be saved to startup-config to preserve role changes past system restarts.

Discarding Role Changes

The abort command exits role configuration mode without saving pending changes.

Example

- These commands enter role configuration mode to add deny rules, but discard the changes before saving them to the role.

  ```
  switch(config)#role sysuser
  switch(config-role-sysuser)#deny mode exec command reload
  switch(config-role-sysuser)#abort
  switch(config)#show role sysuser
  The default role is network-operator
  ```

  switch(config)#

4.4.4.3 Modifying Roles

Adding Rules to a Role

The deny (Role) command adds a deny rule to the configuration mode role. The permit (Role) command adds a permit rule to the configuration mode role.

To append a rule to the end of a role, enter the rule without a sequence number while in role configuration mode. The new rule’s sequence number is derived by adding 10 to the last rule’s sequence number.
Examples

- These commands enter the first three rules into a new role.

```plaintext
switch(config)#role sysuser
switch(config-role-sysuser)#deny mode exec command reload
switch(config-role-sysuser)#deny mode config command (no |default )?router
switch(config-role-sysuser)#permit command .*
switch(config-role-sysuser)#exit
switch(config)#show role sysuser
```

The default role is network-operator

```plaintext
role: sysuser
  10 deny mode exec command reload
  20 deny mode config command (no |default )?router
  30 permit command .*
```

Inserting a Rule

To insert a rule into a role, enter the rule with a sequence number between the existing rules’ numbers.

Example

- This command inserts a rule between the first two rules by assigning it the sequence number 15.

```plaintext
switch(config)#role sysuser
switch(config-role-sysuser)#15 deny mode config-all command lacp
switch(config-role-sysuser)#exit
switch(config)#show role sysuser
```

The default role is network-operator

```plaintext
role: sysuser
  10 deny mode exec command reload
  15 deny mode config-all command lacp|spanning-tree
  20 deny mode config command (no |default )?router
  30 permit command .*
```

Deleting a Rule

To remove a rule from the current role, perform one of these commands:

- Enter `no`, followed by the sequence number of the rule to be deleted.
- Enter `no`, followed by the rule to be deleted.
- Enter `default`, followed by the sequence number of the rule to be deleted.
- Enter `default`, followed by the rule to be deleted.

Example

- These equivalent commands remove rule 30 from the list.

```plaintext
switch(config-role-sysuser)#no 30
switch(config-role-sysuser)#default 30
switch(config-role-sysuser)#no permit command .*
switch(config-role-sysuser)#default permit command .*
```
This role results from entering one of the preceding commands.

```
switch(config)#show role sysuser
The default role is network-operator

role: sysuser
  10 deny mode exec command reload
  15 deny mode config-all command lACP|spanning-tree
  20 deny mode config command (no |default )?router
```

Redistributing Sequence Numbers

Sequence numbers determine the order of the rules in a role. After a list editing session where existing rules are deleted and new rules are inserted between existing rules, the sequence number distribution may not be uniform. Redistributing rule numbers changes adjusts the sequence number of rules to provide a constant difference between adjacent rules. The `resequence (Role)` command adjusts the sequence numbers of role rules.

**Example**

- The `resequence` command renumbers rules in the `sysuser` role. The sequence number of the first rule is 100; subsequent rules numbers are incremented by 20.

```
switch(config)#show role sysuser
The default role is network-operator

role: sysuser
  10 deny mode exec command reload
  20 deny mode config-all command lACP|spanning-tree
  25 deny mode config command (no |default )?router
  30 permit command .*
```

```
switch(config)#role sysuser
switch(config-role-sysuser)#resequence 100 20
switch(config-role-sysuser)#exit
switch(config)#show role sysuser
The default role is network-operator

role: sysuser
  100 deny mode exec command reload
  120 deny mode config-all command lACP|spanning-tree
  140 deny mode config command (no |default )?router
  160 permit command .*
```

4.4.5 Assigning a Role to a User Name

Roles are assigned to local users through the `username` command and to remote users through RADIUS servers. Each user is assigned one role. Each role can be assigned to multiple local and remote users.

4.4.5.1 Default Roles

Users that are not explicitly assigned a role are assigned the default role. The `aaa authorization policy local default-role` command designates the default role. The network-operator built-in role is the default role when the `aaa authorization policy local default-role` is not configured.
### Examples

- These commands assign `sysuser` as the default role, then displays the name of the default role.

  ```
  switch(config)#aaa authorization policy local default-role sysuser
  switch(config)#show role
  The default role is sysuser
  
  switch(config)#
  ```

- These commands restore `network-operator` as the default role by deleting the `aaa authorization policy local default-role` statement from `running-config`, then displays the default role name.

  ```
  switch(config)#no aaa authorization policy local default-role
  switch(config)#show role
  The default role is network-operator
  
  switch(config)#
  ```

#### 4.4.5.2 Local Security File (Username command)

Roles are assigned to users with the `username` command’s `role` parameter. A user name whose `running-config username` statement does not include a `role` parameter is assigned the `default` role.

The `role` parameter function in a command creating a user name is different from its function in a command editing an existing name.

**Assigning a Role to a New User Name**

A `username` command creating a user name explicitly assigns a role to the user name by including the `role` parameter; commands without a `role` parameter assigns the default role to the user name.

**Example**

- These commands create two user names. The first user is assigned a role; the second user assumes the default role.

  ```
  switch(config)#username FRED secret 0 axced role sysuser1
  switch(config)#username JANE nopassword
  switch(config)#show running-config
  !
  username FRED role sysuser1 secret 5 $1$dhJ6vrPV$PFOvJCX/vcqyIHV.vd.120
  username JANE nopassword
  !
  switch(config)#
  ```

**Editing the Role of an Existing User Name**

The role of a previously configured user name may be edited by a `username` command without altering its password. The role assignment of a user name is not changed by `username` commands that do not include a `role` parameter.
Examples

- These commands assign a role to a previously configured user name.

  ```
  username JANE role sysuser2
  no username FRED role
  ```

- These commands revert a user name to the default role by removing its role assignment.

  ```
  no username FRED role
  ```

Displaying the Role Assignments

The `show user-account` command displays role assignment of the configured users. The `show aaa sessions` command displays roles of users that are currently logged into the switch.

Example

- This command displays the configured users and their role assignments.

  ```
  show user-account
  ```

- This command displays information about the active AAA login sessions.

  ```
  show aaa session
  ```
4.4.5.3 Radius Servers

A role can be assigned to a remote user authenticated through a RADIUS server. Roles are assigned through the vendor specific attribute-value (AV) pair named Arista-AVPair. The switch extracts the remote user’s role upon a successful authentication when RADIUS authentication is enabled.

Example

- This file extract is sample FreeRadius server code that includes the AV pair that assigns roles to three remote users.

  ```
  # Sample RADIUS server users file
  "Jane"      Cleartext-Password := "Abc1235"
  Arista-AVPair = "shell:roles=sysuser2",
  Service-Type = NAS-Prompt-User
  "Mary"      Cleartext-Password := "xYz$2469"
  Arista-AVPair = "shell:roles=sysadmin",
  Service-Type = NAS-Prompt-User
  "Fred"      Cleartext-Password := "rjx4#222"
  Arista-AVPair = "shell:roles=network-operator",
  Service-Type = NAS-Prompt-User
  ```

The `aaa authentication login` command selects the user authentication service (Section 4.5.1.2).

Example

- This command configures the switch to authenticate users through all RADIUS servers.

  ```
  switch(config)#aaa authentication login default group radius
  switch(config)#
  ```

4.4.5.4 Enable Role Based Access Control

To enable Role Based Access Control on the switch, apply the following configuration:

  ```
  switch(config)#aaa authorization commands all default local
  switch(config)#
  ```
4.5 Activating Security Services

After configuring the access databases, `aaa authentication`, `aaa authorization`, and `aaa accounting` commands designate active and backup services for handling access requests. These sections describe the methods of selecting the database that the switch uses to authenticate users and authorize access to network resources.

4.5.1 Authenticating Usernames and the Enable Password

Service lists specify the services the switch uses to authenticates usernames and the enable password.

4.5.1.1 Service List Description

Service list elements are service options, ordered by their priority.

Important! When the local file is one of the service list elements, any attempts to locally authenticate a username that is not included in the local file will result in the switch continuing to the next service list element.

Example

- This is an example service list for username authentication:
  1. Location_1 server group – specifies a server group (Section 4.3: Server Groups).
  2. Location_2 server group – specifies a server group (Section 4.3: Server Groups).
  3. TACACS+ servers – specifies all hosts for which a `tacacs-server host` command exists.
  4. Local file – specifies the local file.
  5. None – specifies that no authentication is required – all access attempts succeed.

To authenticate a username, the switch checks Location_1 server group. If a server in the group is available, the switch authenticates the username through that group. Otherwise, it continues through the list until it finds an available service or utilizes option 5, which allows the access attempt to succeed without authentication.

4.5.1.2 Configuring Service Lists

Service lists are incorporated into these `aaa authentication` commands to specify services the switch uses to authenticate usernames and the enable password.

- `aaa authentication login` specifies services the switch uses to authenticates usernames.
- `aaa authentication enable` specifies services the switch uses to authenticates the enable password.

Examples

- This command configures the switch to authenticate usernames through the TAC-1 server group. The local database is the backup method if TAC-1 servers are unavailable.
  
  `switch(config)#aaa authentication login default group TAC-1 local`

- This command configures the switch to authenticate usernames through all TACACS+ servers, then all RADIUS servers if the TACACS+ servers are not available. If the RADIUS servers are unavailable, the switch does not authenticate any login attempts.
  
  `switch(config)#aaa authentication login default group tacacs+ group radius none`
• This command configures the switch to authenticate the enable password through all TACACS+ servers, then through the local database if the TACACS+ servers are unavailable.

switch(config)#aaa authentication enable default group TACACS+ local

4.5.2 Authorization

Authorization commands control EOS shell access, CLI command access, and configuration access through the console port. The switch also supports role based authorization, which allows access to specified CLI commands by assigning command profiles (or roles) to usernames. Section 4.4 describes role based authorization.

During the exec authorization process, TACACS+ server responses may include attribute-value (AV) pairs. The switch recognizes the mandatory AV pair named `priv-lvl=x` (where `x` is between 0 and 15).

By default, a TACACS+ server that sends any other mandatory AV pair is denied access to the switch. The receipt of optional AV pairs by the switch has no affect on decisions to permit or deny access to the TACACS+ server. The `tacacs-server policy` command programs the switch to allow access to TACACS+ servers that send unrecognized mandatory AV pairs.

Authorization to switch services is configured by these `aaa authorization` commands

• To specify the method of authorizing the opening of an EOS shell, enter `aaa authorization exec`.
• To specify the method of authorizing CLI commands, enter `aaa authorization commands`.

Examples

• This command specifies that TACACS+ servers authorize users attempting to open a CLI shell.

switch(config)#aaa authorization exec default group tacacs+
switch(config)#

• This command programs the switch to authorize configuration commands (privilege level 15) through the local file and to deny command access to users not listed in the local file.

switch(config)#aaa authorization commands all default local
switch(config)#

• This command programs the switch to permit all commands entered on the CLI.

switch(config)#aaa authorization commands all default none
switch(config)#

• This command configures the switch to permit access to TACACS+ servers that send unrecognized mandatory AV pairs.

switch(config)#tacacs-server policy unknown-mandatory-attribute ignore
switch(config)#

All commands are typically authorized through `aaa authorization commands`. However, the `no aaa authorization config-commands` command disables the authorization of configuration commands. In this state, authorization to execute configuration commands can be managed by controlling access to Global Configuration commands. The default setting authorizes configuration commands through the policy specified for all other commands.

• To enable the authorization of configuration commands with the policy specified for all other commands, enter `aaa authorization config-commands`.
• To require authorization of commands entered on the console, enter `aaa authorization console`.

By default, EOS does not verify authorization of commands entered on the console port.
Examples

- This command disables the authorization of configuration commands.
  
  ```
  switch(config)#no aaa authorization config-commands
  switch(config)#
  ```

- This command enables the authorization of configuration commands.
  
  ```
  switch(config)#aaa authorization config-commands
  switch(config)#
  ```

- This command configures the switch to authorize commands entered on the console, using the method specified through a previously executed `aaa authorization command`.
  
  ```
  switch(config)#aaa authorization console
  switch(config)#
  ```

4.5.3 Accounting

The accounting service collects information for billing, auditing, and reporting. The switch supports TACACS+ and RADIUS accounting by reporting user activity to either the TACACS+ server or RADIUS server in the form of accounting records.

The switch supports two types of accounting:

- EXEC: Provides information about user CLI sessions.
- Commands: Command authorization for all commands, including configuration commands that are associated with a privilege level.

The accounting mode determines when accounting notices are sent. Mode options include:

- start-stop: a `start` notice is sent when a process begins; a `stop` notice is sent when it ends.
- stop-only: a `stop` accounting record is generated after a process successfully completes.

Accounting is enabled by the `aaa accounting` command.

Examples

- This command configures the switch to maintain start-stop accounting records for all commands executed by switch users and submits them to all TACACS+ hosts.
  
  ```
  switch(config)#aaa accounting commands all default start-stop group tacacs+
  switch(config)#
  ```

- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.
  
  ```
  switch(config)#aaa accounting exec console stop group tacacs+
  switch(config)#
  ```
4.6 TACACS+ Configuration Examples

These sections describe two sample TACACS+ host configurations.

4.6.1 Single Host Configuration

The single host configuration consists of a TACACS+ server with these attributes:

- IP address: 10.1.1.10
- encryption key: example_1
- port number: 49 (global default)
- timeout: 5 seconds (global default)

The switch authenticates the username and enable command against all TACACS+ servers which, in this case, is one host. If the TACACS+ server is unavailable, the switch authenticates with the local file.

**Step 1** This step configures TACACS+ server settings – port number and timeout are global defaults.

```
switch(config)# tacacs-server host 10.1.1.10 key example_1
```

**Step 2** This step configures the login authentication service.

```
switch(config)# aaa authentication login default group tacacs+ local
```

**Step 3** This step configures the enable command password authentication service.

```
switch(config)# aaa authentication enable default group tacacs+ local
```

4.6.2 Multiple Host Configuration

The multiple host configuration consists of three TACACS+ servers at these locations:

- IP address 10.1.1.2 – port 49
- IP address 13.21.4.12 – port 4900
- IP address 16.1.2.10 – port 49

The configuration combines the servers into these server groups:

- Bldg_1 group consists of the servers at 10.1.1.2 and 13.21.4.12
- Bldg_2 group consists of the servers at 16.1.2.10

All servers use these global TACACS+ defaults:

- encryption key – example_2
- timeout – 10 seconds

The switch authenticates these access methods:

- username access against Bldg_1 group then, if they are not available, against the local file.
- enable command against Bldg_2 group, then Bldg_1 group, then against the local file.

**Step 1** TACACS+ Host commands:

These commands configure the IP address and ports for the three TACACS+ servers. The port for the first and third server is default 49.

```
switch(config)# tacacs-server host 10.1.1.12
switch(config)# tacacs-server host 13.21.4.12 port 4900
switch(config)# tacacs-server host 16.1.2.10
```

**Step 2** Global Configuration Commands:
These commands configure the global encryption key and timeout values.

```
switch(config)#tacacs-server key example_2
switch(config)#tacacs-server timeout 10
```

**Step 3  Group Server Commands:**

The `aaa group server` commands create the server groups and place the CLI in server group configuration mode, during which the servers are placed in the group. The port number must be included if it is not the default port, as in the line that adds 192.168.1.1.

```
switch(config)#aaa group server tacacs+ Bldg_1
switch(config-sg-tacacs+-Bldg_1)#server 10.1.1.2
switch(config-sg-tacacs+-Bldg_1)#server 192.168.1.1 port 4900
switch(config-sg-tacacs+-Bldg_1)#exit
switch(config)#aaa group server tacacs+ Bldg_2
switch(config-sg-tacacs+-Bldg_2)#server 192.168.2.2
switch(config-sg-tacacs+-Bldg_2)#exit
switch(config)#
```

**Step 4  Login and enable configuration authentication responsibility commands:**

These commands configure the username and enable command password authentication services.

```
switch(config)#aaa authentication login default group Bldg_1 local
switch(config)#aaa authentication enable default group Bldg_1 group Bldg_2 local
```

4.7 AAA Commands

Local Security File Commands
- `aaa root`
- `enable secret`
- `username`
- `username sshkey`
- `show privilege`
- `show user-account`
- `show users`

Accounting, Authentication, and Authorization Commands
- `aaa accounting`
- `aaa accounting dot1x`
- `aaa accounting system`
- `aaa authentication enable`
- `aaa authentication login`
- `aaa authentication policy local`
- `aaa authentication policy log`
- `aaa authorization commands`
- `aaa authorization config-commands`
- `aaa authorization console`
- `aaa authorization exec`
- `aaa authorization policy local default-role`
- `clear aaa counters`
- `clear aaa counters radius`
- `clear aaa counters tacacs+`
- `show aaa`
- `show aaa counters`
- `show aaa method-lists`
- `show aaa sessions`

Server (RADIUS and TACACS+) Configuration Commands
- `ip radius source-interface`
- `radius-server deadtime`
- `radius-server host`
- `radius-server key`
- `radius-server retransmit`
- `radius-server timeout`
- `show radius`
- `ip tacacs source-interface`
- `tacacs-server host`
- `tacacs-server key`
- `tacacs-server policy`
- `tacacs-server timeout`
- `show tacacs`

Server Group Configuration Commands
- `aaa group server radius`
- `aaa group server tacacs+`
- `server (server-group-RADIUS configuration mode)`
- server (server-group-TACACS+ configuration mode)

**Role Based Authorization Configuration Commands**

- role
- deny (Role)
- permit (Role)
- no <sequence number> (Role)
- resequence (Role)
- show role
aaa accounting

The **aaa accounting** command configures accounting method lists for a specified authorization type. Each list consists of a prioritized list of methods. The accounting module uses the first available listed method for the authorization type.

The **no aaa accounting** and **default aaa accounting** commands clear the specified method list by removing the corresponding **aaa accounting** command from *running-config*.

**Command Mode**
Global Configuration

**Command Syntax**
- `aaa accounting TYPE CONNECTION MODE [METHOD_1] [METHOD_2] ... [METHOD_N]`
- `no aaa accounting TYPE CONNECTION`
- `default aaa accounting TYPE CONNECTION`

**Parameters**
- **TYPE**    authorization type for which the command specifies a method list. Options include:
  - **EXEC** records user authentication events.
  - **COMMANDS ALL** records all entered commands.
  - **COMMANDS level** records entered commands of the specified level (ranges from 0 to 15).
- **CONNECTION** connection type of sessions for which method lists are reported. Options include:
  - **console** console connection.
  - **default** all connections not covered by other command options.
- **MODE**    accounting mode that defines when accounting notices are sent. Options include:
  - **none** no notices are sent.
  - **start-stop** a start notice is sent when a process begins; a stop notice is sent when it ends.
  - **stop-only** a stop accounting record is generated after a process successfully completes.
- **METHOD_X** server groups (methods) to which the switch can send accounting records. The switch sends the method list to the first listed group that is available.

Parameter value is not specified if **MODE** is set to **none**. If **MODE** is not set to **none**, the command must provide at least one method. Each method is composed of one of the following:

- **group name** the server group identified by **name**.
- **group radius** server group that includes all defined RADIUS hosts.
- **group tacacs+** server group that includes all defined TACACS+ hosts.
- **logging** log all accounting messages to syslog.

**Examples**
- This command configures the switch to maintain start-stop accounting records for all commands executed by switch users and submits them to all TACACS+ hosts.
  ```
  switch(config)#aaa accounting commands all default start-stop group tacacs+
  ```
- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.
  ```
  switch(config)#aaa accounting exec console stop group tacacs+
  ```
aaa accounting dot1x

The **aaa accounting system** command enables the accounting of requested 802.1X services for network access.

The **no aaa accounting system** and **default aaa accounting system** commands disable the specified method list by removing the corresponding **aaa accounting system** command from **running-config**.

**Command Mode**
- Global Configuration

**Command Syntax**
```
aaa accounting dot1x default MODE [METHOD_1] [METHOD_2] ... [METHOD_N]
no aaa accounting dot1x default
default aaa accounting dot1z default
```

**Parameters**
- **MODE** accounting mode that defines when accounting notices are sent. Options include:
  - **start-stop** a **start** notice is sent when a process begins; a **stop** notice is sent when it ends.
  - **METHOD_X** server groups (methods) to which the switch can send accounting records. The switch sends the method list to the first listed group that is available.

Parameter value is not specified if **MODE** is set to **none**. If **MODE** is not set to **none**, the command must provide at least one method. Each method is composed of one of the following:

- **group name** the server group identified by **name**.
- **group radius** server group that includes all defined RADIUS hosts.
- **logging** server group that includes all defined TACACS+ hosts.

**Examples**
- This example configures IEEE 802.1x accounting on the switch.
  ```
  switch(config)#aaa accounting dot1x default start-stop group radius
  switch(config)#
  ```
- This example disables IEEE 802.1x accounting on the switch.
  ```
  switch(config)#no aaa accounting dot1x default
  switch(config)#
  ```
aaa accounting system

The `aaa accounting system` command performs accounting for all system-level events.

The `no aaa accounting system` and `default aaa accounting system` commands clear the specified method list by removing the corresponding `aaa accounting system` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
aaa accounting system default MODE [METHOD_1] [METHOD_2] ... [METHOD_N]
```

```
no aaa accounting system default
```

default aaa accounting system default

**Parameters**

- **MODE** accounting mode that defines when accounting notices are sent. Options include:
  - none no notices are sent.
  - start-stop a *start* notice is sent when a process begins; a *stop* notice is sent when it ends.
  - stop-only a *stop* accounting record is generated after a process successfully completes.

- **METHOD_X** server groups (methods) to which the switch can send accounting records. The switch sends the method list to the first listed group that is available.

Parameter value is not specified if **MODE** is set to **none**. If **MODE** is not set to **none**, the command must provide at least one method. Each method is composed of one of the following:

- **group name** the server group identified by **name**.
- **group radius** server group that includes all defined RADIUS hosts.
- **group tacacs+** server group that includes all defined TACACS+ hosts.
- **logging** server group that includes all defined TACACS+ hosts.

**Examples**

- This command configures AAA accounting to not use any accounting methods.

  ```
  switch(config)#aaa accounting system default none
  switch(config)#
  ```

- This command configures the switch to maintain stop accounting records for all user EXEC sessions performed through the console and submits them to all TACACS+ hosts.

  ```
  switch(config)#aaa accounting exec console stop group tacacs+
  switch(config)#
  ```
aaa authentication enable

The `aaa authentication enable` command configures the service list that the switch references to authorize access to Privileged EXEC command mode.

The list consists of a prioritized list of service options. Available service options include:

- a named server group
- all defined TACACS+ hosts
- all defined RADIUS hosts
- local authentication
- no authentication

The switch authorizes access by using the first listed service option that is available. When the local file is a service list element, attempts to locally authenticate a username that is not in the local file result in the switch continuing to the next service list element.

When the list is not configured, it is set to `local`.

The `no aaa authentication enable` and `default aaa authentication enable` commands revert the list configuration as `local` by removing the `aaa authentication enable` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
aaa authentication enable default METHOD_1 [METHOD_2] ... [METHOD_N]
no aaa authentication enable default
default aaa authentication enable default
```

**Parameters**

- `METHOD_X` authentication service method list. The command must provide at least one method. Each method is composed of one of the following:
  - `group name` the server group identified by `name`.
  - `group radius` a server group that consists of all defined RADIUS hosts.
  - `group tacacs+` a server group that consists of all defined TACACS+ hosts.
  - `local` local authentication.
  - `none` users are not authenticated; all access attempts succeed.

**Example**

- This command configures the switch to authenticate the enable password through all configured TACACS+ servers. Local authentication is the backup if TACACS+ servers are unavailable.

```
switch(config)#aaa authentication default enable group TACACS+ local
switch(config)#
```
aaa authentication login

The `aaa authentication login` command configures service lists the switch references to authenticate usernames. Service lists consist of service options ordered by usage priority. The switch authenticates usernames through the first available service option. Supported service options include:

- a named server group
- all defined TACACS+ hosts
- all defined RADIUS hosts
- local authentication
- no authentication

When the local file is a service list element, attempts to locally authenticate a username that is not in the local file result in the switch continuing to the next service list element.

The switch supports a `console` list for authenticating usernames through the console and a default list for authenticating usernames through all other connections.

- When the `console` list is not configured, the console connection uses the `default` list.
- When the `default` list is not configured, it is set to `local`.

The `no aaa authentication login` and `default aaa authentication login` commands revert the specified list configuration to its default by removing the corresponding `aaa authentication` login command from `running-config`.

Command Mode
Global Configuration

Command Syntax
```
aaa authentication login CONNECTION SERVICE_1 [SERVICE_2] ... [SERVICE_N]
no aaa authentication login CONNECTION
default aaa authentication login CONNECTION
```

Parameters

- `CONNECTION` connection type of sessions for which authentication list is used
  - `default` the default authentication list.
  - `console` the authentication list for console logins.
- `SERVICE_X` an authentication service. Settings include:
  - `group name` identifies a previously defined server group.
  - `group radius` a server group that consists of all defined RADIUS hosts.
  - `group tacacs+` a server group that consists of all defined TACACS+ hosts.
  - `local` local authentication.
  - `none` the switch does not perform authentication. All access attempts succeed.

Examples
- This command configures the switch to authenticate usernames through the TAC-1 server group. The local database is the backup method if TAC-1 servers are unavailable.

```
switch(config)#aaa authentication login default group TAC-1 local
switch(config)#
```
• This command configures the switch to authenticate usernames through all TACACS+ servers, then all RADIUS servers if the TACACS+ servers are not available. If the RADIUS servers are also unavailable, the switch allows access to all login attempts without authentication.

switch(config)#aaa authentication login default group tacacs+ group radius none
switch(config)#
aaa authentication policy local

The `aaa authentication policy local allow-nopassword-remote-login` command permits usernames without passwords to log in from any port. The default switch setting only allows unprotected usernames to log in from the console.

The `no aaa authentication policy local allow-nopassword-remote-login` and `default aaa authentication policy local allow-nopassword-remote-login` commands return the switch to the default setting of denying unprotected usernames to log in except from the console.

**Command Mode**

Global Configuration

**Command Syntax**

`aaa authentication policy local allow-nopassword-remote-login`
`no aaa authentication policy local allow-nopassword-remote-login`
`default aaa authentication policy local allow-nopassword-remote-login`

**Examples**

- This command configures the switch to allow unprotected usernames to log in from any port.

  `switch(config)#aaa authentication policy local allow-nopassword-remote-login`

- This command configures the switch to allow unprotected usernames to log in only from the console port.

  `switch(config)#no aaa authentication policy local allow-nopassword-remote-login`
aaa authentication policy log

The `aaa authentication policy log` command configure TACACS+ for remote AAA services.

A Common Criteria compliant AAA setup with EOS requires the use of TACACS+ as the AAA solution. For security it must be run inside of an SSH Tunnel. The remote TACACS+ server being connected to must implement TACACS+ protocol version 1.78 or greater to be considered Common Criteria compliant.

The `no aaa authentication policy log` and `default aaa authentication policy log` commands return the switch to the default setting of denying unprotected usernames to log in except from the console.

**Command Mode**

Global Configuration

**Command Syntax**

```
aaa authentication policy LOGIN_TYPE log
no aaa authentication policy LOGIN_TYPE log
default aaa authentication policy LOGIN_TYPE log
```

**Parameters**

- `MODE` accounting mode that defines when accounting notices are sent. Options include:
  - `on-failure` a notice is sent when a process begins; a `stop` notice is sent when it ends.
  - `on-success` a record is generated after a process successfully completes.

**Examples**

To configure TACACS+ on the switch run all of the following commands.

- Configure the server and keys:
  ```
  switch(config)#tacacs-server host HOST key TACACS_KEY
  ```

- Configure user authentication:
  ```
  switch(config)#aaa authentication login default group tacacs+ local
  switch(config)#aaa authentication enable default group tacacs+ local
  ```

- Configure authentication policy to log successful and failed login attempts:
  ```
  switch(config)#aaa authentication policy on-success log
  switch(config)#aaa authentication policy on-failure log
  ```
aaa authorization commands

The **aaa authorization commands** command configures the service list that authorizes CLI command access. All switch commands are assigned a privilege level that corresponds to the lowest level command mode from which it can be executed:

- Level 1: Commands accessible from EXEC mode.
- Level 15: Commands accessible from any mode except EXEC.

Command usage is authorized for each privilege level specified in the command.

The list consists of a prioritized list of service options. The switch authorizes access by using the first listed service option that is available. The available service options include:

- a named server group
- all defined TACACS+ hosts
- all defined RADIUS hosts
- local authorization
- no authorization

The list is set to **none** for all unconfigured privilege levels, allowing all CLI access attempts to succeed.

The **no aaa authorization commands** and **default aaa authorization commands** commands revert the list contents to **none** for the specified privilege levels.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
aaa authorization commands PRIV default SERVICE_1 [SERVICE_2] ... [SERVICE_N]
no aaa authorization commands PRIV default
default aaa authorization commands PRIV default
```

**Parameters**

- **PRIV** Privilege levels of the commands. Options include:
  - `level` numbers from 0 and 15. Number, range, comma-delimited list of numbers and ranges.
  - `all` commands of all levels.
- **SERVICE_X** Authorization service. Command must list at least one service. Options include:
  - `group name` the server group identified by `name`.
  - `group tacacs+` a server group that consists of all defined TACACS+ hosts.
  - `local` local authorization.
  - `none` the switch does not perform authorization. All access attempts succeed.

**Examples**

- This command authorizes configuration commands (privilege level 15) through the local file. The switch denies command access to users not listed in the local file.
  ```plaintext
  switch(config)#aaa authorization commands all default local
  switch(config)#
  ```

- This command authorizes all commands entered on the CLI.
  ```plaintext
  switch(config)#aaa authorization commands all default none
  switch(config)#
  ```
aaa authorization config-commands

The **aaa authorization config-commands** command enables authorization of commands in any configuration mode, such as global Configuration and all interface configuration modes. Commands are authorized through the policy specified by the **aaa authorization commands** setting. Authorization is enabled by default, so issuing this command has no effect unless **running-config** contains the **no aaa authorization config-commands** command.

The **no aaa authorization config-commands** command disables configuration command authorization. When configuration command authorization is disabled, **running-config** contains the **no aaa authorization config-commands** command. The **default aaa authorization config-commands** command restores the default setting by removing the **no aaa authorization config-commands** from **running-config**.

**Command Mode**
- Global Configuration

**Command Syntax**
- `aaa authorization config-commands`
- `no aaa authorization config-commands`
- `default aaa authorization config-commands`

**Example**
- This command disables the authorization of configuration commands.
  ```
  switch(config)#no aaa authorization config-commands
  switch(config)#
  ```
- This command enables the authorization of configuration commands.
  ```
  switch(config)#aaa authorization config-commands
  switch(config)#
  ```
aaa authorization console

The **aaa authorization console** command configures the switch to authorize commands entered through the console. By default, commands entered through the console do not require authorization.

The **no aaa authorization console** and **default aaa authorization console** commands restore the default setting.

**Command Mode**
- Global Configuration

**Command Syntax**
- `aaa authorization console`
- `no aaa authorization console`
- `default aaa authorization console`

**Example**
- This command configures the switch to authorize commands entered on the console, using the method specified through a previously executed **aaa authorization command**.
  ```
  switch(config)#aaa authorization console
  switch(config)#
  ```
aaa authorization exec

The `aaa authorization exec` command configures the service list that the switch references to authorize access to open an EOS CLI shell.

The list consists of a prioritized list of service options. The switch authorizes access by using the first listed service option to which the switch can connect. When the switch cannot communicate with an entity that provides a specified service option, it attempts to use the next option in the list.

The available service options include:
- a named server group
- all defined TACACS+ hosts
- all defined RADIUS hosts
- local authentication
- no authentication

When the list is not configured, it is set to `none`, allowing all CLI access attempts to succeed.

The `no aaa authorization exec` and `default aaa authorization exec` commands set the list contents to `none`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
aaa authorization exec default METHOD_1 [METHOD_2] ... [METHOD_N]
no aaa authorization exec default
default aaa authorization exec default
```

**Parameters**
- `METHOD_X` authorization service (method). The switch uses the first listed available method.
  - The command must provide at least one method. Each method is composed of one of the following:
    - `group name` the server group identified by `name`.
    - `group radius` a server group that consists of all defined RADIUS hosts.
    - `group tacacs+` a server group that consists of all defined TACACS+ hosts.
    - `local` local authentication.
    - `none` the switch does not perform authorization. All access attempts succeed.

**Guidelines**

During the exec authorization process, the TACACS+ server response may include attribute-value (AV) pairs. The switch recognizes `priv-lvl=x` (where `x` is an integer between 0 and 15), which is a mandatory AV pair. A TACACS+ server that sends any other mandatory AV pair is denied access to the switch. The receipt of optional AV pairs by the switch has no affect on decisions to permit or deny access to the TACACS+ server.

**Example**
- This command specifies that the TACACS+ servers authorize users that attempt to open an EOS CLI shell.

  ```
  switch(config)#aaa authorization exec default group tacacs+
  switch(config)#
  ```
aaa authorization policy local default-role

The **aaa authorization policy local** command specifies the name of the default role. A role is a data structure that supports local command authorization through its assignment to user accounts. Roles consist of permit and deny rules that define authorization levels for specified commands. Applying a role to a username authorizes the user to execute commands specified by the role.

The default role is assigned to the following users:

- local or remote users assigned to a role that is not configured.
- local users to whom a role is not assigned.

When the default-role is not specified, **network-operator** is assigned to qualified users as the default role. The network-operator role authorizes assigned users access to all CLI commands in EXEC and Privileged EXEC modes.

The **no aaa authentication policy local default-role** and **default aaa authorization policy local default-role** commands remove the **authentication policy local default-role** statement from **running-config**. Removing this statement restores **network-operator** as the default role.

**Command Mode**

Global Configuration

**Command Syntax**

```
aaa authorization policy local default-role role_name
no aaa authorization policy local default-role
default aaa authorization policy local default-role
```

**Parameters**

- **role_name** Name of the default role.

**Related Commands**

The **role** command places the switch in role configuration mode for creating and editing roles.

**Examples**

- This command configures the sysuser as the default role.

  ```
  switch(config)#aaa authorization policy local default-role sysuser
  switch(config)#
  ```

- This command restores **network-operator** as the default role.

  ```
  switch(config)#no aaa authorization policy local default-role
  switch(config)#
  ```

- This command displays the contents of the **network-operator** role.

  ```
  switch#show role network-operator
  The default role is network-operator
  
  role: network-operator
  10 deny mode exec command bash\|\|
  20 permit mode exec command .*
  
  switch#
  ```
aaa group server radius

The `aaa group server radius` command enters the server-group-radius configuration mode for the specified group name. The command creates the specified group if it was not previously created. Commands are available to add servers to the group.

A server group is a collection of servers that are associated with a single label. Subsequent authorization and authentication commands access all servers in a group by invoking the group name. Server group members must be previously configured with a `radius-server host` command.

The `no aaa group server radius` and `default aaa group server radius` commands delete the specified server group from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
aaa group server radius group_name
no aaa group server radius group_name
default aaa group server radius group_name
```

**Parameters**

- `group_name` name (text string) assigned to the group. Cannot be identical to a name already assigned to a TACACS+ server group.

**Commands Available in server-group-radius Configuration Mode**

- `server (server-group-RADIUS configuration mode)`

**Related Commands**

- `aaa group server tacacs+`

**Example**

- This command creates the RADIUS server group named RAD-SV1 and enters server group configuration mode for the new group.

```
switch(config)#aaa group server radius RAD-SV1
switch(config-sg-radius-RAD-SV1)#
```
aaa group server tacacs+

The `aaa group server tacacs+` command enters server-group-tacacs+ configuration mode for the specified group name. The command creates the specified group if it was not previously created. Commands are available to add servers to the group.

A server group is a collection of servers that are associated with a single label. Subsequent authorization and authentication commands access all servers in a group by invoking the group name. Server group members must be previously configured with a `tacacs-server host` command.

The `no aaa group server tacacs+` and `default aaa group server tacacs+` commands delete the specified server group from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
    aaa group server tacacs+ group_name
    no aaa group server tacacs+ group_name
    default aaa group server tacacs+ group_name
```

Parameters
- `group_name` name (text string) assigned to the group. Cannot be identical to a name already assigned to a RADIUS server group.

Commands Available in server-group-tacacs+ Configuration Mode
- `server` (server-group-TACACS+ configuration mode)

Related Commands
- `aaa group server radius`

Example
- This command creates the TACACS+ server group named TAC-GR and enters server group configuration mode for the new group.

```
switch(config)#aaa group server tacacs+ TAC-GR
switch(config-sg-tacacs+-TAC-GR)#
```
aaa root

The `aaa root` command specifies the password security level for the root account and can assign a password to the account.

The `no aaa root` and `default aaa root` commands disable the root account by removing the `aaa root` command from `running-config`. The root account is disabled by default.

**Command Mode**

Global Configuration

**Command Syntax**

```
aaa root  SECURITY_LEVEL [ENCRYPT_TYPE] [password]
no aaa root
default aaa root
```

**Parameters**

- `SECURITY_LEVEL` password assignment level. Settings include
  - `secret` the root account is assigned to the password.
  - `nopassword` the root account is not password protected.
- `ENCRYPT_TYPE` encryption level of the `password` parameter. This parameter is present only when `SECURITY_LEVEL` is `secret`. Settings include:
  - `<no parameter>` the password is entered as clear text.
  - `0` the password is entered as clear text. Equivalent to `<no parameter>`.
  - `5` the password is entered as an md5 encrypted string.
  - `sha512` the password is entered as an sha512 encrypted string.
- `password` text that authenticates the username. The command includes this parameter only if `SECURITY_LEVEL` is `secret`.
  - `password` must be in clear text if `ENCRYPT_TYPE` specifies clear text.
  - `password` must be an appropriately encrypted string if `ENCRYPT_TYPE` specifies encryption.

Encrypted strings entered through this parameter are generated elsewhere.

**Examples**

- These equivalent commands assign `f4980` as the root account password.
  ```
  switch(config)#aaa root secret f4980
  switch(config)#aaa root secret 0 f4980
  ```

- This command assigns the text (ab234) that corresponds to the encrypted string of `$1$HW05LEY8$QEVEw6JqD9VqDfDh.O8r.b` as the root password.
  ```
  switch(config)#aaa root secret 5 $1$HW05LEY8$QEVEw6JqD9VqDfDh.O8r.b
  ```

- This command removes the password from the root account.
  ```
  switch(config)#aaa root nopassword
  ```

- This command disables the root login.
  ```
  switch(config)#no aaa root
  ```
clear aaa counters

The **clear aaa counters** command resets the counters that track the number of service transactions performed by the switch since the last time the counters were reset. The **show aaa counters** command displays the counters reset by the **clear aaa counters** command.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
clear aaa counters [SERVICE_TYPE]
```

**Example**

- These commands display the effect of the **clear aaa counters** command on the aaa counters.

```
switch#clear aaa counters
switch#show aaa counters
Authentication
   Successful: 0
   Failed: 0
   Service unavailable: 0
Authorization
   Allowed: 1
   Denied: 0
   Service unavailable: 0
Accounting
   Successful: 0
   Error: 0
   Pending: 0

Last time counters were cleared: 0:00:44 ago
```
clear aaa counters radius

The `clear aaa counters radius` command resets the counters that track the statistics for the RADIUS servers that the switch accesses. The `show radius` command displays the counters reset by the `clear aaa counters radius` command.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear aaa counters radius
```

**Example**
- These commands display the effect of the `clear aaa counters radius` command on the RADIUS counters.

```plaintext
switch# show radius
RADIUS server            : radius/10
  Connection opens:        204
  Connection closes:        0
  Connection disconnects:    199
  Connection failures:       10
  Connection timeouts:       2
  Messages sent:            1490
  Messages received:        1490
  Receive errors:           0
  Receive timeouts:         0
  Send timeouts:            0

Last time counters were cleared: never

switch# clear aaa counters radius
switch# show radius
RADIUS server            : radius/10
  Connection opens:         0
  Connection closes:         0
  Connection disconnects:    0
  Connection failures:       0
  Connection timeouts:       0
  Messages sent:             0
  Messages received:         0
  Receive errors:            0
  Receive timeouts:          0
  Send timeouts:             0

Last time counters were cleared: 0:00:03 ago
switch#
```
clear aaa counters tacacs+

The **clear aaa counters tacacs+** command resets the counters that track the statistics for the TACACS+ servers that the switch accesses. The **show tacacs** command displays the counters reset by the **clear aaa counters tacacs+** command.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
clear aaa counters tacacs+
```

**Example**

- These commands display the effect of the **clear aaa counters tacacs+** command on the tacacs+ counters.

  ```
  switch#show tacacs
  TACACS+ server : tacacs/49
  Connection opens: 15942
  Connection closes: 7
  Connection disconnects: 1362
  Connection failures: 0
  Connection timeouts: 0
  Messages sent: 34395
  Messages received: 34392
  Receive errors: 0
  Receive timeouts: 2
  Send timeouts: 0

  Last time counters were cleared: never

  TACACS+ source-interface: Enabled
  TACACS+ outgoing packets will be sourced with an IP address associated with the Loopback0 interface
  switch#clear aaa counters tacacs+
  switch#show tacacs
  TACACS+ server : tacacs/49
  Connection opens: 0
  Connection closes: 0
  Connection disconnects: 0
  Connection failures: 0
  Connection timeouts: 0
  Messages sent: 0
  Messages received: 0
  Receive errors: 0
  Receive timeouts: 0
  Send timeouts: 0

  Last time counters were cleared: 0:00:03 ago
  switch#
  ```

  TACACS+ source-interface: Enabled
  TACACS+ outgoing packets will be sourced with an IP address associated with the Loopback0 interface
  switch#
deny (Role)

The `deny` command adds a deny rule to the configuration mode role. Deny rules prohibit access of specified commands from usernames to which the role is applied. Sequence numbers determine rule placement in the role. Commands are compared sequentially to rules within a role until it matches a rule. A command’s authorization is determined by the first rule it matches. Sequence numbers for commands without numbers are derived by adding 10 to the number of the role’s last rule.

Deny rules use regular expression to denote commands. A `mode` parameter specifies command modes from which commands are restricted. Modes are denoted either by predefined keywords, a command mode’s short key, or a regular expression that specifies the long key of one or more command modes.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode role. The `no <sequence number> (Role)` command also removes the specified rule from the role.

Command Mode

Role Configuration

Command Syntax

```
[SEQ_NUM] deny [MODE_NAME] command command_name
no deny [MODE_NAME] command command_name
default deny [MODE_NAME] command command_name
```

Parameters

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - `<no parameter>`  Number is derived by adding 10 to the number of the role’s last rule.
  - `<1 – 256>`  Number assigned to entry.
- **MODE_NAME**  Command mode from which command access is prohibited. Values include:
  - `<no parameter>`  All command modes
  - `mode short_name`  Exact match of a mode’s short key name.
  - `mode long_name`  Regular expression matching long key name of one or more modes.
  - `mode config`  Global configuration mode.
  - `mode config-all`  All configuration modes, including global configuration mode.
  - `mode exec`  EXEC and Privileged EXEC modes.
  - `command_name`  Regular expression that denotes the name of one or more commands.

Guidelines

These CLI prompt format commands program the prompt to display the following mode keys:

- `%p`  short mode key.
- `%P`  long mode key.

Deny statements are saved to `running-config` only upon exiting role configuration mode.

Related Commands

The `role` command places the switch in role configuration mode.
Example

- These commands append a deny rule at the end of the `sysuser` role that restricts access to the `reload` command from EXEC and Privileged EXEC mode.

```
switch(config)#role sysuser
switch(config-mode-sysuser)#deny mode exec command reload
switch(config-mode-sysuser)#
```
enable secret

The enable secret command creates a new enable password or changes an existing password. The no enable secret and default enable secret commands delete the enable password by removing the enable secret command from running-config.

Command Mode
Global Configuration

Command Syntax

```
enable secret [ENCRYPT_TYPE] password
no enable secret
default enable secret
```

Parameters

- **ENCRYPT_TYPE** encryption level of the password parameter. Settings include:
  - <no parameter> the password is entered as clear text.
  - 0 the password is entered as clear text. Equivalent to <no parameter>.
  - 5 the password is entered as an md5 encrypted string.
  - sha512 the password is entered as an sha512 encrypted string.
- **password** text that authenticates the username.
  - password must be in clear text if ENCRYPT_TYPE specifies clear text.
  - password must be an appropriately encrypted string if ENCRYPT_TYPE specifies encryption.

Encrypted strings entered through this parameter are generated elsewhere.

Examples

- These equivalent commands assign xyrt1 as the enable password.
  ```
  switch(config)#enable secret xyrt1
  switch(config)#enable secret 0 xyrt1
  ```
- This command assigns the enable password to the clear text (12345) that corresponds to the encrypted string $1$8bPBrJnd$Z8wbKLPJe7d4tc5Z/6h/. The string was generated by an MD5-encryption program using 12345 as the seed.
  ```
  switch(config)#enable secret 5 $1$8bPBrJnd$Z8wbKLPJe7d4tc5Z/6h/
  ```
- This command deletes the enable password.
  ```
  switch(config)#no enable secret
  ```
ip radius source-interface

The **ip radius source-interface** command specifies the interface from which the IPv4 address is derived for use as the source for outbound RADIUS packets. When a source interface is not specified, the switch selects an interface.

The **no ip radius source-interface** and **default ip radius source-interface** commands remove the **ip radius source-interface** command from *running-config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip radius [VRF_INST] source-interface INT_NAME
no ip radius [VRF_INST] source-interface
default ip radius [VRF_INST] source-interface
```

**Parameters**

- **VRF_INST** specifies the VRF instance used to communicate with the specified server.
- **<no parameter>** switch communicates with the server using the default VRF.
- **vrf vrf_name** switch communicates with the server using the specified user-defined VRF.
- **INT_NAME** Interface type and number. Options include:
  - **interface ethernet e_num** Ethernet interface specified by *e_num*.
  - **interface loopback l_num** Loopback interface specified by *l_num*.
  - **interface management m_num** Management interface specified by *m_num*.
  - **interface port-channel p_num** Port-Channel Interface specified by *p_num*.
  - **interface vlan v_num** VLAN interface specified by *v_num*.

**Example**

- This command configures the source address for outbound RADIUS packets as the IPv4 address assigned to the loopback interface.

```
switch(config)#ip radius source-interface loopback 0
switch(config)#
```
ip tacacs source-interface

The `ip tacacs source-interface` command specifies the interface from which the IPv4 address is derived for use as the source for outbound TACACS+ packets. When a source interface is not specified, the switch selects an interface.

The `no ip tacacs source-interface` and `default ip tacacs source-interface` commands remove the `ip tacacs source-interface` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip tacacs [VRF_INST] source-interface INT_NAME  
no ip tacacs [VRF_INST] source-interface  
default ip tacacs [VRF_INST] source-interface
```

**Parameters**

- `VRF_INST` specifies the VRF instance used to communicate with the specified server.
- `<no parameter>` switch communicates with the server using the default VRF.
- `vrf vrf_name` switch communicates with the server using the specified user-defined VRF.
- `INT_NAME` Interface type and number. Options include:
  - `interface ethernet e_num` Ethernet interface specified by `e_num`.
  - `interface loopback l_num` Loopback interface specified by `l_num`.
  - `interface management m_num` Management interface specified by `m_num`.
  - `interface port-channel p_num` Port-Channel Interface specified by `p_num`.
  - `interface vlan v_num` VLAN interface specified by `v_num`.

**Example**

- This command configures the source address for outbound TACACS+ packets as the IPv4 address assigned to the loopback interface.

```bash
switch(config)#ip tacacs source-interface loopback 0
switch(config)#
```
no <sequence number> (Role)

The no <sequence number> command removes the rule with the specified sequence number from the configuration mode role. The default <sequence number> command also removes the specified rule.

Command Mode

Role Configuration

Command Syntax

```
no sequence_num
default sequence_num
```

Parameters

- `sequence_num` sequence number of rule to be deleted. Values range from 1 to 256.

Guidelines

Role statement changes are saved to running-config only upon exiting role configuration mode.

Related Commands

The role command places the switch in role configuration mode.

Example

- These commands display the rules in the sysuser role, removes rule 30 from the role, then displays the edited role.

  ```
  switch(config)#show role sysuser
  The default role is network-operator

  role: sysuser
     10 deny mode exec command reload
     20 deny mode config command (no |default )?router
     30 deny mode config command (no |default )?(ip|mac) access-list
     40 deny mode if command (no |default )?(ip|mac) access-group
     50 deny mode config-all command lacp|spanning-tree
     60 permit command .*
  switch(config)#role sysuser
  switch(config-role-sysuser)#no 30
  switch(config-role-sysuser)#exit
  switch(config)#show role sysuser
  The default role is network-operator

  role: sysuser
     10 deny mode exec command reload
     20 deny mode config command (no |default )?router
     40 deny mode if command (no |default )?(ip|mac) access-group
     50 deny mode config-all command lacp|spanning-tree
     60 permit command .*
  switch(config)#
  ```
permit (Role)

The `permit` command adds a permit rule to the configuration mode role. Permit rules authorize access to specified commands for usernames to which the role is applied. Sequence numbers determine rule placement in the role. Commands are compared sequentially to rules within a role until it matches a rule. A command’s authorization is determined by the first rule it matches. Sequence numbers for commands without numbers are derived by adding 10 to the number of the role’s last rule.

Permit rules use regular expression to denote commands. A `mode` parameter specifies command modes in which commands are authorized. Modes are denoted either by predefined keywords, a command mode’s short key, or a regular expression that specifies the long key of one or more command modes.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode role. The `no <sequence number> (Role)` command also removes the specified rule from the role.

Command Mode

Role Configuration

Command Syntax

```
[SEQ_NUM] permit [MODE_NAME] command command_name
no permit [MODE_NAME] command command_name
default permit [MODE_NAME] command command_name
```

Parameters

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - `<no parameter>`  Number is derived by adding 10 to the number of the role’s last rule.
  - `<1 – 256>`  Number assigned to entry.
- **MODE_NAME**  Command mode in which command access is authorized. Values include:
  - `<no parameter>`  All command modes
  - `mode short_name`  Exact match of a mode’s short key name.
  - `mode long_name`  Regular expression matching long key name of one or more modes.
  - `mode config`  Global configuration mode.
  - `mode config-all`  All configuration modes, including global configuration mode.
  - `mode exec`  EXEC and Privileged EXEC modes.
  - `command_name`  Regular expression that denotes the name of one or more commands.

Guidelines

These CLI prompt format commands program the prompt to display the following mode keys:

- `%p`  short mode key.
- `%P`  long mode key.

Permit statements are saved to `running-config` only upon exiting role configuration mode.

Related Commands

The `role` command places the switch in role configuration mode.
Example

• These commands append a permit rule at the end of the sysuser role that authorizes all commands from VLAN 1 or VLAN 2 interface configuration modes.

  switch(config)#role sysuser
  switch(config-mode-sysuser)#permit mode if-Vl(1|2) command .*
  switch(config-mode-sysuser)#
radius-server deadtime

The `radius-server deadtime` command defines global deadtime period, when the switch ignores a non-responsive RADIUS server. A non-responsive server is one that failed to answer any attempt to retransmit after a timeout expiry. Deadtime is disabled if a value is not configured.

The `no radius-server deadtime` and `default radius-server deadtime` commands restore the default global deadtime period of three minutes by removing the `radius-server deadtime` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
radius-server deadtime dead_interval
no radius-server deadtime
default radius-server deadtime
```

Parameters

- `dead_interval` period that the switch ignores non-responsive servers (minutes). Value ranges from 1 to 1000. Default is 3.

Related Commands
- `radius-server host`

Example

- This command programs the switch to ignore a server for two hours if it fails to respond to a request during the period defined by timeout and retransmit parameters.

```
switch(config)#radius-server deadtime 120
switch(config)#
```
radius-server host

The `radius-server host` command sets parameters for communicating with a specific RADIUS server. These values override global settings when the switch communicates with the specified server.

A RADIUS server is defined by its server address, authorization port, and accounting port. Servers with different address-authorization port-accounting port combinations have separate configurations.

The `no radius-server host` and `default radius-server` commands remove settings for the RADIUS server configuration at the specified address-authorization port-accounting port location by deleting the corresponding `radius-server host` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
radius-server host ADDR [VRF_INST] [AUTH] [ACCT] [TIMEOUT] [DEAD] [RETRAN] [ENCRYPT]
no radius-server host [ADDR][VRF_INST][AUTH][ACCT]
derefault radius-server host [ADDR][VRF_INST][AUTH][ACCT]
```

**Parameters**

- **ADDR**  
  RADIUS server location. Options include:
  - `ipv4_addr`  
    server’s IPv4 address.
  - `host_name`  
    server’s DNS host name (FQDN).
- **VRF_INST**  
  specifies the VRF instance used to communicate with the specified server.
  - `<no parameter>`  
    switch communicates with the server using the default VRF.
  - `vrf vrf_name`  
    switch communicates with the server using the specified user-defined VRF.
- **AUTH**  
  Authorization port number.
  - `<no parameter>`  
    default port of 1812.
  - `auth-port number`  
    `number` ranges from 1 to 65535.
- **ACCT**  
  Accounting port number.
  - `<no parameter>`  
    default port of 1813.
  - `acct-port number`  
    `number` ranges from 1 to 65535.
- **TIMEOUT**  
  timeout period (seconds). Ranges from 1 to 1000.
  - `<no parameter>`  
    assigns global timeout value (see `radius-server timeout`).
  - `timeout number`  
    assigns `number` as the timeout period. Ranges from 1 to 1000.
- **DEAD**  
  period (minutes) when the switch ignores a non-responsive RADIUS server.
  - `<no parameter>`  
    assigns global deadtime value (see `radius-server deadtime`).
  - `deadtime number`  
    specifies deadtime, where `number` ranges from 1 to 1000.
- **RETRAN**  
  attempts to access RADIUS server after the first timeout expiry.
  - `<no parameter>`  
    assigns global retransmit value (see `radius-server retransmit`).
  - `retransmit number`  
    specifies number of attempts, where `number` ranges from 1 to 100.
- **ENCRYPT**  
  encryption key that switch and server use to communicate.
  - `<no parameter>`  
    assigns global encryption key (see `radius-server key`).
  - `key key_text`  
    where `key_text` is in clear text.
  - `key 5 key_text`  
    where `key_text` is in clear text.
  - `key 7 key_text`  
    where `key_text` is provide in an encrypted string.
Examples

- This command configures the switch to communicate with the RADIUS server located at \textit{10.1.1.5}. The switch uses the global timeout, deadtime, retransmit, and key settings to communicate with this server, and communicates through port 1812 for authorization and 1813 for accounting.

  \begin{verbatim}
  switch(config)#radius-server host 10.1.1.5
  switch(config)#
  \end{verbatim}

- This command configures the switch to communicate with the RADIUS server assigned the host name \textit{RAD-1}. Communication for authorization is through port 1850; communication for accounting is through port 1813 (the default).

  \begin{verbatim}
  switch(config)#radius-server host RAD-1 auth-port 1850
  switch(config)#
  \end{verbatim}
radius-server key

The `radius-server key` command defines the global encryption key the switch uses when communicating with any RADIUS server for which a key is not defined.

The `no radius-server key` and `default radius-server key` commands remove the global key from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
radius-server key [ENCRYPT_TYPE] encrypt_key
no radius-server key
default radius-server key
```

**Parameters**

- `ENCRYPT_TYPE` encryption level of `encrypt_key`.
  - `<no parameter>` encryption key is entered as clear text.
  - `0` encryption key is entered as clear text. Equivalent to `<no parameter>`.
  - `7` `encrypt_key` is an encrypted string.
- `encrypt_key` shared key that authenticates the username.
  - `encrypt_key` must be in clear text if `ENCRYPT_TYPE` specifies clear text.
  - `encrypt_key` must be an encrypted string if `ENCRYPT_TYPE` specifies an encrypted string.

Encrypted strings entered through this parameter are generated elsewhere.

**Related Commands**
- `radius-server host`

**Examples**

- This command configures `cv90jr1` as the global encryption key.
  ```
  switch(config)#radius-server key 0 cv90jr1
  switch(config)#
  ```

- This command assigns `cv90jr1` as the key by specifying the corresponding encrypted string.
  ```
  switch(config)#radius-server key 7 020512025B0C1D70
  switch(config)#
  ```
radius-server retransmit

The `radius-server retransmit` command defines the global retransmit count, which specifies the number of times the switch attempts to access the RADIUS server after the first timeout expiry.

The `no radius-server retransmit` and `default radius-server retransmit` commands restore the global retransmit count to its default value of three by deleting the `radius-server retransmit` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
radius-server retransmit count
no radius-server retransmit
default radius-server retransmit
```

**Parameters**
- `count` retransmit attempts after first timeout expiry. Settings range from 1 to 100. Default is 3.

**Related Commands**
- `radius-server host`

**Example**
- This command configures the switch to attempt five RADIUS server contacts after the initial timeout. If the timeout parameter is set to 50 seconds, then the total period that the switch waits for a response is 
\[(5+1) \times 50\] = 300 seconds.

```
switch(config)#radius-server retransmit 5
switch(config)#
```
radius-server timeout

The `radius-server timeout` command defines the global timeout the switch uses when communicating with any RADIUS server for which a timeout is not defined.

The `no radius-server timeout` and `default radius-server timeout` commands restore the global timeout default period of five seconds by removing the `radius-server timeout` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
radius-server timeout time_period
no radius-server timeout
default radius-server timeout
```

**Parameters**

- `time_period` timeout period (seconds). Range from 1 to 1000. Default is 5.

**Related Commands**

- `radius-server host`
- `radius-server key`
- `radius-server deadtime`
- `radius-server retransmit`

**Example**

- This command configures the switch to wait 50 seconds for a RADIUS server response before issuing an error.

```
switch(config)#radius-server timeout 50
switch(config)#
```
**resequence (Role)**

The `resequence` command assigns sequence numbers to rules in the configuration mode role. Command parameters specify the number of the first rule and the numeric interval between consecutive rules.

The maximum sequence number is 256.

**Command Mode**

Role Configuration

**Command Syntax**

```
resequence start_num inc_num
```

**Parameters**

- `start_num` sequence number assigned to the first rule. Value ranges from 1 to 256. Default is 10.
- `inc_num` numeric interval between consecutive rules. Value ranges from 1 to 256. Default is 10.

**Guidelines**

Role statement changes are saved to `running-config` only upon exiting role configuration mode.

**Related Commands**

The `role` command places the switch in role configuration mode.

**Example**

- The `resequence` command renumbers the rules in the sysuser role, starting the first rule at 15 and incrementing subsequent lines by 5.

  ```
  switch(config)#show role sysuser
  The default role is network-operator

  role: sysuser
  10 deny mode exec command reload
  20 deny mode config command (no |default )?router
  40 deny mode if command (no |default )?(ip|mac) access-group
  50 deny mode config-all command lacp|spanning-tree
  60 permit command .*
  switch(config)#role sysuser
  switch(config-role-sysuser)#resequence 15 5
  switch(config-role-sysuser)#exit
  switch(config)#show role sysuser
  The default role is network-operator

  role: sysuser
  15 deny mode exec command reload
  20 deny mode config command (no |default )?router
  25 deny mode if command (no |default )?(ip|mac) access-group
  30 deny mode config-all command lacp|spanning-tree
  35 permit command .*
  switch(config)#role sysuser
  ```
role

The `role` command places the switch in role configuration mode, which is a group change mode that modifies a role. A role is a data structure that supports local command authorization through its assignment to user accounts. Roles consist of permit and deny rules that define authorization levels for specified commands. Applying a role to a username authorizes the user to execute commands specified by the role.

The `role` command specifies the name of the role that subsequent commands modify and creates a role if it references a nonexistent role. All changes in a group change mode edit session are pending until the session ends:

- The `exit` command saves pending changes to `running-config` and returns the switch to global configuration mode. Changes are also saved by entering a different configuration mode.
- The `abort` command discards pending changes, returning the switch to global configuration mode.

The `no role` and `default role` commands delete the specified role by removing the role and its statements from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
role role_name
no role role_name
default role role_name
```

**Parameters**

- `role_name` Name of role.

**Commands Available in Role configuration mode:**

- `deny (Role)`
- `permit (Role)`
- `no <sequence number> (Role)`
- `resequence (Role)`

**Related Commands**

- `show role`

**Examples**

- This command places the switch in role configuration mode to modify the speaker role.
  ```
  switch(config)#role speaker
  switch(config-role-speaker)#
  ```

- This command saves changes to `speaker` role, then returns the switch to global configuration mode.
  ```
  switch(config-role-speaker)#exit
  switch(config)#
  ```

- This command discards changes to `speaker`, then returns the switch to global configuration mode.
  ```
  switch(config-role-speaker)#abort
  switch(config)#
  ```
server (server-group-RADIUS configuration mode)

The `server (server-group-RADIUS configuration mode)` command adds the specified RADIUS server to the configuration mode group. Servers must be configured with the `radius-server host` command before adding them to the server group.

A RADIUS server is defined by its server address, authorization port, and accounting port. A group can contain multiple servers with the same IP address that have different authorization or accounting ports.

The `no server` and `default server` commands remove the specified server from the group.

**Command Mode**

Server-Group-RADIUS Configuration

**Command Syntax**

```
server LOCATION [VRF_INST] [AUTH] [ACCT]
no server LOCATION [VRF_INST] [AUTH] [ACCT]
default server LOCATION [VRF_INST] [AUTH] [ACCT]
```

**Parameters**

- **LOCATION**  RADIUS server location. Options include:
  - `ipv4_addr`  server’s IPv4 address.
  - `host_name`  server’s DNS host name (FQDN).
- **VRF_INST**  specifies the VRF instance used to communicate with the specified server.
  - `<no parameter>`  switch communicates with the server using the default VRF.
  - `vrf vrf_name`  switch communicates with the server using the specified user-defined VRF.
- **AUTH**  Authorization port number.
  - `<no parameter>`  default port of 1812.
  - `auth-port number`  number ranges from 1 to 65535.
- **ACCT**  Accounting port number.
  - `<no parameter>`  default port of 1813.
  - `acct-port number`  number ranges from 1 to 65535.

**Related Commands**

The `aaa group server radius` command places the switch in server-group-radius configuration mode.

**Example**

- These commands add two servers to the RAD-SV1 server group.

```
switch(config)#aaa group server radius RAD-SV1
switch(config-sg-radius-RAD-SV1)#server RAC-1
switch(config-sg-radius-RAD-SV1)#server 10.1.5.14 acct-port 1851
switch(config-sg-radius-RAD-SV1)#
```
server (server-group-TACACS+ configuration mode)

The `server (server-group-TACACS+ configuration mode)` command adds the specified TACACS+ server to the configuration mode group. Servers must be configured with the `tacacs-server host` command before adding them to the server group.

A TACACS+ server is defined by its server address and port number. Servers with different address-port combinations have separate statements in `running-config`.

The `no server` and `default server` commands remove the specified server from the group.

Command Mode

Server-Group-TACACS+ Configuration

Command Syntax

```
server LOCATION [VRF_INST] [PORT]
no server LOCATION [VRF_INST] [PORT]
default server LOCATION [VRF_INST] [PORT]
```

Parameters

- **LOCATION**  TACACS+ server location. Options include:
  - `ipv4_addr`  server’s IPv4 address.
  - `ipv6_addr`  server’s IPv6 address.
  - `host_name`  server’s DNS host name (FQDN).
- **VRF_INST**  specifies the VRF instance used to communicate with the specified server.
  - `<no parameter>`  switch communicates with the server using the default VRF.
  - `vrf vrf_name`  switch communicates with the server using the specified user-defined VRF.
- **PORT**  TCP connection port number.
  - `<no parameter>`  default port of 49.
  - `port number number`  ranges from 1 to 65535.

Related Commands

The `aaa group server tacacs+` command places the switch in server-group-radius configuration mode.

Example

- These commands add two servers to the TAC-GR server group with default port number 49.

```
switch(config)#aaa group server tacacs+ TAC-GR
switch(config-sg-tacacs+-TAC-GR)#server TAC-1
switch(config-sg-tacacs+-TAC-GR)#server 10.1.4.14
switch(config-sg-tacacs+-TAC-GR)#
```
show aaa

The `show aaa` command displays the user database. The command displays the encrypted enable password first, followed by a table of usernames and their corresponding encrypted password. The command does not display unencrypted passwords.

**Command Mode**
Privileged EXEC

**Command Syntax**
`show aaa`

**Example**
- This command configures the switch to authenticate the enable password through all configured TACACS+ servers. Local authentication is the backup if TACACS+ servers are unavailable.

```
switch#show aaa
Enable password (encrypted): $1$UL4gDWy6$3KqCPYPGRVxDUG3gA/Hs/
Username  Encrypted passwd
--------  ----------------------------------
admin     $1$VVnDH/Ea$iwsfnrGNO8nbDsf0tazp9/
thomas    $1$/MmXTUil$.fJxLfcumzppNSEDVDWq9.
switch#
```
show aaa counters

The `show aaa counters` command displays the number of service transactions performed by the switch since the last time the counters were reset.

Command Mode
Privileged EXEC

Command Syntax
`show aaa counters`

Example
- This command displays the number of authentication, authorization, and accounting transactions.

```
switch#show aaa counters
Authentication
    Successful: 30
    Failed: 0
    Service unavailable: 0

Authorization
    Allowed: 188
    Denied: 0
    Service unavailable: 0

Accounting
    Successful: 0
    Error: 0
    Pending: 0

Last time counters were cleared: never
switch#
```
show aaa method-lists

The `show aaa method-lists` command displays all the named method lists defined in the specified authentication, authorization, and accounting (AAA) service.

**Command Mode**

Privileged EXEC

**Command Syntax**

`show aaa method-lists SERVICE_TYPE`

**Parameters**

- `SERVICE_TYPE` the service type of the method lists that the command displays.
  - `accounting` accounting services.
  - `authentication` authentication services.
  - `authorization` authorization services.
  - `all` accounting, authentication, and authorization services.

**Example**

- This command configures the named method lists for all AAA services.

```
switch#show aaa method-lists all
Authentication method lists for LOGIN:
   name=default methods=group tacacs+, local
Authentication method list for ENABLE:
   name=default methods=local
Authorization method lists for COMMANDS:
   name=privilege0-15 methods=group tacacs+, local
Authentication method list for EXEC:
   name=exec methods=group tacacs+, local
Accounting method lists for COMMANDS:
   name=privilege0-15 default-action=none
Accounting method list for EXEC:
   name=exec default-action=none
switch#
```
**show aaa sessions**

The `show aaa sessions` command displays information about active AAA login sessions. Information includes username, roles, TTY, state of the session (pending or established), duration, authentication method, and if available, remote host and remote username.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show aaa sessions
```

**Example**

- This command displays information about the active AAA login sessions.

```
switch# show aaa session
Session Username Roles           TTY    State Duration  Auth          Remote Host
-------   ---------- ------ ----- --------  ------------- ------------
2         admin     network-admin    ttyS0  E     0:01:21  local
4         joe       sysadmin         telnet E     0:02:01  local
                      sf.example.com
6         alice     sysadmin         ssh    E     0:00:52  group radius  ny.example.com
7         bob       sysadmin         ssh    E     0:00:48  group radius  la.example.com
8         kim       network-admin1   ssh    E     0:00:55  group radius  de.example.com
9         admin     network-admin   ssh    E     0:00:07  local         bj.example.com
10        max       network-admin   telnet E     0:00:07  local         sf.example.com
```
show privilege

The `show privilege` command displays the current privilege level for the CLI session.

**Command Mode**

EXEC

**Command Syntax**

```
show privilege
```

**Example**

- This command displays the current privilege level.
  ```
  switch>show privilege
  Current privilege level is 15
  switch>
  ```
**show radius**

The `show radius` command displays statistics for the RADIUS servers that the switch accesses.

**Command Mode**
EXEC

**Command Syntax**
`show radius`

**Example**
- This command displays statistics for connected TACACS+ servers.

```
switch>show radius
RADIUS server  : radius/10
    Connection opens: 204
    Connection closes: 0
    Connection disconnects: 199
    Connection failures: 10
    Connection timeouts: 2
    Messages sent: 1490
    Messages received: 1490
    Receive errors: 0
    Receive timeouts: 0
    Send timeouts: 0

Last time counters were cleared: never
switch>
```
**show role**

The `show role` command displays the name of the default role and the contents of the specified roles. Commands that do not specify a role display the rules in all built-in and configured roles.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show role [ROLE_LIST]
```

**Parameters**
- `ROLE_LIST` Roles that the command displays. Options include:
  - `<no parameter>` Command displays all roles.
  - `role_name` Name of role displayed by command.

**Related Commands**
The `role` command places the switch in role configuration mode, which is used to create new roles or modify existing roles.

**Example**
- This command displays the contents of all user-defined and built-in roles.

```
switch#show role
The default role is network-operator

role: network-admin
   10 permit command .*
role: network-operator
   10 deny mode exec command bash
   20 permit mode exec command .*
role: sysuser
   15 deny mode exec command reload
   20 deny mode config command (no |default )?router
   25 deny mode if command (no |default )?(ip|mac) access-group
   30 deny mode config-all command lacp|spanning-tree
   35 permit command .*
   40 deny mode exec command .*
   50 permit mode exec command show|clear (counters|platform)|configure

switch#
```
**show tacacs**

The **show tacacs** command displays statistics for the TACACS+ servers that the switch accesses.

**Command Mode**

EXEC

**Command Syntax**

```
show tacacs
```

**Example**

- This command displays statistics for connected TACACS+ servers.

```plaintext
switch>show tacacs
TACACS+ server       : tacacs/49
    Connection opens: 15942
    Connection closes: 7
    Connection disconnects: 1362
    Connection failures: 0
    Connection timeouts: 0
    Messages sent: 34395
    Messages received: 34392
    Receive errors: 0
    Receive timeouts: 2
    Send timeouts: 0

Last time counters were cleared: never

TACACS+ source-interface: Enabled
TACACS+ outgoing packets will be sourced with an IP address associated with the Loopback0 interface

switch>
```
show user-account

The `show user-account` command displays the names, roles, and privilege levels of users that are listed in `running-config`. The ssh public-key is also listed for names for which an SSH key is configured.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show user-account
```

**Example**

- This command displays the usernames that are configured on the switch.

```
switch# show user-account
user: FRED
  role: <unknown>
  privilege level: 1
  ssh public key: ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQDjUg2VDiBX7In0qHtN5PyH0wTvIoe2sxS5YmesQ/...admin@switch
switch#
user: JANE
  role: sysuser2
  privilege level: 1
user: admin
  role: network-admin
  privilege level: 1
```
show users

The show users command displays the usernames that are currently logged into the switch.

Command Mode
Privileged EXEC

Command Syntax

Example
- This command displays the users that are logged into the switch.

```
switch#show users
Line   User  Host(s)  Idle       Location
 1 vty 2  john  idle                       1d 10.22.6.113
 2 vty 4  jane  idle                 21:33:00  10.22.26.26
 3 vty 6  ted  idle               00:00:01  10.17.18.71

switch#
```
tacacs-server host

The `tacacs-server host` command sets communication parameters for communicating with a specific TACACS+ server. These values override global settings when the switch communicates with the specified server.

A TACACS+ server is defined by its server address and port number. Servers with different combinations of address-port-VRF-multiplex settings have separate statements in `running-config`.

The `no tacacs-server host` and `default tacacs-server host` commands remove settings for the TACACS+ server configuration at the specified address-port-VRF combination by deleting the corresponding `tacacs-server host` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
tacacs-server host SERVER_ADDR [MULTIPLEX] [VRF_INST] [PORT] [TIMEOUT] [ENCRYPT]
no tacacs-server host [SERVER_ADDR] [MULTIPLEX] [VRF_INST] [PORT]
default tacacs-server host [SERVER_ADDR] [MULTIPLEX] [VRF_INST] [PORT]
```

**Parameters**
- **SERVER_ADDR**  TACACS+ server location. Options include:
  - `ipv4_addr`  server’s IPv4 address.
  - `ipv6_addr`  server’s IPv6 address.
  - `host_name`  server’s DNS host name (FQDN).
- **MULTIPLEX**  TACACS+ server support of multiplex sessions on a TCP connection.
  - `<no parameter>`  server does not support multiplexing.
  - `single-connection`  server supports session multiplexing.
- **VRF_INST**  specifies the VRF instance used to communicate with the specified server.
  - `<no parameter>`  switch communicates with the server using the default VRF.
  - `vrf vrf_name`  switch communicates with the server using the specified user-defined VRF.
- **PORT**  port number of the TCP connection.
  - `<no parameter>`  default port of 49.
  - `port number`  `number` ranges from 1 to 65535.
- **TIMEOUT**  timeout period (seconds).
  - `<no parameter>`  assigns the globally configured timeout value (see `tacacs-server timeout`).
  - `timeout number`  `number` ranges from 1 to 1000.
- **ENCRYPT**  encryption key the switch and server use to communicate. Settings include
  - `<no parameter>`  assigns the globally configured encryption key (see `tacacs-server key`).
  - `key key_text`  where `key_text` is in clear text.
  - `key 5 key_text`  where `key_text` is in clear text.
  - `key 7 key_text`  where `key_text` is an encrypted string.
Examples

- This command configures the switch to communicate with the TACACS+ server located at 10.1.1.5. The switch uses the global timeout, encryption key, and port settings.

  switch(config)#tacacs-server host 10.1.1.5
  switch(config)#

- This command configures the switch to communicate with the TACACS+ server assigned the host name TAC_1. The switch defines the timeout period as 20 seconds and the encryption key as rp31E2v.

  switch(config)#tacacs-server host TAC_1 timeout 20 key rp31E2v
  switch(config)#

- This command configures the switch to communicate with the TACACS+ server located at 10.12.7.9, indicates that the server supports multiplexing sessions on the same TCP connection, and that access is through port 54.

  switch(config)#tacacs-server host 10.12.7.9 single-connection port 54
  switch(config)#
**tacacs-server key**

The `tacacs-server key` command defines the global encryption key the switch uses when communicating with any TACACS+ server for which a key is not defined.

The `no tacacs-server key` and `default tacacs-server key` commands remove the global key from running-config.

**Command Mode**
Global Configuration

**Command Syntax**
```
tacacs-server key [ENCRYPT_TYPE] encrypt_key
no tacacs-server key
default tacacs-server key
```

**Parameters**
- **ENCRYPT_TYPE** encryption level of `encrypt_key`.
  - `<no parameter>` encryption key is entered as clear text.
  - `0` encryption key is entered as clear text. Equivalent to `<no parameter>`.
  - `7` `encrypt_key` is an encrypted string.
- `encrypt_key` shared key that authenticates the username.
  - `encrypt_key` must be in clear text if `ENCRYPT_TYPE` specifies clear text.
  - `encrypt_key` must be an encrypted string if `ENCRYPT_TYPE` specifies an encrypted string.

Encrypted strings entered through this parameter are generated elsewhere.

**Related Commands**
- `tacacs-server host`

**Examples**
- This command configures `cv90jr1` as the encryption key.
  ```
  switch(config)#tacacs-server key 0 cv90jr1
  switch(config)#
  ```
- This command assigns `cv90jr1` as the key by specifying the corresponding encrypted string.
  ```
  switch(config)#tacacs-server key 7 020512025B0C1D70
  switch(config)#
  ```
tacacs-server policy

The **tacacs-server policy** command programs the switch to permit access to TACACS+ servers that send mandatory attribute-value (AV) pairs that the switch does not recognize. By default, the switch denies access to TACACS+ servers when it received unrecognized AV pairs from the server.

The switch recognizes the following mandatory AV pairs:

- `priv-lvl=x` where x is an integer between 0 and 15.

The **no tacacs-server policy** and **default tacacs-server policy** commands restore the switch default of denying access to servers from which it receives unrecognized mandatory AV pair by deleting the **tacacs-server policy** statement from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
tacacs-server policy unknown-mandatory-attribute ignore
no tacacs-server policy unknown-mandatory-attribute ignore
default tacacs-server policy unknown-mandatory-attribute ignore
```

**Example**

- This command configures the switch to permit access to TACACS+ servers that send unrecognized mandatory AV pairs.

  ```
  switch(config)#tacacs-server policy unknown-mandatory-attribute ignore
  switch(config)#
  ```
**tacacs-server timeout**

The `tacacs-server timeout` command defines the global timeout the switch uses when communicating with any TACACS+ server for which a timeout is not defined.

The `no tacacs-server timeout` and `default tacacs-server timeout` commands restore the global timeout default period of five seconds by removing the `tacacs-server timeout` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
tacacs-server timeout time_period
no tacacs-server timeout
default tacacs-server timeout
```

**Parameters**

- `time_period` timeout period (seconds). Settings range from 1 to 1000. Default is 5.

**Related Commands**

- `tacacs-server host`

**Example**

- This command configures the switch to wait 20 seconds for a TACACS+ server response before issuing an error.

```
switch(config)#tacacs-server timeout 20
switch(config)#
```
username

The **username** command adds a username to the local file and assigns a password to a username. If the command specifies an existing username, the command replaces the password in the local file. The command can define a username without a password or remove the password from a username.

The **no username** and **default username** commands delete the specified username by removing the corresponding **username** statement from **run-ning-config**.

The **no username role** command assigns the default role assignment to the specified **username** statement by editing the corresponding **username** statement in **running-config**. The **default username role** command reverts the specified username to its default role by editing the corresponding **username** statement in **running-config**. For the admin username, this restores **network-admin** as its role.

**Command Mode**

Global Configuration

**Command Syntax**

```
username name [PRIVILEGE_LEVEL] SECURITY [ROLE_USER]
no username name [role]
default username name [role]
```

All parameters except **name** can be placed in any order.

**Parameters**

- **name**
  
  Username text that the user enters at the login prompt to access the CLI.

  Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:

  `@ # $ % ^ & * - _ = + ; < > , . ~ |`

- **PRIVILEGE_LEVEL**
  
  User's initial session privilege level. This parameter is used when an authorization command includes the local option.

  - `<no parameter>` the privilege level is set to 1.
  - **privilege rank** where **rank** is an integer between 0 and 15.

- **SECURITY**
  
  Password assignment option.

  - **nopassword** **name** is not password protected.
  - **secret password** **name** is protected by specified password (clear-text string).
  - **secret 0 password** **name** is protected by specified password (clear-text string).
  - **secret 5 password** **name** is protected by specified password. (md5 encrypted string).
  - **secret sha5 password** **name** is protected by specified password (sha512 encrypted string).

- **ROLE_USER**
  
  Specifies the role for performing command authorization. Options include:

  - `<no parameter>` user is assigned default role (**aaa authorization policy local default-role**).
  - **role role_name** specifies role assigned to the user.

**Guidelines**

Encrypted strings entered through this parameter are generated elsewhere. The **secret 5** option (**SECURITY**) is typically used to enter a list of username-passwords from a script.

The **SECURITY** parameter is mandatory for unconfigured usernames. For previously configured users, the command can specify a **PRIVILEGE_LEVEL** or **ROLE** without a **SECURITY** setting.
admin is a reserved username that is provided by the initial configuration. The admin username cannot be deleted, but its parameters are editable. The initial admin configuration is:

```
username admin privilege 1 role network-admin nopassword
```

**Examples**

- These equivalent commands create the username john and assigns it the password x245. The password is entered in clear text because the ENCRYPTION parameter is either omitted or zero.

  ```
  switch(config)#username john secret x245
  switch(config)#username john secret 0 x245
  ```

- This command creates the username john and assigns it to the text password that corresponds to the encrypted string $1$sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1. The string was generated by an MD5-encryption program using x245 as the seed.

  ```
  switch(config)#username john secret 5 $1$sU.7hptc$TsJ1qslCL7ZYVbyXNG1wg1
  ```

  A user authenticates the username john by entering x245 when the CLI prompts for a password.

- This command creates the username jane without securing it with a password. It also removes a password if the jane username exists.

  ```
  switch(config)#username jane nopassword
  ```

- This command removes the username william from the local file.

  ```
  switch(config)#no username william
  ```
username sshkey

The **username sshkey** command configures an ssh key for the specified username. Command options allow the key to be entered directly into the CLI or referenced from a file.

The specified username must be previously configured through a **username** command.

The **no username sshkey** and **default username sshkey** commands delete the sshkey for the specified username by removing the corresponding **username sshkey** command from **running-config**.

The **no username sshkey role** and **default username sshkey role** commands perform the following:
- delete the sshkey for the specified username by removing the corresponding **username sshkey** command from **running-config**.
- delete the role assignment from the specified username by editing the corresponding **username** statement in **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
username name sshkey KEY
no username name sshkey [role]
default username name sshkey [role]
```

**Parameters**

- **name** username text that the user enters at the login prompt to access the CLI.
  
  Valid usernames begin with A-Z, a-z, or 0-9 and may also contain any of these characters:
  
  `@ # $ % ^ & * - _ = + ; < > , . ~ |`

- **KEY** SSH key. Options include:
  
  - `key_text` username is associated with ssh key specified by `key_text` string.
  - `file key_file` username is associated with ssh key in the specified file.

**Example**

- These commands create the username `john`, assign it the password `x245`, then associate it to the SSH key listed in the file named `john-ssh`.

  ```
  switch(config)#username john secret x245
  switch(config)#username john sshkey file john-ssh
  switch(config)#
  ```
Chapter 5

Administering the Switch

This chapter describes administrative tasks that are typically performed only after initially configuring the switch or after recovery procedures.

This chapter includes these sections:

- Section 5.1: Managing the Switch Name
- Section 5.2: Managing the System Clock
- Section 5.3: Synchronizing the Time Settings
- Section 5.4: Managing Display Attributes
- Section 5.5: Event Monitor
- Section 5.6: Switch Administration Commands

5.1 Managing the Switch Name

These sections describe how to configure the switch’s domain and host name.

- Section 5.1.1: Assigning a Name to the Switch describes the assigning of an FQDN to the switch.
- Section 5.1.2: Specifying DNS Addresses describes the adding of name servers to the configuration.

5.1.1 Assigning a Name to the Switch

A fully qualified domain name (FQDN) labels the switch and defines its organization ID in the Domain Name System hierarchy. The switch’s FQDN consists of a host name and domain name.

The host name is uniquely associated with one device within an IP-domain. The default host name is **localhost**. You can configure the prompt to display the host name, as described in Section 5.4.2: Prompt.

- To assign a host name to the switch, use the **hostname** command. To return the switch’s host name to the default value of **localhost**, use the **no hostname** command.
- To specify the domain location of the switch, use the **ip domain-name** command.

Example

- This command assigns the string **main-host** as the switch’s host name.

  ```
  switch(config)#hostname main-host
  main-host(config)#
  ```

- This command configures **aristanetworks.com** as the switch’s domain name.

  ```
  switch(config)#ip domain-name aristanetworks.com
  switch(config)#
  ```
• This procedure configures sales1.samplecorp.org as the switch’s FQDN.
  
  switch(config)#ip domain-name samplecorp.org
  switch(config)#

• This running-config extract contains the switch’s host name and IP-domain name.

  switch#show running-config
  ! Command: show running-config
  ! device: switch (DCS-7150S-64-CL, EOS-4.13.2F)
  !
  <--------OUTPUT OMITTED FROM EXAMPLE-------->
  vlan 3-4
  !
  username john secret 5 $1$a7Hjept9$TIKRX6ytkg8o.ENja.na50
  !
  hostname sales1
  ip name-server 172.17.0.22
  ip domain-name samplecorp.org
  !
  <--------OUTPUT OMITTED FROM EXAMPLE-------->
  end

  switch#

5.1.2 Specifying DNS Addresses

The Domain Name Server (DNS) maps FQDN labels to IP addresses and provides addresses for network devices. Each network requires at least one server to resolve addresses. The configuration file can list a maximum of three server addresses.

To add name servers to the configuration, use the ip name-server command. Each command can add one to three servers. The switch disregards any attempt to add a fourth server to the configuration. All server addresses must be in a single VRF. If servers have been previously configured in a different VRF they must be removed before adding a new server to the configuration.

Example

• This code performs these actions:
  • adds three name servers to the configuration in the default VRF
  • attempts to add a fourth server, resulting in an error message
  • displays the configuration file.

  switch(config)#ip name-server 10.1.1.24 10.1.1.25 172.17.0.22
  switch(config)#ip name-server 10.15.3.28
  % Maximum number of nameservers reached. '10.15.3.28' not added
  switch(config)#show running-config
  ! device: Switch (EOS-4.11.2-1056939.EOS4112)
  !
  username david secret 5 $1$a7Hjept9$TIKRX6ytkg8o.ENja.na50
  !
  hostname Switch
  ip name-server 10.1.1.24
  ip name-server 10.1.1.25
  ip name-server 172.17.0.22
  ip domain-name aristanetworks.com
  <--------OUTPUT OMITTED FROM EXAMPLE-------->

The switch assigns source IP addresses to outgoing DNS requests. To force the switch to use a single, user-defined source interface for all requests, use the ip domain lookup command.
Example

- This command forces the switch to use VLAN 5 as the source interface for DNS requests originating from the default VRF.
  
  `switch(config)#ip domain lookup source-interface Vlan5
  switch(config)#`

- This command forces the switch to use VLAN 10 as the source interface for DNS requests originating from VRF “purple.”
  
  `switch(config)#ip domain lookup vrf purple source-interface Vlan10
  switch(config)#`
5.2 Managing the System Clock

The switch uses the system clock for displaying the time and time-stamping messages. The system clock is set to Coordinated Universal Time (UTC). The switch calculates local time based on the time zone setting. Time-stamps and time displays are in local time.

5.2.1 Configuring the Time Zone

The time zone setting is used by the switch to convert the system time (UTC) to local time. To specify the time zone, use the `clock timezone` command.

**Examples**

- These commands configure the switch for the United States Central Time Zone.

  ```
  switch(config)#clock timezone US/Central
  switch(config)#show clock
  Mon Jan 14 18:42:49 2013
timezone is US/Central
  switch(config)#
  ```

- To view the predefined time zone labels, enter `clock timezone` with a question mark.

  ```
  switch(config)#clock timezone ?
  Africa/Abidjan                        Africa/Accra
  WET                                    WET timezone
  Zulu                                   Zulu timezone
  ```

- This command displays all time zone labels that start with `America`.

  ```
  switch(config)#clock timezone AMERICA?
  America/Adak                           America/Anchorage
  America/Yellowknife                     <------OUTPUT OMITTED FROM EXAMPLE------->
  ```

5.2.2 Setting the System Clock Manually

The `clock set` command manually configures the system clock time and date, in local time. Any NTP servers properly configured on the switch override time that is manually entered.

**Example**

- This command manually sets the switch time.

  ```
  switch#clock set 08:15:24 14 Jan 2013
  Mon Jan 14 08:15:25 2013
timezone is US/Central
  ```

5.2.3 Displaying the Time

To display the local time and configured time zone, enter the `show clock` command.
Example

- This command displays the switch time.

  `switch(config)>show clock`
  Mon Jan 14 16:32:46 2013
timezone is America/Los_Angeles
5.3 Synchronizing the Time Settings

Time settings are synchronized through Network Time Protocol (NTP).

5.3.1 Network Time Protocol (NTP)

Network Time Protocol (NTP) servers synchronize time settings of systems running an NTP client. The switch supports NTP versions 1 through 4. The default is version 4.

After configuring the switch to synchronize with an NTP server, it may take up to ten minutes for the switch to set its clock. The running-config lists NTP servers that the switch is configured to use.

5.3.1.1 Configuring the NTP Server

The ntp server command adds a server to the list or modifies the parameters of a previously listed address. When the system contains multiple NTP servers, the prefer keyword can be used to specify a preferred NTP server, which will be used as the NTP server if not discarded by NTP.

Note that all NTP servers must be in the same VRF, and that they are added in the default VRF if no VRF is specified.

Example

- These commands add three NTP servers, designating the second server as preferred.

```
switch(config)#ntp server local-NTP
switch(config)#ntp server 172.16.0.23 Prefer
switch(config)#ntp server 172.16.0.25
```

5.3.1.2 Configuring the NTP Source

The ntp source command configures an interface as the source of NTP packets. That interface’s IP address is then used as the source address for all NTP packets unless a server-specific source is configured using the source option of the ntp server command. For an ntp source command to take effect, the specified interface and the NTP server must both belong to the same VRF.

Example

- This command configures VLAN interface 25 as the source of NTP update packets.

```
switch(config)#ntp source vlan 25
switch(config)#
```

5.3.1.3 Configuring the Switch as an NTP Server

To configure the switch to accept NTP requests on all interfaces, use the ntp serve all command to enable NTP server mode globally on the switch. To configure an individual interface to accept or deny NTP requests, use the ntp serve command. Interface level settings override the global settings, and changing the settings at either the global or interface level also causes the switch to re-synchronize with its upstream NTP server. NTP server mode is disabled by default.

Example

- This command configures the switch to act as an NTP server, accepting NTP requests.

```
switch(config)# ntp serve all
switch(config)#
```
5.3.4 Configuring NTP Authentication

The switch can be configured to synchronize its clock using NTP packets only from an authenticated source. NTP authentication is disabled by default.

To configure the switch to authenticate NTP packets, create one or more authentication keys using the `ntp authentication-key` command, specify which keys are trusted by using the `ntp trusted-key` command, and use the `ntp authenticate` command to enable NTP authentication. The NTP server must be configured to use the same authentication key and key ID number.

Example

- These commands configure the switch to authenticate NTP packets using key 328 with the plaintext password “timeSync.”

  switch(config)# ntp authentication-key 328 md5 timeSync
  switch(config)# ntp trusted key 328
  switch(config)# ntp authenticate

5.3.5 Viewing NTP Settings and Status

To display the status of Network Time Protocol (NTP) on the switch, use the `show ntp status` command. To display the status of connections to NTP servers, use the `show ntp associations` command. Note that for IPv4 addresses, the reference ID is the IPv4 address of the NTP server. For IPv6 addresses, the reference ID is the first four octets of the MD5 hash of the NTP server’s IP address.

Example

- This command displays the status of the switch’s NTP connection.

  switch#show ntp status
  unsynchronised
  time server re-starting
  polling server every 64 s
  switch #

- This command displays data about the NTP servers in the configuration.

  switch#show ntp associations

  remote          refid  st t when poll reach   delay  offset   jitter
  ---------------------------------------------------------------
  moose.aristanet 66.187.233.4     2 u    9  64  377  0.118  9440948  0.017
  172.17.2.6      .INIT.          16 u   -1024  0  0.000    0.000   0.000
  *LOCAL(0)        .LOCL.          10 l   41  64  377  0.000    0.000   0.000
  switch#

5.3.2 Precision Time Protocol (PTP)

The Precision Time Protocol (PTP) enhances the accuracy of real-time clocks in networked devices by providing sub-microsecond clock synchronization. Inbound clock signals are organized into a master-slave hierarchy. PTP identifies the switch port that is connected to the device with the most precise clock. This clock is referred to as the master clock. All the other devices on the network synchronize their clocks with the master and are referred to as slaves.
The master clock sends out a sync message every second. The slave clock sends a delay request message to the master clock noting the time it was sent in order to measure and eliminate packet delays. The master clock then replies with the time stamp the delay message was received. The slave clock then computes the master clock time compensated for delays and finalizes synchronization. Constantly exchanged timing messages ensure continued synchronization.

5.3.2.1 Enable PTP
The following PTP commands are required to enable PTP on a device:

- **Set the PTP Mode**
- **Enable PTP on An Interface**

**Set the PTP Mode**
To specify the Precision Time Protocol (PTP), use the `ptp mode` command. PTP mode options include:

- **boundary**   The device acts as a boundary clock, and both runs and participates in the best master clock algorithm.
- **disabled**   PTP is disabled, and the device forwards all PTP packets as normal traffic.
- **end-to-end transparent**   The device acts as an end-to-end transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time.
- **peer-to-peer transparent**   The device acts as a peer-to-peer transparent clock, synchronizing all ports to a connected master clock and updating the time interval field of forwarded PTP packets using switch residence time and inbound path delays.
- **generalized Precision Time Protocol (gPTP)**   The device runs generalized Precision Time Protocol (gPTP), participating in the best master clock algorithm but also updating the interval field of forwarded PTP packets using switch residence time and inbound path delays.

**Example**
- This command configures the device as a PTP boundary clock.

```
switch(config)# ptp mode boundary
```

**Enable PTP on An Interface**
To enable PTP on a specific interface on the device, use the `ptp enable` command.

**Example**
- This command enables PTP on Ethernet interface 5.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp enable
```

5.3.2.2 Configuring PTP Global Options
The following PTP global commands are optional:

- **Configure the PTP Domain**
- **Configure the Offset Hold Time**
- **Set the PTP Priority 1**
- **Set the PTP Priority 2**
Configure the Source IP
Configure the TTL for the PTP Packets

Configure the PTP Domain
To set the domain number to use for the clock, use the `ptp domain` command.
- The `ptp domain` command configures the domain 1 to use with a clock.
  ```plaintext
  switch(config)# ptp domain 1
  switch(config)#
  ```

Configure the Offset Hold Time
To set the PTP offset hold time, use the `ptp hold-ptp-time` command.
- The `ptp hold-ptp-time` command configures the PTP offset hold time to 600 seconds.
  ```plaintext
  switch(config)# ptp hold-ptp-time 600
  switch(config)#
  ```

Set the PTP Priority 1
To set the priority 1 value, use the `ptp priority1` command. Lower values take precedence.
- The `ptp priority1` command configures the priority 1 value of 120 to use when advertising the clock.
  ```plaintext
  switch(config)# ptp priority1 120
  switch(config)#
  ```

Set the PTP Priority 2
To set the priority 2 value for the clock, use the `ptp priority2` command.
- The `ptp priority2` command configures the priority 2 value of 128.
  ```plaintext
  switch(config)# ptp priority2 128
  switch(config)#
  ```

Configure the Source IP
To set the source IP address for all PTP packets, use the `ptp source ip` command.
- The `ptp source ip` command configures the source IP address of 10.0.2.1 for all PTP packets.
  ```plaintext
  switch(config)# ptp source ip 10.0.2.1
  switch(config)#
  ```

Configure the TTL for the PTP Packets
To set the time to live (TTL) of the PTP packets, use the `ptp ttl` command. Time to live is the maximum number of hops that a PTP packet may make.
- The `ptp ttl` command configures the time to live (TTL) of 64 hops for PTP packets.
  ```plaintext
  switch(config)# ptp ttl 64
  switch(config)#
  ```

5.3.2.3 Configuring PTP Interface Options
The following PTP interface commands are optional:
- Set the PTP Announcement Interval
- Set the PTP Timeout Interval
Synchronizing the Time Settings

• Configure the PTP Delay Mechanism
• Set the Delay Request Interval
• Set the Peer Delay Request Interval
• Set the Peer Link Propagation Threshold
• Set the Interval for Sending Synchronization Messages
• Set the PTP Transport Type

Set the PTP Announcement Interval

To set the interval between PTP announcement messages before a timeout occurs, use the `ptp announce interval` command.

• The `ptp announce interval` command configures the interval between PTP announcement messages before a timeout occurs.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp announce interval 1
```

Set the PTP Timeout Interval

To set the time for sending timeout messages, use the `ptp announce timeout` command. The range is 2 to 10 seconds. The default is 3 (8 seconds).

• The `ptp announce timeout` command specifies the time for announcing timeout messages.

```
switch(config-if-Et5)# ptp announce timeout 5
```

Configure the PTP Delay Mechanism

To set the delay in the boundary clock, use the `ptp delay-mechanism` command.

• The `ptp delay-mechanism` command configures the delay in boundary clock mode.

```
switch(config-if-Et5)# ptp delay-mechanism p2p
```

Set the Delay Request Interval

To set the time for the slave devices to send delay request messages, use the `ptp delay-req interval` command.

• The `ptp delay-req interval` command sets the time the slave devices to send delay request messages to the master state to 3.

```
switch(config-if-Et5)# ptp delay-request interval 3
```

Set the Peer Delay Request Interval

To set the minimum interval between the PTP peer delay-request messages, use the `ptp pdelay-req interval` command.

• The `ptp pdelay-req interval` command configures the interval between Precision Time Protocol (PTP) peer delay-request messages to 3.

```
switch(config-if-Et5)# ptp pdelay-request interval 3
```
Set the Peer Link Propagation Threshold

To set the delay threshold for which the peer will be considered unable to run generalized Precision Time Protocol (gPTP), use the `ptp pdelay-neighbor-threshold` command.

- The `ptp pdelay-neighbor-threshold` command sets the link propagation delay threshold on Ethernet interface 5 to 200000 nanoseconds.

```
switch(config-if-Et5)# ptp pdelay-neighbor-threshold 200000
switch(config-if-Et5)#
```

Set the Interval for Sending Synchronization Messages

To set the interval for sending synchronization messages, use the `ptp sync interval` command.

- The `ptp sync interval` command configures the time for sending synchronization messages to 3.

```
switch(config-if-Et5)# ptp sync interval 3
switch(config-if-Et5)#
```

Set the PTP Transport Type

To set the PTP transport type, use the `ptp transport` command.

- The `ptp transport` command configures the PTP transport type for a specific interface.

```
switch(config-if-Et5)# ptp transport ipv4
switch(config-if-Et5)#
```

5.3.2.4 Viewing PTP Settings and Status

The following commands display the status of the switch PTP server connections:

- Show General PTP Information
- Show PTP Clock and Offset
- Show PTP Parent Information
- Show PTP Clock Properties
- Show PTP Information for all Interfaces
- Show PTP Interface Counters
- Show PTP Foreign Master
- Show PTP Source IP

Show General PTP Information

To display general Precision Time Protocol (PTP) information, use the `show ptp` command.
The `show ptp` command displays PTP summary and port status information.

```
switch#show ptp
PTP Mode: gptp - Generalized PTP Clock
Clock Identity: 2001:0DB8:73:ff:ff:26:fd:90
Grandmaster Clock Identity: 2001:0DB8:96:ff:fe:6c:ed:02
Number of slave ports: 1
Number of master ports: 6
Slave port: Ethernet33
Mean Path Delay (nanoseconds): 718
Steps Removed: 1
Neighbor Rate Ratio: 1.00000007883
Rate Ratio: 1.00000007883
```

### Show PTP Clock and Offset

The `show ptp clock` command displays the local PTP clock and offset.

```
switch#show ptp clock
PTP Mode: Boundary Clock
Clock Identity: 0x00:1c:73:ff:ff:1e:83:24
Clock Domain: 1
Number of PTP ports: 24
Priority1: 128
Priority2: 128
Clock Quality:
    Class: 248
    Accuracy: 0x30
    OffsetScaledLogVariance: 0xffff
Offset From Master: 0
Mean Path Delay: 0
Steps Removed: 0
```
Show PTP Parent Information

The `show ptp parent` command displays the PTP clock's parent and grandmaster identity and configuration.

```
switch# show ptp parent
Parent Clock:
Parent Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Parent Port Number: 0
Parent IP Address: N/A
Observed Parent Offset (log variance): N/A
Observed Parent Clock Phase Change Rate: N/A

Grandmaster Clock:
Grandmaster Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Grandmaster Clock Quality:
    Class: 248
    Accuracy: 0x30
    OffsetScaledLogVariance: 0xffff
    Priority1: 128
    Priority2: 128
switch#
```

Show PTP Clock Properties

The `show ptp time-property` command displays PTP clock properties.

```
switch# show ptp time-property
Current UTC offset valid: False
Current UTC offset: 0
Leap 59: False
Leap 61: False
Time Traceable: False
Frequency Traceable: False
PTP Timescale: False
Time Source: 0x0
switch#
```
Show PTP Information for all Interfaces

The `show ptp interface` command displays PTP information for specified interfaces.

```
switch# show ptp interface
Interface Ethernet1
  PTP: Disabled
  Port state: Disabled
  Sync interval: 1.0 seconds
  Announce interval: 2.0 seconds
  Announce interval timeout multiplier: 3
  Delay mechanism: end to end
  Delay request message interval: 32.0 seconds
  Transport mode: ipv4

Interface Ethernet5
  PTP: Disabled
  Port state: Disabled
  Sync interval: 8.0 seconds
  Announce interval: 2.0 seconds
  Announce interval timeout multiplier: 5
  Delay mechanism: peer to peer
  Peer delay request message interval: 8.0 seconds
  Peer Mean Path Delay: 0
  Transport mode: ipv4

switch#
```

Show PTP Interface Counters

The `show ptp interface counters` command displays PTP interface counters for specified interfaces.

```
switch# show ptp interface ethernet 5 counters
Interface Ethernet5
  Announce messages sent: 0
  Announce messages received: 0
  Sync messages sent: 0
  Sync messages received: 0
  Follow up messages sent: 0
  Follow up messages received: 0
  Delay request messages sent: 0
  Delay request messages received: 0
  Delay response messages sent: 0
  Delay response messages received: 0
  Peer delay request messages sent: 0
  Peer delay request messages received: 0
  Peer delay response messages sent: 0
  Peer delay response messages received: 0

switch#
```

Show PTP Foreign Master

The `show ptp foreign-master-record` command displays information about foreign masters (PTP sources not designated as the switch’s master from which the switch has received sync packets).

```
switch# show ptp clocks foreign-masters-record
No Foreign Master Records
switch#
```
Show PTP Source IP

The `show ptp source ip` command displays PTP IP source information.

```
switch#show ptp source ip
PTP source IP: 10.0.2.1
switch#
```
5.4 Managing Display Attributes

Display commands control the content of the banner and the command line prompt.

5.4.1 Banners

The switch can display two banners:

- **Login banner**: The login banner precedes the login prompt. One common use for a login banner is to warn against unauthorized network access attempts.

- **motd banner**: The message of the day (motd) banner is displayed after a user logs into the switch.

This output displays both banners in bold:

```
This is a login banner
switch login: john
Password:
Last login: Mon Jan 14 09:24:36 2013 from adobe-wrks.aristanetworks.com
This is an motd banner
switch>
```

These commands create the login and motd banner shown earlier in this section.

```
switch(config)#banner login
Enter TEXT message. Type 'EOF' on its own line to end.
This is a login banner
EOF
switch(config)#banner motd
Enter TEXT message. Type 'EOF' on its own line to end.
This is an motd banner
EOF
```

To create a banner:

**Step 1** Enter global configuration mode.

```
switch#config
switch(config)#
```

**Step 2** Enter banner edit mode by typing the desired command:

- To create a login banner, type `banner login`.
- To create a motd banner, type `banner motd`.

The switch responds with instructions on entering the banner text.

```
switch(config)#banner login
Enter TEXT message. Type 'EOF' on its own line to end.
```

**Step 3** Enter the banner text.

```
This is the first line of banner text.
This is the second line of banner text.
```

**Step 4** Press Enter to place the cursor on a blank line after completing the banner text.

**Step 5** Exit banner edit mode by typing EOF.

```
EOF
```

EOF

switch(config)#
5.4.2 Prompt

The prompt provides an entry point for EOS commands. The prompt command configures the contents of the prompt. The no prompt command returns the prompt to the default of %H%P.

Characters allowed in the prompt include A-Z, a-z, 0-9, and these punctuation marks:

! @ # $ % ^ & * ( ) - _ + f g [ ] ; : < > , . ? / ~ n

The prompt supports these control sequences:

- %s – space character
- %t – tab character
- %% – percent character
- %H – host name
- %D – time and date
- %D{f_char} – time and date, format specified by the BSD strftime (f_char) time conversion function.
- %h – host name up to the first ‘.’
- %P – extended command mode
- %p – command mode
- %r – redundancy status on modular systems (has no effect on a fixed system)
- %R – extended redundancy status on modular systems – includes status and slot number (has no effect on a fixed system)

Example

- This command creates a prompt that displays system 1 and the command mode.
  host-name.dut103(config)#prompt system%s1%P
  system 1(config) #

- This command creates a prompt that displays the command mode.
  host-name.dut103(config)#prompt %p
  (config) #

- These equivalent commands create the default prompt.
  % prompt %H%P
  host-name.dut103(config) #

  % no prompt
  host-name.dut103(config) #
5.5 Event Monitor

The event monitor writes system event records to local files for access by SQLite database commands.

5.5.1 Description

The event monitor receives notifications for changes to the mac table, route table, and arp table. These changes are logged to a fixed-size circular buffer. The size of this buffer is configurable, but it does not grow dynamically. Buffer contents can be stored to permanent files to increase the event monitor effective capacity. The permanent file size and the number of permanent files is configurable. The buffer is stored at a fixed location on the switch. The location of the permanent files is configurable and can be in any switch file directory, including flash (/mnt/flash).

Specific event monitor queries are available through CLI commands. For queries not available through specific commands, manual queries are supported through other CLI commands. When the user issues a query command, the relevant events from the circular buffer and permanent files are written to and accessed from a temporary SQLite database file. The database keeps a separate table for each logging type (mac, arp, route). When the monitor receives notification of a new event, the database file is deleted, then recreated.

5.5.2 Configuring the Event Monitor

Enabling the Event Monitor

The event-monitor <log enable> command enables the event monitor and specifies the types of events that are logged. The event monitor is an event logging service that records system events to a local database. The event monitor records these events:

- arp changes to the ARP table (IP address to MAC address mappings).
- IGMP snooping changes to the IGMP snooping table.
- mac changes to the MAC address table (MAC address to port mappings).
- mroute changes to the IP multicast routing table.
- route changes to the IP routing table.

By default, the event monitor is enabled and records each type of event. The no event-monitor all command disables the event monitor. The no event-monitor command, followed by a log type parameter, disables event recording for the specified type.

Example

- This command disables the event monitor for all types of events.
  
  switch(config)#no event-monitor all

- This command enables the event monitor for routing table changes.
  
  switch(config)#event-monitor route

The event-monitor clear command removes the contents of the event monitor buffer. If event monitor backup is enabled, this command removes the contents from all event monitor backup files.

Example

- This command clears the contents of the event monitor buffer.
  
  switch#event-monitor clear
  switch(config)#
Configuring the Buffer

The `event-monitor buffer max-size` command specifies the size of the event monitor buffer. The event monitor buffer is a fixed-size circular data structure that receives event records from the event monitor. When event monitor backup is enabled, the buffer is copied to a backup file before each rollover. Buffer size ranges from 6 Kb to 50 Kb. The default size is 32 Kb.

Example

- This command configures a buffer size of 48 Kb.

  switch(config)#event-monitor buffer max-size 48
  switch(config)#

Configuring Permanent Files

The `event-monitor backup path` command enables storage of the event monitor buffer to permanent switch files and specifies the path/name of these files. The command references file location either from the flash drive root directory where the CLI operates (`/mnt/flash`) or from the switch root directory (`/`).

The event monitor buffer is circular – after the buffer is filled, new data replaces older data at the beginning of the buffer. The buffer is copied into a new backup file after each buffer writing cycle before the switch starts re-writing the buffer.

Example

- These commands configure the switch to store the event monitor buffer in sw-event.log, then display the new file in the flash directory.

  switch(config)#event-monitor backup path sw-event.log
  switch(config)#dir
  Directory of flash:/
  -rwx   245761935           Jan 18 04:18  EOS-4.9.0.swi
  -rwx   245729161           Jan 17 06:57  EOS-4.9.0f.swi
  -rwx          25            Jan 5 08:59  boot-config
  -rwx          14            Jun 20 2011  boot-extensions
  -rwx        2749           Nov 22 2011  startup-config
  -rwx        418884           Jan 18 13:55  sw-event.log.0
  -rwx          13            Nov 9 2011  zerotouch-config

  931745792 bytes total (190517248 bytes free)
  switch(config)#

The `event-monitor backup max-size` command specifies the quantity of event monitor backup files the switch maintains. The switch appends a extension number to the file name when it creates a new file. After every 500 events, the switch deletes the oldest backup file if the file limit is exceeded.

Example

- These commands configure the switch to back up the event buffer to a series of files named sw-event.log. The switch can store a maximum of four files.

  switch(config)#event-monitor backup path sw-event.log
  switch(config)#event-monitor backup max-size 4
  switch(config)#
The first five files that the switch creates to store event monitor buffer contents are:

sw-event.log.0
sw-event.log.1
sw-event.log.2
sw-event.log.3
sw-event.log.4

The switch deletes `sw-event.log.0` the first time it verifies the number of existing backup files after the creation of `sw-event.log.4`.

5.5.3 Querying the Event Monitor

These CLI commands perform SQL-style queries on the event monitor database:

- The `show event-monitor arp` command displays ARP table events.
- The `show event-monitor mac` command displays MAC address table events.
- The `show event-monitor route` command displays routing table events.

Example

- This command displays all events triggered by MAC address table events.

  ```
  switch#show event-monitor mac
  Writing 0 Arp, 0 Route, 1 Mac events to the database
  2012-01-19 13:57:55|1|08:08:08:08:08:08|Ethernet1|configuredStaticMac|added|0
  ```

For other database queries, the `show event-monitor sqlite` command performs an SQL-style query on the database, using the statement specified in the command.

Example

- This command displays all entries from the route table.

  ```
  switch#show event-monitor sqlite select * from route;
  2012-01-19 13:53:01|16.16.16.0/24|0|0|0
  2012-01-19 13:53:01|16.16.16.17/32|0|0|0
  2012-01-19 13:53:01|16.16.16.18/32|0|0|0
  2012-01-19 13:53:01|16.16.16.240/32|0|0|0
  2012-01-19 13:53:01|16.16.16.255/32|0|0|0
  2012-01-19 13:53:01|192.168.1.0/24|0|0|0
  2012-01-19 13:53:01|192.168.1.5/32|0|0|0
  2012-01-19 13:53:01|192.168.1.6/32|0|0|0
  ```

5.5.4 Accessing Event Monitor Database Records

The `event-monitor interact` command replaces the CLI prompt with an SQLite prompt. The event monitor buffer and all backup logs are synchronized into a single SQLite file and loaded for access from the prompt.

- To access help from the SQLite prompt, enter `.help`
- To exit SQLite and return to the CLI prompt, enter `.quit` or `.exit`

The `event-monitor sync` command combines the event monitor buffer and all backup logs and synchronizes them into a single SQLite file. The data can be accessed through SQLite or by using the `show event-monitor` commands described above.
Examples

- This command replaces the EOS CLI prompt with an SQLite prompt.
  
  ```
  switch# event-monitor interact
  sqlite>
  ```

- This command exits SQLite and returns to the EOS CLI prompt.
  
  ```
  sqlite> .quit
  switch#
  ```

- This command synchronizes the buffer and backup logs into a single SQLite file.
  
  ```
  switch(config)# event-monitor sync
  switch(config)#
  ```
5.6 Switch Administration Commands

Switch Name Configuration Commands
- hostname
- ip domain-list
- ip domain-lookup
- ip domain-name
- ip host
- ip name-server
- ipv6 host
- show hostname
- show hosts
- show ip domain-name
- show ip name-server

Banner Configuration Commands
- banner login
- banner motd
- show banner

Prompt Configuration Command
- prompt

Event Manager Commands
- no event-monitor
- event-monitor <log enable>
- event-monitor backup max-size
- event-monitor backup path
- event-monitor buffer max-size
- event-monitor clear
- event-monitor interact
- event-monitor sync
- show event-monitor arp
- show event-monitor mac
- show event-monitor route
- show event-monitor sqlite

Email Configuration Command
- email

System Clock Commands
- clock set
- clock timezone
- show clock

NTP Configuration Commands
- ntp authenticate
- ntp authentication-key
- ntp serve
- ntp serve all
- ntp server
- ntp source
• ntp trusted-key
• show ntp associations
• show ntp status

PTP Configuration Commands
• clear ptp interface counters
• ptp announce interval
• ptp announce timeout

**banner login**

The **banner login** command configures a message that the switch displays before login and password prompts. The login banner is available on console, telnet, and ssh connections.

The **no banner login** and **default banner login** commands delete the login banner.

**Command Mode**  
Global Configuration

**Command Syntax**  
```plaintext
banner login  
no banner login  
default banner login
```

**Parameters**

- **banner_text**  
  To configure the banner, enter a message when prompted. The message may span multiple lines. Banner text supports the following keywords:
  - `$(hostname)`  
    displays the switch’s host name.
  - `EOF`  
    To end the banner editing session, type `EOF` on its own line and press **enter**.

**Examples**

- These commands create a two-line login banner.
  ```plaintext
  switch(config)#banner login  
Enter TEXT message. Type 'EOF' on its own line to end.  
This is a login banner for $(hostname).  
Enter your login name at the prompt.  
EOF
  
switch(config)#
  
This output displays the login banner.
  
This is a login banner for switch.  
Enter your login name at the prompt.  
switch login: john  
Password:  
Last login: Mon Jan 14 09:05:23 2013 from adobe-wrks.aristanetworks.com  
switch>
  ```
banner motd

The banner motd command configures a “message of the day” (motd) that the switch displays after a user logs in. The motd banner is available on console, telnet, and ssh connections.

The no banner motd and default banner motd commands delete the motd banner.

**Command Mode**

Global Configuration

**Command Syntax**

```
banner motd
no banner motd
default banner motd
```

**Parameters**

- **banner_text** To configure the banner, enter a message when prompted. The message may span multiple lines. Banner text supports this keyword:
  - \$(hostname) displays the switch’s host name.
- **EOF** To end the banner editing session, type EOF on its own line and press enter.

**Examples**

- These commands create an motd banner.
  
  ```
  switch(config)#banner motd
  Enter TEXT message. Type 'EOF' on its own line to end.
  This is an motd banner for $(hostname)
  EOF
  ```

  This output displays the motd banner.

  ```
  switch login: john
  Password:
  Last login: Mon Jan 14 09:17:09 2013 from adobe-wrks.aristanetworks.com
  This is an motd banner for Switch
  switch>
  ```
clear ptp interface counters

The clear ptp interface counters command resets the Precision Time Protocol (PTP) packet counters.

Command Mode
Privileged EXEC

Command Syntax
    clear ptp interface [INTERFACE_NAME] counters

Parameters
- **INTERFACE_NAME**  Interface type and numbers. Options include:
  - <no parameter>  Display information for all interfaces.
  - ethernet e_range  Ethernet interface range specified by e_range.
  - loopback l_range  Loopback interface specified by l_range.
  - management m_range  Management interface range specified by m_range.
  - port-channel p_range  Port-Channel Interface range specified by p_range.
  - vlan v_range  VLAN interface range specified by v_range.
  - vxlan vx_range  VXLAN interface range specified by vx_range.

Valid parameter formats include number, number range, or comma-delimited list of numbers and ranges.

Example
- This command clears all PTP counters.
  switch# clear ptp counters
  switch#
clock set

The `clock set` command sets the system clock time and date. If the switch is configured with an NTP server, NTP time synchronizations override manually entered time settings.

Time entered by this command is local, as configured by the `clock timezone` command.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
clock set hh:mm:ss date
```

**Parameters**

- `hh:mm:ss` is the current time (24-hour notation).
- `date` is the current date. Date formats include:
  - `mm/dd/yy` example: 05/15/2012
  - `Month day year` example: May 15 2012
  - `day month year` example: 15 May 2012

**Example**

- This command manually sets the switch time.

```
switch#clock set 08:15:24 14 Jan 2013
Mon Jan 14 08:15:25 2013
timezone is US/Central
```
clock timezone

The **clock timezone** command specifies the UTC offset that converts system time to local time. The switch uses local time for time displays and to time-stamp system logs and messages.

The **no clock timezone** and **default clock timezone** commands delete the **timezone** statement from **running-config**, setting local time to UTC.

**Command Mode**
- Global Configuration

**Command Syntax**

```plaintext
clock timezone zone_name
no clock timezone
default clock timezone
```

**Parameters**

- **zone_name** the time zone. Settings include a list of predefined time zone labels.

**Examples**

- This command configures the switch for the United States Central Time Zone.

```
switch(config)#clock timezone US/Central
switch(config)#show clock
Fri Jan 11 18:42:49 2013
timezone is US/Central
```

- To view the predefined time zone labels, enter **clock timezone** with a question mark.

```
switch(config)#clock timezone ?
Africa/Abidjan   Africa/Accra
Africa/Addis_Ababa  Africa/Algiers
Africa/Asmara   Africa/Asmera
Africa/Bamako  Africa/Bangui
                      <-------OUTPUT OMITTED FROM EXAMPLE-------->
W-SU            W-SU timezone
WET            WET timezone
Zulu           Zulu timezone
```

- This command displays all time zone labels that start with **America**.

```
switch(config)#clock timezone AMERICA?
America/Adak    America/Anchorage
America/Anguilla America/Antigua
America/Araguaina America/Argentina/Buenos_Aires
                      <-------OUTPUT OMITTED FROM EXAMPLE-------->
America/Virgin  America/Whitehorse
America/Winnipeg America/Yakutat
America/Yellowknife
```

```
switch(config)#clock timezone AMERICA
```
email

The `email` command places the switch in email client configuration mode. If you configure a `from-user` and an outgoing SMTP server on the switch, you can then use an email address as an output modifier to a `show` command and receive the output as email.

**Command Mode**
Global Configuration

**Command Syntax**
```
email
```

**Example**
- This command places the switch in email client configuration mode.

```
switch(config)#email
switch(config)#
```
no event-monitor

The no event-monitor and default event-monitor commands remove the specified event-monitor configuration statements from running-config, returning the switch to the specified default state.

- no event-monitor <with no parameters> restores all default setting states:
  - event monitor is enabled.
  - buffer backup is disabled.
- no event-monitor backup disables the backup.

To disable the event monitor, enter the no event-monitor all command (event-monitor <log enable>).

**Command Mode**

Global Configuration

**Command Syntax**

no event-monitor [PARAMETER]

default event-monitor [PARAMETER]

**Parameters**

- **PARAMETER** the event monitor property that is returned to the default state.
  - <no parameter> all event monitor properties.
  - backup event monitor buffer backup is disabled.

**Example**

- This command removes all event monitor configuration statements from running-config.

  switch(config)#no event-monitor
  switch(config)#
event-monitor <log enable>

The `event-monitor <log enable>` command enables the event monitor and specifies the types of events that are logged. The event monitor is an event logging service that records system events to a local database. The event monitor records these events:

- **arp** changes to the ARP table (IP address to MAC address mappings).
- **IGMP snooping** changes to the IGMP snooping table.
- **mac** changes to the MAC address table (MAC address to port mappings).
- **mroute** changes to the IP multicast routing table.
- **route** changes to the IP routing table.

The database maintains a separate table for each event type.

By default, the event monitor is enabled and records each type of event.

- The `no event-monitor all` command disables the event monitor.
- The `no event-monitor` command, followed by a log type parameter, disables event recording for the specified type.
- The `event-monitor` and `default event-monitor` commands enable the specified event logging type by removing the corresponding `no event-monitor` command from `running-config`.

The `no event-monitor` and `default event-monitor` commands, without a `LOG_TYPE` parameter, restore the default event monitor settings by deleting all event monitor related commands from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
  event-monitor LOG_TYPE
  no event-monitor LOG_TYPE
  default event-monitor LOG_TYPE
```

**Parameters**

- `LOG_TYPE` specifies the event logging type. Options include:
  - **all** all event logging types.
  - **arp** changes to ARP table.
  - **igmpsnooping** changes to IGMP snooping table.
  - **mac** changes to MAC address table.
  - **mroute** changes to multicast routing table.
  - **route** changes to IP routing table.

**Related Commands**
- `no event-monitor`

**Examples**
- This command disables the event monitor for all types of events.

```
switch(config)#no event-monitor all
switch(config)#
```
• This command enables the event monitor for routing table changes.

```
switch(config)#event-monitor route
switch(config)#
```
**event-monitor backup max-size**

The *event-monitor backup max-size* command specifies the quantity of event monitor backup files the switch maintains. Values range from 1 to 200 files with a default of ten files.

The *event-monitor backup path* command specifies the path/name of these files. The switch appends an extension to the file name that tracks the creation order of backup files. When the quantity of files exceeds the configured limit, the switch deletes the oldest file.

The no *event-monitor backup max-size* and *default event-monitor backup max-size* command restores the default maximum number of backup files the switch can store to ten by removing the corresponding *event-monitor backup max-size* command from *running-config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
  event-monitor backup max-size file_quantity
  no event-monitor backup max-size
  default event-monitor backup max-size
```

**Parameters**

- `file_quantity` maximum number of backup files. Value ranges from 1 to 200. Default is 10.

**Examples**

- These commands configure the switch to back up the event buffer to a series of files named sw-event.log. The switch can store a maximum of four files.

  ```
  switch(config)#event-monitor backup path sw-event.log
  switch(config)#event-monitor backup max-size 4
  switch(config)#
  ```

  The first five files that the switch creates to store event monitor buffer contents are:

  - sw-event.log.0
  - sw-event.log.1
  - sw-event.log.2
  - sw-event.log.3
  - sw-event.log.4

  The switch deletes *sw-event.log.0* the first time it verifies the number of existing backup files after the creation of *sw-event.log.4*. 
event-monitor backup path

The event-monitor backup path command enables the storage of the event monitor buffer to switch files and specifies the path/name of these files. The command references the file location either from the flash drive root directory (/mnt/flash) where the CLI operates or from the switch root directory (/).

The event monitor buffer is circular – after the buffer is filled, new data is written to the beginning of the buffer, replacing old data. At the conclusion of each buffer writing cycle, it is copied into a new backup file before the switch starts re-writing the buffer. The switch appends a extension number to the file name when it creates a new file. After every 500 events, the switch deletes the oldest backup file if the file limit specified by the event-monitor backup max-size command is exceeded.

running-config can contain a maximum of one event-monitor backup path statement. Subsequent event-monitor backup path commands replace the existing statement in running-config, changing the name of the file where event monitor backup files are stored.

The no event-monitor backup path and default event-monitor backup path commands disable the storage of the event monitor buffer to switch files by deleting the event-monitor backup path command from running-config.

Command Mode
Global Configuration

Command Syntax

```
  event-monitor backup path URL_FILE
  no event-monitor backup path
  default event-monitor backup path
```

Parameters

- **URL_FILE** path and file name of the backup file
  - **path_string** specified path is appended to /mnt/flash/
  - **file: path_string** specified path is appended to /
  - **flash: path_string** specified path is appended to /mnt/flash/

Examples

- These commands configure the switch to store the event monitor buffer in sw-event.log, then display the new file in the flash directory.

  ```
  switch(config)#event-monitor backup path sw-event.log
  switch(config)#dir
  Directory of flash:/

  -rwX 245761935 Jan 18 04:18 EOS-4.9.0.swi
  -rwX 245729161 Jan 17 06:57 EOS-4.9.0f.swi
  -rwX 25 Jan 5 08:59 boot-config
  -rwX 14 Jun 20 2011 boot-extensions
  -rwX 2749 Nov 22 2011 startup-config
  -rwX 418884 Jan 18 13:55 sw-event.log.0
  -rwX 13 Nov 9 2011 zerotouch-config
  ```

931745792 bytes total (190517248 bytes free)

switch(config)#
The event-monitor buffer max-size command specifies the size of the event monitor buffer. The event monitor buffer is a fixed-size circular data structure that receives event records from the event monitor. When event monitor backup is enabled (event-monitor backup path), the buffer is copied to a backup file before each rollover.

Buffer size ranges from 6 Kb to 50 Kb. The default size is 32 Kb.

The no event-monitor buffer max-size and default event-monitor buffer max-size commands restore the default buffer size of 32 Kb by removing the event-monitor buffer max-size command from running-config.

**Command Mode**

Global Configuration

**Command Syntax**

```
  event-monitor buffer max-size buffer_size
  no event-monitor buffer max-size
  default event-monitor buffer max-size
```

**Parameters**

- `buffer_size` buffer capacity (Kb). Values range from 6 to 50. Default value is 32.

**Example**

- This command configures a buffer size of 48 Kb.

```
switch(config)#event-monitor buffer max-size 48
switch(config)#
```
event-monitor clear

The `event-monitor clear` command removes the contents of the event monitor buffer. If event monitor backup is enabled, this command removes the contents from all event monitor backup files.

**Command Mode**
Privileged EXEC

**Command Syntax**
event-monitor clear

**Example**
- This command clears the contents of the event monitor buffer.

```
switch# event-monitor clear
switch#
```
**event-monitor interact**

The **event-monitor interact** command replaces the CLI prompt with an SQLite prompt. The event monitor buffer and all backup logs are synchronized into a single SQLite file and loaded for access from the prompt.

- To access help from the SQLite prompt, enter `.help`
- To exit SQLite and return to the CLI prompt, enter `.quit` or `.exit`

**Command Mode**

Privileged EXEC

**Command Syntax**

```
 event-monitor interact
```

**Examples**

- This command replaces the EOS CLI prompt with an SQLite prompt.
  ```
  switch# event-monitor interact
  sqlite>
  ```
- This command exits SQLite and returns to the EOS CLI prompt.
  ```
  sqlite> .quit
  switch#
  ```
event-monitor sync

The `event-monitor buffer sync` command combines the event monitor buffer and all backup logs and synchronizes them into a single SQLite file, which is stored at `/var/log/eventMon.db`

**Command Mode**
- Privileged EXEC

**Command Syntax**

```
event-monitor sync
```

**Example**

- This command synchronizes the buffer and backup logs into a single SQLite file.

```
switch(config)#event-monitor sync
switch(config)#
```
hostname

The `hostname` command assigns a text string as the switch’s host name. The default host name is `localhost`.

The prompt displays the host name when appropriately configured through the `prompt` command.

The `no hostname` and `default hostname` commands return the switch’s host name to the default value of `localhost`.

**Command Mode**

Global Configuration

**Command Syntax**

```
hostname string
no hostname
default hostname
```

**Parameters**

- `string`  
  host name assigned to the switch.

**Example**

- This command assigns the string `main-host` as the switch’s host name.

  ```
  switch(config)#hostname main-host
  main-host(config)#
  ```

  The prompt was previously configured to display the host name.
ip domain-list

The ip domain-list command specifies a domain name to add to the IP domain list.

The no ip domain-list and default ip domain-list commands return the IP domain list to its default state, in which the switch selects source IP addresses for each DNS request from the specified VRF.

Command Mode
Global Configuration

Command Syntax
- `ip domain-list [IP_DOMAIN_NAME]`
- `no ip domain-list [IP_DOMAIN_NAME]`
- `default ip domain-list [IP_DOMAIN_NAME]`

Parameters
- `IP_DOMAIN_NAME` specifies the IP domain name.

Examples
- This command specifies foo.com as the IP domain name to add to the IP domain list.
  
  switch(config)#ip domain-list foo.com
  switch(config)#

- This command removes foo.com and returns the IP domain list to its default state.
  
  switch(config)#no ip domain-list foo.com
  switch(config)#
**ip domain lookup**

The *ip domain lookup* command specifies the source interface for all DNS requests sent from the specified VRF.

The *no ip domain lookup* and *default ip domain lookup* commands return the switch to its default state, in which the switch selects source IP addresses for each DNS request from the specified VRF.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip domain lookup [VRF_INSTANCE] source-interface INTF_NAME
no ip domain lookup [VRF_INSTANCE] source-interface
default ip domain lookup [VRF_INSTANCE] source-interface
```

**Parameters**

- **VRF_INSTANCE** specifies the VRF instance being modified.
  - <no parameter> changes are made to the default VRF.
  - `vrf vrf_name` changes are made to the specified VRF.
- **INTF_NAME** name of source interface to be used for DNS requests. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.

**Examples**

- This command specifies VLAN 5 as the source interface for DNS requests originating from the default VRF.
  ```
  switch(config)#ip domain lookup source-interface Vlan5
  switch(config)#
  ```

- This command specifies VLAN 10 as the source interface for DNS requests originating from VRF "purple."
  ```
  switch(config)#ip domain lookup vrf purple source-interface Vlan10
  switch(config)#
  ```
**ip domain-name**

The `ip domain-name` command configures the switch’s domain name. The switch uses this name to complete unqualified host names.

The `no ip domain-name` and `default ip domain-name` commands delete the domain name by removing the `ip domain-name` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
   ip domain-name string
   no ip domain-name
   default ip domain-name
```

**Parameters**

- `string` domain name (text string)

**Example**

- This command configures `aristanetworks.com` as the switch’s domain name.

```
switch(config)#ip domain-name aristanetworks.com
switch(config)#
```
ip host

The `ip host` command associates a hostname to an IPv4 address. This command supports local hostname resolution based on local hostname-IP address maps. Multiple hostnames can be mapped to an IP address. IPv4 and IPv6 addresses can be mapped to the same hostname (to map an IPv6 address to a hostname, use the `ipv6 host` command). The `show hosts` command displays the local hostname-IP address mappings.

The `no ip host` and `default ip host` commands removes hostname-IP address maps by deleting the corresponding `ip host` command from `running-config`, as specified by command parameters:

- no parameters: command removes all hostname-IP address maps.
- `hostname` parameter: command removes all IP address maps for the specified hostname.
- `hostname` and `IP address` parameters: command removes specified hostname-IP address maps.

Command Mode

Global Configuration

Command Syntax

```
ip host  hostname  hostadd_1  [hostadd_2]  ...  [hostadd_X]
no ip host  [hostname]  [hostadd_1]  [hostadd_2]  ...  [hostadd_X]
default ip host  [hostname]  [hostadd_1]  [hostadd_2]  ...  [hostadd_X]
```

Parameters

- `hostname`    hostname (text).
- `hostadd_N`   IPv4 address associated with hostname (dotted decimal notation).

Related Commands

- `ipv6 host`
- `show hosts`

Examples

- This command associates the hostname `test_lab` with the IP addresses `10.24.18.5` and `10.24.16.3`.
  
  ```
  switch(config)#ip host test_lab 10.24.18.5 10.24.16.3
  ```

- This command removes all IP address maps for the hostname `production_lab`.
  
  ```
  switch(config)#no ip host production_lab
  ```
**ip name-server**

The `ip name-server` command adds name server addresses to `running_config`. The switch uses name servers for name and address resolution. The switch can be configured with up to three name servers. Although a command can specify multiple name server addresses, `running_config` stores each address in a separate statement. Name server addresses can be IPv4 and IPv6; each command can specify both address types.

Attempts to add a fourth server generate an error message. All name server addresses must be configured in the same VRF. When name servers were previously configured in a VRF, they must all be removed before adding new name server entries.

The `no ip name-server` and `default ip name-server` commands remove specified name servers from `running_config`. Commands that do not list an address remove all name servers.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip name-server [VRF_INSTANCE] SERVER_1 [SERVER_2] [SERVER_3]
no ip name-server [VRF_INSTANCE] [SERVER_1] [SERVER_2] [SERVER_3]
default ip name-server [VRF_INSTANCE] [SERVER_1] [SERVER_2] [SERVER_3]
```

**Parameters**

- `VRF_INSTANCE` specifies the VRF instance containing the addresses.
  - `<no parameter>` default VRF.
  - `vrf_vrf_name` a user-defined VRF.
- `SERVER_X` IP address of the name server (dotted decimal notation). Options include:
  - `ipv4_addr` (A.B.C.D)
  - `ipv6_addr` (A:B:C:D:E:F:G:H)

A command can contain both (IPv4 and IPv6) address types.

**Guidelines**

All configured name server addresses must come from the same VRF. To use a user defined VRF for connection to a name server, first remove any name servers configured in the default VRF.

**Examples**

- This command adds two name servers to the configuration.
  ```
switch(config)#ip name-server 172.0.14.21 3:4F21:1902::
switch(config)#
  ```
- This command attempts to add a name server when the configuration already lists three servers.
  ```
switch(config)#ip name-server 172.1.10.22
% Maximum number of nameservers reached. '172.1.10.22' not added
switch(config)#
  ```
**ipv6 host**

The `ipv6 host` command associates a hostname to an IPv6 address. This command supports local hostname resolution based on local hostname-IP address maps. Multiple hostnames can be mapped to an IPv6 address. IPv4 and IPv6 addresses can be mapped to the same hostname (to map IPv4 addresses to a hostname, use the `ip host` command). The `show hosts` command displays the local hostname-IP address mappings.

The `no ipv6 host` and `default ipv6 host` commands remove hostname-IP address maps by deleting the corresponding `ipv6 host` command from `running-config`, as specified by command parameters:

- **no parameters**: command removes all hostname-IPv6 address maps.
- **hostname** parameter: command removes all IPv6 address maps for the specified hostname.
- **hostname** and **IP address** parameters: command removes specified hostname-IP address maps.

**Command Mode**

Global Configuration

**Command Syntax**

```
ipv6 host hostname hostadd_1 [hostadd_2] ... [hostadd_X]
no ipv6 host [hostname] [hostadd_1] [hostadd_2] [hostadd_X]
default ipv6 host [hostname] [hostadd_1] [hostadd_2] [hostadd_X]
```

**Parameters**

- **hostname** hostname (text).
- **hostadd_N** IPv6 addresses associated with hostname (dotted decimal notation).

**Related Commands**

- `ip host`
- `show hosts`

**Example**

- This command associates the hostname *support_lab* with the IPv6 address 2001:0DB8:73:ff:ff:26:fd:90.

  ```
  switch(config)#ipv6 host support_lab 2001:0DB8:73:ff:ff:26:fd:90
  switch(config)#
  ```
**ntp authenticate**

The `ntp authenticate` command enables the authentication of incoming NTP packets. When authentication is enabled, NTP packets will be used to synchronize time on the switch only if they include a trusted authentication key. Authentication keys are created on the switch using the `ntp authentication-key` command, and the `ntp trusted-key` command is used to specify which keys are trusted. NTP authentication is disabled by default.

The `no ntp authenticate` and `default ntp authenticate` commands disable NTP authentication on the switch by removing the corresponding `ntp authenticate` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
ntp authenticate
no ntp authenticate
default ntp authenticate
```

**Examples**

- This command enables NTP authentication on the switch.
  ```
  switch(config)# ntp authenticate
  switch(config)#
  ```

- This command disables NTP authentication on the switch.
  ```
  switch(config)# no ntp authenticate
  switch(config)#
  ```
**ntp authentication-key**

The `ntp authentication-key` command creates an authentication key for use in authenticating incoming NTP packets. For the key to be used in authentication:

- It must be configured as a trusted key using the `ntp trusted-key` command.
- NTP authentication must be enabled on the switch using the `ntp authenticate` command.
- The same key must be configured on the NTP server.

The `no ntp authentication-key` and `default ntp authentication-key` commands remove the specified authentication key by removing the corresponding `ntp authentication-key` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
ntp authentication-key key_id ENCRYPT_TYPE password_text
no ntp authentication-key key_id
default ntp authentication-key key_id
```

**Parameters**
- `key_id` key ID number. Value ranges from 1 to 65534.
- `ENCRYPT_TYPE` encryption method. Values include:
  - `md5` `key_text` is MD5 encrypted.
  - `sha1` `key_text` is SHA-1 encrypted.
- `password_text` the authentication-key password.

**Example**
- This command creates an NTP authentication key with ID 234 and password “timeSync” using MD5 encryption.
  ```
switch(config)#ntp authentication-key 234 md5 timeSync
  
  Running-config stores the password as plain text.
  ```
- This command removes NTP authentication key 234.
  ```
switch(config)#no ntp authentication-key 234
  ```
**ntp serve**

The `ntp serve` command configures the command mode interface to accept incoming NTP requests regardless of the global setting.

The `no ntp serve` command configures the command mode interface to refuse incoming NTP requests regardless of the global setting. The `default ntp serve` command configures the command mode interface to follow the global setting.

Using this command also causes the switch to re-synchronize with its upstream NTP server.

**Command Modes**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration
- Interface-VXLAN Configuration

**Command Syntax**

```
ntp serve
no ntp serve
default ntp serve
```

**Example**

- These commands configure Ethernet interface 5 to accept incoming NTP requests regardless of global settings.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#ntp serve
  switch(config-if-Et5)#
  ```

- These commands configure Ethernet interface 5 to deny incoming NTP requests regardless of global settings.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no ntp serve
  switch(config-if-Et5)#
  ```

- These commands configure Ethernet interface 5 to use global settings in responding to incoming NTP requests.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#default ntp serve
  switch(config-if-Et5)#
  ```
The `ntp serve all` command configures the switch to act as an NTP server by accepting incoming NTP requests.

Using this command also causes the switch to re-synchronize with its upstream NTP server.

Individual interfaces can be configured separately to accept or deny NTP requests by using the `ntp serve` command, and these settings override the global setting.

**Command Mode**

Global Configuration

**Command Syntax**

- `ntp serve all`
- `no ntp serve all`
- `default ntp serve all`

**Example**

- This command configures the switch to accept incoming NTP requests.
  ```bash
  switch(config)#ntp serve all
  switch(config)#
  ```

- This command configures the switch to deny incoming NTP requests.
  ```bash
  switch(config)#no ntp serve all
  switch(config)#
  ```
ntp server

The ntp server command adds a Network Time Protocol (NTP) server to running-config. If the command specifies a server that already exists in running-config, it will modify the server settings. The switch synchronizes the system clock with an NTP server when running-config contains at least one valid NTP server.

The switch supports NTP versions 1 through 4. The default is version 4.

The prefer option specifies a preferred NTP server, which will be used as the NTP server if not discarded by NTP.

The no ntp server and default ntp server commands remove the specified NTP server from running-config. To remove an NTP server configured in a user-defined VRF, include the VRF name in the no ntp server command.

Command Mode
Global Configuration

Command Syntax

ntp server [VRF_INSTANCE] SERVER_NAME
[PREFERENCE] [NTP_VERSION] [IP_SOURCE] [burst] [iburst] [AUTH_KEY] [MAX_POLL_INT] [MIN_POLL_INT]
no ntp [server [VRF_INSTANCE] SERVER_NAME]
default ntp [server [VRF_INSTANCE] SERVER_NAME]

All parameters except VRF_INSTANCE and SERVER_NAME can be placed in any order.

Parameters

- **VRF_INSTANCE** the VRF instance to be used for connection to the specified server.
  - <no parameter> connects using the default VRF.
  - vrf vrf_name connects using the specified user-defined VRF.
  - **SERVER_NAME** NTP server location. Options include:
    - IP address in dotted decimal notation
    - an FQDN host name
  - **PREFERENCE** indicates priority of this server when the switch selects a synchronizing server.
    - <no parameter> server has no special priority.
    - prefer server has priority when the switch selects a synchronizing server.
  - **NTP_VERSION** specifies the NTP version. Settings include:
    - <no parameter> sets NTP version to 4 (default).
    - version number, where number ranges from 1 to 4.
  - **IP_SOURCE** specifies the source interface for NTP updates for the specified NTP server. This option overrides global settings created by the ntp source command. Options include:
    - <no parameter> sets the source interface to the global default.
    - source ethernet e_num Ethernet interface specified by e_num.
    - source loopback l_num loopback interface specified by l_num.
    - source management m_num management interface specified by m_num.
    - source port-channel p_num port-channel interface specified by p_num.
    - source vlan v_num VLAN interface specified by v_num.
burst indicates that when the NTP server is reached, the switch sends packets to the server in bursts of eight instead of the usual one. Recommended only for local servers. Off by default.

iburst indicates that the switch sends packets to the server in bursts of eight instead of the usual one until the server is reached. Recommended for general use to speed synchronization. Off by default.

AUTH_KEY the authentication key to use in authenticating NTP packets from the server.

- <no parameter> no authentication key is specified.
- key <1 to 65534> switch will use the specified key to authenticate NTP packets from the server.

MAX_POLL_INT specifies the maximum polling interval for the server (as the base-2 logarithm of the interval in seconds). Settings include:

- <no parameter> sets the maximum polling interval to 10 (1,024 seconds, the default).
- maxpoll number, where number is the base-2 logarithm of the interval in seconds. Values range from 3 (8 seconds) to 17 (131,072 seconds, approximately 36 hours).

MIN_POLL_INT specifies the minimum polling interval for the server (as the base-2 logarithm of the interval in seconds). Settings include:

- <no parameter> sets the minimum polling interval to 6 (64 seconds, the default).
- minpoll number where number is the base-2 logarithm of the interval in seconds. Values range from 3 (8 seconds) to 17 (131,072 seconds, approximately 36 hours).

Guidelines

To configure multiple parameters for a single server, include them all in a single ntp server command. Using the command again for the same server overwrites parameters previously configured in running-config.

All NTP servers must use the same VRF. If no VRF is specified, the server is configured in the default VRF. To use a user-defined VRF for connection to an NTP server, first use the no ntp server command to remove any NTP servers configured in the default VRF.

When specifying a source interface, choose an interface in the same VRF as the server. If the source interface is not in the same VRF, the source data will be included in running-config but will not be added to NTP packets.

An NTP server may be configured using an invalid or inactive VRF, but the status of the NTP server will remain inactive until the VRF is active.

Examples

- This command configures the switch to update its time with the NTP server at address 172.16.0.23 and designates it as a preferred NTP server.
  switch(config)#ntp server 172.16.0.23 prefer
- This command configures the switch to update its time through an NTP server named local-nettime.
  switch(config)#ntp server local-nettime
- This command configures the switch to update its time through a version 3 NTP server.
  switch(config)#ntp server 171.18.1.22 version 3
These commands reconfigure the switch to access the above NTP servers through VRF "magenta."

```
switch(config)#no ntp server 172.16.0.23
switch(config)#no ntp server local-nettime
switch(config)#no ntp server 171.18.1.22
switch(config)#ntp server vrf magenta 172.16.0.23 prefer
switch(config)#ntp server vrf magenta local-nettime
switch(config)#ntp server vrf magenta 171.18.1.22 version 3
switch(config)#
```
**ntp source**

The `ntp source` command configures an interface as the source of NTP updates. That interface's IP address is then used as the source address for all NTP packets sent to all destinations unless a server-specific source interface has been specified using the `source` option of the `ntp server` command.

The `no ntp source` and `default ntp source` commands remove the `ntp source` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
ntp source [VRF_INSTANCE] INT_PORT
no ntp source
default ntp source
```

**Parameters**
- `VRF_INSTANCE`  the VRF instance to be used for connection to the specified server.
  - `<no parameter>`  connects using the default VRF.
  - `vrf vrf_name`  connects using the specified user-defined VRF.
- `INT_PORT`  the interface port that specifies the NTP source. Settings include:
  - `ethernet e_range`  Ethernet interface list.
  - `loopback l_range`  loopback interface list.
  - `management m_range`  management interface list.
  - `port-channel c_range`  port channel interface list.
  - `vlan v_range`  VLAN interface list.

**Examples**
- This command configures VLAN interface 25 as the source of NTP update packets.
  ```
  switch(config)#ntp source vlan 25
  switch(config)#
  ```
- This command removes the NTP source command from the configuration.
  ```
  switch(config)#no ntp source
  switch(config)#
  ```
ntp trusted-key

The `ntp trusted-key` command specifies which authentication keys will be trusted for authentication of NTP packets. A packet with a trusted key will be used to update the local time if authenticated.

The `no ntp trusted-key` and `default ntp trusted-key` commands remove the specified authentication keys from the trusted key list by removing the corresponding `ntp trusted-key` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
ntp trusted-key key_list
no ntp trusted-key
default ntp trusted-key
```

**Parameters**

- `key_list` specified one or more keys. Formats include a number (1 to 65534), number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command configures the switch to trust authentication keys 234 and 237 for authentication of NTP packets.

  ```
  switch(config)#ntp trusted-key 234,237
  switch(config)#
  ```
prompt

The prompt command specifies the contents of the CLI prompt. Characters allowed in the prompt include A-Z, a-z, 0-9, and these punctuation marks:

! @ # $ % ^ & * () - = + f g [ ] ; : <> , . ? / n

The prompt supports these control sequences:

- %s – space character
- %t – tab character
- %% – percent character
- %D – time and date
- %D{f_char} – time and date, format specified by the BSD strftime (f_char) time conversion function.
- %H – host name
- %h – host name up to the first ‘.’
- %P – extended command mode
- %p – command mode
- %r1 – redundancy status on modular systems
- %R2 – extended redundancy status on modular systems – includes status and slot number

Table 5-1 displays Command Mode and Extended Command Mode prompts for various modes.

The no prompt and default prompt commands return the prompt to the default of %H%R%P.

Command Mode

Global Configuration

Command Syntax

prompt p_string
no prompt
default prompt

1. When logged into a fixed system or a supervisor on a modular system, this option has no effect.
2. When logged into a fixed system, this option has no effect.
Parameters

- **p_string** prompt text (character string). Elements include letters, numbers, and control sequences.

Examples

- This command creates a prompt that displays `system 1` and the command mode.
  ```
  host-name.dut103(config)#prompt system%s1%P
  system 1(config) #
  ```

- This command creates a prompt that displays the command mode.
  ```
  host-name.dut103(config)#prompt %p
  (config) #
  ```

- These equivalent commands create the default prompt.
  ```
  % prompt %HP
  host-name.dut103(config) #
  ```

  ```
  % no prompt
  host-name.dut103(config) #
  ```
ptp announce interval

The `ptp announce interval` command configures the interval between PTP announcement messages before a timeout occurs on the configuration mode interface. The `no ptp announce interval` command resets the timeout interval to its default of 1.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

Command Syntax
```
ptp announce interval log_interval
no ptp announce interval
default ptp announce interval
```

Parameters
- `log_interval`  The number of log seconds between PTP announcement message (base 2 log (seconds)). Value ranges from 0 to 4; default value is 1.

Examples
- These commands set the interval between PTP announcements on interface Ethernet 5 to 2.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp announce interval 1
  switch(config-if-Et5)#
  ```
- These commands reset the PTP announcement interval on interface Ethernet 5 to the default value of 1.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp announce interval
  switch(config-if-Et5)#
  ```
ptp announce timeout

The ptp announce timeout command specifies the time for announcing timeout messages. The range is 2 to 10 log seconds. The default is 3 (8 seconds). The no ptp announce timeout command disables the feature.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

Command Syntax
- ptp announce timeout log_interval
- no ptp announce timeout
- default ptp announce timeout

Parameters
- log_interval The range is 2 to 10 log seconds (base 2 log (seconds)). The default is 3 (8 seconds).

Examples
- These commands set the timeout interval for PTP announcements on interface Ethernet 5 to 5 log seconds.
  
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp announce timeout 5
  switch(config-if-Et5)#

- These commands reset the PTP timeout interval on interface Ethernet 5 to the default value of 3 (8 seconds).
  
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp announce timeout
  switch(config-if-Et5)#
ptp delay-mechanism

The **ptp delay-mechanism** command configures the delay mechanism in boundary clock mode. The **no ptp delay-mechanism** command disables the feature.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
ptp delay-mechanism MECH_TYPE
no ptp delay-mechanism
default ptp delay-mechanism
```

**Parameters**

- **MECH_TYPE** The delay mechanism. Options include:
  - **e2e** The delay request or response mechanism used in the boundary clock mode.
  - **p2p** The peer-to-peer mechanism used in the boundary clock mode.

**Examples**

- This command sets the delay mechanism to p2p in the boundary clock mode.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp delay-mechanism p2p
```

- This command sets the delay mechanism to e2e in the boundary clock mode.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp delay-mechanism e2e
```

- This command removes the delay mechanism configuration from Ethernet 5.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# no ptp delay-mechanism e2e
```
**ptp delay-req interval**

The **ptp delay-req interval** command specifies the time in log seconds recommended to the slave devices to send delay request messages. You must enable PTP on the switch first and configure the source IP address for PTP communication. The **no ptp delay-req interval** command resets the interval to its default of 5 (32 seconds).

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
- `ptp delay-req interval log_interval`
- `no ptp delay-req interval`
- `default ptp delay-req interval`

**Parameters**
- **log_interval** The range is -1 to 8 log seconds (base 2 log (seconds)). The default is 5 (32 seconds).

**Examples**
- These commands set the minimum interval allowed between PTP delay request messages on Ethernet interface 5 to 3 (8 seconds).
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp delay-request interval 3
  switch(config-if-Et5)#
  ```
- These commands reset the minimum interval allowed between PTP delay-request messages to the default of 5 (32 seconds).
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp delay-request interval
  switch(config-if-Et5)#
  ```
ptp domain

The `ptp domain` command sets the domain number to use for the clock. The `no ptp domain` command disables the feature.

**Command Mode**

Global Configuration

**Command Syntax**

```
ptp domain  domain_number
no ptp domain
default ptp domain
```

**Parameters**

- `domain_number` Value ranges from 0 to 255.

**Examples**

- This command shows how to configure domain 1 for use with a clock.
  ```
  switch(config)# ptp domain 1
  switch(config)#
  ```

- This command removes the configured domain 1 for use with a clock.
  ```
  switch(config)# no ptp domain 1
  switch(config)#
  ```
**ptp enable**

The `ptp enable` command enables PTP on the interface. The `no ptp enable` command disables PTP on the interface.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
- `ptp enable`
- `no ptp enable`
- `default ptp enable`

**Examples**
- This command enables PTP on Ethernet interface 5.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp enable
  ```
- This command disables PTP on Ethernet interface 5.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp enable
  ```
The `ptp forward-v1` command configures the switch to forward Precision Time Protocol version packets as regular multicast traffic. By default, PTP v1 packets are trapped by the CPU, logged and discarded.

The `no ptp forward-v1` and `default ptp forward-v1` commands restore the default forwarding behavior by removing the corresponding `ptp forward-v1` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

- `ptp forward-v1`
- `no ptp forward-v1`
- `default ptp forward-v1`

**Examples**

- This command configures the switch to forward PTP v1 packets as regular multicast traffic.

```
switch(config)# ptp forward-v1
switch(config)#
```

- This command configures the switch to log and discard PTP v1 packets.

```
switch(config)# no ptp forward-v1
switch(config)#
```
The `ptp hold-ptp-time` command configures the PTP offset hold time in seconds. The `no ptp hold-ptp-time` command disables the feature.

**Command Mode**
Global Configuration

**Command Syntax**

```
ptp hold-ptp-time offset
no ptp hold-ptp-time
default ptp hold-ptp-time
```

**Parameters**
- `offset` Value ranges from 0 to 86400.

**Examples**
- This command shows how to configure the PTP offset hold time.
  ```
  switch(config)# ptp hold-ptp-time 600
  switch(config)#
  ```
- This command removes the configured PTP offset hold time.
  ```
  switch(config)# no ptp hold-ptp-time
  switch(config)#
  ```
ptp mode

The `ptp mode` command configures the Precision Time Protocol (PTP) packet forwarding mode for the switch. The default `ptp mode` is `disabled`.

The `no ptp mode` and `default ptp mode` commands return the forwarding mode to `disabled` by removing the `ptp mode` command from `running-config`.

Command Mode
Global Configuration

Command Syntax
- `ptp mode MODE_NAME`
- `no ptp mode`
- `default ptp mode`

Parameters
- `MODE_NAME` Options include:
  - `boundary`
  - `disabled`
  - `e2etransparent`
  - `p2ptransparent`
  - `gptp`

Examples
- This command configures the boundary mode for PTP.
  ```
  switch(config)# ptp mode boundary
  switch(config)#
  ```
- This command restores PTP to disabled mode.
  ```
  switch(config)# no ptp mode
  switch(config)#
  ```
ptp pdelay-neighbor-threshold

The `ptp pdelay-neighbor-threshold` command configures the propagation delay threshold above which the switch will consider the neighbor connected to this port to be incapable of participating in generalized Precision Time Protocol (gPTP).

The `no ptp pdelay-neighbor-threshold` and `default ptp pdelay-neighbor-threshold` commands restore the threshold to 100000 nanoseconds by removing the corresponding `ptp pdelay-neighbor-threshold` command from `running-config`.

Command Mode

Interface-Ethernet Configuration
Interface-Port Channel Configuration

Command Syntax

```
ptp pdelay-neighbor-threshold link_prop
no ptp pdelay-neighbor-threshold
default ptp pdelay-neighbor-threshold
```

Parameters

- `link_prop` Threshold in nanoseconds. Value ranges from 0 to 10000000000 (ten billion). Default is 100000.

Examples

- These commands set the link propagation delay threshold on Ethernet interface 5 to 200000 nanoseconds.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp pdelay-neighbor-threshold 200000
  switch(config-if-Et5)#
  ```

- These commands restore the link propagation delay threshold on Ethernet interface 5 to its default value of 100000 nanoseconds.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp pdelay-neighbor-threshold
  switch(config-if-Et5)#
  ```
ptp pdelay-req interval

The `ptp pdelay-req interval` command configures the interval between Precision Time Protocol peer delay-request messages. The `no ptp pdelay-req interval` command removes the configuration.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
ptp pdelay-req interval log_interval
no ptp pdelay-req interval
default ptp pdelay-req interval
```

**Parameters**
- `log_interval` The log interval in seconds (base 2 log (seconds)). Value ranges from 0 to 5.

**Examples**
- This command shows how to configure the interval allowed between PTP peer delay request messages on interface Ethernet 5.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp pdelay-request interval 3
  switch(config-if-Et5)#
  ```
- This command removes the configure the interval allowed between PTP peer delay request messages on interface Ethernet 5.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp pdelay-request interval
  switch(config-if-Et5)#
  ```
ptp priority1

The `ptp priority1` command configures the priority 1 value for advertising the switch’s PTP clock. Priority 1 is the most significant of the six factors used by devices in the selection of a master clock. Lower values indicate higher priority.

The `no ptp priority1` and `default ptp priority1` commands restore the priority 1 default setting of 128.

**Command Mode**

Global Configuration

**Command Syntax**

```
ptp priority1 priority_rate
no ptp priority1
default ptp priority1
```

**Parameters**

- `priority_rate` Value ranges from 0 to 255. Default is 128.

**Examples**

- This command sets the priority 1 level for the switch’s PTP clock to 120.
  
  ```
  switch(config)# ptp priority1 120
  switch(config)#
  ```

- This command restores the default priority 1 level of 128.
  
  ```
  switch(config)# no ptp priority1
  switch(config)#
  ```
ptp priority2

The ptp priority2 command sets the priority 2 value for the clock. The range is from 0 to 255. Priority 2 is the fifth most significant of the six factors used by devices in the selection of a master clock. Lower values indicate higher priority.

The no ptp priority2 and default ptp priority2 commands restore the priority 2 default setting of 128.

Command Mode
Global Configuration

Command Syntax

ptp priority2 priority_rate
no ptp priority2
default ptp priority2

Parameters

• priority_rate  Specifies the priority 2 level for the PTP clock. Value ranges from 0 to 255; default value is 128.

Examples

• This command sets the priority 2 level for the switch’s PTP clock to 120.
  switch(config)# ptp priority2 120
  switch(config)#

• This command restores the default priority 2 level of 128.
  switch(config)# no ptp priority2
  switch(config)#
**ptp source ip**

The *ptp source ip* command configures the source IP address for all PTP packets. The IP address can be in IPv4 format. The *no ptp source ip* command removes this configuration.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
ptp source ip ipv4_addr
no ptp source ip
default ptp source ip
```

**Parameters**

- *ipv4_addr*  IPv4 address

**Examples**

- This command configures the source IP address *10.0.2.1* for all PTP packets.
  ```plaintext
  switch(config)# ptp source ip 10.0.2.1
  switch(config)#
  ```

- This command removes the source IP address *10.0.2.1* for all PTP packets.
  ```plaintext
  switch(config)# no ptp source ip
  switch(config)#
  ```
ptp sync interval

The **ptp sync interval** command configures the time for sending synchronization messages. The command configures the interval by specifying its log₂ value. Parameter value ranges from -1 (1/2 second) to 3 (eight seconds). The default value is 0 (one second).

The **no ptp sync interval** and **default ptp sync interval** commands restore the default sync interval setting of 0 by removing the corresponding **ptp ptp sync interval** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
ptp sync interval log_interval
no ptp sync interval
default ptp sync interval
```

**Parameters**
- **log_interval**  The interval between PTP synchronization messages sent from the master to the slave (base 2 log(seconds)). Values range from -1 to 3; default value is 0 (1 second).

**Examples**

- These commands set the interval for PTP synchronization messages on Ethernet interface 5 to 3 (8 seconds).
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp sync interval 3
  switch(config-if-Et5)#
  ```

- These commands restore the interval for PTP synchronization messages on Ethernet interface 5 to its default of 0 (1 second).
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp sync interval
  switch(config-if-Et5)#
  ```
**ptp sync timeout**

A PTP synchronization timeout occurs if a sync message is not received for a specified period of time, calculated as a multiple of the PTP sync interval. The `ptp sync timeout` command configures the sync timeout multiplier. The range is 2 to 255, with a default of 20 (20 times the sync interval). To configure the sync interval, use the `ptp sync interval` command.

The `no ptp sync timeout` and `default ptp sync timeout` commands restore the PTP sync timeout multiplier to its default value of 20.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
ptp sync timeout interval_multiplier
no ptp sync timeout
default ptp sync timeout
```

**Parameters**

- **interval_multiplier** The number of sync intervals that must pass without the configuration mode interface receiving a PTP sync message before a timeout occurs. Value ranges from 2 to 255. Default value is 20.

**Examples**

- These commands configure the sync timeout on Ethernet interface 5 to ten times the configured sync interval.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# ptp sync timeout 10
switch(config-if-Et5)#
```
ptp transport

The `ptp transport` command configures the PTP transport type for a specific interface. Any values set in interface PTP configuration mode override the settings in the PTP configuration profile associated with the interface. The `no ptp transport` command removes the setting from the running configuration.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

Command Syntax

```
ptp transport TRANSPORT_TYPE
no ptp transport
default ptp transport
```

Parameters
- **TRANSPORT_TYPE**  The transport mode in boundary clock mode. Options include:
  - `ipv4`  The IPv4 address used as the transport type on the interface.
  - `layer2`  The Layer 2 protocol used as the transport type on the interface.

Examples
- This command overrides the transport type in the profile and sets it to be IPv4 for the interface.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# ptp transport ipv4
  switch(config-if-Et5)#
  ```
- This command removes the interval for PTP synchronization messages on interface Ethernet 5.
  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# no ptp transport
  switch(config-if-Et5)#
  ```
**ptp ttl**

The **ptp ttl** command configures the time-to-live value of the PTP packets. The **no ptp ttl** resets the time to live to the default value of 1 hop by removing the **ptp ttl** command from the running configuration.

**Command Mode**

Global Configuration

**Command Syntax**

```
ptp ttl hop_count
no ptp ttl
default ptp ttl
```

**Parameters**

- **hop_count**  The time to live measured in hops. Value ranges from 1 to 255, default is 1.

**Example**

- This command sets the time to live of the PTP packets to 60 hops.
  
  ```
  switch(config)# ptp ttl 60
  switch(config)#
  ```

- This command resets the time to live of the PTP packets to the default value of 1 hop.
  
  ```
  switch(config)# no ptp ttl
  switch(config)#
  ```
show banner

The `show banner` command displays the specified banner.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show banner BANNER_TYPE
```

**Parameters**
- `BANNER_TYPE` banner that the command displays. Options include
  - `login` command displays login banner.
  - `motd` command displays message of the day banner.

**Example**
- These commands configure and display the message of the day banner.
  ```
  switch(config)#banner motd
  Enter TEXT message. Type 'EOF' on its own line to end.
  This is an motd banner for $(hostname)
  EOF
  ```
  ```
  switch(config)#show banner motd
  This is an motd banner for $(hostname)
  ```
  ```
  switch(config)#
  ```
show clock

The `show clock` command displays the current system clock time and configured time zone. The switch uses the system clock for system log messages and debugging traces.

**Command Mode**

EXEC

**Command Syntax**

`show clock`

**Example**

- This command displays the current system clock time and configured time zone.

  ```
  switch>show clock
  Wed Nov  2 10:29:32 2011
  timezone is America/Los_Angeles
  switch>
  ```
show event-monitor arp

The show event-monitor arp command performs an SQL-style query on the event monitor database and displays ARP table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

Command Mode
Privileged EXEC

Command Syntax
show event-monitor arp [GROUP] [MESSAGES] [INTERFACE] [IP] [MAC] [TIME]

Optional parameters can be placed in any order.

Parameters
- **GROUP** used with aggregate functions to group results. Analogous to SQL `group by` command.
  - `<no parameter>` results are not grouped.
  - `group-by ip` results are grouped by IP address.
  - `group-by mac` results are grouped by MAC address.
- **MESSAGES** number of message returned from query. Analogous to SQL `limit` command.
  - `<no parameter>` result-set size is not limited.
  - `limit msg_quantity` number of results that are displayed. Values range from 1 to 15,000.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - `<no parameter>` result-set not restricted by interface.
  - `match-interface ethernet e_range` Ethernet interface list.
  - `match-interface loopback l_range` loopback interface list.
  - `match-interface management m_range` management interface list.
  - `match-interface port-channel c_range` port channel interface list.
  - `match-interface vlan v_range` VLAN interface list.
- **IP** restricts result-set to events that include specified IP address (SQL Like command).
  - `<no parameter>` result-set not restricted to specific IP addresses.
  - `match-ip ip_address_rex` IP address, as represented by regular expression.
- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).
  - `<no parameter>` result-set not restricted to specific MAC addresses.
  - `match-mac mac_address_rex` MAC address, as represented by regular expression.
- **TIME** restricts result-set to events generated during specified period.
  - `<no parameter>` result-set not restricted by time of event.
  - `match-time last-minute` includes events generated during last minute.
  - `match-time last-day` includes events generated during last day.
  - `match-time last-hour` includes events generated during last hour.
  - `match-time last-week` includes events generated during last week.
Example

- This command displays ARP table events listed in the event monitor database.

```bash
switch# show event-monitor arp
% Writing 220017 Arp, 234204 Route, 1732559 Mac events to the database
2012-11-06 12:36:10|10.33.6.159|Vlan1417|00:00:00:dc:cc:0d|0|added|2186271

switch#
```
show event-monitor mac

The **show event-monitor mac** command performs an SQL-style query on the event monitor database and displays MAC address table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show event-monitor mac [GROUP] [MESSAGES] [INTERFACE] [MAC] [TIME]
```
Optional parameters can be placed in any order.

**Parameters**
- **GROUP** used with aggregate functions to group results. Analogous to SQL `group by` command.
  - `<no parameter>` results are not grouped.
  - `group-by interface` results are grouped by interface.
  - `group-by mac` results are grouped by MAC address.
- **MESSAGES** number of message returned from query. Analogous to SQL `limit` command.
  - `<no parameter>` result-set size is not limited.
  - `limit msg_quantity` number of results that are displayed. Values range from 1 to 15,000.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - `<no parameter>` result-set not restricted by interface.
  - `match-interface ethernet e_range` Ethernet interface list.
  - `match-interface loopback l_range` loopback interface list.
  - `match-interface management m_range` management interface list.
  - `match-interface port-channel c_range` port channel interface list.
  - `match-interface vlan v_range` VLAN interface list.
- **MAC** restricts result-set to events that include specified MAC address (SQL Like command).
  - `<no parameter>` result-set not restricted to specific MAC addresses.
  - `match-mac mac_address_rex` MAC address, as represented by regular expression.
- **TIME** restricts result-set to events with specified period.
  - `<no parameter>` result-set not restricted by time of event.
  - `match-time last-minute` includes events generated during last minute.
  - `match-time last-day` includes events generated during last day.
  - `match-time last-hour` includes events generated during last hour.
  - `match-time last-week` includes events generated during last week.

**Examples**
- This command displays all events triggered by MAC address table events.
  ```
  switch#show event-monitor mac
  % Writing 0 Arp, 0 Route, 1 Mac events to the database
  2012-01-19 13:57:55|1|08:08:08:08:08:08|Ethernet1|configuredStaticMac|added|0
  ```
This command displays events triggered by MAC address table changes.

```
switch#show event-monitor mac match-mac 08:08:08:08:
2012-01-19 13:57:55|1|08:08:08:08:08:08|Ethernet1|configuredStaticMac|added|0
```
show event-monitor route

The `show event-monitor route` command performs an SQL-style query on the event monitor database and displays routing table events as specified by command parameters. The event monitor buffer and all backup logs are synchronized into a single SQLite file.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show event-monitor route [GROUP] [MESSAGES] [IP] [TIME]
```
Optional parameters can be placed in any order.

**Parameters**
- **GROUP** used with aggregate functions to group results. Analogous to SQL `group by` command.
  - `<no parameter>` results are not grouped.
  - `group-by ip` results are grouped by IP address.
- **MESSAGES** number of message returned from query. Analogous to SQL `limit` command.
  - `<no parameter>` result-set size is not limited.
  - `limit msg_quantity` number of results that are displayed. Values range from 1 to 15,000.
- **INTERFACE** restricts result-set to events that include specified interface (SQL Like command).
  - `<no parameter>` result-set not restricted by interface.
  - `match-interface ethernet e_range` Ethernet interface list.
  - `match-interface loopback l_range` loopback interface list.
  - `match-interface management m_range` management interface list.
  - `match-interface port-channel c_range` port channel interface list.
  - `match-interface vlan v_range` VLAN interface list.
- **IP** restricts result-set to events that include specified IP address (SQL Like command).
  - `<no parameter>` result-set not restricted to specific IP addresses.
  - `match-ip ip_address_rex` IP address, as represented by regular expression.
- **TIME** restricts result-set to events with specified period.
  - `<no parameter>` result-set not restricted by time of event.
  - `match-time last-minute` includes events generated during last minute.
  - `match-time last-day` includes events generated during last day.
  - `match-time last-hour` includes events generated during last hour.
  - `match-time last-week` includes events generated during last week.
Example

- This command displays 10 routing table events listed in the event monitor database.

```
switch#show event-monitor route limit 10
% Writing 0 Arp, 2 Route, 0 Mac events to the database
2012-11-07 12:48:02|10.44.54.0/23|ospfAseE2|30|110|changed|2186957

switch#
```
show event-monitor sqlite

The `show event-monitor sqlite` command performs an SQL-style query on the event monitor database, using the statement specified in the command.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show event-monitor sqlite statement
```

**Parameters**
- `statement` SQLite statement.

**Example**
- This command displays all entries from the route table.

```
switch# show event-monitor sqlite select * from route;
2012-01-19 13:53:01|16.16.16.0/24||||removed|0
2012-01-19 13:53:01|16.16.16.17/32||||removed|1

2012-01-19 13:53:01|192.168.1.6/32||||removed|10
switch#
```
show hostname

The show hostname command displays the hostname and the fully qualified domain name (FQDN) of the switch.

**Command Mode**

EXEC

**Command Syntax**

    show hostname

**Example**

- This command displays the hostname and FQDN of the switch.

    switch>show hostname
    Hostname: switch_1
    FQDN:     switch_1.aristanetworks.com

    switch>
show hosts

The `show hosts` command displays the default domain name, name lookup service style, a list of name server hosts, and the static hostname-IP address maps.

**Command Mode**

EXEC

**Command Syntax**

`show hosts`

**Example**

- This command displays the switch’s IP domain name:

  ```
  switch> `show hosts`
  Default domain is: aristanetworks.com
  Name/address lookup uses domain service
  Name servers are: 172.22.22.40, 172.22.22.10
  
  Static Mappings:
  
<table>
<thead>
<tr>
<th>Hostname</th>
<th>IP</th>
<th>Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEST_LAB</td>
<td>IPV4</td>
<td>10.24.18.6</td>
</tr>
<tr>
<td>PRODUCTION_LAB</td>
<td>IPV4</td>
<td>10.24.18.7</td>
</tr>
<tr>
<td>SUPPORT_LAB</td>
<td>IPV6</td>
<td>2001:0DB8:73:ff:ff:26:fd:90</td>
</tr>
</tbody>
</table>
  
  switch>
  ```
show ip domain-name

The **show ip domain-name** command displays the switch’s IP domain name that is configured with the `ip domain name` command.

**Command Mode**

EXEC

**Command Syntax**

```
show ip domain-name
```

**Example**

- This command displays the switch’s IP domain name:

  ```
  switch>show ip domain-name
  aristanetworks.com
  switch>
  ```
show ip name-server

The `ip name-server` command displays the ip addresses of name-servers in `running-config`. The name servers are configured by the `ip name-server` command.

**Command Mode**

EXEC

**Command Syntax**

`show ip name-server`

**Example**

- This command displays the IP address of name servers that the switch is configured to access.

```
switch>show ip name-server
172.22.22.10
172.22.22.40
switch>
```
show ntp associations

The `show ntp associations` command displays the status of connections to NTP servers.

Command Mode
EXEC

Command Syntax
`show ntp associations`

Display Values
- st (stratum): number of steps between the switch and the reference clock.
- t (transmission type): u – unicast; b – broadcast; l – local.
- when: interval since reception of last packet (seconds unless unit is provided).
- poll: interval between NTP poll packets. Maximum (1024) reached as server and client syncs.
- reach: octal number that displays status of last eight NTP messages (377 - all messages received).
- delay: round trip delay of packets to selected reference clock.
- offset: difference between local clock and reference clock.
- jitter: maximum error of local clock relative to reference clock.

Example
- This command displays the status of the switch’s NTP associations.

```
switch>show ntp associations
remote refid st t when poll reach delay offset jitter
------- --------- ---- ---- ---- ---- ---- --------
172.1.1.1  .INIT.  16 u -1024 0 0.000 0.000
0.000
moose.aristanet 192.187.233.4  2 u 9 64 377 0.118 9440498 0.017
172.17.2.6  .INIT.  16 u -1024 0 0.000 0.000
0.000
*LOCAL(0) .LOCL.  10 1 41 64 377 0.000 0.000 0.000
```
**show ntp status**

The **show ntp status** command displays the status of NTP on the switch. If the switch clock is not synchronized to an NTP server, the status reads “unsynchronised” and shows the server polling interval. If the clock is synchronized to an NTP server, the status shows the reference ID and stratum of the server, the precision of the synchronization, and the polling interval.

---

**Important!** As specified in RFC5905, for servers with IPv4 addresses the reference ID is the four-octet IPv4 address, but for servers with IPv6 addresses the reference ID is the first four octets of the MD5 hash of the IPv6 address.

---

**Command Mode**

EXEC

**Command Syntax**

```
show ntp status
```

**Example**

- This command displays the switch’s NTP status.

```
switch>show ntp status
synchronised to NTP server (172.16.1.50) at stratum 4
time correct to within 77 ms
polling server every 1024 s
switch>
```
show ptp

The `show ptp` command displays summary Precision Time Protocol (PTP) information and PTP status of switch ports.

**Command Mode**

EXEC

**Command Syntax**

`show ptp`

**Example**

- This command displays summary PTP information.

```plaintext
switch#show ptp
PTP Mode: gptp - Generalized PTP Clock

```

<--------OUTPUT OMITTED FROM EXAMPLE-------->

```
show ptp clock

The `show ptp clock` command displays the Precision Time Protocol (PTP) clock information.

**Command Mode**

EXEC

**Command Syntax**

`show ptp clock`

**Example**

- This command shows how to display the PTP local clock and offset.

```
switch#show ptp clock
PTP Mode: Boundary Clock
Clock Identity: 0x00:1c:73:ff:ff:1e:83:24
Clock Domain: 1
Number of PTP ports: 24
Priority1: 128
Priority2: 128
Clock Quality:
  Class: 248
  Accuracy: 0x30
  OffsetScaledLogVariance: 0xffff
Offset From Master: 0
Mean Path Delay: 0
Steps Removed: 0
switch#
```
show ptp foreign-master-record

The `show ptp foreign-master-record` command displays information about foreign masters (PTP sources not designated as the switch's master from which the switch has received sync packets).

**Command Mode**

EXEC

**Command Syntax**

```
show ptp foreign-master-record
```

**Examples**

- This command displays information about PTP foreign masters.

```
switch# show ptp clocks foreign-masters-record
No Foreign Master Records
switch#
```
show ptp interface

The **show ptp interface** command displays PTP information for all the interfaces on the device.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show ptp [INTERFACE_NAME] [STATUS_FILTER]
```

**Parameters**

- **INTERFACE_NAME** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

- **STATUS_FILTER** Filters interfaces by their configuration status. Options include:
  - `<no parameter>` all interfaces.
  - `enabled` PTP configured interfaces.

**Examples**

This command displays PTP information for all the interfaces on the device.

```plaintext
switch# show ptp interface
Interface Ethernet1
PTP: Disabled
Port state: Disabled
Sync interval: 1.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 3
Delay mechanism: end to end
Delay request message interval: 32.0 seconds
Transport mode: ipv4

<------OUTPUT OMITTED FROM EXAMPLE-------->

Interface Ethernet5
PTP: Disabled
Port state: Disabled
Sync interval: 8.0 seconds
Announce interval: 2.0 seconds
Announce interval timeout multiplier: 5
Delay mechanism: peer to peer
Peer delay request message interval: 8.0 seconds
Peer Mean Path Delay: 0
Transport mode: ipv4

<------OUTPUT OMITTED FROM EXAMPLE-------->
```

switch#
show ptp interface counters

The **show ptp interface counters** command displays PTP interface counters for all interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show ptp [INTERFACE_NAME] counters
```

**Parameters**

- **INTERFACE_NAME**  Interface type and numbers. Options include:
  - *<no parameter>*  Display information for all interfaces.
  - **ethernet e_range**  Ethernet interface range specified by *e_range*.
  - **loopback l_range**  Loopback interface specified by *l_range*.
  - **management m_range**  Management interface range specified by *m_range*.
  - **port-channel p_range**  Port-Channel Interface range specified by *p_range*.
  - **vlan v_range**  VLAN interface range specified by *v_range*.
  - **vxlan vx_range**  VXLAN interface range specified by *vx_range*.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command displays the PTP interface counters.

  ```
  switch# show ptp interface ethernet 5 counters
  Interface Ethernet5
  Announce messages sent: 0
  Announce messages received: 0
  Sync messages sent: 0
  Sync messages received: 0
  Follow up messages sent: 0
  Follow up messages received: 0
  Delay request messages sent: 0
  Delay request messages received: 0
  Delay response messages sent: 0
  Delay response messages received: 0

  Peer delay response messages received: 0
  Peer delay response follow up messages sent: 0
  Peer delay response follow up messages received: 0
  switch#
  ```
**show ptp parent**

The `show ptp parent` command displays information about the switch’s PTP parent and grand master clocks.

**Command Mode**
- Privileged EXEC

**Command Syntax**
```
show ptp parent
```

**Examples**
- This command displays information about the switch's PTP parent and grand master clocks.

```
switch# show ptp parent
Parent Clock:
Parent Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Parent Port Number: 0
Parent IP Address: N/A
Observed Parent Offset (log variance): N/A
Observed Parent Clock Phase Change Rate: N/A

Grandmaster Clock:
Grandmaster Clock Identity: 0x00:1c:73:ff:ff:00:72:40
Grandmaster Clock Quality:
  Class: 248
  Accuracy: 0x30
  OffsetScaledLogVariance: 0xffff
  Priority1: 128
  Priority2: 128
switch#
```
show ptp source ip

The `show ptp source ip` command displays the PTP source IP for the device.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
show ptp source ip
```

**Examples**

- This command shows the PTP source IP to be 10.0.2.1.

```
switch#show ptp source ip
PTP source IP: 10.0.2.1
switch#
```
**show ptp time-property**

The **show ptp time-property** command displays the Precision Time Protocol (PTP) clock properties.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
show ptp time-property
```

**Examples**

- This command shows the PTP clock properties.

  ```
  switch# show ptp time-property
  Current UTC offset valid: False
  Current UTC offset: 0
  Leap 59: False
  Leap 61: False
  Time Traceable: False
  Frequency Traceable: False
  PTP Timescale: False
  Time Source: 0x0
  switch#
  ```
Booting the Switch

This chapter describes the switch boot process, describes configuration options, and lists the components it requires, including the boot loader, the boot loader shell, and other configuration files.

This chapter includes the following sections:

- Section 6.1: Boot Loader – Aboot
- Section 6.2: Configuration Files
- Section 6.3: Supervisor Redundancy
- Section 6.4: System Reset
- Section 6.5: Aboot Shell
- Section 6.6: Aboot Configuration Commands
- Section 6.7: Switch Booting Commands

6.1 Boot Loader – Aboot

Aboot is the boot loader for Arista switches. In addition to booting the switch EOS, Aboot provides a shell for changing boot parameters, restoring default switch settings, diagnosing hardware problems, and managing switch files. Section 6.5: Aboot Shell describes the Aboot shell.

The boot process loads an EOS image file, initiates switch processes, performs self tests, restores interface settings, and configures other network parameters. The replacement image file can be in the switch’s flash or on a device in the flash drive port. Configuration files stored in flash memory specify boot parameters.

Aboot supports most available USB flash drive models. The flash drive must be formatted with the FAT or VFAT file system. Windows NT File System (NTFS) is not supported.

Aboot initiates a system reboot upon a reload command or by restoring power to the switch. Before loading the EOS image file, Aboot provides an option to enter the Aboot shell. The user can either enter the shell to modify boot parameters or allow the switch to boot.

The boot process can be monitored through a terminal connected to the console port. The console port is configured to interact with the terminal by configuration file settings.
6.2 Configuration Files

Three files define boot and running configuration parameters.

- **boot-config**: Contains the location and name of the image to be loaded.
- **running-config**: Contains the current switch configuration.
- **startup-config**: Contains the switch configuration that is loaded when the switch boots.

The **running-config** and **startup-config** are different when configuration changes have not been saved since the last boot.

6.2.1 boot-config

The **boot-config** file is an ASCII file that Aboot uses to configure console communication settings, locate the EOS flash image, and specify initial network configuration settings.

Aboot attempts to boot the EOS flash software image (with the extension .swi) referenced by **boot-config** if the user does not interrupt the boot process. See Section 6.5: Aboot Shell describes how Aboot uses **boot-config**.

You can view and edit the **boot-config** file contents. Viewing and editing options include:

- View **boot-config** file contents with the **more boot-config** command:
  ```
  switch(config)#more boot-config
  SWI=flash:/EOS.swi
  CONSOLESPEED=2400
  Aboot password (encrypted): $1$A8dZ3GLZ$knKrBpTyg5dhmtGdCdwNM.
  switch(config)#
  ```

- View **boot-config** settings with the **show boot-config** command:
  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: 2400
  Aboot password (encrypted): $1$A8dZ3GLZ$knKrBpTyg5dhmtGdCdwNM.
  Memory test iterations: (not set)
  switch(config)#
  ```

- Modify file settings from the command line with EOS **boot** commands.
  See Section 6.2.1.3: Programming boot-config from the CLI for a list of **boot** commands.

- Edit the file directly by using vi from the Bash shell.
  See Section 6.2.1.2: boot-config Command Line Content for a list of **boot-config** parameters.

6.2.1.1 boot-config File Structure

Each line in the **boot-config** file specifies a configuration setting and has this format:

```
NAME=VALUE
```

- **NAME** is the parameter label.
- **VALUE** indicates the parameter’s bootup setting.

The **NAME** and **VALUE** fields cannot contain spaces.

Aboot ignores blank lines and lines that begin with a # character.

6.2.1.2 boot-config Command Line Content

Aboot configuration commands that **boot-config** files can contain include:
• **SWI** specifies the location and file name of the EOS image file that Aboot loads when booting, using the same format as the boot command to designate a local or network path.

**Example**
- SWI=flash:EOS.swi (flash drive location)
- SWI=usb1:/EOS1.swi (USB drive location)
- SWI=file:/tmp/EOSexp.swi (switch directory location)
- SWI=/mnt/flash/EOS.swi
- SWI=http://foo.com/images/EOS.swi
- SWI=ftp://foo.com/images/EOS.swi
- SWI=tftp://foo.com/EOS.swi
- SWI=nfs://foo.com/images/EOS.swi

• **CONSOLESPEED** specifies the console baud rate. To communicate with the switch, the connected terminal must match the specified rate. Baud rates are 1200, 2400, 4800, 9600, 19200, or 38400. The default baud rate is 9600.

**Example**
- CONSOLESPEED=2400
- CONSOLESPEED=19200

• **PASSWORD (ABOOT)** specifies the Aboot password, as described in Section 6.5.2: Accessing the Aboot Shell. If boot-config does not contain a PASSWORD line, the Aboot shell does not require a password.

**Example**
- PASSWORD=$1$CdWp5wfe$pzNtE3ujBoFEL8vjq7jo/

• **NET commands** NET commands in the boot-config file are used by Aboot during switch booting to configure the network interface that will be used for switch configuration. These commands can also be entered manually in Aboot.

NETDEV indicates which network interface is being configured. If boot-config does not contain a NETDEV setting, the booting process does not attempt to configure a network interface. Other NET commands specify settings that Aboot uses to configure the interface.

**Examples**
- This NETDEV command specifies management port 1 as the network interface to be configured by boot-config.
  
  NETDEV=ma1
  This NETAUTO command instructs the switch to configure the network interface through a DHCP server, ignoring other NET settings.
  NETAUTO=dhcp
  These NET commands configure the network interface.
  NETIP=10.12.15.10
  NETMASK=255.255.255.0
  NETGW=10.12.15.24
  NETDOMAIN=mycompany.com
  NETDNS=10.12.15.13
Programming boot-config from the CLI

The switch CLI provides `boot` commands for editing `boot-config` contents. The `boot` commands are not accessible from a console port CLI. Parameters not configurable from a boot command can be modified by directly editing the `boot-config` file.

Commands that configure boot parameters include `boot system`, `boot secret`, and `boot console`.

**boot system**

The `boot system` command provides the EOS image file location to Aboot.

*Example*

- This command specifies EOS1.swi on USB flash memory as the software image load file.
  
  ```
  switch(config)#boot system usb1:EOS1.swi
  ```

  The `boot system` command above adds this line to `boot-config`.

  ```
  SWI=usb1:/EOS1.swi
  ```

- This command designates EOS.swi, on the switch flash, as the EOS software image load file.
  
  ```
  switch(config)#boot system flash:EOS.swi
  ```

  The `boot system` command above adds this line to `boot-config`.

  ```
  SWI=flash:/EOS.swi
  ```

**boot secret**

The `boot secret` command sets the Aboot password.

*Example*

- These equivalent commands set the Aboot password to `xr19v`.
  
  ```
  switch(config)#boot secret xr19v
  ```

  ```
  switch(config)#boot secret 0 xr19v
  ```

  This command shows the password that has been set.

  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: (not set)
  Aboot password (encrypted): $1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
  ```

  The `boot secret` commands above add this line to `boot-config`.

  ```
  PASSWORD=$1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
  ```

  The user must enter `xr19v` at the login prompt to access the Aboot shell.

- This command sets the Aboot password to `xr123`. The encrypted string was previously generated with `xr123` as the clear-text seed.
  
  ```
  switch(config)#boot secret 5 $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
  ```

  This command shows the password that has been set.

  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: (not set)
  Aboot password (encrypted): $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
  ```
The `boot secret` command above adds this line to `boot-config`.

```
PASSWORD=$1$QfbYkVWb$PIXG0udEQuw0wOSi2BN3D/
```

The user must enter `xr123` at the login prompt to access the Aboot shell.

- This command removes the Aboot password; subsequent Aboot access is not authenticated.

```
switch(config)#no boot secret
```

This command shows that there is now no Aboot password.

```
switch(config)#show boot-config
Software image: flash:/EOS.swi
Console speed: (not set)
Aboot password (encrypted): (not set)
```

**boot console**

The `boot console` command sets console settings for attaching devices.

**Example**

- This command sets the console speed to 4800 baud:

```
switch(config)#boot console speed 4800
```

This command shows the console speed.

```
switch(config)#show boot-config
Software image: flash:/EOS.swi
Console speed: 4800
Aboot password (encrypted): (not set)
```

The `boot console` command above adds this line to `boot-config`.

```
CONSOLESPEED=4800
```

### 6.2.2 Running-Config

`running-config` is a virtual file that contains the system’s operating configuration, formatted as a command sequence. Commands entered from the CLI modify `running-config`. Copying a file to `running-config` updates the operating configuration by executing the commands in the copied file.

`running-config` commands include:

- `show running-config` displays `running-config`.
- `copy running-config startup-config` copies `running-config` contents to the `startup-config`.
- `write` copies `running-config` contents to the `startup-config` file.

### 6.2.3 Startup-Config

The `startup-config` file is stored in flash memory and contains the configuration that the switch loads when booting. During a switch boot, `running-config` is replaced by `startup-config`. Changes to `running-config` that are not copied to `startup-config` are lost when the system reboots.

`startup-config` commands include:

- `show startup-config` displays `startup-config`.
- `copy <filename> startup-config` copies contents of the specified file to `startup-config`.
- `erase startup-config` deletes the `startup-config` file.
6.3 Supervisor Redundancy

On modular switches with redundant supervisor modules, control of the switch can be transferred to the standby supervisor to minimize downtime and data loss in the case of a reset, reload, or failure of the active supervisor. How the switchover takes place is determined by the redundancy protocol on the active supervisor.

To display the state and the current redundancy protocol of both supervisors, use the `show redundancy states` command. To display the state of configuration file synchronization between the supervisors, use the `show redundancy file-replication` command.

6.3.1 Redundancy Supervisor Protocols

There are three available supervisor redundancy protocols.

**Route Processor Redundancy (RPR)**

The default redundancy protocol is route processor redundancy (RPR), which synchronizes `startup-config` files between the supervisor modules and partially boots the standby supervisor to a “standby warm” state, but does not synchronize `running-config`. If the active supervisor fails, or a manual switchover is initiated with the `redundancy force-switchover` command, the standby supervisor will become active. Running state, including spanning tree, is lost, and all links are temporarily brought down.

Under RPR, the CLI of the standby supervisor can be accessed by SSH or through the console port, but the available command set is limited. Any configuration changes made to the standby supervisor will be lost when the supervisor reboots.

**Stateful Switchover (SSO)**

In stateful switchover (SSO) protocol, the switch synchronizes both `startup-config` and `running-config` files between the supervisor modules and fully boots the standby module to a “standby hot” state to speed the switchover process and minimize packet loss. If the active supervisor fails, or a manual switchover is initiated, the standby supervisor immediately becomes active, and L2 running state is maintained. An SSO switchover is largely transparent from the outside, but because L3 state is not synchronized the switchover can result in traffic loss for traffic forwarded on routes learned by a dynamic routing protocol. Enabling nonstop forwarding can eliminate most packet loss for BGP and OSPF.

Under SSO, the CLI of the standby supervisor can be accessed only through the console port, and the command set is limited. Any configuration changes made on the standby supervisor will be lost when the supervisor reboots.

**Important!** When upgrading the EOS on a dual-supervisor switch to an SSO-capable version (4.11.0 or higher) from a version that does not support SSO, both supervisors will reset simultaneously, causing several seconds of system downtime.

**Simplex**

When the switch is set to simplex protocol, the standby supervisor is disabled and switchover will not occur even if the active supervisor fails. Reloading the active supervisor results in system downtime while the supervisor reboots, and the standby supervisor remains disabled. To transfer control of the switch to the standby supervisor, the redundancy protocol must be changed to RPR or SSO.

Under simplex protocol, the CLI of the disabled supervisor can be accessed only through the console port, and the command set is limited. Any configuration changes made on the standby supervisor will be lost when the supervisor reboots.
### 6.3.2 Configuring Supervisor Redundancy

The supervisor redundancy protocol is configured using the `protocol` command in redundancy configuration mode (accessed with the `redundancy` command).

Changing the redundancy protocol on the active supervisor resets the standby supervisor regardless of redundancy protocol, and executing the `write` command on the active supervisor synchronizes the `startup-config` files between supervisors in RPR and SSO modes.

#### Examples

- These commands display the current redundancy state of the switch and the most recent file synchronization information.

  ```
  switch# show redundancy state
  my state = ACTIVE
  peer state = STANDBY WARM
  Unit = Primary
  Unit ID = 1
  
  Redundancy Protocol (Operational) = Route Processor Redundancy
  Redundancy Protocol (Configured) = Route Processor Redundancy
  Communications = Up
  Ready for switchover
  
  Last switchover time = 7:23:56 ago
  Last switchover reason = Supervisor has control of the active supervisor lock
  Switch# show redundancy file-replication
  0 files unsynchronized, 2 files synchronized, 0 files failed, 2 files total.
  
  File                   Status         Last Synchronized
  ---------------------- -------------- -------------------
  file:persist/sys       Synchronized   0:10:04 ago
  flash:startup-config   Synchronized   0:10:04 ago
  ```

- These commands set the redundancy protocol for the active supervisor to stateful switchover (SSO).

  ```
  switch# config
  switch(config)# redundancy
  switch(config-redundancy)# protocol sso
  Peer supervisor will be restarted.
  switch(config-redundancy)#
  ```
6.4 System Reset

When a reset condition exists, Aboot can either reset the switch without user intervention or facilitate a manual reset through the Aboot shell. A reset operation clears the switch, including memory states and other hardware logic

- **Fixed systems**: The power supply remains powered up through the reset. Power is removed from all other switch components for two to five seconds.

- **Modular systems**: The power supply on the active supervisor remains powered up through the reset. Power is removed from all other supervisor components for at least one second. In stateful switchover (SSO) and route processor redundancy (RPR) modes, resetting the standby supervisor has no effect on the active supervisor, but resetting the active supervisor causes the standby supervisor to immediately become active. After the supervisor becomes functional, it manages the power-cycling of all line cards.

The `reload` command initiates an immediate reset, terminating all CLI instances not running through the console port. The console port CLI displays messages that the switch generates during a reset. On modular switches with redundant supervisors, CLI sessions on the standby supervisor are not terminated.

The `reload <scheduled>` command schedules a reset operation to initiate at a specific time or after a specified period.

6.4.1 Typical Reset Sequence

The `reload` command power cycles the switch, then resets it under Aboot control. The hard reset clears the switch, including memory states and other hardware logic.

By default, the `reload` command triggers a request to store unsaved `running-config` commands and an option to open the Aboot shell before starting the reboot when accessing the CLI through the console port. The switch then begins the reboot process controlled by Aboot.

This procedure is an example of a typical restart.

**Step 1** Begin the reboot process by typing the `reload` command:

```
switch#reload
```

The switch sends a message to confirm the reload request:

```
Proceed with reload? [confirm]
```

**Step 2** Press `enter` or type `y` to confirm the requested reload. Pressing any other key terminates the reload operation.

The switch sends a series of messages, including a notification that a message was broadcast to all open CLI instances, informing them that the system is being rebooted. The reload pauses when the CLI displays the Aboot shell notification line.

```
Broadcast message from root@mainStopping sshd: [ OK ]
SysRq : Remount R/O
Restarting system

Aboot 1.9.0-52504.EOS2.0

Press Control-C now to enter Aboot shell
```

**Step 3** To continue the reload process, do nothing. Typing `Ctrl-C` opens the Aboot shell; see Section 6.5.5: Commands for Aboot editing instructions.
The switch continues the reset process, displaying messages to indicate the completion of individual tasks. The reboot is complete when the CLI displays a login prompt.

**Boot Loading**

- Booting flash:/EOS.swi
- Unpacking new kernel
- Starting new kernel
- Switching to root
- Welcome to Arista Networks EOS 4.4.0
- Mounting filesystems: [ OK ]
- Entering non-interactive startup
- Starting EOS initialization stage 1: [ OK ]
- ip6tables: Applying firewall rules: [ OK ]
- iptables: Applying firewall rules: [ OK ]
- iptables: Loading additional modules: nf_conntrack_tftp [ OK ]
- Starting system logger: [ OK ]
- Starting system message bus: [ OK ]
- Starting NorCal initialization: [ OK ]
- Starting EOS initialization stage 2: [ OK ]
- Starting ProcMgr: [ OK ]
- Completing EOS initialization: [ OK ]
- Starting Power On Self Test (POST): [ OK ]
- Generating SSH2 RSA host key: [ OK ]
- Starting isshd: [ OK ]
- Starting sshd: [ OK ]
- Starting xinetd: [ OK ]
- [ OK ] crond: [ OK ]

```
switch login:
```

**Step 4** Log into the switch to resume configuration tasks.

### 6.4.2 Switch Recovery

Aboot can automatically erase the internal flash and copy the contents of a USB drive that has been inserted before powering up or rebooting the switch. This recovery method does not require access to the switch console or Aboot password entry, even if the `boot-config` file lists one.

Aboot invokes the recovery mechanism only if each of these two conditions is met:

- The USB drive must contain a file called **fullrecover**
  - The file's contents are ignored; an empty text file is sufficient.
- If the USB drive contains a file named **boot-config**, its timestamp must differ from the timestamp of the `boot-config` file on the internal flash.
  - This prevents Aboot from invoking the recovery mechanism again on every boot if you leave the flash key inserted.

To use this recovery mechanism, set up a USB drive with the files to be installed on the internal flash – for example, a current EOS software image, and a customized or empty `boot-config` – plus an empty file named `fullrecover`.

Check that the timestamp of `boot-config` is current to ensure that the above conditions are met.

### 6.4.3 Display Reload Cause

The **show reload cause** command displays the cause of the most recent system reset and lists recommended actions, if any exist, to avoid future spontaneous resets or resolve other issues that may have caused the reset.
Example

- To display the reset cause, type `show reload cause` at the prompt.

```
switch# show reload cause
Reload Cause 1:
-------------------
Reload requested by the user.

Recommended Action:
-------------------
No action necessary.

Debugging Information:
----------------------
None available.
switch#
```

6.4.4 Configuring Zero Touch Provisioning

Zero Touch Provisioning (ZTP) is a switch configuration method that uses files referenced by a DHCP server to initially provision the switch without user intervention. A switch enters ZTP mode when it is reloaded if flash memory does not contain a `startup-config`.

Canceling ZTP boots the switch without using a `startup-config` file. When ZTP mode is canceled, a `startup-config` file is not stored to flash memory. Until a `startup-config` file is stored to flash, the switch returns to ZTP mode on subsequent reboots. This section describes steps required to implement, monitor, and cancel ZTP.

6.4.4.1 Configuring the Network for ZTP

A switch performs the following after booting in ZTP mode:

- Configures each physical interface to `no switchport` mode.
- Sends a DHCP query packet on all Ethernet and management interfaces.

After the switch receives a DHCP offer, it responds with a DHCP request for Option 66 (TFTP server name), Option 67 (bootfile name), and dynamic network configuration settings. When the switch receives a valid DHCP response, it configures the network settings, then fetches the file from the location listed in Option 67. If Option 67 returns a network URL (http:// or ftp://), the switch obtains the file from the network. If Option 67 returns a file name, the switch retrieves the file from the TFTP server listed in Option 66.

The Option 67 file can be a `startup-config` file or a boot script. The switch distinguishes between a `startup-config` file and a boot script by examining the first line in the file:

- The first line of a boot file must consist of the `#!/` characters followed by the interpreter path. The switch executes the code in the script, then reboots. The boot script may fetch an EOS software image or perform required customization tasks.

  The following boot file fetches an EOS software image and stores a startup configuration file to flash.

  ```
  #!/usr/bin/Cli -p2
  copy http://company.com/startup-config flash:startup-config
  config
  boot system flash:EOS-2.swi
  ```

  - The switch identifies any other file as a `startup-config` file. The switch copies the `startup-config` file into flash as `mnt/flash/startup-config`, then reboots.
The switch uses its system MAC address as the DHCP client identifier and Arista as the Vendor Class Identifier (Option 60). When the switch receives an http URL through Option 67, it sends the following http headers in the GET request:

X-Arista-SystemMAC: 
X-Arista-HardwareVersion: 
X-Arista-SKU: 
X-Arista-Serial: 
X-Arista-Architecture: 

6.4.4.2 Monitoring ZTP Progress

A switch displays the following message after rebooting when it does not contain a startup-config file:

No startup-config was found.

The device is in Zero Touch Provisioning mode and is attempting to download the startup-config from a remote system. The device will not be fully functional until either a valid startup-config is downloaded from a remote system or Zero Touch Provisioning is cancelled. To cancel Zero Touch Provisioning, login as admin and type 'zerotouch cancel' at the CLI.

switch login:

The switch displays a CONFIG_DOWNLOAD_SUCCESS message after it successfully downloads a startup-config file, then continues the reload process as described in Section 6.4.1.

===============================================================================
Successful download
-------------------

Apr 15 21:36:46 switch ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21, Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9, Management1, Management2 ]
Apr 15 21:36:56 switch ZeroTouch: %ZTP-5-DHCP_SUCCESS: DHCP response received on Ethernet24 [ Mtu: 1500; Ip Address: 10.10.0.4/16; Nameserver: 10.10.0.1; Domain: aristanetworks.com; Gateway: 10.10.0.1; Boot File: http://10.10.0.2:8080/tmp/172.17.11.196-startup-config.1 ]
Apr 15 21:37:01 switch ZeroTouch: %ZTP-5-CONFIG_DOWNLOAD: Attempting to download the startup-config from http://10.10.0.2:8080/tmp/172.17.11.196-startup-config.1
Apr 15 21:37:02 switch ZeroTouch: %ZTP-5-CONFIG_DOWNLOAD_SUCCESS: Successfully downloaded startup-config from http://10.10.0.2:8080/tmp/172.17.11.196-startup-config.1
Apr 15 21:37:02 switch ZeroTouch: %ZTP-5-RELOAD: Rebooting the system
Broadcast messagStopping sshd: [ OK ]
watchdog is not running
SysRq : Remount R/O
Restarting system

Aboot 1.9.0-52504.EOS2.0

Press Control-C now to enter Aboot shell
6.4.4.3 ZTP Failure Notification

The switch displays a DHCP_QUERY_FAIL message when it does not receive a valid DHCP response within 30 seconds of sending the query. The switch then sends a new DHCP query and waits for a response. The switch continues sending queries until it receives a valid response or until ZTP mode is canceled.

```
switch login: admin
admin
switch> Apr 15 21:28:21 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21, Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9, Management1, Management2 ]
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-DHCP_QUERY_FAIL: Failed to get a valid DHCP response
Apr 15 21:28:51 localhost ZeroTouch: %ZTP-5-RETRY: Retrying Zero Touch Provisioning from the begining (attempt 1)
Apr 15 21:29:22 localhost ZeroTouch: %ZTP-5-DHCP_QUERY: Sending DHCP request on [ Ethernet10, Ethernet13, Ethernet14, Ethernet17, Ethernet18, Ethernet21, Ethernet22, Ethernet23, Ethernet24, Ethernet7, Ethernet8, Ethernet9, Management1, Management2 ]
```

6.4.4.4 Canceling ZTP Mode

To boot the switch without a `startup-config` file, log into the console, then cancel ZTP mode. After the switch boots, it uses all factory default settings. A `startup-config` file must be saved to flash memory to prevent the switch from entering ZTP mode on subsequent boots.

6.4.5 Configuring the Networks

If the `boot-config` file contains a NETDEV statement, Aboot attempts to configure the network interface, as specified by Network configuration commands. See Section 6.2.1.2: `boot-config Command Line Content` for a list of commands that define the network configuration.
6.5 **Aboot Shell**

The Aboot shell is an interactive command-line interface used to manually boot a switch, restore the internal flash to its factory-default state, run hardware diagnostics, and manage files. The Aboot shell is similar to the Linux Bourne Again Shell (Bash).

The Aboot shell provides commands for restoring the state of the internal flash to factory defaults or a customized default state. You can use these recovery methods to:

- restore the factory-default flash contents before transferring the switch to another owner.
- restore Aboot shell access if the Aboot password is lost or forgotten.
- restore console access if baud rate or other settings are incompatible with the terminal.
- replace the internal flash contents with configuration or image files stored on a USB flash drive.

6.5.1 **Operation**

When the switch is powered on or rebooted, Aboot reads its configuration from `boot-config` on the internal flash and attempts to boot an EOS software image (with the extension .swi) automatically if one is configured.

You can monitor the automatic boot process or enter the Aboot shell only from the console port. You can connect a PC or terminal directly to the port and run a terminal emulator to interact with the serial port or access it through a serial concentrator device.

Console settings are stored in `boot-config`; the factory-default settings for Arista switches are 9600 baud, no parity, 8 character bits, and 1 stop bit. If you do not know the current settings, perform a full flash recovery to restore the factory-default settings. When the console port is connected and the terminal settings are configured properly, the terminal displays a message similar to the following a few seconds after powering up the switch:

```
Aboot 1.0.0

Press Control-C now to enter the Aboot shell
```

To abort the automatic boot process and enter the Aboot shell, press Ctrl-C (ASCII 3 in the terminal emulator) after the `Press Control-C now to enter Aboot shell` message appears. Pressing Ctrl-C can interrupt the boot process up through the starting of the new kernel.

If the `boot-config` file does not contain a password command, the Aboot shell starts immediately. Otherwise, you must enter the correct password at the password prompt to start the shell. If you enter the wrong password three times, Aboot displays this message:

```
Type "fullrecover" and press Enter to revert /mnt/flash to factory default state, or just press Enter to reboot:
```

- Pressing `Enter` continues a normal soft reset without entering the Aboot shell.
- Typing `fullrecover` and pressing `Enter` performs a full flash recovery to restore the factory-default settings, removing all previous contents of the flash drive.

The Aboot shell starts by printing:

```
Welcome to Aboot.
```

Aboot then displays the Aboot# prompt.

Aboot reads its configuration from `boot-config` on the internal flash.
6.5.2 Accessing the Aboot Shell

This procedure accesses the Aboot Shell:

**Step 1** Reload the switch and press `enter` or type `y` when prompted, as described by step 1 and step 2 in Section 6.4.1: Typical Reset Sequence.

The command line displays this Aboot entry prompt.

Press Control-C now to enter Aboot shell

**Step 2** Type Ctrl-C.

If the `boot-config` file does not contain a PASSWORD command, the CLI displays an Aboot welcome banner and prompt.

```
^CWelcome to Aboot.
Aboot#
```

If the `boot-config` file contains a PASSWORD command, the CLI displays a password prompt. In this case, proceed to step 3. Otherwise, the CLI displays the Aboot prompt.

**Step 3** If prompted, enter the Aboot password.

```
Press Control-C now to enter Aboot shell
^CAbOOT password:
Welcome to Aboot.
Aboot#
```

Aboot allows three attempts to enter the correct password. After the third attempt, the CLI prompts the user to either continue the reboot process without entering the Aboot shell or to restore the flash drive to the factory default state.

```
Press Control-C now to enter Aboot shell
^CAboot password:
icorrect password
Aboot password:
icorrect password
Aboot password:
icorrect password
Type "fullrecovery" and press Enter to revert /mnt/flash to factory default state, or just press Enter to reboot: fullrecovery
All data on /mnt/flash will be erased; type "yes" and press Enter to proceed, or just press Enter to cancel:
```

The fullrecovery operation replaces the flash contents with a factory default configuration. The CLI displays text similar to the following when performing a fullrecovery, finishing with another entry option into the Aboot shell.

```
Erasing /mnt/flash
Writing recovery data to /mnt/flash
boot-config
startup-config
EOS.swi
210770 blocks
Restarting system.
```

```
Aboot 1.9.0-52504.EOS2.0
```

Press Control-C now to enter Aboot shell
6.5.3 File Structure

When you enter the Aboot CLI, the current working directory is the root directory on the switch. Switch image and configuration files are at /mnt/flash. When exiting the Aboot shell, only the contents of /mnt/flash are preserved. The /mnt directory contains the file systems of storage devices. Aboot mounts the internal flash device at /mnt/flash.

When a USB flash drive is inserted in one of the flash ports, Aboot mounts its file system on /mnt/usb1. The file system is unmounted when the USB flash drive is removed from the port. Most USB drives contain an LED that flashes when the system is accessing it; do not remove the drive from the flash port until the LED stops flashing.

6.5.4 Booting From the Aboot Shell

Aboot attempts to boot the EOS software image (with the extension .swi) configured in boot-config automatically if you take no action during the boot process. If the boot process fails for any reason, such as an incorrectly configured software image, Aboot enters the shell, allowing you to correct the configuration or boot a software image manually. The boot command loads and boots an EOS software image file.

The boot command syntax is

```
boot SWI
```

where SWI lists the location of the EOS image that the command loads. SWI settings include:

- **DEVICE:PATH** loads the image file from the specified storage device. The default DEVICE value is flash; other values include file and usb1.
- **/PATH** loads the image file from the specified path in the switch directory.
- **http://SERVER/PATH** loads the image file from the HTTP server on the host server.
- **ftp://SERVER/PATH** loads the image file from the FTP server on the host server.
- **tftp://SERVER/PATH** loads the image file from the TFTP server on the host server
- **nfs://SERVER/PATH** mounts the path’s parent directory from the host server and loads the image file from the loaded directory.

The accepts the same commands as the SWI variable in the boot-config file. See Section 6.2.1.2: boot-config Command Line Content for a list of boot command formats.

If an image file is not specified in boot-config, or if booting the image results in an error condition (for example, an incorrect path or unavailable HTTP server), Aboot halts the boot process and drops into the shell.

**Example**

- To boot EOS.swi from internal flash, enter one of these commands on the Aboot command line:

  ```
  boot flash:EOS.swi
  boot /mnt/flash/EOS.swi.
  ```

6.5.5 Commands

To list the contents of the internal flash, enter `ls /mnt/flash` at the Aboot# prompt.

**Example**

```
Aboot# ls /mnt/flash
EOS.swi boot-config startup-config
```
Commonly used commands include:

- `ls` Prints a list of the files in the current working directory.
- `cd` Changes the current working directory.
- `cp` Copies a file.
- `more` Prints the contents of a file one page at a time.
- `vi` Edits a text file.
- `boot` Boots a software image file.
- `swiinfo` Prints information about a software image.
- `recover` Recovers the factory-default configuration.
- `reboot` Reboots the switch.
- `udhcpc` Configures a network interface automatically via DHCP.
- `ifconfig` Prints or alters network interface settings.
- `wget` Downloads a file from an HTTP or FTP server.

Many Aboot shell commands are provided by Busybox, an open-source implementation of UNIX utilities. Busybox command help is found at http://www.busybox.net/downloads/BusyBox.html. Aboot provides access to only a subset of the documented commands.

Aboot can access networks through the Ethernet management ports. Aboot provides network interfaces mgmt1 and mgmt2. These ports are unconfigured by default; you can configure management port settings using Aboot shell commands like `ifconfig` and `udhcpc`. When a management interface is configured, use `wget` to transfer files from an HTTP or FTP server, `tftp` to transfer files from a TFTP server, or `mount` to mount an NFS filesystem.
6.6 Aboot Configuration Commands

This section describes the Aboot configuration commands that a `boot-config` file can contain.

- SWI
- CONSOLESPEED
- PASSWORD (ABOOT)
- NET commands
CONSOLE SPEED

CONSOLE SPEED specifies the console baud rate. To communicate with the switch, the connected terminal must match the specified rate. Baud rates are 1200, 2400, 4800, 9600, 19200, or 38400.

The default baud rate is 9600.

Command Syntax

CONSOLE SPEED=baud_rate

Parameters

• baud_rate specifies the console speed. Values include 1200, 2400, 4800, 9600, 19200, or 38400.

Examples

• These lines are CONSOLE SPEED command examples:

  CONSOLE SPEED=2400
  CONSOLE SPEED=19200
NET commands

NET commands in the boot-config file are used by Aboot during switch booting to configure the network interface that will be used for switch configuration. These commands can also be entered manually in Aboot.

NETDEV indicates which network interface is being configured. If boot-config does not contain a NETDEV setting, the booting process does not attempt to configure a network interface. Other NET commands specify settings that Aboot uses to configure the interface.

Command Syntax

```
NETDEV=interface
NETAUTO=auto_setting
NETIP=interface_address
NETMASK=interface_mask
NETGW=gateway_address
NETDOMAIN=domain_name
NETDNS=dns_address
```

Parameters

- `interface` the network interface. Settings include:
  - `NETDEV=ma1` management port 1.
  - `NETDEV=ma2` management port 2.
- `auto_setting` the configuration method. Settings include
  - `NETAUTO=dhcp` interface is configured through a DHCP server; other NET commands are ignored.
  - `NETAUTO` command is omitted interface is configured with other NET commands,
- `interface_address` interface IP address, in dotted-decimal notation.
- `interface_mask` interface subnet mask, in dotted-decimal notation.
- `gateway_address` default gateway IP address, in dotted decimal notation.
- `domain_name` interface domain name.
- `dns_address` IP address of the Domain Name Server, in dotted decimal notation.

Examples

- This NETDEV command specifies management port 1 as the network interface to be configured for management traffic.
  ```
  NETDEV=ma1
  ```
- This NETAUTO command instructs the switch to configure the network interface through a DHCP server, ignoring other NET settings.
  ```
  NETAUTO=dhcp
  ```
- These NET commands configure the network interface.
  ```
  NETIP=10.12.15.10
  NETMASK=255.255.255.0
  NETGW=10.12.15.24
  NETDOMAIN=mycompany.com
  NETDNS=10.12.15.13
  ```
PASSWORD (ABOOT)

PASSWORD specifies the Aboot password, as described in Section 6.5.2: Accessing the Aboot Shell. If `boot-config` does not contain a PASSWORD line, the Aboot shell does not require a password.

`boot-config` stores the password as an MD5-encrypted string as generated by the UNIX passwd program or the crypt library function from a clear-text seed. When entering the Aboot password, the user types the clear-text seed.

There is no method of recovering the password from the encrypted string. If the clear-text password is lost, delete the corresponding PASSWORD command line from the `boot-config` file.

The EOS boot secret command is the recommended method of adding or modifying the PASSWORD configuration line.

Command Syntax

```
PASSWORD=encrypted_string
```

Parameters

- `encrypted_string` the encrypted string that corresponds to the clear-text Aboot password.

Example

- This line is a PASSWORD command example where the encrypted string corresponds with the clear-text password `abcde`.

```
PASSWORD=$1$CdWp5wfe$pzNtE3ujBoFEL8vjcq7jo/
```
SWI

SWI specifies the location and file name of the EOS image file that Aboot loads when booting, using the same format as `boot-config` to designate a local or network path.

**Command Syntax**

```
SWI=FILE_LOCATION
```

**Parameters**

- `FILE_LOCATION` specifies the location of the EOS image file. Formats include:
  - `device:path` storage device location:
    - `device` denotes a storage device. Settings include `flash`, `file` and `usb1`. Default is `flash`.
    - `path` denotes a file location.

**Examples**

- **flash drive location**
  - `SWI=flash:EOS.swi`
- **usb drive location**
  - `SWI=usb1:/EOS1.swi`
- **switch directory location**
  - `SWI=file:/tmp/EOSexp.swi`
- **switch directory location**
  - `SWI=/mnt/flash/EOS.swi`
- **HTTP server location**
  - `SWI=http://foo.com/images/EOS.swi`
- **FTP server location**
  - `SWI=ftp://foo.com/images/EOS.swi`
- **TFTP server location**
  - `SWI=tftp://foo.com/EOS.swi`
- **nfs server location**
  - `SWI=nfs://foo.com/images/EOS.swi`
6.7 Switch Booting Commands

- boot console
- boot secret
- boot system
- erase startup-config
- protocol
- redundancy
- redundancy force-switchover
- reload
- reload <scheduled>
- service sequence-numbers
- show redundancy file-replication
- show redundancy states
- show redundancy switchover sso
- show reload
- show reload cause
**boot console**

The *boot console* command configures terminal settings for serial devices connecting to the console port. Console settings that you can specify from *boot-config* include:

- **speed**

Factory-default console settings are 9600 baud, no parity, 8 character bits, and 1 stop bit. If you do not know the current settings, restore the factory-default settings as described in Section 2.4.3: Restoring the Factory Default EOS Image and Startup Configuration.

The *no boot console* and *default boot console* commands restore the factory default settings on the switch and remove the corresponding CONSOLESPEED command from the *boot-config* file.

**Command Mode**
Global Configuration

**Command Syntax**

```
boot console speed baud
no boot console speed
default boot console speed
```

**Parameters**

- **baud**  console baud rate. Settings include 1200, 2400, 4800, 9600, 19200, and 38400.

**Example**

- This command sets the console speed to 4800 baud

  ```
  switch(config)#boot console speed 4800
  ```

  This code displays the result of the command:

  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: 4800
  Aboot password (encrypted): (not set)
  ```

  The above *boot console* command adds the following line to *boot-config*.

  ```
  CONSOLESPEED=4800
  ```
### boot secret

The `boot secret` command creates or edits the Aboot shell password and stores the encrypted string in the PASSWORD command line of the `boot-config` file.

The `no boot secret` and `default boot secret` commands remove the Aboot password from the `boot-config` file. When the Aboot password does not exist, entering Aboot shell does not require a password.

#### Command Mode
- Global Configuration

#### Command Syntax

```
boot secret [ENCRYPT_TYPE] password
no boot secret
default boot secret
```

#### Parameters
- **ENCRYPT_TYPE** indicates the encryption level of the password parameter. Settings include:
  - `<no parameter>` the `password` is clear text.
  - `0` the `password` is clear text. Equivalent to the `<no parameter>` case.
  - `5` the `password` is an md5 encrypted string.
  - `sha512` the password is entered as an sha512 encrypted string.
- `password` specifies the boot password.
  - `password` must be in clear text if `ENCRYPT_TYPE` specifies clear text.
  - `password` must be an appropriately encrypted string if `ENCRYPT_TYPE` specifies encryption.

#### Restrictions
- The `sha512` encryption option is not available on Trident platform switches.

#### Examples
- These equivalent commands set the Aboot password to xr19v:

  ```
  switch(config)#boot secret xr19v
  ```

  ```
  switch(config)#boot secret 0 xr19v
  ```

  This CLI code displays the result:

  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: (not set)
  Aboot password (encrypted): $1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
  ```

  The `boot secret` commands above add this line to `boot-config`.

  ```
  PASSWORD=$1$k9YHFW8D$cgM8DSN.e/yY0p3k3RUvk.
  ```

  The user must enter `xr19v` at the login prompt to access the Aboot shell.

- These commands set the Aboot password to xr123, then displays the resulting `boot-config` code. The encrypted string was previously generated with `xr123` as the clear-text seed.

  ```
  switch(config)#boot secret 5 $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
  ```

  ```
  switch(config)#show boot-config
  Software image: flash:/EOS.swi
  Console speed: (not set)
  Aboot password (encrypted): $1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
  ```
The `boot secret` command above adds this line to `boot-config`.

```
PASSWORD=$1$QfbYkVWb$PIXG0udEquW0wOSiZBN3D/
```

The user must enter xr123 at the login prompt to access the Aboot shell.

- This command removes the Aboot password, allowing access to the Aboot shell without a password.

```
switch(config)#no boot secret
```
**boot system**

The **boot system** command specifies the location of the EOS software image that Aboot loads when the switch boots. The command can refer to files on flash or on a module in the USB flash port.

**Command Mode**

Global Configuration

**Command Syntax**

`boot system DEVICE file_path`

**Parameters**

- **DEVICE**  
  Location of the image file. Options include
  - **file**: file is located in the switch file directory.
  - **flash**: file is located in flash memory.
  - **usb1**: file is located on a drive inserted in the USB flash port. Available if a drive is in the port.
- **file_path**  
  Path and name of the file.

**Examples**

- This command designates EOS1.swi, on USB flash memory, as the EOS software image load file.

  `switch(config)#boot system usbl:EOS1.swi`

  The *boot system* command above adds this line to **boot-config**.

  ```
  SWI=usbl:/EOS1.swi
  ```

- This command designates EOS.swi, on the switch flash, as the EOS software image load file.

  `switch(config)#boot system flash:EOS.swi`

  The *boot system* command above adds this line to **boot-config**.

  ```
  SWI=flash:/EOS.swi
  ```
**erase startup-config**

The `erase startup-config` command erases or deletes the startup configuration.

**Command Mode**

Privileged EXEC

**Command Syntax**

`erase startup-config [CONFIRMATION]`

**Parameters**

- **CONFIRMATION**
  - `<no parameter>` the switch requires a confirmation before starting the erase.
  - **now** the erase begins immediately without prompting the user to confirm the request.

**Examples**

- This command deletes the startup configuration from the switch. When the `erase startup-config` command is entered, the switch sends a message prompting the user to confirm the `erase startup-config` request.

  ```
  switch# erase startup-config
  Proceed with erasing startup configuration? [confirm]y
  switch#
  ```

- This command deletes the startup configuration from the switch immediately without prompting.

  ```
  switch# erase startup-config now
  switch#
  ```
The protocol command configures how the supervisors on a modular switch will handle switchover events. By default, the switch is set to route processor redundancy (RPR), which synchronizes startup-config files between the supervisor modules and partially boots the standby supervisor. The mode can also be set to simplex (manual switchover only) or to stateful switchover (SSO) which synchronizes both startup-config and running-config files between the supervisor modules and fully boots the standby module to speed the switchover process and minimize packet loss. Note that SSO synchronizes L2 state between the supervisors, but that L3 state is not synchronized. This can result in traffic loss for traffic forwarded on routes learned by a dynamic routing protocol. Enabling nonstop forwarding can eliminate most packet loss for BGP and OSPF.

The no protocol and default protocol commands set the redundancy protocol to the default value (rpr) by removing the protocol command from running-config.

**Command Mode**
Redundancy Configuration

**Command Syntax**
```
protocol PROTOCOL_NAME
no protocol
default protocol
```

**Parameters**
- **PROTOCOL_NAME** specifies the location of the image file. Settings include
  - rpr route processor redundancy protocol (the default).
  - simplex no redundancy. Switchover must be initiated manually.
  - sso stateful switchover.

**Related Commands**
- redundancy Places switch in redundancy configuration mode.

**Example**
- These commands enter redundancy configuration mode and set the redundancy protocol to stateful switchover.
```
switch(config)#redundancy
switch(config-redundancy)#protocol sso
switch(config-redundancy)#
```
redundancy

The redundancy command places the switch in redundancy configuration mode.

Command Mode
Global Configuration

Command Syntax
redundancy

Commands Available in Redundancy Configuration Mode
- protocol

Related Commands
- redundancy force-switchover Manually initiates a switchover.

Example
- These commands enter redundancy configuration mode and set the redundancy protocol to stateful switchover.
  switch(config)# redundancy
  switch(config-redundancy)# protocol sso
  switch(config-redundancy)#
redundancy force-switchover

The `redundancy force-switchover` command immediately switches control of the switch to the standby supervisor. If the redundancy mode is set to simplex or the standby supervisor is unavailable for any other reason, this command will not function.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
redundancy force-switchover
```

**Related Commands**

- **redundancy** Places the switch in redundancy configuration mode.

**Example**

- This command forces a switchover to the standby supervisor. The switchover is executed immediately without further confirmation from the user.

  switch# redundancy force-switchover

  This supervisor will be restarted.
**reload**

The `reload` command power cycles the switch, then resets it under Aboot control. The hard reset clears the switch, including memory states and other hardware logic.

---

**Important!**

The `reload` commands are used to initiate Accelerated Switch Update (ASU) and Smart Switch Update (SSU); for descriptions of these features and the appropriate command syntax, please refer to the Accelerated Software Upgrade (ASU) and Leaf Smart System Upgrade (Leaf SSU) sections.

- Fixed 1-RU systems: The power supply remains powered up through the reset. Power is removed from all other switch components for two to five seconds.
- Modular systems: The power supply on the active supervisor remains powered up through the reset. Power is removed from all other supervisor components for at least one second. After the supervisor becomes functional, it manages the power-cycling of all line cards.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
reload [TARGET] [CONFIRMATION]
```

**Parameters**

- **TARGET** specifies which supervisor(s) will be reset. Some options are available only on dual-supervisor switches.
  - <no parameter> the active supervisor is reset.
  - all both supervisors are reset.
  - peer the peer supervisor is reset.
  - power the active supervisor is reset.
- **CONFIRMATION** specifies when the switch resets.
  - <no parameter> the switch requires a confirmation before starting the reset.
  - now the reset begins immediately without prompting the user to confirm the request.

**Related Commands**

- `reload <scheduled>` Schedules a pending reload operation.
- `show reload cause` Displays cause of most recent reload.

**Example**

- Begin the reboot process by typing the `reload` command:
  ```
  switch#reload
  ```  

  When the `reload` command is entered, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, then asks the user to confirm the reload request.

  `System configuration has been modified. Save? [yes/no/cancel/diff]:n
  Proceed with reload? [confirm]`
The switch responds by broadcasting a series of messages, including a notification that the system is being rebooted, to all open CLI instances. The reload pauses to provide an option for the user to enter Aboot shell; the Aboot shell supports commands that restore the state of the internal flash to factory defaults or create a customized default state.

**Broadcast message from root@main**

switch login:
**reload <scheduled>**

The `reload <scheduled>` command configures the switch to reset at a specified time or after a specified interval. Refer to `reload` for details on the functional details of the reset operation.

The switch prompts to save the configuration and confirm the reload request. After the request is confirmed, the switch resumes normal operation until the reload initiates.

The `reload cancel`, `no reload`, and `default reload` commands cancel the pending reload operation.

**Command Mode**
- Privileged EXEC

**Command Syntax**
```
reload [power] TIMEFRAME [COMMENT]
reload cancel
no reload
default reload
```

**Parameters**
- **power** Parameter has no functional affect.
- **TIMEFRAME** specifies when the switch resets.
  - **at absolute** specifies the time when a reset begins.
  - **in relative** specifies the period until the reset begins.

  **absolute** denotes time-date (24-hour notation): `hh:mm [month date]` or `hh:mm [date month]`
  **relative** designates a time period: `hh:mm`

- **COMMENT** descriptive text for denoting the reset reason. This option has no functional effect on the reset operation.
  - `<no parameter>` reason for system reset is not stated.
  - **reason comment_string** text that describes the reset.

**Related Commands**
- `reload` Initiate an immediate reload operation.
- `show reload` Displays time and reason of any pending reload operation.

**Examples**
- This command schedules a switch reset to begin in twelve hours.
  ```
  switch#reload in 12:00
  System configuration has been modified. Save? [yes/no/cancel/diff]:y
  Proceed with reload? [confirm]
  Reload scheduled for Tue Mar 27 05:57:25 2012 ( in 11 hours 59 minutes )
  ```
- This command cancels a scheduled switch reset.
  ```
  switch#no reload
  Scheduled reload has been cancelled
  ```
service sequence-numbers

The service sequence-numbers command causes the sequence numbers of syslog messages to be visible when the messages are displayed.

The no service sequence-numbers and default service sequence-numbers commands remove the service sequence-numbers command from running-config.

Command Mode
Global Configuration

Command Syntax

service sequence-numbers
no service sequence-numbers
default service sequence-numbers

Examples

• This command enables sequence numbering that can been seen when syslog messages are displayed.

switch(config)#service sequence-numbers
switch(config)#

• To display the service sequence number, issue the show logging command.

switch#show logging
Syslog logging: enabled
  Buffer logging: level debugging
  Console logging: level informational
  Synchronous logging: disabled
  Trap logging: level informational
  Sequence numbers: enabled
  Syslog facility: local4
  Hostname format: Hostname only
  Repeat logging interval: disabled

switch#
**show redundancy file-replication**

The `show redundancy file-replication` command displays the status and last synchronization date of file replication between the supervisors on the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show redundancy file-replication
```

**Related Commands**

- `show redundancy states`  Displays status and redundancy protocol of supervisors.
- `show redundancy switchover sso`  Displays stateful switchover information since last reload.

**Example**

- This command displays the current file replication status of the supervisors.

```
switch#show redundancy file-replication
0 files unsynchronized, 2 files synchronized, 0 files failed, 2 files total.

<table>
<thead>
<tr>
<th>File</th>
<th>Status</th>
<th>Last Synchronized</th>
</tr>
</thead>
<tbody>
<tr>
<td>file:persist/sys</td>
<td>Synchronized</td>
<td>25 days, 19:48:26 ago</td>
</tr>
<tr>
<td>flash:startup-config</td>
<td>Synchronized</td>
<td>25 days, 19:48:26 ago</td>
</tr>
</tbody>
</table>

switch#
```
**show redundancy states**

The *show redundancy states* command displays the current status (active or standby) and the configured redundancy protocol of both supervisors, as well as summary information about the latest switchover event.

**Command Mode**

EXEC

**Command Syntax**

```
show redundancy states
```

**Related Commands**

- *show redundancy file-replication* Displays status of file replication between supervisors.
- *show redundancy switchover sso* Displays stateful switchover information since last reload.

**Example**

- This command displays redundancy information for both supervisors and a summary of the latest switchover.

  ```
  switch# show redundancy states
  my state = ACTIVE
  peer state = STANDBY HOT
    Unit = Secondary
    Unit ID = 2

  Redundancy Protocol (Operational) = Stateful Switchover
  Redundancy Protocol (Configured) = Stateful Switchover
  Communications = Up
  Ready for switchover

  Last switchover time = 25 days, 19:51:34 ago
  Last switchover reason = Other supervisor stopped sending heartbeats
  ```
**show redundancy switchover sso**

The `show redundancy switchover sso` command displays the number of stateful switovers since the last reload and a log of the events in the latest stateful switchover.

**Command Mode**

EXEC

**Command Syntax**

```
show redundancy switchover sso
```

**Related Commands**

- `show redundancy file-replication` Displays status of file replication between supervisors.
- `show redundancy states` Displays status and redundancy protocol of supervisors.

**Example**

This command displays stateful switchover information.

```
switch#show redundancy switchover sso
Total number of Stateful Switchover completed since reload: 4

Latest Stateful Switchover occurred 29 days, 12:48:22 ago @ 2012-06-09 19:47:50

```
show reload

The `show reload` command displays the time and reason of any pending reload operation. The `reload <scheduled>` command schedules a reload operation and can be used to cancel a pending reload.

Command Mode
EXEC

Command Syntax
`show reload`

Related Commands
- `reload <scheduled>` Schedules a pending reload operation.
- `show reload cause` Displays cause of most recent reload.

Example
- These commands schedule a reload for 2:45 pm, display the time of the pending reload, then cancel the scheduled reload.

```
switch>reload at 14:45
Proceed with reload? [confirm]
Reload scheduled for Tue Mar 27 14:45:00 2012 ( in 4 hours 11 minutes )
switch>show reload
Reload scheduled for Tue Mar 27 14:45:00 2012 ( in 4 hours 11 minutes )
switch>reload cancel
Scheduled reload has been cancelled
switch>
```
**show reload cause**

The `show reload cause` command displays the reason of the most recent reload operation. The command displays recommended actions and debug information related to the executed reload.

**Command Mode**

EXEC

**Command Syntax**

`show reload cause`

**Related Commands**

- `reload`  Initiates an immediate reload operation.
- `show reload`  Displays time and reason of all pending reload operations.

**Example**

- This command displays the cause of the recent reload operation.

```
switch>show reload cause
Reload Cause 1:
-------------------
Reload requested by the user.

Recommended Action:
-------------------
No action necessary.

Debugging Information:
----------------------
None available.
switch>
```
Chapter 7

Upgrades and Downgrades

This chapter describes the procedures for upgrading or downgrading the switch software.

This chapter contains these sections:

- Section 7.1: Upgrade/Downgrade Overview
- Section 7.2: Accelerated Software Upgrade (ASU)
- Section 7.3: Leaf Smart System Upgrade (Leaf SSU)
- Section 7.4: Standard Upgrades and Downgrades
- Section 7.5: Upgrade/Downgrade Commands

7.1 Upgrade/Downgrade Overview

Upgrading or downgrading Arista switch software is accomplished by replacing the EOS image and reloading the switch. Depending on the switch model and the software change being made, there are different options for minimizing (or potentially eliminating) downtime and packet loss during the upgrade/downgrade.

**Accelerated Software Upgrade (ASU):** ASU is available on the 7050SX-64, 7050SX-128, 7050Q-32, and 7050Q-32S and can be used on both leaf and spine switches. It significantly reduces reload time by streamlining and optimizing the reload procedure for upgrades, and continues sending LACP PDUs while the CPU is rebooting, keeping port channels operational during the reload. Downtime during the upgrade is reduced to 30 seconds. Note: ASU does not support software downgrades.

**Leaf Smart System Upgrade (Leaf SSU):** SSU is available only on 7050X platforms (excluding 7050SX-72 and 7050SX-96), and can only be used on leaf switches. It includes the core functionality of ASU, plus additional elements that permit a hitless restart of several features. SSU does not support software downgrades, and is incompatible with VRRP.

**Standard Upgrades and Downgrades:** In those cases where an accelerated upgrade is not an option (such as software downgrades and unsupported platforms), performing a standard upgrade or downgrade using the steps described here will minimize downtime and packet loss.

---

**Important!** To upgrade the software on switches participating in an MLAG, see Section 12.3.3: Upgrading MLAG Peers.
7.2 Accelerated Software Upgrade (ASU)

The Accelerated Software Upgrade (ASU) process significantly decreases downtime and packet loss during a software upgrade in three ways:

- performing time-intensive tasks (including copying the EOS image) before rebooting the control plane
- forwarding packets in hardware (based on the last known state) while the control-plane is offline
- optimizing the boot process by performing only tasks essential for software upgrade

After the control plane has fully loaded, the data plane is restarted, causing approximately 30 seconds of downtime.

7.2.1 Upgrading the EOS image with Accelerated Software Upgrade

Using ASU to upgrade the active EOS image is a five-step process:

**Step 1** Prepare switch for upgrade (Section 7.2.1.1).

**Step 2** Transfer image file to the switch (Section 7.2.1.2). (Not required if desired file is on the switch).

**Step 3** Modify `boot-config` file to point to the desired image file (Section 7.2.1.3).

**Step 4** Start the ASU process (Section 7.2.1.4).

**Step 5** Verify that switch is running the new image (Section 7.2.1.5).

7.2.1.1 Prepare the Switch

Before upgrading the EOS image, ensure that backup copies of the currently running EOS version and the `running-config` file are available in case of corruption during the upgrade process. To copy the `running-config` file, use the `copy running-config` command. In this example, `running-config` is copied to a file in the flash drive on the switch.

```
switch# copy running-config flash:/cfg_06162014
Copy completed successfully.
switch#
```

Determine the size of the new EOS image. Then verify that there is enough space available on the flash drive for two copies of this image (use the `dir` command to check the “bytes free” figure).

```
switch# dir flash:
Directory of flash:/
-rwx 293168526 Nov 4 22:17 EOS4.11.0.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014

606638080 bytes total (602841088 bytes free)
```
Ensure that the switch has a management interface configured with an IP addresses and default gateway (see Assigning an IP Address to a Specific Ethernet Management Port and Configuring a Default Route to the Gateway), and confirm that it can be reached through the network by using the `show interfaces status` command and pinging the default gateway.

```
switch# show interfaces status
Port       Name              Status       Vlan        Duplex  Speed Type
Et3/1                        notconnect   1             auto   auto 1000BASE-T
Ma1/1                        connected    routed       unconf unconf Unknown
```

```
switch# ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

### 7.2.1.2 Transfer the Image File

The target image must be copied to the file system on the switch, typically onto the flash drive. After verifying that there is space for two copies of the image, use the `copy` command to copy the image to the flash drive, then confirm that the new image file has been correctly transferred.

These command examples transfer an image file to the flash drive from various locations.

**USB Memory**

**Command**

```
copy usb1:/sourcefile flash:/destfile
```

**Example**

```
Sch# copy usb1:/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

**FTP Server**

**Command**

```
copy ftp:/ftp-source/sourcefile flash:/destfile
```

**Example**

```
Sch# copy ftp:/user:password@10.0.0.3/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

**SCP**

**Command**

```
copy scp://scp-source/sourcefile flash:/destfile
```

**Example**

```
sch# copy scp://user@10.1.1.8/user/EOS-4.14.4.swi flash:/EOS-4.14.4.swi
```

**HTTP**

**Command**

```
copy http://http-source/sourcefile flash:/destfile
```
Example

```sh
```

Once the file has been transferred, verify that it is present in the directory, then confirm the MD5 checksum using the `verify` command. The MD5 checksum is available from the EOS download page of the Arista website.

```sh
switch#dir flash:
Directory of flash:/
-rwx 293168526 Nov 4 22:17 EOS4.14.2.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014
-rwx 394559902 May 30 02:57 EOS-4.13.1.swi
```

606638080 bytes total (208281186 bytes free)

```sh
switch#53#
verify /md5 flash:EOS-4.14.4.swi
```

```
verify /md5 (flash:EOS-4.14.4.swi) =c277a965d0ed48534de6647b12a86991
```

7.2.1.3 Modify boot-config

After transferring and confirming the desired image file, use the `boot system` command to update the `boot-config` file to point to the new EOS image.

This command changes the `boot-config` file to point to the image file located in flash memory at EOS-4.14.4.swi.

```sh
switch#configure terminal
switch(config)#boot system flash:/EOS-4.14.4.swi
```

Use the `show boot-config` command to verify that the boot-config file is correct:

```sh
switch(config)#show boot-config
```

```
Software image: flash:/EOS-4.14.4.swi
Console speed: (not set)
Aboot password (encrypted): $1$ap1QMbmz$DTqsFYeauuMSa7/Qxbi21l
```

Save the configuration to the `startup-config` file with the `write` command.

```sh
switch#write
```

7.2.1.4 Start the ASU Process

After updating the `boot-config` file, start the ASU process using the `reload fast-boot` command to reload the switch and activate the new image. If `running-config` has not been saved, the CLI will prompt to save any modifications to the system configuration; failure to save modifications will abort the reload.

Note

Once the system configuration is saved, there is a significant delay before the user is prompted to confirm the reload.

```sh
switch#reload fast-boot
```

```
System configuration has been modified. Save? [yes/no/cancel/diff]:y
Proceed with reload? [confirm]y
Proceeding with reload
```
7.2.1.5 Verify

After the switch finishes reloading, log into the switch and use the `show version` command to confirm the correct image is loaded. The `Software image version` line displays the version of the active image file.

```
switch#show version
Arista DCS-7150S-64-CL-F
Hardware version:  01.01
Serial number:      JPE13120819
System MAC address: 001c.7326.fd0c

Software image version: 4.14.4F
Architecture:           i386
Internal build version: 4.14.4F-1649184.4144F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                14 hours and 48 minutes
Total memory:          4017088 kB
Free memory:           1569760 kB
```

switch>
7.3 Leaf Smart System Upgrade (Leaf SSU)

The Smart System Upgrade (SSU) process includes the core functionality of Accelerated Software Upgrade, plus additional optimizations that permit a hitless restart of several features. SSU leverages protocols capable of graceful restart to minimize traffic loss during upgrade. For protocols not capable of graceful restart, SSU generates control plane messages and buffers them in hardware to be slowly released when the control plane is offline. Additionally, under SSU, the forwarding ASIC does not get reset and ports do not flap.

Features capable of hitless restart under SSU include:
- QinQ
- 802.3ad Link Aggregation/LACP
- 802.3x flow control
- BGP (BGP graceful restart must be enabled: see Configuring BGP)
- MP-BGP (BGP graceful restart must be enabled: see Configuring BGP)
- 128-way Equal Cost Multipath Routing (ECMP)
- VRF
- route maps
- L2 MTU
- QoS

Important! SSU is not compatible with VRRP. If VRRP is configured on the switch, another upgrade method must be used.

7.3.1 Upgrading the EOS image with Smart System Upgrade

Using SSU to upgrade the active EOS image is a five-step process:

Step 1 Prepare switch for upgrade (Section 7.3.1.1).
Step 2 Transfer image file to the switch (Section 7.3.1.2). (Not required if desired file is on the switch).
Step 3 Modify boot-config file to point to the desired image file (Section 7.3.1.3).
Step 4 Start the SSU process (Section 7.3.1.4).
Step 5 Verify that the upgrade was successful (Section 7.3.1.5).

7.3.1.1 Prepare the Switch

Preparation of the switch for SSU includes:
- Backing Up Critical Software
- Making Room on the Flash Drive
- Verifying Connectivity
- Verifying Configuration
- Configuring BGP
Backing Up Critical Software

Before upgrading the EOS image, ensure that copies of the currently running EOS version and the `running-config` file are available in case of corruption during the upgrade process. To copy the `running-config` file, use the `copy running-config` command. In this example, `running-config` is copied to a file in the flash drive on the switch.

```
switch#copy running-config flash:/cfg_06162014
Copy completed successfully.
```

Making Room on the Flash Drive

Determine the size of the new EOS image. Then verify that there is enough space available on the flash drive for two copies of this image, plus a recommended 240MB (if available) for diagnostic information in case of a fatal error. Use the dir command to check the “bytes free” figure.

```
switch#dir flash:
Directory of flash:
-rwx 293168526 Nov 4 22:17 EOS4.11.0.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014
606638080 bytes total (602841088 bytes free)
```

Verifying Connectivity

Ensure that the switch has a management interface configured with an IP addresses and default gateway (see Assigning an IP Address to a Specific Ethernet Management Port and Configuring a Default Route to the Gateway), and confirm that it can be reached through the network by using the `show interfaces status` command and pinging the default gateway.

```
switch#show interfaces status
Port Name Status Vlan Duplex Speed Type
Et3/1 notconnect 1 auto auto 1000BASE-T

<-------OUTPUT OMITTED FROM EXAMPLE-------->

Ma1/1 connected routed unconf unconf Unknown
```

```
switch#ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```
Verifying Configuration
Verify that the switch configuration is valid for SSU by using the `show reload hitless` command. If parts of the configuration are blocking execution of SSU, an error message will be displayed explaining what they are. For SSU to proceed, the configuration conflicts must be corrected before issuing the `reload hitless` command.

```
switch#show reload hitless
switch#'reload hitless' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports
switch#
```

Configuring BGP
For hitless restart of BGP and MP-BGP, BGP graceful restart must first be enabled using the `graceful-restart` command. The default restart time value (300 seconds) is appropriate for most configurations.

The BGP configuration mode in which the `graceful-restart` command is issued determines which BGP connections will restart gracefully.

- For all BGP connections, use the `graceful-restart` command in BGP configuration mode:
  ```
  switch#config
  switch(config)#router bgp 64496
  switch(config-router-bgp)#graceful-restart
  switch(config-router-bgp)#
  ```

- For all BGP connections in a specific VRF, use the `graceful-restart` command in BGP VRF configuration mode:
  ```
  switch#config
  switch(config)#router bgp 64496
  switch(config-router-bgp)#vrf purple
  switch(config-router-bgp-vrf-purple)#graceful-restart
  switch(config-router-bgp-vrf-purple)#exit
  switch(config-router-bgp)#
  ```

- For all BGP connections in a specific BGP address family, use the `graceful-restart` command in BGP address-family configuration mode:
  ```
  switch#config
  switch(config)#router bgp 64496
  switch(config-router-bgp)#address-family ipv6
  switch(config-router-bgp-af)#graceful-restart
  switch(config-router-bgp-af)#exit
  switch(config-router-bgp)#
  ```

BGP graceful restart can also be configured for a specific interface.

7.3.1.2 Transfer the Image File
The target image must be copied to the file system on the switch, typically onto the flash drive. After verifying that there is space for two copies of the image plus an optional 240MB for diagnostic information, use the `copy` command to copy the image to the flash drive, then confirm that the new image file has been correctly transferred.

These command examples transfer an image file to the flash drive from various locations.
USB Memory
Command
copy usb1:/sourcefile flash:/destfile
Example
Sch#copy usb1:/EOS-4.14.4.swi flash:/EOS-4.14.4.swi

FTP Server
Command
copy ftp:/ftp-source/sourcefile flash:/destfile
Example
Sch#copy ftp:/user:password@10.0.0.3/EOS-4.14.4.swi flash:/EOS-4.14.4.swi

SCP
Command
copy scp://scp-source/sourcefile flash:/destfile
Example
sch#copy scp://user@10.1.1.8/user/EOS-4.14.4.swi flash:/EOS-4.14.4.swi

HTTP
Command
copy http://http-source/sourcefile flash:/destfile
Example

Once the file has been transferred, verify that it is present in the directory, then confirm the MD5 checksum using the verify command. The MD5 checksum is available from the EOS download page of the Arista website.

switch#dir flash:
Directory of flash:/
-rwx 293168526 Nov 4 22:17 EOS4.14.2.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014
-rwx 394559902 May 30 02:57 EOS-4.13.1.swi

<--------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (208281186 bytes free)
switch#53#verify /md5 flash:EOS-4.14.4.swi
verify /md5 (flash:EOS-4.14.4.swi) =c277a965d0ed48534de6647b12a86991

7.3.1.3 Modify boot-config

After transferring and confirming the desired image file, use the boot system command to update the boot-config file to point to the new EOS image.
This command changes the **boot-config** file to point to the image file located in flash memory at EOS-4.14.4.swi.

```
switch#configure terminal
switch(config)#boot system flash:/EOS-4.14.4.swi
```

Use the **show boot-config** command to verify that the boot-config file is correct:

```
switch(config)#show boot-config
Software image: flash:/EOS-4.14.4.swi
Console speed: (not set)
Aboot password (encrypted): $1$ap1QMbmz$DTqsFYeavuMSa7/Qxbi211
```

Save the configuration to the **startup-config** file with the **write** command.

```
switch#write
```

### 7.3.1.4 Start the SSU Process

After updating the **boot-config** file, verify that your configuration supports SSU (if you have not already done so) by using the **show reload hitless** command. If parts of the configuration are blocking execution of SSU, an error message will be displayed explaining what they are.

```
switch#show reload hitless
switch#'reload hitless' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports
```

Then start the SSU process using the **reload hitless** command to reload the switch and activate the new image. The CLI will identify any changes that must be made to the configuration before starting SSU, prompt to save any modifications to the system configuration, and request confirmation before reloading.

```
switch#reload hitless
System configuration has been modified. Save? [yes/no/cancel/diff]: y
Copy completed successfully.
Proceed with reload? [confirm]y
```

**Important!** Any configuration changes must be saved for SSU to continue. However, once the upgrade has begun, no changes should be made to the configuration until the “LAUNCHER-6-BOOT_STATUS: 'reload hitless' reconciliation complete.” syslog message has been generated by the switch.

### 7.3.1.5 Verify Success of the Upgrade

Before making any configuration changes to the switch after reload, verify that the SSU process is complete using the command **show boot stages log**. If the process is complete, the last message should be “Asu Hitless boot stages complete.”

```
switch#show boot stages log
Timestamp             Delta Begin Msg
2015-03-28 15:18:30   000.000000 Asu Hitless boot stages started
2015-03-28 15:18:30   000.069732 stage CriticalAgent started
2015-03-28 15:18:30   000.069811   event CriticalAgent:SuperServer completed
2015-03-28 15:20:20   110.224504 stage BootSanityCheck is complete
2015-03-28 15:20:20   110.225439 Asu Hitless boot stages complete
switch#
```

Completion of the SSU process may also be verified by checking the syslog for the following message:

```
LAUNCHER-6-BOOT_STATUS: 'reload hitless' reconciliation complete
```
To verify whether the SSU upgrade was successful, use the **show reload cause** command. If a fatal error occurred during the upgrade process, the switch will have completely rebooted and the fatal error will be displayed along with the directory in which diagnostic information can be found. If the SSU upgrade succeeded, it will read “Hitless reload requested by the user.”

**Fatal Error Display**

```
switch#show reload cause
Reload Cause 1:
-------------------
Reload requested by the user.

Reload Time:
------------
Reload occurred at Sat Feb 28 02:34:26 2015 PST.

Recommended Action:
-------------------
No action necessary.

Debugging Information:
----------------------
None available.

Reload Cause 2:
-------------------
Fatal error during 'reload hitless'. (stageMgr - LinkStatusUpdate timed out)

Reload Time:
------------
Reload occurred at Sat Feb 28 02:33:54 2015 PST.

Recommended Action:
-------------------
A fatal error occurred during hitless reload.
If the problem persists, contact your customer support representative.

Debugging Information:
----------------------
/mnt/flash/persist/fatalError-2015-02-28_023355
switch#
```
Successful Upgrade Display

```
switch#show reload cause
Reload Cause 1:-------------------
Hitless reload requested by the user.

Reload Time:------------
Reload occurred at Wed Mar 25 14:49:04 2015 PDT.

Recommended Action:-------------------
No action necessary.

Debugging Information:----------------------
None available.
```

The `show version` command will confirm whether the correct image is loaded. The `Software image version` line displays the version of the active image file.

```
switch#show version
Arista DCS-7050QX-32-F
Hardware version: 02.00
Serial number: JPE14071098
System MAC address: 001c.7355.556f

Software image version: 4.14.5F-2353054.EOS4145F
Architecture: i386
Internal build version: 4.14.5F-2353054.EOS4145F
Internal build ID: e8748ea7-916d-4217-878f-4bfe2adc7122

Uptime: 4 minutes
Total memory: 3981328 kB
Free memory: 1342408 kB
```

Important! If a fatal error occurs during the SSU process, the new EOS image will still be loaded and booted.
7.4 Standard Upgrades and Downgrades

Standard software upgrades and downgrades on Arista switches are accomplished by installing a different EOS image and reloading the switch. On switches with redundant supervisors, the EOS image must be installed on both supervisors. Using the procedure described below will minimize packet loss during a standard upgrade or downgrade.

These sections describe standard switch upgrade and downgrade procedures

- Section 7.4.1: Upgrading or Downgrading the EOS on a Single-Supervisor Switch
- Section 7.4.2: Upgrading or Downgrading the EOS on a Dual-Supervisor Switch

7.4.1 Upgrading or Downgrading the EOS on a Single-Supervisor Switch

Modifying the active EOS image is a five-step process:

**Step 1** Prepare switch for upgrade (Section 7.4.1.1).

**Step 2** Transfer image file to the switch (Section 7.4.1.2). (Not required if desired file is on the switch).

**Step 3** Modify *boot-config* file to point to the desired image file (Section 7.4.1.3).

**Step 4** Reload switch (Section 7.4.1.4).

**Step 5** Verify that switch is running the new image (Section 7.4.1.5).

7.4.1.1 Prepare the Switch

Before upgrading the EOS image, ensure that backup copies of the currently running EOS version and the *running-config* file are available in case of corruption during the upgrade process. To copy the *running-config* file, use the *copy running-config* command. In this example, *running-config* is copied to a file in the flash drive on the switch.

```
switch#copy running-config flash:/cfg_06162014
Copy completed successfully.
```

Determine the size of the new EOS image and verify that there is enough space available for two copies of it on the flash drive, using the *dir* command to check the “bytes free” figure. The EOS boot process makes a copy of the .swi image file to the internal flash, and the switch will boot to the Aboot prompt if there is insufficient room for both copies.

```
switch#dir flash:
Directory of flash: /
-rwx 293168526 Nov 4 22:17 EOS4.11.0.swi
-rwx 36 Nov 8 10:24 boot-config
-rwx 37339 Jun 16 14:18 cfg_06162014

<--------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (602841088 bytes free)
```

Ensure that the switch has a management interface configured with an IP addresses and default gateway (see Assigning an IP Address to a Specific Ethernet Management Port and Configuring a Default Route to the Gateway), and confirm that it can be reached through the network by using the
show interfaces status command and pinging the default gateway. To configure a virtual IP address to access the active supervisor on a modular switch, see also Assigning a Virtual IP Address to Access the Active Ethernet Management Port.

```
switch#show interfaces status
Port       Name              Status       Vlan        Duplex  Speed Type
Et3/1                        notconnect   1             auto   auto 1000BASE-T
<br>
Ma1/1                        connected    routed       unconf unconf Unknown
```

```
switch#ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

7.4.1.2 Transfer the Image File

The target image must be copied to the file system on the switch, typically onto the flash drive. After verifying that there is space for the image, use the CLI copy command to copy the image to the flash drive, then confirm that the new image file has been correctly transferred.

These command examples transfer an image file to the flash drive from various locations.

**USB Memory**

**Command**

```
copy usb1:/sourcefile flash:/destfile
```

**Example**

```
Sch#copy usb1:/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**FTP Server**

**Command**

```
copy ftp:/ftp-source/sourcefile flash:/destfile
```

**Example**

```
sch#copy ftp:/user:password@10.0.0.3/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**SCP**

**Command**

```
copy scp://scp-source/sourcefile flash:/destfile
```

**Example**

```
sch#copy scp://user:password@10.1.1.8/user/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**HTTP**

**Command**

```
copy http://http-source/sourcefile flash:/destfile
```
Example

```
sch# copy http://10.0.0.10/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

Once the file has been transferred, verify that it is present in the directory, then confirm the MD5 checksum using the `verify` command. The MD5 checksum is available from the EOS download page of the Arista website.

```
switch# dir flash:
Directory of flash:/
  -rwx  293168526 Nov 4 22:17   EOS4.11.0.swi
  -rwx      36 Nov 8 10:24   boot-config
  -rwx    37339 Jun 16 14:18  cfg_06162014
  -rwx   394559902 May 30 02:57  EOS-4.12.2.swi

<------OUTPUT OMITTED FROM EXAMPLE-------->
```

```
switch#53# verify /md5 flash:EOS-4.13.2.swi
verify /md5 (flash:EOS-4.13.2.swi) =c277a965d0ed48534de6647b12a86991
```

7.4.1.3 Modify boot-config

After transferring and confirming the desired image file, use the `boot system` command to update the `boot-config` file to point to the new EOS image.

This command changes the `boot-config` file to point to the image file located in flash memory at EOS-4.12.2.swi.

```
switch(config)# boot system flash:/EOS-4.13.2.swi
```

Use the `show boot-config` command to verify that the boot-config file is correct:

```
switch(config)# show boot-config
Software image: flash:/EOS-4.13.2.swi
Console speed: (not set)
Aboot password (encrypted): $1$ap1QMbmz$DTqsFYeauuMSa7/Qxbi211
```

Save the configuration to the `startup-config` file with the `write` command.

```
switch# write
```

7.4.1.4 Reload

After updating the `boot-config` file, reset the switch to activate the new image. The `reload` command resets the switch, resulting in temporary downtime and packet loss on single supervisor switches.

When reloading from the console port, all rebooting messages are displayed on the terminal. From any port except the console, the CLI displays this text:

```
switch# reload
The system is going down for reboot NOW!
```

Important! The EOS boot process makes a copy of the .swi image file in the internal flash while booting, so sufficient space for two copies must be present when loading the new EOS image. If the switch is reloaded without adequate space on the flash drive, it will boot to the Aboot prompt from which you can delete files from /mnt/flash to free up additional space. Exiting Aboot will begin the boot process again.
7.4.1.5 Verify

After the switch finishes reloading, log into the switch and use the `show version` command to confirm the correct image is loaded. The **Software image version** line displays the version of the active image file.

```
switch#show version
Arista DCS-7150S-64-CL-F
Hardware version: 01.01
Serial number: JPE13120819
System MAC address: 001c.7326.fd0c

Software image version: 4.13.2F
Architecture: i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID: eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime: 14 hours and 48 minutes
Total memory: 4017088 kB
Free memory: 1569760 kB
```

7.4.2 Upgrading or Downgrading the EOS on a Dual-Supervisor Switch

Modifying the active EOS image is a four-step process:

**Step 1** Prepare switch for upgrade (Section 7.4.2.1).

**Step 2** Transfer image file to primary supervisor (Section 7.4.2.2). (Not required if desired file is on switch)

**Step 3** Use the `install` command to install the new EOS image and update `boot-config` (Section 7.4.2.3).

**Step 4** Verify that the switch is running the new image (Section 7.4.2.4).

**Important!** Due to a change in the supervisor heartbeat timeout, booting one supervisor with a post-SSO image (version 4.10.0-SSO, 4.11.X and later) while the other supervisor is running a pre-SSO image will cause the supervisor running the pre-SSO image to reload. This will cause a disruption as both supervisors will be inactive for a short time. To minimize downtime, upgrade the images on both supervisors and reload the entire chassis using the `install` command.

7.4.2.1 Prepare the Switch

To prepare the switch for an EOS upgrade, take the following steps:

- Back up essential files.
- Ensure that you are logged in to the primary supervisor.
- Ensure that both supervisors are reachable and have management interfaces configured.
- Ensure that there is enough room on both supervisors for the new image file.
- Ensure that any extensions running on the active supervisor are also available on the standby.
Before upgrading the EOS image, ensure that backup copies of the currently running EOS version and the `running-config` file are available in case of corruption during the upgrade process. To copy the `running-config` file, use the `copy running-config` command. In this example, `running-config` is being copied to a file called “backup2” on the flash drive.

```
switch#copy running-config backup2
switch#
```

Ensure that you are logged in to the primary supervisor, not the standby. Use the `show redundancy states` command, and verify that `my state` reads “ACTIVE” and not “STANDBY.”

```
switch#show redundancy states
my state = ACTIVE
peer state = STANDBY HOT
  Unit = Secondary
  Unit ID = 1

Redundancy Protocol (Operational) = Stateful Switchover
Redundancy Protocol (Configured) = Stateful Switchover
Communications = Up
Ready for switchover

  Last switchover time = 25 days, 19:51:34 ago
  Last switchover reason = Other supervisor stopped sending heartbeats
```

Ensure that each supervisor has a management interface configured with an IP addresses and default gateway (see Assigning a Virtual IP Address to Access the Active Ethernet Management Port and Configuring a Default Route to the Gateway), and confirm that both management interfaces can be reached through the network by using the `show interfaces status` command and pinging the default gateway.

```
switch#show interfaces status
Port       Name              Status       Vlan        Duplex  Speed Type
Et3/1                        notconnect   1             auto   auto 1000BASE-T
Ma1/1                        connected    routed       unconf unconf Unknown
Ma2/1                        connected    routed      a-full  a-100M 10/100/1000

switch#ping 1.1.1.10
PING 172.22.26.1 (172.22.26.1) 72(100) bytes of data.
80 bytes from 1.1.1.10: icmp_seq=1 ttl=64 time=0.180 ms
80 bytes from 1.1.1.10: icmp_seq=2 ttl=64 time=0.076 ms
80 bytes from 1.1.1.10: icmp_seq=3 ttl=64 time=0.084 ms
80 bytes from 1.1.1.10: icmp_seq=4 ttl=64 time=0.073 ms
80 bytes from 1.1.1.10: icmp_seq=5 ttl=64 time=0.071 ms
```

Determine the size of the new EOS image and verify that there is space available for it on the flash drive of both supervisors, using the `dir` command to check the “bytes free” figure.
Primary supervisor:

```
switch#dir flash:
Directory of flash:/
  -rwx 293168526 Nov 4 22:17   EOS4.11.0.swi
  -rwx 36 Nov 8 10:24   boot-config
  -rwx 37339 Jun 16 14:18   cfg_06162014
```

<--------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (602841088 bytes free)

Standby supervisor:

```
switch#dir supervisor-peer:mnt/flash/
Directory of flash:/
  -rwx 293168526 Nov 4 22:17   EOS4.11.0.swi
  -rwx 36 Nov 8 10:24   boot-config
  -rwx 37339 Jun 16 14:18   cfg_06162014
```

<--------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (602841088 bytes free)

And, finally, ensure that any extensions running on the primary supervisor are also available on the secondary supervisor.

### 7.4.2.2 Transfer the Image File to the Primary Supervisor

Load the desired image to the file system on the primary supervisor, typically into the flash. Use the CLI `copy` command to load files to the flash on the primary supervisor, then confirm that the new image file has been correctly transferred.

These command examples transfer an image file to flash from various locations.

**USB Memory**

**Command**

```bash
copy usb1:/sourcefile flash:/destfile
```

**Example**

```
Sch#copy usb1:/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**FTP Server**

**Command**

```bash
copy ftp:/ftp-source/sourcefile flash:/destfile
```

**Example**

```
Sch#copy ftp:/user:password@10.0.0.3/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**SCP**

**Command**

```bash
copy scp://scp-source/sourcefile flash:/destfile
```
Example

```bash
sch#copy scp://user:password@10.1.1.8/user/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

**HTTP**

**Command**

```bash
copy http://http-source/sourcefile flash:/destfile
```

Example

```bash
sch#copy http://10.0.0.10/EOS-4.13.2.swi flash:/EOS-4.13.2.swi
```

Once the file has been transferred, verify that it is present in the directory, then confirm the MD5 checksum using the `verify` command. The MD5 checksum for each available image can be found on the EOS download page of the Arista website.

```bash
switch#dir flash:
Directory of flash:/
-rwx  293168526 Nov 4 22:17 EOS4.11.0.swi
-rwx       36 Nov 8 10:24 boot-config
-rwx  37339 Jun 16 14:18 cfg_06162014
-rwx 394559902 May 30 02:57 EOS-4.12.2.swi

<--------OUTPUT OMITTED FROM EXAMPLE-------->

606638080 bytes total (208281186 bytes free)
```

```
switch#53#verify /md5 flash:EOS-4.13.2.swi
verify /md5 (flash:EOS-4.13.2.swi) =c277a965d0ed48534de6647b12a86991
```

### 7.4.2.3 Install the New EOS Image

Once the EOS image has been copied to the flash drive of the primary supervisor, use the `install` command to update the `boot-config`, copy the new image to the secondary supervisor and reload both supervisors. When upgrading to a new image, both supervisors will briefly be unavailable; using the `install` command minimizes packet loss during reload.

```
switch(config)#install source EOS-4.13.2.swi reload
Preparing new boot-config... done.
Copying new software image to standby supervisor... done.
Copying new boot-config to standby supervisor... done.
Committing changes on standby supervisor... done.
Reloading standby supervisor... done.
Committing changes on this supervisor... done.
Reloading this supervisor...
```
7.4.2.4 Verify the New Image

After the switch finishes reloading, log into the switch and use the `show version` command to confirm the correct image is loaded. The **Software image version** line displays the version of the active image file.

```
switch# show version
Arista DCS-7504
Hardware version:    01.01
Serial number:       JPE13120819
System MAC address:  001c.7326.fd0c

Software image version: 4.13.2F
Architecture:           i386
Internal build version: 4.13.2F-1649184.4132F.2
Internal build ID:      eeb3c212-b4bd-4c19-ba34-1b0aa36e43f1

Uptime:                 1 hour and 36 minutes
Total memory:           4017088 kB
Free memory:            1473280 kB

switch#
```
7.5 Upgrade/Downgrade Commands

- install
- reload fast-boot
- reload hitless
install

The install command copies the specified EOS image onto the switch (if the source is external), configures the boot-config file to point to the specified EOS image, copies the image to the standby supervisor (on dual-supervisor switches), and optionally reloads the switch to run the new EOS.

Command Mode
Privileged EXEC

Command Syntax
install source source_path [destination destination_path] [now] [reload]

Parameters
• source_path  file path and name of EOS image. If no file path is specified, the switch will look for the image on the flash drive of the primary supervisor.
• destination destination_path  destination file path and name of the EOS image. If no destination or name is specified, the EOS image will be stored on the flash drive with its original file name.
• now  command is executed immediately without further prompts.
• reload  supervisor is reloaded after the image and updated boot-config file are installed. On dual-supervisor switches, reloads both supervisors, after which control is returned to the primary supervisor.

Example
• This command updates the boot-config file to point to the EOS.swi file on the primary supervisor’s flash drive, copies the image and boot-config file to the secondary supervisor, and reboots both.

```
switch(config)#install source EOS.swi reload
Preparing new boot-config... done.
Copying new software image to standby supervisor... done.
Copying new boot-config to standby supervisor... done.
Committing changes on standby supervisor... done.
Reloading standby supervisor... done.
Committing changes on this supervisor... done.
Reloading this supervisor...
```
**reload fast-boot**

The `reload fast-boot` command starts the Accelerated Software Upgrade (ASU) process using the EOS image specified by the `boot-config` file (configured by the `boot system` command).

ASU significantly decreases downtime and packet loss during a software upgrade, but the data plane is still restarted after the control plane has loaded, resulting in approximately 30 seconds of downtime. If available, Arista recommends using Smart System Upgrade (SSU) instead.

ASU shortens downtime and minimizes packet loss during EOS upgrades in three ways:

- performing time-intensive tasks (including copying the EOS image) before rebooting the control plane
- forwarding packets in hardware (based on the last known good state) while the control-plane is offline
- optimizing the boot process by performing only tasks essential for software upgrade

**Command Mode**

Privileged EXEC

**Command Syntax**

`reload fast-boot`

**Guidelines**

- ASU is supported only for upgrades (not downgrades).
- ASU is not supported if the EOS upgrade requires an FPGA upgrade.
- Enough free space must be available on the flash drive to store two copies of the target EOS image.

**Example**

- This command starts the Accelerated Software Upgrade process.

  ```
  switch#reload fast-boot
  Proceed with reload? [confirm]
  ```

  When the `reload fast-boot` command is entered, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, then asks the user to confirm the reload request.
**reload hitless**

The `reload hitless` command starts the Smart System Upgrade (SSU) process using the EOS image specified by the `boot-config` file (configured by the `boot system` command).

**Command Mode**

Privileged EXEC

**Command Syntax**

```plaintext
reload hitless
```

**Guidelines**

- SSU is supported only for upgrades (not downgrades).
- SSU is not supported if the EOS upgrade requires an FPGA upgrade.
- Enough free space must be available on the flash drive to store two copies of the target EOS image. It is also recommended that an additional 240MB be available to store diagnostic information.

**Example**

- This command starts the SSU process.
  ```plaintext
  switch# reload hitless
  Proceed with reload? [confirm]
  
  If there are issues with the current switch configuration that will prevent SSU from being performed, the switch lists the changes that must be made before SSU can begin.
  ```

  ```plaintext
  switch# reload hitless
  switch# 'reload hitless' cannot proceed due to the following:
  Spanning-tree portfast is not enabled for one or more ports
  Spanning-tree BPDU guard is not enabled for one or more ports
  switch#
  ```

  When the `reload hitless` command is entered, the switch sends a message prompting the user to save the configuration if it contains unsaved modifications, then asks the user to confirm the reload request.

  ```plaintext
  switch# reload hitless
  System configuration has been modified. Save? [yes/no/cancel/diff]: y
  Copy completed successfully.
  Proceed with reload? [confirm] y
  ```
Switch Environment Control

The following sections describe the commands that display temperature, fan, and power supply status:

- Section 8.1: Environment Control Introduction
- Section 8.2: Environment Control Overview
- Section 8.3: Configuring and Viewing Environment Settings
- Section 8.4: Environment Commands

The switch chassis, fans, power supplies, line cards, and supervisors also provide LEDs that signal status and conditions that require attention. The Quick Start Guide for the individual switches provides information about their LEDs.

8.1 Environment Control Introduction

Arista Networks switching platforms are designed to work reliably in common data center environments. To ensure their reliable operation and to monitor or diagnose the switch's health, Arista provides a set of monitoring capabilities available through the CLI or SNMP entity MIBs to monitor and diagnose potential problems with the switching platform.

8.2 Environment Control Overview

8.2.1 Temperature

Arista switches include internal temperature sensors. The number and location of the sensors vary with each switch model. Each sensor is assigned temperature thresholds that denote alert and critical conditions. Temperatures that exceed the threshold trigger the following:

- **Alert Threshold**: All fans run at maximum speed and a warning message is logged.
- **Critical Threshold**: The component is shut down immediately and its Status LED flashes orange.

In modular systems, cards are shut down when their temperatures exceed the critical threshold. The switch is shut down if the temperature remains above the critical threshold for three minutes.
8.2.2 Fans

Arista switches include fan modules that maintain internal components at proper operating temperatures. The number and type of fans vary with switch chassis type:

- **Fixed configuration switches** contain hot-swappable independent fans. Fan models with different airflow directions are available. All fans within a switch must have the same airflow direction.
- **Modular switches** contain independent fans that circulate air from front-to-rear panel. Power supplies for modular switches also include fans that cool the power supply and supervisors.

The switch operates normally when one fan is not operating. Non-functioning modules should not be removed from the switch unless they are immediately replaced; adequate switch cooling requires the installation of all components, including a non-functional fan.

Two non-operational fans trigger an *insufficient fan shutdown* condition. Under normal operations, this condition initiates a switch power down procedure.

Fans are accessible from the rear panel.

8.2.2.1 Power

Arista switches contain power supplies which provide power to internal components.

- **Fixed configuration switches** contain two power supplies, providing 1+1 redundancy.
- **Modular switches** contain four power supplies, providing a minimum of 2+2 redundancy.

Power supply LED indicators are visible from the rear panel.
8.3 Configuring and Viewing Environment Settings

8.3.1 Overriding Automatic Shutdown

8.3.1.1 Overheating

The switch can be configured to continue operating during temperature shutdown conditions. Ignoring a temperature shutdown condition is strongly discouraged because operating at high temperatures can damage the switch and void the warranty.

Temperature shutdown condition actions are specified by the `environment overheat action` command. The switch displays this warning when configured to ignore shutdown temperature conditions.

```
Switch(config)#environment overheat action ignore
====================================================================
WARNING: Overriding the system shutdown behavior when the system is overheating is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty. To re-enable the shutdown-on-overheat behavior, use the 'environment overheat action shutdown' command.
====================================================================
Switch(config)#
```

The `running-config` contains the `environment overheat action` command when it is set to `ignore`. When the command is not in `running-config`, the switch shuts down when an overheating condition exists.

The following `running-config` file lists the `environment overheat action` command.

```
switch#show running-config
! Command: show running-config
! device: switch (DCS-7150S-64-CL, EOS-4.13.2F)

!
environment overheat action ignore
!
!
end
switch#
```

8.3.1.2 Insufficient Fans

The switch can be configured to ignore the `insufficient fan shutdown` condition. This is strongly discouraged because continued operation without sufficient cooling may lead to a critical temperature condition that can damage the switch and void the warranty.
Insufficient-fans shutdown override is configured by the `environment insufficient-fans action` command. The switch displays this warning when configured to ignore insufficient-fan conditions.

```
Switch(config)#environment insufficient-fans action ignore
WARNING: Overriding the system shutdown behavior when the system has insufficient fans inserted is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty. To re-enable the shutdown-on-overheat behavior, use the 'environment insufficient-fans action shutdown' command.
```

The `running-config` contains the `environment insufficient-fans action` command when it is set to `ignore`. When `running-config` does not contain this command, the switch shuts down when it detects an insufficient-fans condition.

### 8.3.1.3 Fan Speed

The switch can be configured to override the automatic fan speed. The switch normally controls the fan speed to maintain optimal operating temperatures. The fans can be configured to operate at a constant speed regardless of the switch temperature conditions.

Fan speed override is configured by the `environment fan-speed` command. The switch displays this warning when its control of fan speed is overridden.

```
switch(config)#environment fan-speed override 50
WARNING: Overriding the system fan speed is unsupported and should only be done under the direction of an Arista Networks engineer. You can risk damaging hardware by setting the fan speed too low and doing so without direction from Arista Networks can be grounds for voiding your warranty. To set the fan speed back to automatic mode, use the 'environment fan-speed auto' command
```

The `running-config` contains the `environment fan-speed override` command if it is set to override. When `running-config` does not contain this command, the switch controls the fan speed.
8.3.2 Viewing Environment Status

8.3.2.1 Temperature Status

To display internal temperature sensor status, enter `show environment temperature`.

```
switch>show environment temperature
System temperature status is: Ok

<table>
<thead>
<tr>
<th>Sensor</th>
<th>Description</th>
<th>Temperature</th>
<th>Alert Threshold</th>
<th>Critical Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Front-panel temp sensor</td>
<td>22.000C</td>
<td>65C</td>
<td>75C</td>
</tr>
<tr>
<td>2</td>
<td>Fan controller 1 sensor</td>
<td>23.000C</td>
<td>75C</td>
<td>85C</td>
</tr>
<tr>
<td>3</td>
<td>Fan controller 2 sensor</td>
<td>28.000C</td>
<td>75C</td>
<td>85C</td>
</tr>
<tr>
<td>4</td>
<td>Switch chip 1 sensor</td>
<td>40.000C</td>
<td>105C</td>
<td>115C</td>
</tr>
<tr>
<td>5</td>
<td>VRM 1 temp sensor</td>
<td>48.000C</td>
<td>105C</td>
<td>110C</td>
</tr>
</tbody>
</table>
```

System temperature status is the first line that the command displays. System temperature status values indicate the following:

- **Ok**: All sensors report temperatures below the alert threshold.
- **Overheating**: At least one sensor reports a temperature above its alert threshold.
- **Critical**: At least one sensor reports a temperature above its critical threshold.
- **Unknown**: The switch is initializing.
- **Sensor Failed**: At least one sensor is not functioning.

8.3.2.2 Fans

The `show environment cooling` command displays the cooling and fan status.

Example

This command displays the fan and cooling status.

```
switch>show environment cooling
System cooling status is: Ok
Ambient temperature: 22C
Airflow: front-to-back

<table>
<thead>
<tr>
<th>Fan Tray</th>
<th>Status</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>2</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>3</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>4</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>5</td>
<td>Ok</td>
<td>35%</td>
</tr>
</tbody>
</table>
```

8.3.2.3 Power

The `show environment power` command displays the status of the power supplies.
Example
- This command displays the status of the power supplies:

```
switch>show environment power
```

<table>
<thead>
<tr>
<th>Power Supply</th>
<th>Model</th>
<th>Capacity</th>
<th>Input Current</th>
<th>Output Current</th>
<th>Output Power</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PWR-650AC</td>
<td>650W</td>
<td>0.44A</td>
<td>10.50A</td>
<td>124.0W</td>
<td>Ok</td>
</tr>
</tbody>
</table>

8.3.2.4 System Status

The `show environment all` command lists the temperature, cooling, fan, and power supply information that the individual `show environment` commands display, as described in Section 8.3.2.1, Section 8.3.2.2, and Section 8.3.2.3.

Example
- This command displays the temperature, cooling, fan, and power supply status:

```
switch>show environment all
```

```
System temperature status is: Ok

<table>
<thead>
<tr>
<th>Sensor</th>
<th>Description</th>
<th>Temperature</th>
<th>Alert Threshold</th>
<th>Critical Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Front-panel temp sensor</td>
<td>22.750C</td>
<td>65C</td>
<td>75C</td>
</tr>
<tr>
<td>2</td>
<td>Fan controller 1 sensor</td>
<td>24.000C</td>
<td>75C</td>
<td>85C</td>
</tr>
<tr>
<td>3</td>
<td>Fan controller 2 sensor</td>
<td>29.000C</td>
<td>75C</td>
<td>85C</td>
</tr>
<tr>
<td>4</td>
<td>Switch chip 1 sensor</td>
<td>41.000C</td>
<td>105C</td>
<td>115C</td>
</tr>
<tr>
<td>5</td>
<td>VRM 1 temp sensor</td>
<td>49.000C</td>
<td>105C</td>
<td>110C</td>
</tr>
</tbody>
</table>

System cooling status is: Ok

Ambient temperature: 22C
Airflow: front-to-back

<table>
<thead>
<tr>
<th>Fan Tray</th>
<th>Status</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>2</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>3</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>4</td>
<td>Ok</td>
<td>35%</td>
</tr>
<tr>
<td>5</td>
<td>Ok</td>
<td>35%</td>
</tr>
</tbody>
</table>

8.3.3 Locating Components on the Switch

When a component requires service, the switch administrator may use the `locator-led` command to assist a technician in finding the component. The command causes the status LED on the specified component to flash, and also displays a “service requested” message on the LCD panel of modular switches or lights the blue locator light on the front of fixed switches. Use the `show locator-led` command to display all locator LEDs currently enabled on the switch.
Examples

- This command enables the locator LED on fan tray 3:

  ```
  switch# locator-led fan tray 3
  Enabling locator led for FanTray3
  switch#
  ```

- This command displays all locator LEDs enabled on the switch:

  ```
  switch# show locator-led
  There are no locator LED enabled
  switch#
  ```
8.4 Environment Commands

Environment Control Configuration Commands

- environment fan-speed
- environment insufficient-fans action
- environment overheat action
- locator-led

Environment Display Commands

- show environment all
- show environment cooling
- show environment power
- show environment temperature
- show locator-led
environment fan-speed

The **environment fan-speed** command determines the method of controlling the speed of the switch fans. The switch automatically controls the fan speed by default.

The switch normally controls the fan speed to maintain optimal operating temperatures. The fans can be configured to operate at a constant speed regardless of the switch temperature conditions.

The **no environment fan-speed** and **default environment fan-speed** commands restore the default action of automatic fan-speed control by removing the **environment fan-speed override** statement from **running-config**.

**Important!** Overriding the system fan speed is unsupported and should only be done under the direction of an Arista Networks engineer. You can risk damaging hardware by setting the fan speed too low. Doing so without direction from Arista Networks can be grounds for voiding your warranty.

**Command Mode**
Global Configuration

**Command Syntax**

```
environment fan-speed ACTION
no environment fan-speed
default environment fan-speed
```

**Parameters**

- **ACTION**  
  - fan speed control method. Valid settings include:
    - **auto**  
      - fan speed is controlled by the switch.
      - This option restores the default setting by removing the **environment fan-speed override** command from **running-config**.
    - **override percent**  
      - fan speed is set to the specified percentage of the maximum. Valid **percent** settings range from 30 to 100.

**Examples**

- This command overrides the automatic fan speed control and configures the fans to operate at 50% of maximum speed.

  ```
  switch(config)#environment fan-speed override 50
  WARNING: Overriding the system fan speed is unsupported and should only be done under the direction of an Arista Networks engineer.
  You can risk damaging hardware by setting the fan speed too low and doing so without direction from Arista Networks can be grounds for voiding your warranty.
  To set the fan speed back to automatic mode, use the 'environment fan-speed auto' command
  switch(config)#
  ```

- This command restores control of the fan speed to the switch.

  ```
  switch(config)#environment fan-speed auto
  switch(config)#
  ```
**environment insufficient-fans action**

The `environment insufficient-fans` command controls the switch response to the insufficient fan condition. By default, the switch initiates a shutdown procedure when it senses insufficient fans.

The switch operates normally when one fan is not operating. Non-functioning modules should not be removed from the switch unless they are immediately replaced; adequate switch cooling requires the installation of all components, including a non-functional fan.

Two non-operational fans trigger an **insufficient fan shutdown** condition. This condition normally initiates a power down procedure.

The `no environment insufficient-fans` and `default environment insufficient-fans` commands restore the default shutdown response to the insufficient-fans condition by removing the `environment insufficient-fans action ignore` statement from `running-config`.

**Important!** Overriding the system shutdown behavior when the system has insufficient fans inserted is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
environment insufficient-fans action REMEDY
no environment insufficient-fans action
default environment insufficient-fans action
```

**Parameters**

- `REMEDY` configures action when switch senses an insufficient fan condition. Settings include:
  - `ignore` switch continues operating when insufficient fans are operating.
  - `shutdown` switch shuts power down when insufficient fans are operating.

The `shutdown` parameter restores default behavior by removing the `environment insufficient-fans action ignore` command from `running-config`.

**Examples**

- This command configures the switch to continue operating after it senses insufficient fan condition.
  ```plaintext
  switch(config)#environment insufficient-fans action ignore
  WARNING: Overriding the system shutdown behavior when the system has insufficient fans inserted is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty. To re-enable the shutdown-on-overheat behavior, use the 'environment insufficient-fans action shutdown' command.
  ```

- This command configures the switch to shut down when it senses an insufficient fan condition.
  ```plaintext
  switch(config)#environment insufficient-fans action shutdown
  ```
environment overheat action

The `environment overheat` command controls the switch response to an overheat condition. By default, the switch shuts down when it senses an overheat condition.

**Important!** Overriding the system shutdown behavior when the system is overheating is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty.

Arista switches include internal temperature sensors. The number and location of the sensors vary with each switch model. Each sensor is assigned temperature thresholds that denote alert and critical conditions. Temperatures that exceed the threshold trigger the following:

- **Alert Threshold**: All fans run at maximum speed and a warning message is logged.
- **Critical Threshold**: The component is shut down immediately and its Status LED flashes orange.

In modular systems, cards are shut down when their temperatures exceed the critical threshold. The switch normally shuts down if the temperature remains above the critical threshold for three minutes.

The `no environment overheat action` and `default environment overheat action` commands restore the default shutdown response to the environment overheat condition by removing the `environment overheat action ignore` statement from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
environment overheat action REMEDY
no environment overheat action
default environment overheat action
```

**Parameters**

- **REMEDY** reaction to an overheat condition. Default value is `shutdown`.
  - `shutdown` switch shuts power down by an overheat condition.
  - `ignore` switch continues operating during an overheat condition.

**Examples**

- This command configures the switch to continue operating after it senses an overheat condition.
  ```
  switch(config)#environment overheat action ignore
  WARNING: Overriding the system shutdown behavior when the system is overheating is unsupported and should only be done under the direction of an Arista Networks engineer. You risk damaging hardware by not shutting down the system in this situation, and doing so without direction from Arista Networks can be grounds for voiding your warranty. To re-enable the shutdown-on-overheat behavior, use the 'environment overheat action shutdown' command.
  switch(config)#
  ```

- This command configures the switch to shut down when it senses an overheat condition.
  ```
  switch(config)#environment overheat action shutdown
  switch(config)#
  ```
**locator-led**

When a component requires service, the **locator-led** command activates a locator to assist a technician in finding the component. The command causes the status LED on the specified component to flash, and also displays a “service requested” message on the LCD panel of modular switches or lights the blue locator light on the front of fixed switches. The available locators vary by platform; to see a list of the locator LEDs available on the switch, use the **locator-led ?** command. To disable the locator LED, use the **no locator-led** command.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
locator-led
fantray tray_num | interface interface | module module_num | powersupply supply_num
no locator-led
fantray tray_num | interface interface | module module_num | powersupply supply_num
```

**Parameters**

- **fantray tray_num** activates locator on specified fan tray.
- **interface interface** activates locator on specified interface.
- **module module_num** activates locator on specified module.
- **powersupply supply_num** activates locator on specified power supply.

**Examples**

- This command enables the locator LED on fan tray 3.
  ```
  switch#locator-led fantray 3
  Enabling locator led for FanTray3
  switch#
  ```

- This command disables the locator LED on fan tray 3.
  ```
  switch#no locator-led fantray 3
  Disabling locator led for FanTray3
  switch#
  ```

- This command displays the locator LEDs available on the switch.
  ```
  switch#locator-led ?
  fantray Fan tray LED
  interface Interface LED
  module Module LED
  powersupply Power supply LED
  switch#
  ```
show environment all

The show environment all command displays temperature, cooling, and power supply status.

Command Mode
EXEC

Command Syntax

show environment all

Examples

• This command displays the switch’s temperature, cooling, and power supply status

switch>show environment all
System temperature status is: Ok

<table>

switch>
show environment cooling

The `show environment cooling` command displays fan status, air flow direction, and ambient temperature on the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show environment cooling [INFO_LEVEL]
```

**Parameters**

- `INFO_LEVEL` specifies level of detail that the command displays. Options include:
  - `<no parameter>` displays the fan status, air flow direction, and ambient switch temperature.
  - `detail` also displays actual and configured fan speed of each fan.

**Display Values**

- **System cooling status**:
  - `Ok` no more than one fan has failed or is not inserted.
  - `Insufficient fans` more than one fan has failed or is not inserted. This status is also displayed if fans with different airflow directions are installed. The switch shuts down if the error is not resolved.

- **Ambient temperature** temperature of the surrounding area.

- **Airflow** indicates the direction of the installed fans:
  - `front-to-back` all fans flow air from the front to the rear of the chassis.
  - `back-to-front` all fans flow air from the rear to the front of the chassis.
  - `incompatible fans` fans with different airflow directions are inserted.
  - `Unknown` The switch is initializing.

- **Fan Tray Status** table displays the status and operating speed of each fan. Status values indicate the following conditions:
  - `OK` The fan is operating normally.
  - `Failed` The fan is not operating normally.
  - `Unknown` The system is initializing.
  - `Not Inserted` The system is unable to detect the specified fan.
  - `Unsupported` The system detects a fan that the current software version does not support.
Example

- This command displays the fan status, air flow direction, and ambient switch temperature.

```
switch>show environment cooling
System cooling status is: Ok
Ambient temperature: 30C
Airflow: front-to-back

+----------+--------+-----+
<table>
<thead>
<tr>
<th>Fan Tray</th>
<th>Status</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ok</td>
<td>51%</td>
</tr>
<tr>
<td>2</td>
<td>Ok</td>
<td>51%</td>
</tr>
<tr>
<td>3</td>
<td>Ok</td>
<td>51%</td>
</tr>
<tr>
<td>4</td>
<td>Ok</td>
<td>51%</td>
</tr>
<tr>
<td>5</td>
<td>Ok</td>
<td>51%</td>
</tr>
</tbody>
</table>

switch>
```
show environment power

The `show environment power` command displays the status of all power supplies in the switch.

**Command Mode**

EXEC

**Command Syntax**

`show environment power [INFO_LEVEL]`

**Parameters**

- `INFO_LEVEL` specifies level of detail that the command displays. Options include:
  - `<no parameter>` displays current and power levels for each supply.
  - `detail` also includes status codes that can report error conditions.

**Example**

- This command displays the status of power supplies on the switch.

```
switch> show environment power

Power Supply Model Capacity Input Current Output Current Power Status
---------- -------------------- --------- -------- -------- -------- --------------
1 PWR-760AC 760W 0.81A 11.00A 132.8W Ok
2 PWR-760AC 760W 0.00A 0.00A 0.0W AC Loss

switch>
```
show environment temperature

The show environment temperature command displays the operating temperature of all sensors on the switch.

Command Mode

EXEC

Command Syntax

    show environment temperature [MODULE_NAME][INFO_LEVEL]

Parameters

- **MODULE_NAME** Specifies modules for which data is displayed. This parameter is only available on modular switches. Options include:
  - <no parameter> All modules (identical to all option).
  - linecard line_num Line card module. Number range varies with switch model.
  - supervisor super_num Supervisor module. Number range varies with switch model.
  - mod_num Supervisor (1 to 2) or line card (3 to 18) module.
  - all All modules.

- **INFO_LEVEL** specifies level of detail that the command displays. Options include:
  - <no parameter> displays table that lists the temperature and thresholds of each sensor.
  - detail displays data block for each sensor listing the current temperature and historic data.

Display Values

- **System temperature status** is the first line that the command displays. Values report the following:
  - Ok All sensors report temperatures below the alert threshold.
  - Overheating At least one sensor reports a temperature above its alert threshold.
  - Critical At least one sensor reports a temperature above its critical threshold.
  - Unknown The switch is initializing.
  - Sensor Failed At least one sensor is not functioning.

Examples

- This command displays a table that lists the temperature measured by each sensor.

  switch> show environment temperature
  System temperature status is: Ok

  Sensor Description                        Temperature  Alert Threshold  Critical Threshold
  --------- --------------------------------- -------------- ------------------- -------------------
  1        Front-panel temp sensor        30.750C        65C              75C              
  2        Fan controller 1 sensor        32.000C        75C              85C              
  3        Fan controller 2 sensor        38.000C        75C              85C              
  4        Switch chip 1 sensor           50.000C        105C             115C             
  5        VRM 1 temp sensor              60.000C        105C             110C             

  switch>
This command lists the temperature detected by each sensor, and includes the number of previous alerts, the time of the last alert, and the time of the last temperature change.

```plaintext
switch> show environment temperature detail
TempSensor1 - Front-panel temp sensor
  Current State  Count  Last Change
  Temperature    30.750C
  Max Temperature 35.000C  4 days, 23:35:24 ago
  Alert           False  0                  never

TempSensor2 - Fan controller 1 sensor
  Current State  Count  Last Change
  Temperature    32.000C
  Max Temperature 36.000C  4 days, 23:32:46 ago
  Alert           False  0                  never

TempSensor3 - Fan controller 2 sensor
  Current State  Count  Last Change
  Temperature    38.000C
  Max Temperature 41.000C  4 days, 23:37:56 ago
  Alert           False  0                  never

TempSensor4 - Switch chip 1 sensor
  Current State  Count  Last Change
  Temperature    51.000C
  Max Temperature 53.000C  4 days, 23:35:16 ago
  Alert           False  0                  never

TempSensor5 - VRM 1 temp sensor
  Current State  Count  Last Change
  Temperature    60.000C
  Max Temperature 62.000C  4 days, 22:54:51 ago
  Alert           False  0                  never

switch>
```
show locator-led

The `show locator-led` command displays the status of locator LEDs enabled on the switch.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show locator-led
```

**Example**

- This command displays all locator LEDs enabled on the switch.

```
switch#show locator-led
There are no locator LED enabled
switch#
```
Chapter 9

Maintenance Mode

This chapter describes configuration for performing maintenance of switch elements.

This chapter contains these sections:

- Section 9.1: Overview
- Section 9.2: Maintenance Mode Elements
- Section 9.3: Maintenance Mode Features
- Section 9.4: Maintenance Mode Configuration
- Section 9.5: Maintenance Mode Commands
9.1 Overview

Using maintenance mode, you can perform several maintenance activities such as:

- EOS image upgrade
- Initial configuration or reconfiguration of a production system
- Replacement of hardware
- Changing linecards or transceiver modules
- Replace, reattach, and reroute cables

Maintenance mode uses BGP to divert traffic away from the switch on which the maintenance tasks need to be performed, minimizing traffic impact. You can set the traffic thresholds and time limits at which the switch, or parts of the switch, is considered to be available for maintenance tasks.

Maintenance mode can be activated on a switch at boot-up or during operation. The mode provides the following benefits:

- Rerouting of traffic when the mode is activated during operation and other routes are present
- Replacement of hardware in modular systems or systems with redundant hardware

The switch is placed into maintenance mode, serviced, and then returned to normal operation.
9.2 Maintenance Mode Elements

Maintenance mode elements include Units, Groups of Interfaces and BGP Peers, and Profiles. Arista Network switches provide maintenance mode operations performed on a fundamental, configurable element, referred to as a Unit. Maintenance mode will quiesce a unit, which places the unit into maintenance mode by gracefully transitioning traffic away from it.

The most common maintenance mode operations such as removing from service an entire switch system or individual components of the switch, including a single linecard, interface, or BGP peer, can be achieved using minimal configuration.

9.2.1 Units

Units are configurable maintenance mode elements that comprise a collection of various groups. In addition, units contain policies which decide whether the member groups should be put into maintenance mode automatically upon boot. Built-in units are configured by default, such as the System unit representing the entire system. All maintenance mode operations are executed at the unit level.

An interface, interface range, and BGP peer (or peer-group) can be directly put under maintenance.

9.2.1.1 Built-in Units

There are various built-in units such as System and Linecardn. Fixed systems contain only one built-in unit called System, which comprises the interface group containing all the Ethernet interfaces and BGP groups per VRF containing all the peers in the respective VRF.

Modular Systems have both System and Linecardn units. Linecardn units are present for each linecard which comprises the linecardn groups containing all Ethernet interfaces of that linecard.
9.2.1.2 User-configured Units

You can also configure customized units containing user-defined groups and policies as shown in the following example. A custom group called BG1 with a custom interface IG1 and a unit profile UP1 is created. The show command displays the details.

switch(config)# maintenance
switch(config-maintenance)# unit UNIT1
switch(config-unit-UNIT1)# group bgp BG1
switch(config-unit-UNIT1)# group interface IG1
switch(config-unit-UNIT1)# profile unit UP1
switch(config-unit-UNIT1)# exit
switch(config-maintenance)# show maintenance units

Unit Name: System
Origin: Built-in
Status: Not Under Maintenance
Unit Profile: Default
Time Since Last State Change: never
Bgp Groups: AllBgpNeighborVrf-default
Interface Groups:
AllEthernetInterface
Unit Name: UNIT1
Origin: User Configured
Status: Under Maintenance
Unit Profile: UP1
Time Since Last State Change: 0:00:08 ago
Bgp Groups: BG1
Interface Groups:
IG1

9.2.2 Groups of Interfaces and BGP Peers

Maintenance mode group types include the groups for interfaces and BGP peers. Groups are identified by a group name unique to a particular group type.

By default, several built-in groups are available on the device such as linecard groups containing physical interfaces.

9.2.2.1 Built-in Groups

There are several built-in groups such as AllEthernetInterface, Linecard1, Linecard2, etc., AllBgpNeighborVrf-<vrf_name>. On fixed-system, AllEthernetInterface is the built-in interface group which contains all the physical Ethernet interfaces on the switch whereas on modulars Linercard1, Linecard2, etc., are the built-in groups which contain respective linecard interfaces and are part of the System unit. AllBgpNeighborVrf-<vrf_name> is the built-in BGP group which contains all the BGP peers in that particular VRF.
9.2.2.2 User-defined Groups

The following set of commands sets up a custom group (IG1) of interfaces, which includes physical ports, port-channels and SVIs.

```
switch(config)#group interface IG1
switch(config-group-if-IG1)#interface Ethernet1
switch(config-group-if-IG1)#interface Port-Channel1,20
switch(config-group-if-IG1)#interface Vlan1-20
switch(config-group-if-IG1)#exit
switch(config)#
```

The following set of commands sets up a custom group (BG1) of BGP peers.

```
switch(config)#group bgp BG1
switch(config-group-bgp-BG1)#neighbor 10.0.0.1
switch(config-group-bgp-BG1)#neighbor BGP_PG1
switch(config-group-bgp-BG1)#vrf vrf1
switch(config-group-bgp-BG1)#exit
switch(config)#
```

Note BGP groups are specific to VRF.

9.2.3 Profiles

Profiles are configurable maintenance mode elements that define policies for related software or hardware components to carry out maintenance mode operations.

9.2.3.1 Default Profiles

Default profiles are the built-in policies which are applied to groups interface/BGP and unit.

The default profile is used in the absence of an explicit interface/BGP profile associated with the group, or explicit unit profile associated with the unit.

- **Interface Profile**

  Default interface profile has rate-monitoring load-interval set to 60 seconds, threshold set to 100 kbps, and shutdown disabled as shown. The max-delay parameter is set to 300 seconds but is not enabled.

  ```
  switch(config-maintenance)#show maintenance profile interface default
  Interface Profile: Default
  Rate Monitoring:
  load-interval: 60 seconds
  threshold (in/out): 100 kbps
  shutdown:
  enabled: no
  max-delay: 300 seconds
  ```
• **BGP Profile**

Default BGP profile has route-map with set clauses—set community GSHUT additive and set local-preference 0.

```
switch(config-maintenance)#show maintenance profile bgp default
Bgp Profile: Default
Initiator route-map: SystemGenerated
route-map SystemGenerated permit 10
Description:
    description System generated initiator route-map
Match clauses:
    SubRouteMap:
Set clauses:
    set local-preference 0
    set community GSHUT additive
```

• **Unit Profile**

Default unit profile has on-boot setting disabled.

```
switch(config-maintenance)#show maintenance profiles unit default
Unit Profile: Default
    On-boot:
    enabled: no
    duration: 300 seconds
```

### 9.2.3.2 User-defined Profiles

You can define your own profiles which can be associated to groups or set as default profiles.

**Interface Profile:** The following set of commands sets up an Interface Profile(IP1) with load interval set to 10 seconds, rate-monitoring threshold set to 100kbps and the maximum delay for shutting down the interface set to 100 seconds. The interface will be shutdown with cause `maint-down` if traffic does not drain below the threshold even after the specified maximum delay period of 100 seconds.

```
switch(config)#{maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#rate-monitoring load-interval 10
switch(config-profile-intf-IP1)#rate-monitoring threshold 100
switch(config-profile-intf-IP1)#shutdown max-delay 100
switch(config-profile-intf-IP1)#exit
switch(config-maintenance)#
```

An interface profile can be associated to only interface groups using the following set of commands.

```
switch(config)#group interface IG1
switch(config-group-if-IG1)#maintenance profile interface IP1
switch(config-group-if-IG1)#exit
switch(config)#
```

You can set the interface profile as the default interface profile using the following set of commands.

```
switch(config)#maintenance
switch(config-maintenance)# profile interface IP1 default
switch(config-maintenance)# exit
switch(config)#
```
**Bgp Profile:** The following set of commands sets up a BGP profile(BP1) with initiator route-map called RM which will be applied for both inbound and outbound directions.

```
switch(config)#maintenance
switch(config-maintenance)#profile bgp BP1
switch(config-profile-bgp-BP1)#initiator route-map RM inout
switch(config-profile-bgp-BP1)#exit
switch(config-maintenance)#
```

A BGP profile can be associated to both interface and bgp groups using the following commands.

```
switch(config)#group interface IG1
switch(config-group-if-IG1)#maintenance profile bgp BP1
switch(config)# group bgp BGL
switch(config-group-bgp-BGL)# maintenance profile bgp BP1
switch(config)#
```

You can set the bgp profile as the default bgp profile using the following set of commands.

```
switch(config)# maintenance
switch(config-maintenance)# profile bgp BP1 default
switch(config-maintenance)# exit
switch(config)#
```

**Unit Profile:** The following set of commands sets up a Unit profile(UP1) with on-boot duration of 300 seconds. The unit will enter into maintenance mode at boot-up and exit maintenance mode at the end of 5 minutes (300sec) after boot-up.

```
switch(config-maintenance)#profile unit UP1
switch(config-profile-unit-UP1)#on-boot duration 300
switch(config-profile-unit-UP1)#exit
switch(config-maintenance)#
```

A Unit profile can be associated to a Unit using the following commands.

```
switch(config)# maintenance
switch(config-maintenance)# unit UNIT1
switch(config-unit-UNIT1)# profile unit UP1
switch(config-unit-UNIT1)# exit
switch(config-maintenance)#
```

You can set the Unit profile as the default Unit profile using the following set of commands.

```
switch(config)# maintenance
switch(config-maintenance)# profile unit UP1 default
switch(config-maintenance)# exit
switch(config)#
```
9.3 Maintenance Mode Features

Arista Network switches provide maintenance mode features including rate monitoring, BGP maintenance route map, on-boot maintenance, and EventMgr integration.

9.3.1 Rate Monitoring

Rate monitoring provides a mechanism to monitor traffic on interfaces identified for maintenance. You can set the traffic threshold and a time limit for the interface to be shutdown for maintenance tasks.

A shutdown parameter can be configured in the interface profile that signals the interface to be shutdown after it has entered maintenance mode.

The max-delay parameter specifies the maximum number of seconds to allow for traffic to dissipate from the interface before the interface is shutdown. The default interface profile settings are shown in the output of the `show maintenance profile interface default` command.

9.3.2 BGP Maintenance Route Map

Route-maps are used within a BGP maintenance profile to tag the inbound and outbound routes in order to direct traffic away from the unit. The default profile tags the inbound and outbound routes with the GSHUT community. Other methods can be configured under the route-map such as alternate communities, or by using as-path prepend operations.

9.3.3 On-boot Maintenance

There are two ways of placing a unit in maintenance mode on switch boot-up:

- The unit is placed into maintenance mode prior to the switch reboot, and the running-config is saved prior to switch boot-up.
- The on-boot property in the unit maintenance profile specifies that the unit will be placed into maintenance mode as part of boot-up, and remains so for the specified duration.

Note
The duration value in the on-boot unit maintenance profile starts as soon as the unit is put into maintenance mode on boot-up.
9.4 Maintenance Mode Configuration

You can configure maintenance mode for the entire device, specific linecards, or any other Unit. You can set up configuration for maintenance mode for the device at boot-up or while it is running.

9.4.1 Unit (System, Linecard\textit{n}, etc.) Configuration

Arista Network switches provide the ability to place the switch in maintenance mode, and configuration options for groups, profiles, associating profiles with groups, units, and maintenance mode operations. **System** is a predefined (built-in) unit on all switches. Built-in groups include **AllEthernetInterface**, **AllBgpNeighborVRF-<vrf\_name>**, and **Linecard\textit{n}**. **Linecard\textit{n}** can also be a built-in unit and can be differentiated depending on the command being used as shown.

- switch(config-maintenance)# unit Linecard\textit{n}
- switch(config)# group interface Linecard\textit{n}

Built-in unit **System** comprises the following groups:

- **AllEthernetInterface** - a built-in interface group which contains all physical Ethernet interfaces on the switch on a fixed system
- **Linecard\textit{n}** - a built-in interface group which contains all interfaces for the linecard numbered ‘\textit{n}’ for modular systems
- **AllBgpNeighborVRF-<vrf\_name>** - a built-in BGP group which contains all the BGP peers in the named VRF.

For each Linecard ‘\textit{n}’, there is a built-in unit which consists of all the **Linecard\textit{n}** groups.

By default, the default interface and BGP profiles are applied to the built-in interface and BGP groups and the default built-in unit profile is applied to the built-in unit. You can also configure your own profiles and choose a default.

In the following example, traffic is flowing through multiple switches in the spine to and from one switch to another, when you elect to put one of the Units (entire switch or parts thereof) in the spine switch in maintenance mode. The traffic is then gracefully steered away from the Unit, provided other paths are available. Traffic will continue to flow through the Unit placed into maintenance mode, if no other path is available.

**Example**

**Note**

The illustration shows an entire switch as the Unit. You can replace switch with Linecard\textit{n} or another relevant Unit as appropriate.
You can see the status of the Unit (System) using the `show maintenance units System` command for the example above before the system is placed into maintenance mode. If the device being placed into maintenance mode is modular and the Unit is a linecard, replace the argument `System` with `Linecardn` to see the status of the Unit (Linecardn).

```
switch(config)# show maintenance units System
Unit Name: System
  Origin: Built-in
  Status: Not Under Maintenance
  Unit Profile: Default
  Time Since Last State Change: never
  Bgp Groups:
    AllBgpNeighborVrf-default
  Interface Groups:
    AllEthernetInterface
```
You can then place the Unit (System) into maintenance mode and recheck the status using the sequence of commands shown.

```
switch(config-maintenance)# unit System
switch(config-built-in-unit-System)# quiesce
switch(config-built-in-unit-System)# exit
switch(config-maintenance)# show maintenance
Flags:
o - On-boot maintenance
v - Violating traffic threshold

Unit Name        Status                  Time since last change Flags
---------------- ----------------------- -------------------------- -----
System           Under Maintenance      0:02:03 ago

switch(config-maintenance)# show ip bgp summary
BGP summary information for VRF default
Router identifier 1.1.1.1, local AS number 101
Neighbor Status Codes: m - Under maintenance
Neighbor   V  AS           MsgRcvd  MsgSent  InQ OutQ  Up/Down State
PfxRcd PfxAcc
m 1.1.1.2    4  100               24        17    0    0 00:00:40 Estab  5  5
m 3.3.3.33    4  102               15        16    0    0 00:06:23 Estab  1  1

Note
The 'o' flag is shown for on-boot maintenance in the show maintenance command and the 'm' neighbor status flag in the show ip bgp summary command indicates that the peer is in maintenance mode.

9.4.2 On-boot Maintenance Mode Configuration

To configure on-boot maintenance, you can use one of two methods:
- Use quiesce config or
- Use on-boot profile

9.4.2.1 Using quiesce config: You must perform the following tasks to place the Unit in maintenance mode on boot-up using the quiesce command.

**Step 1** Place the unit into maintenance mode prior to switch reboot using the following commands.

```
switch(config)# maintenance
switch(config-maintenance)# unit System
switch(config-unit-System)# quiesce
switch(config-unit-System)# exit
switch(config-maintenance)# show maintenance

Flags:
o - On-boot maintenance
v - Violating traffic threshold

Unit Name        Status                  Time since last change Flags
---------------- ----------------------- -------------------------- -----
System           Under Maintenance      00:01:10 ago

```

**Step 2** Save the running-config using the following command.

```
switch(config)# copy running-config startup-config
Copy completed successfully
switch(config)#
```
Step 3  Reload the device.

    switch(config)# reload
    Proceed with reload? [Confirm] Yes
    Connection to switch closed.

After the device comes up, you must execute the no quiesce command for the Unit to come out of maintenance mode. You can check the status of the device after it comes up using the show maintenance command.

    switch# show maintenance
    Flags:
    o - On-boot maintenance
    v - Violating traffic threshold

    Unit Name               Status                  Time since last change    Flags
    ---------------------- ----------------------- -------------------------- -----
    System                  Under Maintenance           00:03:10 ago

9.4.2.2 Using on-boot profile: The on-boot property in the Unit maintenance profile specifies that the Unit will be placed into maintenance mode as part of boot-up for the specified duration. You must perform the following tasks to use this method.

Step 1  Check to see if the on-boot maintenance mode is enabled using the show maintenance profiles unit default.

    switch# show maintenance profiles unit default
    Unit Profile: Default
    On-boot:
        enabled: no
        duration: 300 seconds

Step 2  Configure an on-boot profile with on-boot enabled and a duration specified. Make this the default Unit profile. The following code example shows the creation of an on-boot duration of 300 seconds in the profile unit UP1

    switch(config)#maintenance
    switch(config-maintenance)#profile unit UP1
    switch(config-profile-unit-UP1)#on-boot duration 300
    switch(config-profile-unit-UP1)#exit
    switch(config-maintenance)#profile unit UP1 default
    switch(config-maintenance)#show maintenance profiles unit default
    Unit Profile: UP1
    On-boot:
        enabled: yes
        duration: 300 seconds
    switch(config-maintenance)#

Step 3  Save the running-config and reload the device.

    switch(config)# copy running-config startup-config
    Copy completed successfully
    switch(config)# reload
    Connection to switch closed.
Step 4  After the device comes up, execute the `show maintenance` and `show maintenance units System` commands.

```text
switch(config)# show maintenance
Flags:
o - On-boot maintenance
v - Violating traffic threshold
Unit Name Status Time since last change Flags
---------------------- ----------------------- -------------------------- -----
System Under Maintenance 00:00:08 ago o
```

```
switch(config)# show maintenance units System

Unit Name: System
Origin: Built-in
Status: Under Maintenance (on-boot)
Unit Profile: UP1
Time Since Last State Change: 0:00:16 ago
Will come out of on-boot Maintenance after 0:04:43
Interface Groups:
  AllEthernetInterface
History:
  2017-01-18 00:44:39 old state: 'maintenanceModeEnter' to new state: 'underMaintenance' 0:00:16 ago
  2017-01-18 00:43:54 old state: 'active' to new state: 'maintenanceModeEnter' 0:01:01 ago
```

The 'o' - flag shows that unit System is under maintenance due to on-boot profile. Also, `show maintenance units System` output shows the following - 'Will come out of on-boot Maintenance after 0:04:43', which is the time remaining of the specified duration of 5 minutes.

The Unit will come up in maintenance mode when the device boots up and will exit maintenance mode once the specified duration of 300 seconds in the default profile is completed. The BGP sessions will remain under maintenance for the duration and will resume after the specified duration is over.

9.4.3 Interface-level Maintenance Mode Configuration

To configure interface-level maintenance, you must perform the following tasks.

**Step 1**  Configure an interface-level profile (or use a pre-configured one). The following code example creates a user-defined interface profile IP1 with a rate-monitoring load-interval of 100 seconds, a rate-monitoring threshold of 500 kbps and a maximum shutdown delay of 100 seconds.

```text
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#rate-monitoring load-interval 100
switch(config-profile-intf-IP1)#rate-monitoring threshold 500
switch(config-profile-intf-IP1)#shutdown max-delay 100
```

**Step 2**  Place the unit into maintenance mode.

```text
switch(config-maintenance)#interface IP1
switch(config-maint-intf-IP1)#quiesce
```

**Step 3**  Remove the unit from maintenance mode once the service has been performed.

```text
switch(config-maintenance)#interface IP1
switch(config-maint-intf-IP1)#no quiesce
```

The unit will come out of maintenance mode and resume normal operation.
9.4.4 Entering Maintenance Mode

Enter configuration commands `unit` and `quiesce` using the `neighbor` mode command to place the switch into maintenance mode. The following code sequence places unit foo, the interface 3/3, and BGP 1.1.1.1 in maintenance mode.

Example

```
switch (config)#maintenance
switch (config-maintenance)#unit foo
switch (config-unit-foo)#quiesce
switch (config-unit-foo)#exit
switch (config-maintenance)#interface ethernet 3/3
switch (config-maint-if-Et3/3)#quiesce
switch (config-maint-if-Et3/3)#exit
switch (config-maintenance)#bgp 1.1.1.1
switch (config-maint-bgp-1.1.1.1)#quiesce
switch (config-maint-bgp-1.1.1.1)#exit
switch (config-maintenance)#
```

9.4.5 Exiting Maintenance Mode

Enter configuration commands `unit` and `no quiesce` using the `neighbor` mode command for the switch to exit maintenance mode. The following code sequence causes unit foo, the interface 3/3, and BGP 1.1.1.1 to exit maintenance mode.

Example

```
switch (config)#maintenance
switch (config-maintenance)#unit foo
switch (config-unit-foo)#no quiesce
switch (config-unit-foo)#exit
switch (config-maintenance)#interface ethernet 3/3
switch (config-maint-if-Et3/3)#no quiesce
switch (config-maint-if-Et3/3)#exit
switch (config-maintenance)#bgp 1.1.1.1
switch (config-maint-bgp-1.1.1.1)#no quiesce
switch (config-maint-bgp-1.1.1.1)#exit
switch (config-maintenance)#
```

9.4.6 Configuring Event Handlers

Enter configuration options for the `trigger on-maintenance` command to fire at different stages while entering or exiting maintenance mode.

Example for Maintenance Mode Event Handler for all Stages

```
switch (config)#event-handler foo
switch (config-handler-foo)#trigger on-maintenance enter unit unit-foo all
switch (config-handler-foo)#action bash /mnt/flash/mm-event-handler-script
switch (config-handler-foo)#timeout 20
switch (config-handler-foo)#exit
switch (config)#
```
Note

The user is expected to configure the timeout value. This is time within which the script should complete execution and exit. If the script has not exited by the end of this period, then the following will occur:
1. Send the SIGUSR1 signal to the script.
2. Wait for a GRACE-PERIOD of 10 seconds for the script to exit.
3. If the script does not exit even after that GRACE-PERIOD, then send a SIGKILL to the script.
4. The maintenance operation progresses to the next stage.

GRACE-PERIOD is not configurable.

```
switch(config)#event-handler bar
switch(config-handler-bar)#trigger on-maintenance exit unit unit-foo before stage ratemon
switch(config-handler-bar)#action bash /mnt/flash/mm-event-handler-script
switch(config-handler-bar)#exit
switch(config)#
```

9.4.7 Configuring Groups

Enter the maintenance mode configuration options for groups with the `maintenance` and `group bgp` commands.

**Example for group interface IG1**

```
switch(config)#group interface IG1
switch(config-group-if-IG1)#interface Ethernet1
switch(config-group-if-IG1)#interface Port-Channel1,20
switch(config-group-if-IG1)#interface Vlan1-20
switch(config-group-if-IG1)#exit
switch(config)#
```

**Example for group bgp BG1**

```
switch(config)#group bgp BG1
switch(config-group-bgp-BG1)#neighbor 10.0.0.1
switch(config-group-bgp-BG1)#neighbor BGP_PG1
switch(config-group-bgp-BG1)#vrf vrf1
switch(config-group-bgp-BG1)#exit
switch(config)#
```

Note

BGP groups are specific to VRF.

9.4.8 Configuring Profiles

Enter the maintenance mode configuration options for profiles with the `profile interface`, `rate-monitoring threshold`, `profile bgp`, and `profile unit <profile_name>` commands.

These command examples assign a user configured profile as the default profile.
Example for profile interface IP1
```
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#rate-monitoring load-interval 10
switch(config-profile-intf-IP1)#rate-monitoring threshold 100
switch(config-profile-intf-IP1)#shutdown max-delay 100
switch(config-profile-intf-IP1)#profile interface IP1 default
switch(config-profile-intf-IP1)#exit
switch(config-maintenance)#
```

Example for profile bgp BP1
```
switch(config-maintenance)#profile bgp BP1
switch(config-profile-bgp-BP1)#initiator route-map rmap inout
switch(config-profile-bgp-BP1)#profile bgp BP1 default
switch(config-profile-bgp-BP1)#exit
switch(config-maintenance)#
```

Example for profile unit UP1
```
switch(config-maintenance)#profile unit UP1
switch(config-profile-unit-UP1)#on-boot duration 300
switch(config-profile-unit-UP1)#profile unit UP1 default
switch(config-profile-unit-UP1)#exit
switch(config-maintenance)#
```

9.4.9 Associating Profiles with Groups
Enter the maintenance mode configuration options for associating profiles with groups using the `maintenance` and `group bgp` command.

Example
```
switch(config)#group interface IG1
switch(config-group-if-IG1)#maintenance profile bgp BP1
switch(config-group-if-IG1)#maintenance profile interface IP1
switch(config-group-if-IG1)#
```

Note
An interface/BGP profile can be associated with the interface group, and a BGP profile can be associated with the BGP group.

9.4.10 Configuring Units
Enter the maintenance mode configuration options for units using the `unit`, `group bgp`, and `maintenance` commands.

Example
```
switch(config)#maintenance
switch(config-maintenance)#unit foo
switch(config-unit-foo)#group bgp BG1
switch(config-unit-foo)#group interface IG1
switch(config-unit-foo)#profile unit UP1
```
9.4.11 Show Commands

Maintenance mode show commands display general and detailed information associated with maintenance mode.

9.4.11.1 show maintenance

This example of the `show maintenance` command displays maintenance mode details.

Example

```
switch(config)#show maintenance
Flags:
o - On-boot maintenance
v - Violating traffic threshold

Unit Name       Status                        Time since last change Flags
---------------------- ----------------------- -------------------------- ----- 
System           Not Under Maintenance    never                     
Foo              Under Maintenance          0:00:14 ago             ov     

Interface Name     Status                        Time since last change Flags
---------------------- ----------------------- -------------------------- ----- 
Ethernet4          Entering Maintenance       0:00:24 ago              
Bgp Neighbor(vrf: defa Status                        Time since last change Flags

Bgp Neighbor(vrf: red Status                        Time since last change Flags

---------------------- ----------------------- -------------------------- ----- 
12.12.12.12        Under Maintenance          0:00:04 ago             
12.12.12.13        Under Maintenance          0:00:34 ago             

switch(config)#
```

9.4.11.2 show maintenance summary

This example of the `show maintenance summary` command displays a summary of maintenance mode information.

Example

```
switch(config)#show maintenance summary
Number of Units configured: 3
Number of Units not under maintenance: 2
Number of Units entering maintenance: 1
Number of Units under maintenance: 0
Number of Units exiting maintenance: 0
Directly Put Under Maintenance:
  Number of interfaces entering maintenance: 0
  Number of interfaces under maintenance: 2
  Number of bgp peers entering maintenance: 0
  Number of bgp peers under maintenance: 3
Rate Monitoring:
  Number of interfaces entering maintenance: 0
  Number of interfaces under maintenance: 4
  Number of interfaces under maintenance with threshold violation: 0
  Number of interfaces shutdown for maintenance: 0

switch(config)#
```
9.4.11.3 show maintenance units

This example of the `show maintenance units` command displays maintenance mode units details.

**Example**

```
switch(config)#show maintenance units
Unit Name: Linecard3
  Origin: User Configured
  Status: Under Maintenance
  Unit Profile: Default
  Time Since Last State Change: 0:12:07 ago
  Interface Groups:
    IG1
  Interface Traffic Threshold violations:
    Current violations: 1
    Et1
    Total violations, during maintenance: 5
  History:
    2016-04-27 04:00:42 old state: 'maintenanceModeEnter' to new state: 'underMaintenance' 0:12:07 ago
Unit Name: System
  Origin: Built-in

  Time Since Last State Change: never
  Interface Groups:
    AllEthernetInterface
```

9.4.11.4 show maintenance bgp

This example of the `show maintenance bgp` command displays maintenance mode BGP details for all IPs and VRFs.
Example

```
switch(config)#show maintenance bgp ip all vrf all
BGP peer maintenance information for VRF default
  Router identifier 2.2.2.1, local AS number 1
    Neighbor: 2.2.2.2
      Maintenance State: Not Under Maintenance
  BGP peer maintenance information for VRF red
  Router identifier 6.6.6.1, local AS number 1
    Neighbor: 1.1.1.2
      Maintenance State: Not Under Maintenance
  Router identifier 2.2.2.1, local AS number 1
    Neighbor: 2.2.2.2
      Maintenance State: Not Under Maintenance
    Maintenance route-map: SystemGenerated
      route-map SystemGenerated permit 10
        Description:
        Match clauses:
        Set clauses:
          set community GSHUT additive
          set local-preference 0
      Selected profile from BGP groups: Default
```

```
switch(config)#
```

9.4.11.5 show maintenance interface

This example of the `show maintenance interface status` command displays maintenance mode interface details.

Example

```
switch(config)#show maintenance interface
Flags:
  v - Violating traffic threshold
  s - Shutdown for maintenance

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
<th>Rate (Mbps)</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Under Maintenance</td>
<td>0.4</td>
<td>v</td>
</tr>
<tr>
<td>Ethernet2</td>
<td>Under Maintenance</td>
<td>0.0</td>
<td></td>
</tr>
<tr>
<td>Ethernet3</td>
<td>Not Under Maintenance</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Ethernet4</td>
<td>Under Maintenance</td>
<td>0.0</td>
<td></td>
</tr>
<tr>
<td>Ethernet5</td>
<td>Not Under Maintenance</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
```

switch(config)#

9.4.11.6 show maintenance interface status quiesced

This example of the `show maintenance interface status quiesced` command displays maintenance mode interface status details for quiesced interfaces.
Example

```
switch(config)#show maintenance interface status quiesced
Flags:
v - Violating traffic threshold
s - Shutdown for maintenance

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
<th>Rate (Mbps)</th>
<th>In</th>
<th>Out</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Under Maintenance</td>
<td>0.3</td>
<td>0.0</td>
<td></td>
<td>v</td>
</tr>
<tr>
<td>Ethernet2</td>
<td>Under Maintenance</td>
<td>0.0</td>
<td>0.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ethernet4</td>
<td>Under Maintenance</td>
<td>0.0</td>
<td>0.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

switch(config)#

9.4.11.7 show maintenance groups

This example of the `show maintenance groups` command displays maintenance mode group details.

Example

```
switch(config)#show maintenance groups
Interface Group: IG1
  Interfaces:
    Et4-6
  Profiles:
    Interface Profile: IP1
    Units: newEt
  Bgp Group: BG
  Neighbors:
    IPv4 Peers: 4.4.4.2, 1.1.1.2, 3.3.3.2
    IPv6 Peers: 3::3
  Bgp Profile: prepend
  Units: newBG
```

switch(config)#

9.4.11.8 show maintenance profiles

This example of the `show maintenance profiles` command displays maintenance mode profile details.

Example

```
switch(config)#show maintenance profiles
Interface Profile: INTFPROFILE
  Rate Monitoring:
    load-interval: 444 seconds
    threshold (in/out): 4000 Kbps
  shutdown:
    enabled: yes
    max-delay: 399 seconds
  Bgp Profile: BGPPROFILE
    Initiator route-map:
      name: rm
  Unit Profile: UNITPROFILE
    On-boot:
      enabled: yes
      duration: 340 seconds
```

switch(config)#
Chapter 9: Maintenance Mode

9.4.11.9 show interface status

This example of the `show interface <intf_name> status` command displays maintenance mode information for interfaces.

**Example**

```
switch(config)# show interface status

<table>
<thead>
<tr>
<th>Port</th>
<th>Name</th>
<th>Status</th>
<th>Vlan</th>
<th>Duplex</th>
<th>Speed</th>
<th>Type</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1</td>
<td></td>
<td>connected</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td>mv</td>
</tr>
<tr>
<td>Et2</td>
<td></td>
<td>connected</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td>m</td>
</tr>
<tr>
<td>Et3</td>
<td></td>
<td>maint-down</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td>m</td>
</tr>
<tr>
<td>Et4</td>
<td></td>
<td>maint-down</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td>m</td>
</tr>
<tr>
<td>Et5</td>
<td></td>
<td>connected</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td></td>
</tr>
<tr>
<td>Et6</td>
<td></td>
<td>connected</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>EbraTestPhyP</td>
<td></td>
</tr>
</tbody>
</table>
```

switch(config)#

9.4.11.10 show interface ethernet

This example of the `show interface ethernet` command displays maintenance mode information for an ethernet interface.

**Example**

```
switch(config)# show interface ethernet 4

Ethernet4 is down, line protocol is down (maint-down)
Hardware is Ethernet, address is 0000.0101.0004 (bia 0000.0101.0004)
Ethernet MTU 9214 bytes, BW 10000000 kbit
Full-duplex, 10Gb/s, auto negotiation: off, uni-link: unknown
Down 18 minutes, 39 seconds
Under maintenance for 18 minutes, 42 seconds
2 link status changes since last clear
Last clearing of "show interface" counters never
5 minutes input rate 0 bps (0.0% with framing overhead), 0 packets/sec
5 minutes output rate 0 bps (0.0% with framing overhead), 0 packets/sec
0 packets input, 0 bytes
Received 0 broadcasts, 0 multicast
0 runts, 0 giants
0 input errors, 0 CRC, 0 alignment, 0 symbol, 0 input discards
0 PAUSE input
94 packets output, 11562 bytes
Sent 0 broadcasts, 94 multicast
0 output errors, 0 collisions
0 late collision, 0 deferred, 0 output discards
0 PAUSE output
```

switch(config)#

9.4.11.11 show ip bgp neighbors

This example of the `show ip bgp neighbors` command displays IP BGP neighbors maintenance mode details.
Example

switch(config)#show ip bgp neighbors 1.1.1.2
BGP neighbor is 1.1.1.2, remote AS 1, external link
...
Prefix statistics:

<table>
<thead>
<tr>
<th></th>
<th>Sent</th>

</tr>
</thead>
<tbody>
<tr>
<td>IPv4 prefixes:</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>IPv6 prefixes:</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Inbound route map is foo
Outbound route map is foo
Session is under maintenance
Maintenance-mode:
  Inbound and Outbound policy
  Route map is SystemGenerated

switch(config)#

9.4.11.12 show ip bgp summary

This example of the `show ip bgp summary` command displays maintenance mode information for IP BGP.

Example

switch(config)#show ip bgp summary
BGP summary information for VRF default
Router identifier 192.168.201.13, local AS number 100
Neighbor Status Codes: m - Under maintenance

<table>
<thead>
<tr>
<th>Neighbor</th>
<th>V</th>
<th>AS</th>

<td>ratemon</td>
<td>Interface Rate Monitoring</td>
</tr>
<tr>
<td>2</td>
<td>bgp</td>
<td>BGP Maintenance processing</td>
</tr>
</tbody>
</table>

switch(config)#
Example

```bash
switch(config)#show maintenance bgp receiver route-map
route-map SystemGenerated permit 10
  Description: description System generated receiver route-map
  Match clauses: match community GSHUT-LIST
  SubRouteMap:
  Set clauses:
route-map SystemGenerated permit 50
  Description: description System generated receiver route-map
  Match clauses:
  SubRouteMap:
  Set clauses:
```

tg232(s1)(config)#show maintenance profiles interface
tg232(s1)(config)#show maintenance profiles bgp
tg232(s1)(config)#show maintenance profiles unit
tg232(s1)(config)#show maintenance profiles unit default

Interface Profile: Default
  On-boot:
    enabled: no
    duration: 300 seconds

Example

```bash
switch(config)#show maintenance profiles interface default
Interface Profile: Default
  Rate Monitoring:
    load-interval: 60 seconds
    threshold (in/out): 100 Kbps
  shutdown:
    enabled: no
    max-delay: 300 seconds
```

Example

```bash
switch(config)#show maintenance profiles bgp default
Bgp Profile: Default
  Initiator route-map: SystemGenerated
  route-map SystemGenerated permit 10
  Description: description System generated initiator route-map
  Match clauses:
  SubRouteMap:
  Set clauses:
    set local-preference 0
    set community GSHUT additive
```

switch(config)#
Example

switch(config)#show maintenance profiles unit default
Unit Profile: Default
   On-boot:
       enabled: no
       duration: 300 seconds

switch(config)#

9.4.12 Syslog Messages

Maintenance mode syslog messages are as follows:

- MaintenanceMode: %MMODE-4-MAINT_OP_WARNING: Unit config is deleted for unit foo. The unit is still undergoing maintenance operation.
- MaintenanceMode: %ETH-6-MAINTENANCE_DOWN: Interface Et1 has been shutdown for maintenance.
- MaintenanceMode: %MMODE-5-INTF_PROFILE_CHANGE: For interface Et1 interface profile changed to IP1.
- Rib: %BGP-6-MAINTENANCE-MODE: peer 1.1.1.1 is placed under maintenance.
- Rib: %BGP-6-MAINTENANCE-MODE: peer 1.1.1.1 is taken out of maintenance.
9.5 Maintenance Mode Commands

Global Configuration Commands

- group bgp
- group interface
- maintenance

Group Configuration Commands

- interface
- neighbor
- maintenance profile interface
- maintenance profile bgp
- vrf

Maintenance Configuration Commands

- profile interface
- profile bgp
- profile unit
- unit
- interface
- bgp <peer> [vrf <vrf_name>]
- profile interface <profile_name> default
- profile bgp <profile_name> default
- profile unit <profile_name> default

Unit Configuration Commands

- group bgp <group_name>
- group interface <group_name>
- profile unit
- quiesce

Interface Profile Configuration Commands

- rate-monitoring load-interval
- rate-monitoring threshold
- shutdown max-delay

BGP Profile Configuration Commands

- initiator route-map <route-map-name> inout

Unit Profile Configuration Commands

- on-boot duration

EventMgr Configuration Commands

- trigger on-maintenance

Display Commands

- show maintenance
- show maintenance summary
- show maintenance units
- show maintenance interface
- show maintenance interface status
- show maintenance bgp
- show maintenance groups
- show maintenance profiles
- show maintenance stages
- show maintenance bgp receiver route-map
- show maintenance debug

**Enhanced Commands to show Maintenance Status**

- show interface
- show interface <intf_name> status
- show ip | ipv6 bgp summary [ vrf <vrf_name>]
- show ip | ipv6 bgp neighbors <peer_addr> [vrf <vrf_name>]
group bgp

The **group bgp** `<group_name>` **command** places the switch in group-BGP configuration mode for configuring the members of a BGP group in a particular VRF and associating a BGP maintenance profile for these members.

The command creates the group if the specified group does not exist prior to issuing the command. The **no group bgp** `<group_name>` and **default group bgp** `<group_name>` removes the BGP group.

**Command Mode**

Global Configuration

**Command Syntax**

- `group bgp group_name`
- `no group bgp group_name`
- `default group bgp group_name`

**Parameters**

- `group_name` name of the BGP group

**Commands available in group-BGP configuration mode:**

- `neighbor (ipv4 address | ipv6 address | peer-group)`
- `vrf (vrf-name)`
- maintenance profile bgp

**Note**

Built-in BGP groups like `AllBgpNeighborVrf-default` and `AllBgpNeighborVrf-<vrf_name>` do not allow neighbor configuration. Only BGP maintenance profile can be associated to them.

**Example**

- This command creates a BGP group BG1 and enters into group BGP BG1 configuration mode.

  ```
  switch(config)#group bgp BG1
  switch(config-group-bgp-BG1)# show active
group bgp BG1
  exit
  switch(config-group-bgp-BG1)#
  ```

- This command enters into BGP built-in configuration mode for AllBgpNeighborVrf-default.

  ```
  switch(config)#group bgp AllBgpNeighborVrf-default
  switch(config-built-in-group-bgp-AllBgpNeighborVrf-default)# show active
group bgp AllBgpNeighborVrf-default
  exit
  switch(config-built-in-group-bgp-AllBgpNeighborVrf-default)#exit
  switch(config)#show maintenance groups bgp AllBgpNeighborVrf-default
  BGP Group: AllBgpNeighborVrf-default
  Origin: Built-in
  Neighbors:
  Ipv4 Peers: 1.0.0.1, 1.0.1.2
  Bgp Profile: Default
  Vrf: default
  Units: System
  switch(config)#
  ```
group interface

The group interface command places the switch in group-intf configuration mode for configuring the members of interface group and associating a BGP/interface maintenance profile for these members.

The command creates the group if the specified group does not exist prior to issuing the command.

The no group interface <group_name> and default group interface <group_name> removes the interface group.

Command Mode
Global Configuration

Command Syntax
- `group interface group_name`
- `no group interface group_name`
- `default group interface group_name`

Parameters
- `group_name` name of the interface group

Commands available in group-BGP configuration mode:
- `interface`
- `maintenance profile bgp`
- `maintenance profile interface`

Note
Built-in Interface groups like AllEthernetInterface, Linecard3, Linecard4, etc. do not allow interface configurations. Only BGP/interface maintenance profiles can be associated to them.

Example
- This command creates an interface group IG1 and enters into group interface IG1 configuration mode.
  ```
  switch(config)#group interface IG1
  switch(config-group-if-IG1)# show active
  group interface IG1
  exit
  switch(config-group-if-IG1)#
  ```
- This command enters into built-in interface group AllEthernetInterface.
  ```
  switch(config)#group interface AllEthernetInterface
  switch(config-builtin-group-if-AllEthernetInterface)#show active
  group interface AllEthernetInterface
  exit
  switch(config-builtin-group-if-AllEthernetInterface)#region
  switch(config)# show maintenance groups interface AllEthernetInterface
  Interface Group: AllEthernetInterface
  Origin: Built-in
  Interfaces:
  Et1, Et2, Et3, Et4, Et5/1, … Et34, Et35, Et36
  Profiles:
  Interface Profile: Default
  Bgp Profile: Default
  Units: System#
  ```
**maintenance**

The **maintenance** command allows you to enter maintenance configuration mode and specify maintenance configuration options.

The **no maintenance** and **default maintenance** command removes the maintenance configuration from the *running-config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
maintenance  
no  maintenance
default maintenance
```

**Commands available in maintenance configuration mode:**

- `unit`
- `bgp`
- `interface`
- `profile bgp`
- `profile interface`
- `profile unit`
- `profile interface <profile-name> default`
- `profile bgp <profile-name> default`
- `profile unit <profile-name> default`

**Examples**

- This example shows the commands to enter maintenance configuration mode and configure maintenance related parameters.

```plaintext
switch(config)#maintenance
switch(config-maintenance)#profile unit foo
switch(config-profile-unit-foo)#on-boot duration 300
switch(config-profile-unit-foo)#exit
switch(config-maintenance)#unit U1
switch(config-unit-U1)#group interface IG1
switch(config-unit-U1)#group bgp BG1
switch(config-unit-U1)#profile unit foo
switch(config-unit-U1)#exit
switch(config-maintenance)#show active maintenance
  profile unit foo
    on-boot duration 300
  unit U1
    group interface IG1
    group bgp BG1
    profile unit foo
switch(config-maintenance)#
```
**interface**

The *interface* command adds interfaces to interface group.

The *no interface <intf-name>* and *default interface <intf-name>* removes the interface from the group.

**Command Mode**
- Group-Interface Configuration

**Command Syntax**

- `interface interface-name`
- `no interface interface-name`
- `default interface interface-name`

**Parameters**
- *interface-name*  name of the interface
  - `ethernet e_range`  Ethernet interfaces specified by e_range
  - `port-channel p_range`  port channel interfaces specified by p_range
  - `vlan v_range`  vlans specified by v_range.

Valid *e_range, p_range* and *v_range* formats include number, range, or comma-delimited list of numbers and ranges. Valid Ethernet numbers depend on the Ethernet interfaces available on the switch.

**Example**

- This command adds Ethernet8, Ethernet9, and port-channel10 to the interface group IG1.

```
switch(config)#group interface IG1
switch(config-group-if-IG1)#interface Ethernet8-9
switch(config-group-if-IG1)#interface port-channel10
switch(config-group-if-IG1)#show active
  group interface IG1
    interface Et8-9
    interface Po10
switch(config-group-if-IG1)#exit
switch(config)#
```
neighbor

The `neighbor` command adds BGP peer(s) to a BGP group. The neighbors can be IPv4, IPv6 or a peer-group. The `no neighbor <peer>` and `default neighbor <peer>` removes the BGP peer from the group.

**Command Mode**
Group-BGP Configuration

**Command Syntax**

```
neighbor ipv4_addr
no neighbor ipv4_addr
default neighbor ipv4_addr
neighbor ipv6_addr
no neighbor ipv6_addr
default neighbor ipv6_addr
neighbor peer-group-name
no neighbor peer-group-name
default neighbor peer-group-name
```

**Parameters**
- `ipv4_addr`  BGP neighbor ipv4 address
- `ipv6_addr`  BGP neighbor ipv6 address
- `peer-group-name`  BGP peer group name

**Example**
- This command adds ipv4 peer 1.0.1.1, ipv6 peer 1::1 and peer-group PG to the BGP group BG1.

```
switch(config)#group bgp BG1
switch(config-group-bgp-BG1)#neighbor 1.0.1.1
switch(config-group-bgp-BG1)#neighbor 1::1
switch(config-group-bgp-BG1)#neighbor PG
switch(config-group-bgp-BG1)#group bgp BG1
switch(config-group-bgp-BG1)#neighbor 1.0.1.1
switch(config-group-bgp-BG1)#neighbor 1::1
switch(config-group-bgp-BG1)#neighbor PG
switch(config-group-bgp-BG1)#exit
switch(config)#
```
maintenance profile interface

The `maintenance profile interface <profile-name>` command associates interface profile to interface group.

The `no maintenance profile interface <profile-name>` and `default maintenance profile interface <profile-name>` removes the interface profile from interface group.

**Command Mode**

- Group-Interface Configuration
- Built-in-Group-Interface Configuration

**Command Syntax**

```
maintenance profile interface profile-name
no maintenance profile interface profile-name
default maintenance profile interface profile-name
```

**Parameters**

- `profile-name` name of the interface profile

**Example**

- This command adds interface profile IP1 to interface group IG1.
  ```
  switch(config)#group interface IG1
  switch(config-group-if-IG1)#interface Ethernet8-9
  switch(config-group-if-IG1)#maintenance profile interface IP1
  switch(config-group-if-IG1)#show active
  group interface IG1
    interface Et8-9
      maintenance profile interface IP1
  ```

- This command adds interface profile IP1 to built-in interface group AllEthernetInterface.
  ```
  switch(config)#group interface AllEthernetInterface
  switch(config-built-in-group-if-AllEthernetInterface)#maintenance profile interface IP1
  switch(config-built-in-group-if-AllEthernetInterface)#show active
  group interface AllEthernetInterface
    maintenance profile interface IP1
  ```
maintenance profile bgp

The **maintenance profile bgp** `<profile-name>` command associates a BGP maintenance profile to an interface/BGP group. A BGP profile can be associated to both the interface and BGP group.

The **no maintenance profile bgp** `<profile-name>` and **default maintenance profile bgp** `<profile-name>` removes the profile from the interface/BGP group.

**Command Mode**
- Group-Interface Configuration
- Group-BGP Configuration
- Built-in-Group-Interface Configuration
- Built-in-Group-BGP Configuration

**Command Syntax**
```
maintenance profile bgp profile-name
no maintenance profile bgp profile-name
default maintenance profile profile-name
```

**Parameters**
- **profile name**  name of the BGP profile

**Example**
- This command adds BGP profile **BP1** to a BGP group **BG1**.
  ```
  switch(config)#group bgp BG1
  switch(config-group-bgp-BG1)#neighbor 1.0.1.1
  switch(config-group-bgp-BG1)#neighbor 1::1
  switch(config-group-bgp-BG1)#neighbor PG
  switch(config-group-bgp-BG1)#maintenance profile bgp BP1
  switch(config-group-bgp-BG1)#show active
  group bgp BG1
    neighbor 1.0.1.1
    neighbor 1::1
    neighbor PG
    maintenance profile bgp BP1
  switch(config-group-bgp-BG1)#exit
  switch(config)#
  ```

- This command adds BGP profile **BP1** to interface group **IG1**.
  ```
  switch(config)#group interface IG1
  switch(config-group-if-IG1)#interface Ethernet8-9
  switch(config-group-if-IG1)#maintenance profile bgp BP1
  switch(config-group-if-IG1)#show active
  group interface IG1
    interface Et8-9
    maintenance profile bgp BP1
  switch(config-group-if-IG1)#exit
  switch(config)#
  ```

- This command adds BGP profile **BP1** to built-in interface group **AllEthernetInterface**.
  ```
  switch(config)#group interface AllEthernetInterface
  switch(config-group-if-AllEthernetInterface)#maintenance profile bgp BP1
  switch(config-group-if-AllEthernetInterface)#show active
  group interface AllEthernetInterface
    maintenance profile bgp BP1
  switch(config-group-if-AllEthernetInterface)#
  ```
vrf

The vrf command specifies the VRF for BGP group. All the neighbors configured in the BGP group are considered to be members of the BGP group in the particular VRF context.

The no vrf <vrf-name> and default vrf <vrf-name> removes the VRF configuration from the BGP group and sets the VRF context to “default”.

Command Mode

Group-BGP Configuration

Command Syntax

vrf vrf_name
no vrf vrf_name
default vrf vrf_name

Parameters

- vrf_name name of the VRF in a group belonging to neighbors in that group

Example

- This command specifies VRF VRF1 for the neighbors in the BGP group BGP1.

  switch(config)#group bgp BGP1
  switch(config-group-bgp-BG1)#neighbor 1.0.1.1
  switch(config-group-bgp-BG1)#neighbor 1::1
  switch(config-group-bgp-BG1)#neighbor PG
  switch(config-group-bgp-BG1)#vrf VRF1
  switch(config-group-bgp-BG1)#show active
  group bgp BGI
  neighbor 1.0.1.1
  neighbor 1::1
  neighbor PG
  vrf VRF1
  switch(config-group-bgp-BG1)#exit
  switch(config)#
**profile interface**

The **profile interface** command places the switch in maintenance profile interface configuration mode for configuring rate-monitoring threshold, load-interval, and shutdown max-delay.

The command creates the profile if the specified interface profile does not exist prior to issuing the command.

The **no profile interface <profile-name>** and **default profile interface <profile-name>** removes the profile from running-config.

**Command Mode**

 Maintenance Configuration

**Command Syntax**

```
profile interface profile-name
no profile interface profile-name
default profile interface profile-name
```

**Parameters**

- **profile-name**  name of the interface profile

**Commands available in maintenance profile interface configuration mode:**

- rate-monitoring load-interval
- rate-monitoring threshold
- shutdown max-delay

**Example**

- This command creates interface profile IP1.

```
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#show active
maintenance
    profile interface IP1

switch(config-profile-intf-IP1)#
```
**profile bgp**

The `profile bgp` command places the switch in maintenance profile BGP configuration mode for configuring initiator route-map.

The command creates the profile if the specified BGP profile does not exist prior to issuing the command.

The `no profile bgp <profile-name>` and `default profile bgp <profile-name>` removes the profile from `running-config`.

**Command Mode**

- Maintenance Configuration

**Command Syntax**

```plaintext
profile bgp profile-name
no profile bgp profile-name
default profile bgp profile-name
```

**Parameters**

- `profile-name` name of the BGP profile

**Commands available in maintenance profile BGP configuration mode:**

- `initiator route-map (route-map name) inout`

**Example**

- This command creates BGP profile BP1.

```plaintext
switch(config)#maintenance
switch(config-maintenance)#profile bgp BP1
switch(config-profile-bgp-BP1)#show active maintenance
    profile bgp BP1

switch(config-profile-bgp-BP1)#
```

```plaintext
```
profile unit

The **profile unit** command places the switch in maintenance profile unit configuration mode for configuring on-boot duration.

The command creates the profile if the specified BGP profile does not exist prior to issuing the command.

The **no profile unit <profile-name>** and **default profile unit <profile-name>** removes the profile from running-config.

**Command Mode**

Maintenance Configuration

**Command Syntax**

```
profile unit profile-name
no profile unit profile-name
default profile unit profile-name
```

**Parameters**

- `profile-name` name of the unit profile

**Commands available in maintenance profile unit configuration mode:**

- on-boot duration

**Example**

- This command creates unit profile UP1.

  ```
  switch(config)#maintenance
  switch(config-maintenance)#profile unit UP1
  switch(config-profile-unit-UP1)#show active maintenance
  profile unit UP1
  
  switch(config-profile-unit-UP1)#
  ```
unit

The `unit <unit_name>` command places the switch in maintenance unit configuration mode for configuring BGP/interface groups in the unit.

The command creates the unit if the specified unit profile does not exist prior to issuing the command.

The `no unit <unit-name>` and `default unit <unit-name>` removes the unit from `running-config`.

**Command Mode**

Maintenance Configuration

**Command Syntax**

```
unit linecard l_range | unit_name
no unit linecard l_range | unit_name
default unit linecard l_range | unit_name
```

**Parameters**

- **Linecard l_range** name of the Linecard built-in unit
- **0 l_range** linecards available on the switch
- **unit_name** name of the user-configured unit

**Commands available in maintenance unit configuration mode:**

- `group interface`
- `group bgp`
- `profile unit`
- `quiesce`

**Note**

Built-in units like `System`, `Linecard3`, `Linecard4`, etc. do not allow group configuration but unit profile can be associated to these units.

**Examples**

- This command creates maintenance unit UNIT1.
  ```
  switch(config)#maintenance
  switch(config-maintenance)#unit UNIT1
  switch(config-unit-UNIT1)#show active
  maintenance
  unit UNIT1
  switch(config-unit-UNIT1)#
  ```

- This command enters the built-in `Linecard1` unit configuration mode.
  ```
  switch(config)#maintenance
  switch(config-maintenance)#unit Linecard1
  switch(config-builtin-unit-Linecard1)#show active
  maintenance
  unit Linecard1
  switch(config-builtin-unit-Linecard1)#
  ```
interface

The `interface <intf-name>` command places the switch in maintenance dynamic interface unit configuration mode.

The command creates the dynamic interface unit if the specified dynamic interface unit does not exist prior to issuing the command.

The `no interface <intf-name>` and `default interface <intf-name>` removes the dynamic interface unit from `running-config`.

Command Mode
Maintenance Configuration

Command Syntax

```
interface interface-name
no interface interface-name
default interface interface-name
```

Parameters

- `interface-name` name of the interface
- `ethernet e_range` Ethernet interfaces specified by `e_range`
- `port-channel p_range` port channel interfaces specified by `p_range`
- `vlan v_range` vlans specified by `v_range`.

Valid `e_range`, `p_range` and `v_range` formats include number, range, or comma-delimited list of numbers and ranges.

Note
Different dynamic interface units are created for each interface in the range.

Commands available in maintenance dynamic interface unit configuration mode:

- `quiesce`

Example

- This command creates two dynamic interface units for interfaces Ethernet1-2 under maintenance configuration.

```
switch(config)#maintenance
switch(config-maintenance)#interface Ethernet1-2
switch(config-maint-if-Et1-2)#exit
switch(config-maintenance)#show active
maintenance
    interface Ethernet1
        !
    interface Ethernet2
switch(config-maintenance)#
```
**bgp <peer> [vrf <vrf_name>]**

The `bgp <peer> [vrf <vrf_name>]` command places the switch in maintenance dynamic BGP unit configuration mode. If no VRF is specified, the BGP peer is considered to be in the DEFAULT VRF, otherwise, in the specified VRF.

The command creates the dynamic BGP unit if the specified dynamic BGP unit does not exist prior to issuing the command.

The `no bgp <peer> [vrf <vrf_name>]` and `default bgp <peer> [vrf <vrf_name>]` removes the dynamic BGP unit from `running-config`.

**Command Mode**

Maintenance Configuration

**Command Syntax**

```
bgp ipv4_addr [vrf <vrf_name>]
bgp ipv6_addr [vrf <vrf_name>]
bgp peer_group_name [vrf <vrf_name>]
<no | default> bgp ipv4_addr|ipv6_addr|peer_group_name [vrf <vrf_name>]
```

**Parameters**

- `ipv4_addr` BGP neighbor IPv4 address
- `ipv6_addr` BGP neighbor IPv6 address
- `peer_group_name` BGP peer group name
- `vrf_name` name of the VRF to which the BGP peer belongs

**Commands available in maintenance dynamic interface unit configuration mode:**

- `quiesce`

**Example**

- This command creates dynamic BGP unit for IPv4 addr 1.0.1.1, IPv6 addr 1::1 with quiesce and peer-group PG in VRF VRF1 under maintenance configuration.

  ```
  switch(config)#maintenance
  switch(config-maintenance)#bgp 1.0.1.1
  switch(config-maint-bgp-1.0.1.1)#exit
  switch(config-maintenance)#bgp 1::1
  switch(config-maint-bgp-1::1)#quiesce
  switch(config-maint-bgp-1::1)#exit
  switch(config-maintenance)#bgp PG vrf VRF1
  switch(config-maint-bgp-PG)#exit
  switch(config-maint-bgp-PG)#show active
  maintenance
  bgp 1.0.1.1
  |
  bgp 1::1
  quiesce
  |
  bgp PG vrf VRF1
  switch(config-maintenance)#
  ```
**profile interface <profile_name> default**

The **profile interface <profile_name> default** command configures a user-configured interface profile as default interface profile.

The **no profile interface <profile_name> default** and **default profile interface <profile_name> default** removes the user-configured interface profile as default interface profile.

**Command Mode**
- Maintenance Configuration

**Command Syntax**

`profile interface profile_name default`

`no profile interface profile_name default`

`default profile interface profile_name default`

**Parameters**
- `profile_name` name of the interface profile

**Example**
- This command configures user configured interface profile IP1 as default interface profile.

```
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#rate-monitoring load-interval 100
switch(config-profile-intf-IP1)#rate-monitoring threshold 500
switch(config-profile-intf-IP1)#shutdown max-delay 100
switch(config-profile-intf-IP1)#exit
switch(config-maintenance)#
```

Interface Profile: Default
Rate Monitoring:
- load-interval: 60 seconds
- threshold (in/out): 100 kbps
shutdown:
- enabled: no
- max-delay: 300 seconds

```
switch(config-maintenance)#profile interface IP1 default
```

Interface Profile: IP1
Rate Monitoring:
- load-interval: 100 seconds
- threshold (in/out): 500 kbps
shutdown:
- enabled: yes
- max-delay: 100 seconds

```
switch(config-maintenance)#default profile interface IP1
```

```
switch(config-maintenance)#show active maintenance
profile interface IP1 default
profile interface IP1
  rate-monitoring load-interval 100
  rate-monitoring threshold 500
  shutdown max-delay 100

```

```
switch(config-maintenance)#
```
**profile bgp <profile_name> default**

The `profile bgp <profile_name> default` command configures a user-configured BGP profile as default BGP profile.

The `no profile bgp <profile_name> default` and `default profile bgp <profile_name> default` removes the user-configured BGP profile as default BGP profile.

**Command Mode**

Maintenance Configuration

**Command Syntax**

```
profile bgp profile_name default
no profile bgp profile_name default
default profile bgp profile_name default
```

**Parameters**

- `profile_name` name of the BGP profile

**Example**

- This command configures user configured BGP profile BP1 as default BGP profile.

```
switch(config)#maintenance
switch(config-maintenance)#profile bgp BP1
switch(config-profile-bgp-BP1)#initiator route-map RM1 inout
switch(config-profile-bgp-BP1)#exit
switch(config-maintenance)#
switch(config-maintenance)#show maintenance profile bgp default
Bgp Profile: Default
  Initiator route-map: SystemGenerated
  route-map SystemGenerated permit 10
  Description:
  description System generated initiator route-map
  Match clauses:
  Set clauses:
  set community GSHUT additive
  set local-preference 0

switch(config-maintenance)#
switch(config-maintenance)#profile bgp BP1 default
switch(config-maintenance)#show maintenance profile bgp default
Bgp Profile: BP1
  Initiator route-map: RM1
switch(config-maintenance)#
switch(config-maintenance)#show active maintenance
  profile bgp BP1
  initiator route-map RM1 inout
  profile bgp BP1 default

switch(config-maintenance)#
```
**profile unit <profile_name> default**

The **profile unit <profile_name> default** command configures a user-configured unit profile as default unit profile.

The **no profile unit <profile_name> default** and **default profile unit <profile_name> default** removes the user-configured unit profile as default unit profile.

**Command Mode**
- Maintenance Configuration

**Command Syntax**

```
profile unit profile_name default
no profile unit profile_name default
default profile unit profile_name default
```

**Parameters**
- **profile_name**  name of the interface profile

**Example**
- This command configures user-configured unit profile UP1 as the default unit profile.

```
switch(config)#maintenance
switch(config-maintenance)#profile unit UP1
switch(config-profile-unit-UP1)#on-boot duration 1000
switch(config-profile-unit-UP1)#exit
switch(config-maintenance)#
switch(config-maintenance)#show maintenance profiles unit default
Unit Profile: Default
  On-boot:
    enabled: no
    duration: 300 seconds

switch(config-maintenance)#profile unit UP1 default
switch(config-maintenance)#show maintenance profile unit default
Unit Profile: UP1
  On-boot:
    enabled: yes
    duration: 1000 seconds
switch(config-maintenance)#
switch(config-maintenance)#show active maintenance
profile unit UP1 default
profile unit UP1
  on-boot duration 1000

switch(config-maintenance)#
```
group bgp <group_name>

The `group bgp <group_name>` command adds a BGP group to a unit.

The `no group bgp <group_name>` and `default group bgp <group_name>` removes the BGP group from a unit.

**Command Mode**

Maintenance Unit Configuration

**Command Syntax**

```
group bgp group_name
no group bgp group_name
default group bgp group_name
```

**Parameters**

- `group_name` name of the BGP group

**Example**

- This command adds a BGP group `BG1` to unit `UNIT1`.

```
switch(config)#maintenance
switch(config-maintenance)# unit UNIT1
switch(config-unit-UNIT1)# group bgp BG1
switch(config-unit-UNIT1)# show active
maintenance
    unit UNIT1
        group bgp BG1
switch(config-unit-UNIT1)
```
The `group interface <group_name>` command adds an interface to a unit. The `no group interface <group_name>` and `default group interface <group_name>` removes the interface group from a unit.

**Command Mode**
Maintenance Unit Configuration

**Command Syntax**

```
group interface group_name
no group interface group_name
default group interface group_name
```

**Parameters**

- `group_name` name of the interface group

**Example**

- This command adds an interface group IG1 to unit UNIT1.

```
switch(config)#maintenance
switch(config-maintenance)# unit UNIT1
switch(config-unit-UNIT1)# group interface IG1
switch(config-unit-UNIT1)# show active
maintenance
    unit UNIT1
        group interface IG1
switch(config-unit-UNIT1)
```
profile unit <profile_name>

The `profile unit <profile_name>` command associates unit profile to a particular unit.

The `no profile unit <profile_name>` and `default profile unit <profile_name>` removes the unit profile from a unit.

**Command Mode**
- Maintenance-Unit Configuration
- Maintenance-Built-in-Unit Configuration

**Command Syntax**
```
profile unit profile-name
no profile unit
default profile unit
```

**Parameters**
- `profile-name` name of the unit profile

**Example**
- This command adds unit profile UP1 to UNIT1.

```
switch(config)#maintenance
switch(config-maintenance)#unit UNIT1
switch(config-unit-UNIT1)#group interface IG1
switch(config-unit-UNIT1)#exit
switch(config-maintenance)#show maintenance units UNIT1
  Unit Name: UNIT1
  Origin: User Configured
  Status: Not Under Maintenance
  Unit Profile: Default
  Time Since Last State Change: never
  Interface Groups:
    IG1

switch(config-maintenance)#unit UNIT1
switch(config-unit-UNIT1)#profile unit UP1
switch(config-unit-UNIT1)#show maintenance units UNIT1
  Unit Name: UNIT1
  Origin: User Configured
  Status: Not Under Maintenance
  Unit Profile: UP1
  Time Since Last State Change: never
  Interface Groups:
    IG1
switch(config-unit-UNIT1)#show active maintenance
    unit UNIT1
      group interface IG1
      profile unit UP1

switch(config-unit-UNIT1)#
```
This command adds unit profile **UP2** to built-in unit **System**.

```
switch(config)#maintenance
switch(config-maintenance)#profile unit UP2
switch(config-profile-unit-UP2)#on-boot duration 600
switch(config-profile-unit-UP2)#exit
switch(config-maintenance)#
switch(config-maintenance)#unit System
switch(config-built-in-unit-System)#show active maintenance
   unit System
switch(config-built-in-unit-System)#exit
switch(config-maintenance)#show maintenance units System
Unit Name: System 
   Origin: Built-in 
   Status: Not Under Maintenance 
   Unit Profile: Default 
   Time Since Last State Change: never 
   Interface Groups: 
      AllEthernetInterface

switch(config-maintenance)#
switch(config-maintenance)#unit System
switch(config-built-in-unit-System)#profile unit UP2
switch(config-built-in-unit-System)#show active maintenance
   unit System 
      profile unit UP2
switch(config-built-in-unit-System)#exit
switch(config-maintenance)#show maintenance units System
Unit Name: System 
   Origin: Built-in 
   Status: Not Under Maintenance 
   Unit Profile: UP2 
   Time Since Last State Change: never 
   Interface Groups: 
      AllEthernetInterface

switch(config-maintenance)#
```
**quiesce**

The `quiesce` command places a unit or dynamic interface/BGP unit into maintenance mode, gracefully transitioning traffic away from it.

The `no quiesce` and `default quiesce` exits the unit from maintenance.

**Command Mode**
- Maintenance-Unit Configuration
- Maintenance-Built-in-Unit Configuration
- Maintenance Dynamic-Interface Unit Configuration
- Maintenance Dynamic-Bgp Unit Configuration

**Command Syntax**

- `quiesce`
- `no quiesce`
- `default quiesce`
Examples

- This command places unit UNIT1, interface Et1, BGP peer 1.0.1.1 in VRF default, BGP peer 1::1 in VRF VRF1 into maintenance.

```bash
switch(config)#group interface IG1
switch(config-group-if-IG1)#interface Ethernet3-6
switch(config-group-if-IG1)#maintenance profile interface IPL
switch(config-group-if-IG1)#exit
switch(config)#maintenance
switch(config-maintenance)#unit UNIT1
switch(config-unit-UNIT1)#group interface IG1
switch(config-unit-UNIT1)#quiesce
switch(config-unit-UNIT1)#exit
switch(config-maintenance)#interface Ethernet1
switch(config-maint-if-Et1)#quiesce
switch(config-maint-if-Et1)#exit
switch(config-maintenance)#bgp 1.0.1.1
switch(config-maint-bgp-1.0.1.1)#quiesce
switch(config-maint-bgp-1.0.1.1)#exit
switch(config-maintenance)#bgp 1::1 vrf VRF1
switch(config-maint-bgp-1::1)#quiesce
switch(config-maint-bgp-1::1)#exit
switch(config-maintenance)#show active maintenance
   bgp 1.0.1.1
      quiesce
   !
   bgp 1::1 vrf VRF1
      quiesce
   interface Et1
      quiesce
   unit UNIT1
      quiesce

switch(config-maintenance)#show maintenance
Flags:
  o - On-boot maintenance
  v - Violating traffic threshold

switch(config-maintenance)#
rate-monitoring load-interval

The rate-monitoring load-interval command is a maintenance interface profile configuration option for configuring the interface's rate monitoring load interval with a load interval value between 5 and 600 seconds.

Command Mode
   Maintenance-Profile-Interface Configuration

Command Syntax
   rate-monitoring load-interval load_interval
   no rate-monitoring load-interval
   default rate-monitoring load-interval

Parameters
   • load_interval   load interval value between 5 and 600 seconds

Example
   • This command configures the rate monitoring load interval for the profile interface IP1 to a load interval of 10 seconds.

   switch(config)#maintenance
   switch(config-maintenance)#profile interface IP1
   switch(config-profile-intf-IP1)#rate-monitoring load-interval 10
   switch(config-profile-intf-IP1)#show active
   maintenance
       profile interface IP1
           rate-monitoring load-interval 10

   switch(config-profile-intf-IP1)#
rate-monitoring threshold

The **rate-monitoring threshold** command is a maintenance interface profile configuration option for configuring the interface’s rate monitoring threshold with a threshold value between 1 and 4294967295 kilobytes.

The **no rate-monitoring threshold** and **default rate-monitoring threshold** removes this configuration from the interface profile.

**Command Mode**

Maintenance-Profile-Interface Configuration

**Command Syntax**

```
rate-monitoring threshold threshold_in_kbps
no rate-monitoring threshold
default rate-monitoring threshold
```

**Parameters**

- **threshold_in_kbps** threshold in kilobytes per second (kbps) between 1 and 4294967295 kilobytes

**Example**

- This command configures the rate monitoring threshold for the profile interface IP1 to a threshold of 1000 kilobytes per second (kbps).

```
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#rate-monitoring threshold 1000
switch(config-profile-intf-IP1)# show active maintenance
    profile interface IP1
    rate-monitoring threshold 1000

switch(config-profile-intf-IP1)#
```
**shutdown max-delay**

The `shutdown max-delay` command is a maintenance interface profile configuration option for configuring the maximum duration after which the interface is shutdown with a value between 1 and 4294967295 seconds.

The `no shutdown` and `default shutdown` removes this configuration from the interface profile.

**Command Mode**
- Maintenance-Profile-Interface Configuration

**Command Syntax**
- `shutdown max-delay delay`
- `no shutdown max-delay delay`
- `default shutdown max-delay delay`

**Parameters**
- `delay` maximum shutdown delay between 1 and 4294967295 seconds

**Example**
- This command configures the shutdown max-delay for the profile interface IP1 to 500 seconds or one hour.

```
switch(config)#maintenance
switch(config-maintenance)#profile interface IP1
switch(config-profile-intf-IP1)#shutdown max-delay 500
switch(config-profile-intf-IP1)#show active
maintenance
    profile interface IP1
    shutdown max-delay 500

switch(config-profile-intf-IP1)#
```
**initiator route-map <route-map-name> inout**

The `initiator route-map <route-map-name> inout` command is a maintenance BGP profile configuration option for assigning the initiator route-map, which will be applied to inout (inbound and outbound).

The `no initiator route-map <route-map-name> inout` and `default initiator route-map <route-map-name> inout` removes this configuration from the BGP profile.

**Command Mode**

- Maintenance-Profile-BGP Configuration

**Command Syntax**

```
initiator route-map route-map-name inout
no initiator route-map
default initiator route-map
```

**Parameters**

- `route-map-name`  initiator route-map name

**Example**

- This command configures initiator route-map RM1 within a BGP profile BP1.

```
switch(config)#maintenance
switch(config-maintenance)#profile bgp BP1
switch(config-profile-bgp-BP1)#initiator route-map RM1 inout
switch(config-profile-bgp-BP1)#show active
maintenance
  profile bgp BP1
    initiator route-map RM1 inout

switch(config-profile-bgp-BP1)#
```
on-boot duration

The on-boot duration command is a maintenance unit profile configuration option for specifying the duration after which the associated unit will be brought out of maintenance after reboot. The on-boot property in the maintenance unit profile specifies that the unit will be placed into maintenance mode as part of boot-up, and remain so for the specified duration.

The no on-boot and default on-boot removes this configuration from the unit profile.

Command Mode

Maintenance-Profile-Unit Configuration

Command Syntax

```
on-boot duration duration
no on-boot
default on-boot
```

Parameters

- `duration` number of seconds for which unit will remain under maintenance after reboot (from 300 to 3600 seconds)

Example

- This command configures on-boot duration of 1000 seconds in profile unit UP1.

```
switch(config)#maintenance
switch(config-maintenance)#profile unit UP1
switch(config-profile-unit-UP1)#on-boot duration 1000
switch(config-profile-unit-UP1)#show active
maintenance
    profile unit UP1
        on-boot duration 1000

switch(config-profile-unit-UP1)#
```
**trigger on-maintenance**

The **trigger on-maintenance** command is an event handler configuration for triggering actions during the maintenance operation of a unit, interface and BGP peer at specified stages.

The event-handler configuration takes effect only after exiting the event-handler configuration mode.

**Command Mode**

Event-handler Configuration

**Command Syntax**

```
trigger on-maintenance <enter | exit> <unit <unit_name> | bgp
<ipv4_addr|ipv6_addr| peer_group> [vrf <vrf_name>] | interface <intf_name>>
<beg | end | all |<before | after> stage <stage_name>>
```

**Parameters**

- **enter** trigger on-maintenance event-handler on maintenance enter operation
- **exit** trigger on-maintenance event-handler on maintenance exit operation
- **bgp** trigger event-handler on dynamic BGP unit maintenance operation
  - **pv4_addr** BGP neighbor ipv4 address
  - **pv6_addr** BGP neighbor ipv6 address
  - **peer_group** BGP peer group name
- **vrf vrf_name** name of the VRF to which BGP peer belongs
- **interface** trigger event-handler on dynamic interface unit maintenance operation
  - **intf_name** name of the interface
    - **ethernet** trigger event-handler on specified Ethernet interface
    - **port-channel** trigger event-handler on specified port channel interface
    - **vlan** trigger event-handler on specified vlan

**Note**

Comma-delimited list, ranges are not supported.

- **unit** trigger event-handler on maintenance operation of unit
- **begin** action is triggered in the beginning of maintenance operation
- **end** action is triggered at the end of maintenance operation
- **stage_name** action is triggered at specified stage
  - bgp and ratemon are the two stages
- **all** action is triggered at all the stages
- **before** action is triggered before the specified stage
- **after** action is triggered after the specified stage
Examples

- This command configures event-handler E1, which triggers on maintenance an enter operation of unit UNIT1 at all the stages.

  ```
  switch(config)#event-handler E1
  switch(config-handler-E1)#trigger on-maintenance enter unit UNIT1 all
  switch(config-handler-E1)#action bash FastCli -c "show maintenance"
  switch(config-handler-E1)# exit
  switch(config)# show event-handler E1
  Event-handler E1
  Trigger: Asynchronous on-maintenance enter unit UNIT1 all delay 0 seconds
  Threshold Time Window: 0 Seconds, Event Count: 1 times
  Action: FastCli -c "show maintenance"
  Action expected to finish in less than 10 seconds
  Last Trigger Detection Time: Never
  Total Trigger Detections: 0
  Last Trigger Activation Time: Never
  Total Trigger Activations: 0
  Last Action Time: Never
  Total Actions: 0
  ```

- This command configures event-handler E2, which triggers on maintenance an exit operation of dynamic interface unit Ethernet1 before stage bgp.

  ```
  switch(config)#event-handler E2
  switch(config-handler-E2)#trigger on-maintenance exit interface Ethernet1 before stage bgp
  switch(config-handler-E2)#action bash FastCli -c "show maintenance summary"
  switch(config-handler-E2)# exit
  switch(config)# show event-handler E2
  Event-handler E2
  Trigger: Asynchronous on-maintenance exit interface Ethernet1 before stage bgp delay 0 seconds
  Threshold Time Window: 0 Seconds, Event Count: 1 times
  Action: FastCli -c "show maintenance summary"
  Action expected to finish in less than 10 seconds
  Last Trigger Detection Time: Never
  Total Trigger Detections: 0
  Last Trigger Activation Time: Never
  Total Trigger Activations: 0
  Last Action Time: Never
  Total Actions: 0
  ```
• This command configures event-handler E3, which triggers on maintenance an enter operation of dynamic BGP unit 1:1 in VRF VRF1 at the last stage end.

```
switch(config)#event-handler E3
switch(config-handler-E3)#trigger on-maintenance enter bgp 1::1 vrf VRF1 end
switch(config-handler-E3)#action bash FastCli -c "show maintenance bgp ip all vrf all"
switch(config-handler-E3)# exit
switch(config)# show event-handler E3
Event-handler E3
Trigger: Asynchronous on-maintenance enter bgp 1::1 vrf VRF1 end delay 0 seconds
Threshold Time Window: 0 Seconds, Event Count: 1 times

```

switch(config)#
**show maintenance**

The `show maintenance` command provides brief information about all units/dynamic interface unit/dynamic bgp unit and status.

'o' - flag displays that unit is undergoing or has undergone a maintenance operation because of on-boot.

'v' - flag displays that one/some of the interfaces are violating traffic, i.e. traffic for those interfaces is above threshold.

**Command Mode**

EXEC

**Command Syntax**

```
show maintenance
```

**Examples**

- This command displays maintenance mode details.

```
switch#show maintenance
Flags:
o - On-boot maintenance
v - Violating traffic threshold

Unit Name          Status                   Time since last change  Flags
------------------------------- ----------------------- -------------------------- ----- 
System              Not Under Maintenance                 never                    ----
Foo                 Under Maintenance                0:00:40 ago              o

Interface Name     Status                   Time since last change  Flags
------------------- ----------------------- -------------------------- ----- 
Ethernet16/1        Entering Maintenance           0:00:02 ago              v

Bgp Neighbor(vrf: defa Status                    Time since last change  Flags

```

switch#

show maintenance summary

The `show maintenance summary` command displays summarized information about the maintenance mode operations such as number of units configured, number of units Entering/Exiting maintenance etc.

**Command Mode**

EXEC

**Command Syntax**

`show maintenance summary`

**Example**

- This command displays summary of maintenance mode operations.

```
switch#show maintenance summary
Number of Units Configured: 0
Number of Units Exiting Maintenance: 0
Number of Units Entering Maintenance: 0
Number of Units Not Under Maintenance: 1
Number of Units Under Maintenance: 0
Directly Put Under Maintenance:
    Number of interfaces Entering Maintenance: 0
    Number of interfaces Under Maintenance: 1
    Number of bgp peers Entering Maintenance: 0
    Number of bgp peers Under Maintenance: 1
Rate Monitoring:
    Number of interfaces Entering Maintenance: 0
    Number of interfaces Under Maintenance: 1
    Number of interfaces Under Maintenance with threshold violation: 0
    Number of interfaces shutdown for maintenance: 0

switch#
```
show maintenance units

The show maintenance units command displays detailed information about the particular unit.

Command Mode
EXEC

Command Syntax
show maintenance units [unit_name]

Parameters
• unit_name name of unit

Example
• This command displays maintenance units details.

switch#show maintenance units
Unit Name: System
 Origin: Built-in
 Status: Not Under Maintenance
 Unit Profile: Default
 Time Since Last State Change: never
 Bgp Groups:
   AllBgpNeighborVrf-default
 Interface Groups:
   AllEthernetInterface

Unit Name: UNIT1
 Origin: User Configured
 Status: Under Maintenance
 Unit Profile: UP1
 Time Since Last State Change: 0:00:08 ago
 Bgp Groups:
   BG1
 Interface Groups:
   IG1
 History:
   2016-08-29 23:05:30 old state: 'maintenanceModeEnter' to new state: 'underMaintenance' 0:00:08 ago
   2016-08-29 23:05:30 old state: 'active' to new state: 'maintenanceModeEnter' 0:00:08 ago

switch#
show maintenance interface

The show maintenance interface command displays detailed information about interfaces and their maintenance status with traffic rates.

Command Mode
EXEC

Command Syntax
show maintenance interface [ <intf_name> [detail] | detail ]

Parameters
- **intf_name** name of the interface
- ethernet e_range Ethernet interfaces specified by e_range
- port-channel p_range port channel interfaces specified by p_range
- vlan v_range vlans specified by v_range

Valid **e_range**, **p_range** and **v_range** formats include number, range, or comma-delimited list of numbers and ranges.

- detail provides the detailed rate-monitoring information

Example
- This command displays interface status and traffic rates.

  switch# show maintenance interface
  Flags:
  v - Violating traffic threshold
  s - Shutdown for maintenance

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
<th>Rate (Mbps)</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>In</td>
<td>Out</td>
</tr>
<tr>
<td>Ethernet1</td>
<td>Not Under Maintenance</td>
<td>-</td>
<td>-</td>

</tbody>
</table>

  switch#
This command displays detailed information about the interface Ethernet16/1.

```
switch#show maintenance interface Ethernet16/1 detail
Ethernet16/1 is Under Maintenance
   Groups: AllEthernetInterface
   Selected profiles from Interface groups:
      Interface Maintenance profile: low-load-interval-profile
      Bgp Maintenance profile: Default
   Bgp:
      Maintenance State: Under Maintenance
      Vrf: default
         Neighbor: 1.0.1.2
            Maintenance routemap: SystemGenerated
   Rate Monitoring:
      Passive monitoring since 0:42:25 ago
      Total samples taken: 236
         Before Maintenance:
            Below threshold: 1
            Above threshold: 0
         After Maintenance:
            Below threshold: 235
            Above threshold: 0
   Last sample information:
      Sample taken 0:00:04 ago
         In: 0.0 Mbps
         Out: 0.0 Mbps
```

switch#

show maintenance interface status

The `show maintenance interface status` command displays maintenance status and rates for interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show maintenance interface status active | entering | exiting | quiesced
```

**Parameters**

- **active** interfaces which are active
- **entering** interface which are entering maintenance
- **exiting** interface which are exiting maintenance
- **quiesced** interface which are under maintenance

**Example**

This command displays interface status and traffic rates of interfaces which are quiesced.

```
switch#show maintenance interface status quiesced
Flags:
v - Violating traffic threshold
s - Shutdown for maintenance

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
<th>Rate (Mbps)</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>

<td>10.5</td>
</tr>
<tr>
<td>Port-Channel10</td>
<td>Under Maintenance</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

switch#
```
show maintenance bgp

The show maintenance bgp command displays detailed maintenance information about BGP peers.

Command Mode

EXEC

Command Syntax

show maintenance bgp <ipv4_addr> [vrf <vrf_name>] | <ipv6_addr> [vrf <vrf_name>] | <peer_group> [vrf <vrf_name>] | ip all [ vrf <vrf_name> ] | vrf all | ipv6 all [ vrf <vrf_name> | vrf all ]

Parameters

- ipv4_addr BGP neighbor ipv4 address
- ipv6_addr BGP neighbor ipv6 address
- peer_group BGP peer group name
- vrf_name name of the VRF to which peer belongs
- ip all vrf vrf_name all ipv4 peers in specified VRF
- ipv6 all vrf vrf_name all ipv6 peers in specified VRF
- ip all vrf all all ipv4 peers in all the VRFs
- ipv6 all vrf all all ipv6 peers in all the VRFs

Example

- This command displays maintenance information about BGP peers 1.0.0.1 and 1.0.1.1 and maintenance route-map applied.

switch#show maintenance bgp ip all vrf all
BGP peer maintenance information for VRF default
Router identifier 0.0.1.1, local AS number 200
Neighbor: 1.0.0.1
  Maintenance state: Under Maintenance
  Maintenance route-map: SystemGenerated
Neighbor: 1.0.1.2
  Maintenance state: Under Maintenance
  Maintenance route-map: SystemGenerated

switch#
show maintenance groups

The `show maintenance groups` command displays all the interface/BGP groups along with their members and associated profiles.

**Command Mode**
EXEC

**Command Syntax**
```
show maintenance groups interface | bgp <group_name>
```

**Parameters**
- `interface` display only interface groups
- `bgp` display only BGP groups
- `group_name` name of the group

**Example**
- This command displays group details for built-in interface group `AllEthernetInterface` and built-in BGP group `AllBgpNeighborVrf-default` and user-configured interface group `IG1`.

```
switch#show maintenance groups
Interface Group: AllEthernetInterface
 Origin: Built-in
 Interfaces:
   Et1, Et2, Et3, Et4, Et5/1, Et5/2, Et5/3, Et5/4, Et6/1, Et6/2, Et6/3, Et6/4, Et7/1, Et7/2, Et7/3, Et7/4, Et8/1, Et8/2, Et8/3, Et8/4, Et9/1, Et9/2, Et9/3, Et9/4, Et10/1, Et10/2, Et10/3, Et10/4, Et11/1, Et11/2, Et11/3, Et11/4, Et12/1, Et12/2, Et12/3, Et12/4, Et13/1, Et13/2, Et13/3, Et13/4, Et14/1, Et14/2, Et14/3, Et14/4, Et15/1, Et15/2, Et15/3, Et15/4, Et16/1, Et16/2, Et16/3, Et16/4, Et17/1, Et17/2, Et17/3, Et17/4, Et18/1, Et18/2, Et18/3, Et18/4, Et19/1, Et19/2, Et19/3, Et19/4, Et20/1, Et20/2, Et20/3, Et20/4, Et21/1, Et21/2, Et21/3, Et21/4, Et22/1, Et22/2, Et22/3, Et22/4, Et23/1, Et23/2, Et23/3, Et23/4, Et24/1, Et24/2, Et24/3, Et24/4, Et25/1, Et25/2, Et25/3, Et25/4, Et26/1, Et26/2, Et26/3, Et26/4, Et27/1, Et27/2, Et27/3, Et27/4, Et28/1, Et28/2, Et28/3, Et28/4, Et29, Et30, Et31, Et32, Et33, Et34, Et35, Et36
 Profiles:
   Interface Profile: low-load-interval-profile
   Bgp Profile: Default
 Units: System
Interface Group: IG1
 Origin: User Configured
 Interfaces:
   Et1, Et2, Et3, Et4, Po10, Po11, Po12
 Profiles:
   Interface Profile: IP1
   Bgp Profile: BP1
 Units: UNIT1
Bgp Group: AllBgpNeighborVrf-default
 Origin: Built-in
 Neighbors:
   Ipv4 Peers: 1.0.0.1, 1.0.1.2
 Bgp Profile: Default
 Vrf: default
 Units: System
```

switch#
show maintenance profiles

The `show maintenance profiles` command displays all the interface/BGP/unit profiles configuration.

**Command Mode**

EXEC

**Command Syntax**

```
show maintenance profiles interface | bgp | unit <profile_name>
```

**Parameters**

- `interface` display only interface profiles
- `bgp` display only BGP profiles
- `unit` display only unit profiles
- `profile_name` name of the profile

**Example**

- This command displays profile configuration details for interface profile IP1, unit profile UP1 and BGP profile BP1.

```
switch #show maintenance profiles
Interface Profile: IP1
  Rate Monitoring:
    load-interval: 444 seconds
    threshold (in/out): 4000 Kbps
  shutdown:
    enabled: yes
    max-delay: 399 seconds
Bgp Profile: BP1
  Initiator route-map:
    name: RM1
Unit Profile: UP1
  On-boot:
    enabled: yes
    duration: 340 seconds
```

switch #
show maintenance stages

The `show maintenance stages` command displays stages of maintenance operation while entering/exiting maintenance.

**Command Mode**

EXEC

**Command Syntax**

```
show maintenance stages [enter | exit]
```

**Parameters**

- **enter** display maintenance stages during maintenance enter operation
- **exit** display maintenance stages during maintenance exit operation

**Example**

- This command displays maintenance mode stages details.

  ```
  switch # show maintenance stages
  No. Stage Description
  ------ ---------- --------------------------
  1 bgp       BGP Maintenance processing
  2 ratemon   Interface Rate Monitoring
  ```

  Maintenance Exit Stage Sequence

  ```
  No. Stage Description
  ------ ---------- --------------------------
  1 ratemon   Interface Rate Monitoring
  2 bgp       BGP Maintenance processing
  ```

  switch #

- This command displays maintenance mode stage details during entry.

  ```
  switch # show maintenance stages enter
  No. Stage Description
  ------ ---------- --------------------------
  1 bgp       BGP Maintenance processing
  2 ratemon   Interface Rate Monitoring
  ```

  switch #
**show maintenance bgp receiver route-map**

The `show maintenance bgp receiver route-map` command displays receiver route-map which is applied during maintenance operation.

**Command Mode**

EXEC

**Command Syntax**

`show maintenance bgp receiver route-map`

**Example**

- This command displays receiver route-map contents.

```bash
switch#show maintenance bgp receiver route-map
route-map SystemGenerated permit 10
    Description:
        description System generated receiver route-map
    Match clauses:
        match community GSHUT-LIST
    SubRouteMap:
    Set clauses:
route-map SystemGenerated permit 50
    Description:
        description System generated receiver route-map
    Match clauses:
    SubRouteMap:
    Set clauses:switch#
```
show maintenance debug

The `show maintenance debug` command displays the history of various maintenance operations on a unit/interface/BGP peer.

**Command Mode**

EXEC

**Command Syntax**

```
show maintenance debug bgp [peer_name] | interface [intf_name] | units [unit_name]
```

**Parameters**

- `bgp` display history of all dynamic BGP units which have undergone maintenance operation
- `interface` display history of all dynamic interface units which have undergone maintenance operation
- `units` display history of all units which have undergone maintenance operation
- `peer_name` name of the peer
  - `ipv4_addr` BGP neighbor IPv4 address
  - `ipv6_addr` BGP neighbor IPv6 address
  - `peer-group-name` BGP peer group name
- `intf_name` name of the interface
  - `ethernet e_range` Ethernet interfaces specified by e_range
  - `port-channel p_range` port channel interfaces specified by p_range
  - `vlan v_range` vlans specified by v_range

**Note**

Valid `e_range`, `p_range` and `v_range` formats include number, range, or comma-delimited list of numbers and ranges. Valid Ethernet numbers depend on the Ethernet interfaces available on the switch.

- `unit_name` name of the unit
Example

- This command displays history of maintenance operation on Ethernet 16/1.

```
switch#show maintenance debug interface Ethernet 16/1-4
Interface Ethernet16/1
History:
  Maintenance Enter Stage Progression started 4:07:07 ago @ 2016-08-29 22:38:54

```
**show interface**

The `show interface` command displays detailed information about the interface. It displays an extra line that reads: “Under maintenance for time in hours and minutes”.

**Command Mode**

EXEC

**Command Syntax**

```
show interface intf_name
```

**Parameters**

- `intf_name` name of the interface
  - `ethernet e_range` Ethernet interfaces specified by `e_range`
  - `port-channel p_range` port channel interfaces specified by `p_range`
  - `vlan v_range` vlans specified by `v_range`

**Note**

Valid `e_range`, `p_range` and `v_range` formats include number, range, or comma-delimited list of numbers and ranges. Valid Ethernet numbers depend on the Ethernet interfaces available on the switch.

**Example**

- This command displays detailed information about Ethernet 16/1 interface.

  ```
switch#show interface ethernet 16/1
  Ethernet16/1 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.7373.efc7
  Internet address is 1.0.1.1/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 1500 bytes, BW 40000000 kbit
  Full-duplex, 40Gb/s, auto negotiation: off, uni-link: n/a
  Up 4 hours, 44 minutes, 36 seconds
  Under maintenance for 4 hours, 22 minutes, 26 seconds
  Loopback Mode : None
  2 link status changes since last clear
  Last clearing of "show interface" counters 4:45:12 ago
  5 minutes input rate 20 bps (0.0% with framing overhead), 0 packets/sec
  5 minutes output rate 20 bps (0.0% with framing overhead), 0 packets/sec
  580 packets input, 46286 bytes
  Received 1 broadcasts, 0 multicast
  0 runts, 0 giants
  0 input errors, 0 CRC, 0 alignment, 0 symbol, 0 input discards
  0 PAUSE input
  601 packets output, 48954 bytes
  Sent 7 broadcasts, 15 multicast
  0 output errors, 0 collisions
  0 late collision, 0 deferred, 0 output discards
  0 PAUSE output
  switch#
  ```
**show interface <intf_name> status**

The **show interface <intf_name> status** command displays an ‘m’ flag if the interface is undergoing maintenance operation.

**Command Mode**

EXEC

**Command Syntax**

```
show interface [ intf_name ] status
```

**Parameters**

- `intf_name` name of the interface
- `ethernet e_range` Ethernet interfaces specified by e_range
- `port-channel p_range` port channel interfaces specified by p_range
- `vlan v_range` vlans specified by v_range

**Note**

Valid `e_range`, `p_range` and `v_range` formats include number, range, or comma-delimited list of numbers and ranges. Valid Ethernet numbers depend on the Ethernet interfaces available on the switch.

**Example**

- This command display tabular output and shows ‘m’ flag for Ethernet16/1 status.

```
switch#show interface Ethernet16/1 status
Port  Name       Status   Vlan  Duplex  Speed   Type       Flags
Et1                   disabled  1 auto    auto   1000BASE-T
...                   
Et14/1                connected  2 full    40G  40GBASE-CR4
Et15/1                connected  2 full    40G  40GBASE-CR4
Et16/1                connected  routed  full  40G  40GBASE-CR4  m
Et17/1                notconnect 1 full    10G  Not Present
...                   
switch#
```
show ip | ipv6 bgp summary [ vrf <vrf_name>]

The `show ip | ipv6 bgp summary [ vrf <vrf_name>]` command displays the ‘m’ flag if the BGP IPv4 or IPv6 peer is undergoing maintenance operation.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show ip bgp summary [ vrf <vrf_name> ]
show ipv6 bgp summary [ vrf <vrf_name> ]
```

**Parameters**

- **vrf_name** name of the VRF

**Example**

- This command displays the ‘m’ flag in `show ip bgp summary` output for peer 1.0.1.2 which is in maintenance mode.

```plaintext
switch#show ip bgp summary
BGP summary information for VRF default
Router identifier 0.0.1.1, local AS number 200
Neighbor Status Codes: m - Under maintenance
Neighbor V AS MsgRcvd MsgSent InQ OutQ Up/Down State PfxRcd PfxAcc
1.0.0.1 4 100 292 296 0 0 04:47:44 Estab 1 1
m 1.0.1.2 4 300 292 296 0 0 04:47:44 Estab 1 1
switch#
```
**show ip | ipv6 bgp neighbors <peer_addr> [vrf <vrf_name>]**

The `show ip | ipv6 bgp neighbors <peer_addr> [vrf <vrf_name>]` command displays maintenance-related information when relevant.

**Command Mode**

EXEC

**Command Syntax**

```
show ip bgp neighbors <peer_addr> [vrf <vrf_name>]
show ipv6 bgp neighbors <peer_addr> [vrf <vrf_name>]
```

**Parameters**

- `peer_addr` name of the peer
  - `ipv4_addr` BGP neighbor IPv4 address
  - `ipv6_addr` BGP neighbor IPv6 address
  - `peer-group-name` BGP peer group name
- `vrf_name` name of the VRF
Example

- This command displays the ‘m’ flag in `show ip bgp summary` output for peer 1.0.1.2 which is in maintenance mode.

```
switch#show ip bgp neighbors 1.0.1.2
BGP neighbor is 1.0.1.2, remote AS 300, external link

Ethernet Ports

This chapter describes Ethernet ports supported by Arista switches. Sections covered in this chapter include:

- Section 10.1: Ethernet Ports Introduction
- Section 10.2: Ethernet Standards
- Section 10.3: Ethernet Physical Layer
- Section 10.4: Interfaces
- Section 10.5: Ethernet Configuration Procedures
- Section 10.6: Ethernet Configuration Commands

10.1 Ethernet Ports Introduction
Arista switches support a variety of Ethernet network interfaces. This chapter describes the configuration and monitoring options available in Arista switching platforms.

10.2 Ethernet Standards
Ethernet, standardized in IEEE 802.3, is a group of technologies used for communication over local area networks. Ethernet communication divides data streams into frames containing addresses (source and destination), payload, and cyclical redundancy check (CRC) information.

IEEE 802.3 also describes two types of optical fiber: single-mode fiber (SMF) and multi-mode fiber (MMF).

- SMF is more expensive, but can be used over longer distances (over 300 meters).
- MMF is less expensive, but can only be used over distances of less than 300 meters.

10.2.1 100 Gigabit Ethernet
The 100 Gigabit Ethernet (100GbE) standard defines an Ethernet implementation with a nominal data rate of 100 billion bits per second over multiple 10 gigabit lanes. 100 Gigabit Ethernet implements full duplex point to point links connected by network switches. Arista switches support 100GBASE-10SR through MXP ports.
10.2.2 40 Gigabit Ethernet

The 40 Gigabit Ethernet (40GbE) standard defines an Ethernet implementation with a nominal data rate of 40 billion bits per second over multiple 10 gigabit lanes. 40 Gigabit Ethernet implements full duplex point to point links connected by network switches. 40 gigabit Ethernet standards are named **40GBASE-xyz**, as interpreted by Table 10-1.

</tr>
</tbody>
</table>

10.2.3 10 Gigabit Ethernet

The 10 Gigabit Ethernet (10GbE) standard defines an Ethernet implementation with a nominal data rate of 10 billion bits per second. 10 Gigabit Ethernet implements full duplex point to point links connected by network switches. Half duplex operation, hubs and CSMA/CD do not exist in 10GbE. The standard encompasses several PHY standards; a networking device may support different PHY types through pluggable PHY modules. 10GbE standards are named **10GBASE-xyz**, as interpreted by Table 10-2.

10.2.4 Gigabit Ethernet

The Gigabit Ethernet (GbE), defined by IEEE 802.3-2008, describes an Ethernet version with a nominal data rate of one billion bits per second. GbE cables and equipment are similar to those used in previous standards. While full-duplex links in switches is the typical implementation, the specification permits half-duplex links connected through hubs.

Gigabit Ethernet physical layer standards that Arista switches support include 1000BASE-X (optical fiber), 1000BASE-T (twisted pair cable), and 1000BASE-CX (balanced copper cable).

- 1000BASE-SX is a fiber optic standard that utilizes multi-mode fiber supporting 770 to 860 nm, near infrared (NIR) light wavelength to transmit data over distances ranging from 220 to 550 meters. 1000BASE-SX is typically used for intra-building links in large office buildings, co-location facilities and carrier neutral Internet exchanges.
- 1000BASE-LX is a fiber standard that utilizes a long wavelength laser (1,270–1,355 nm), with a RMS spectral width of 4 nm to transmit data up to 5 km. 1000BASE-LX can run on all common types of multi-mode fiber with a maximum segment length of 550 m.
• 1000BASE-T is a standard for gigabit Ethernet over copper wiring. Each 1000BASE-T network segment can be a maximum length of 100 meters.

10.2.5 10/100/1000 BASE-T
Arista switches provide 10/100/1000 BASE-T Mbps Ethernet out of band management ports. Auto-negotiation is enabled on these interfaces. Speed (10/100/1000), duplex (half/full), and flow control settings are available using the appropriate `speed forced` and `flowcontrol` commands.
10.3 Ethernet Physical Layer

The Ethernet physical layer (PHY) includes hardware components connecting a switch’s MAC layer to the transceiver, cable, and ultimately a peer link partner. Data exist in digital form at the MAC layer. On the line side of the PHY, data exist as analog signals: light blips on optical fiber or voltage pulses on copper cable. Signals may be distorted while in transit and recovery may require signal processing.

Ethernet physical layer components include a PHY and a transceiver.

10.3.1 PHYs

The PHY provides translation services between the MAC layer and transceiver. It also helps to establish links between the local MAC layer and peer devices by detecting and signaling fault conditions. The PHY line-side interface receives Ethernet frames from the link partner as analog waveforms. The PHY uses signal processing to recover the encoded bits, then sends them to the MAC layer.

PHY line-side interface components and their functions include:

- Physical Medium Attachment (PMA): Framing, octet synchronization, scrambling / descrambling.
- Physical Medium Dependent (PMD): Consists of the transceiver.
- Physical Coding Sublayer (PCS): Performs auto-negotiation and coding (8B/10B or 64B/66B).

The MAC sublayer of the PHY provides a logical connection between the MAC layer and the peer device by initializing, controlling, and managing the connection with the peer.

Ethernet frames transmitted by the switch are received by the PHY system-side interface as a sequence of digital bits. The PHY encodes them into a media-specific waveform for transmission through the line-side interface and transceiver to the link peer. This encoding may include signal processing, such as signal pre-distortion and forward error correction.

PHY system-side interface components and their functions include:

- 10 Gigabit Attachment Unit Interface (XAUI): Connects an Ethernet MAC to a 10 G PHY.
- Serial Gigabit Media Independent Attachment (SGMII): Connects an Ethernet MAC to a 1G PHY.

10.3.2 Transceivers

A transceiver connects the PHY to an external cable (optical fiber or twisted-pair copper) and through a physical connector (LC jack for fiber or RJ-45 jack for copper).

- Optical transceivers convert the PHY signal into light pulses that are sent through optical fiber.
- Copper transceivers connect the PHY to twisted-pair copper cabling.

Arista Small Form-Factor Pluggable (SFP+) and Quad Small Form Factor Pluggable (QSFP+) modules and cables provide high-density, low-power Ethernet connectivity over fiber and copper media. Arista offers transceivers that span data rates, media types, and transmission distances.

Arista 10 Gigabit Ethernet SFP+ Modules:

- 10GBASE-SR (Short Reach)
  - Link length maximum 300 meters over multi-mode fiber.
  - Optical interoperability with 10GBASE-SRL.
- 10GBASE-SRL (Short Reach Lite)
  - Link length maximum 100 meters over multi-mode fiber.
  - Optical interoperability with 10GBASE-SR.
• 10GBASE-LRL (Long Reach Lite)
  • Link length maximum 1 km over single-mode fiber.
  • Optical interoperability with 10GBASE-LR (1 km maximum).
• 10GBASE-LR (Long Reach)
  • Link length maximum 10 km over single-mode fiber.
  • Optical interoperability with 10GBASE-LRL (1 km maximum).
• 10GBASE-LRM (Long Reach Multimode)
  • Link length maximum 220 meters over multi-mode fiber (50 um and 62.5 um).
• 10GBASE-ER (Extended Reach)
  • Link length maximum 40 km over single-mode fiber.
• 10GBASE-ZR (Ultra-Extended Reach)
  • Link length maximum 80 km over single-mode fiber.
• 10GBASE-DWDM (Dense Wavelength Division Multiplexing)
  • Link length maximum 80 km over single-mode fiber (40 color options).

Arista 10 Gigabit Ethernet CR Cable Modules:
• 10GBASE-CR SFP+ to SFP+ Cables
  • Link lengths of 0.5, 1, 1.5, 2, 2.5, 3, 5 and 7 meters over twinax copper cable
  • Includes SFP+ connectors on both ends
• 4 x 10GbE QSFP+ to 4 x SFP+ twinax copper cables
  • Link lengths of 0.5, 1, 2 and 3 meters over twinax copper cable

Arista 40 Gigabit Ethernet QSFP+ Cables and Optics:
• 40GBASE-SR4 QSFP+ Transceiver
  • Link length maximum 100 meters over parallel OM3 or 150 meters over OM4 MMF
  • Optical interoperability with 40GBASE-XSR4 (100/150 meter maximum)
• 40GBASE-XSR4 QSFP+ Transceiver
  • Link length maximum 300 meters over parallel OM3 or 450 meters over OM4 MMF
  • Optical interoperability with 40GBASE-SR4 (100/150 meter maximum)
• 40GBASE-LR4 QSFP+
  • Link length maximum 10 km over duplex single-mode fiber
• 40GBASE-CR4 QSFP+ to QSFP+ twinax copper cables
  • Link lengths of 1, 2, 3, 5 and 7 meters over twinax copper cable

Arista Gigabit Ethernet SFP Options:
• 1000BASE-SX (Short Haul)
  • Multi-mode fiber
  • Link length maximum 550 meter
• 1000BASE-LX (Long Haul)
  • Single-mode or multi-mode fiber
  • Link length maximum 10 km (single mode) or 550 meters (multi-mode)
• 1000BASE-T (RJ-45 Copper)
Ethernet Physical Layer

Chapter 10: Ethernet Ports

- Category 5 cabling
- Full duplex 1000Mbps connectivity

Internal ports
Several Arista switches include internal ports that connect directly to an external cable through an RJ-45 jack. Internal ports available on Arista switches include:

- 100/1000BASE-T (7048T-A)
- 100/1000/10GBASE-T (7050-T)

10.3.3 MXP Ports
MXP ports provide embedded optics that operate in one of three modes: 10GbE (12 ports), 40GbE (3 ports), and 100GbE (1 port). Each mode requires a specified cable is implemented through configuration commands. MXP ports utilize multi-mode fiber to provide support over 150 meters.

- 100GbE mode requires an MTP-24 to MTP-24 cable, which uses 20 of 24 fibers to carry 100Gbe across 10 send and 10 receive channels. When connecting two 100GbE MXP ports, the TX lanes must be crossed with the RX lanes.
- 40GbE mode requires an MTP cable that provides a split into three MTP-12 ends. The cable splits the MXP port into three MTP-12 ends, each compatible with standards based 40GBASE-SR4 ports over OM3 or OM4 fiber up to 100m or 150m.
- 10GbE mode requires an MTP cable that provides a split into 12x10G with LC connectors to adapt the MXP port into 12x10GbE. The cable splits the MXP port into twelve LC ends for using SR or SRL optics over multimode OM3/OM4 cables.
10.4 Interfaces

Arista switches provide two physical interface types that receive, process, and transmit Ethernet frames: Ethernet interfaces and Management interfaces.

Each Ethernet interface is assigned a 48-bit MAC address and communicates with other interfaces by exchanging data packets. Each packet contains the MAC address of its source and destination interface. Ethernet interfaces establish link level connections by exchanging packets. Interfaces do not typically accept packets with a destination address of a different interface.

Ethernet data packets are frames. A frame begins with preamble and start fields, followed by an Ethernet header that includes source and destination MAC addresses. The middle section contains payload data, including headers for other protocols carried in the frame. The frame ends with a 32-bit cyclic redundancy check (CRC) field that interfaces use to detect data corrupted during transmission.

10.4.1 Ethernet Interfaces

Ethernet speed and duplex configuration options depend on the media type of the interface:

- **40G QSFP+:** Default operation is as four 10G ports. **Speed forced** command options support configuration as a single 40G port.
- **10GBASE-T:** Mode is **autonegotiate** by default, offering 10G and 1G full duplex and 100M. Default setting is 10G. Half duplex and 10M are not supported. Adjustments may be made using **speed forced** commands.
- **10GBASE (SFP+):** Port operates as a single 10G port. **Speed forced** commands do not affect configuration.
- **1000BASE-T (copper):** Mode is **autonegotiate** by default, offering 1G full and 100M; default setting is 1G full. Autonegotiation that offers only 100M is available through **speed auto 100full** command. Half duplex and 10M are not supported.
- **100G CFP:** Default operation is 100G. It cannot be split, and its speed cannot be changed.
- **100G MXP:** Default operation is as a single 100G port on the 7500 and 7280 platforms, and as three 40G ports on the 7050 platform. On the 7500 and 7280 platforms, available speed/duplex settings are a single 100G port, three 40G ports, or twelve 10G ports. On the 7050 platform, available speed/duplex settings are three 40G ports or twelve 10G ports. Adjustments are made with **speed forced** commands.
- **100G QSFP100:** Available speeds are transceiver-dependent. The QSFP100 transceiver supports a single 100G port, four 25G ports, or two 50G ports; the QSFP+ transceiver supports one 40G port or four 10G ports; the CWDM transceiver supports all five configurations. Adjustments are made using **speed forced** commands. **Note:** 7500 and 7280 families do not currently support 25G or 50G speeds.

For information relating to transceivers, please see **Transceivers.**

10.4.2 Subinterfaces

Subinterfaces divide a single ethernet or port channel interface into multiple logical L3 interfaces based on the 802.1q tag (VLAN ID) of incoming traffic. Subinterfaces are commonly used in the L2/L3 boundary device, but they can also be used to isolate traffic with 802.1q tags between L3 peers by assigning each subinterface to a different VRF.

While subinterfaces can be configured on a port channel interface (the virtual interface associated with a port channel), the following restrictions apply:

- An L3 interface with subinterfaces configured on it should not be made a member of a port channel.
• An interface that is a member of a port channel should not have subinterfaces configured on it.
• A subinterface cannot be made a member of a port channel.

Subinterfaces on multiple ports can be assigned the same VLAN ID, but there is no bridging between subinterfaces (or between subinterfaces and SVIs), and each subinterface is considered to be in a separate bridge domain.

The following features are supported on subinterfaces:

• Unicast and multicast routing
• BGP, OSPF, ISIS, PIM
• VRF
• VRRP
• SNMP
• Subinterface counters (on some platforms)
• VXLAN (on some platforms)
• MPLS (on some platforms)
• GRE (on some platforms)
• PBR (on some platforms)
• QoS (on some platforms)
• Inheriting QoS settings (trust mode and default DSCP) from the parent interface
• Inheriting MTU setting from parent interface

The following are not supported on subinterfaces:

• BFD
• ACL
• Per-subinterface MTU setting
• Per-subinterface SFLOW settings
• Per-subinterface mirroring settings

10.4.3 Agile Ports

Agile Ports are a feature of the 7150S Series that allows the user to configure adjacent blocks of 4 x SFP+ interfaces as a single 40G link. The set of interfaces that can be combined to form a higher speed port is restricted by the hardware configuration. Only interfaces that pass through a common PHY component can be combined. One interface within a combinable set is designated as the primary port. When the primary interface is configured as a higher speed port, all configuration statements are performed on that interface. All other interfaces in the set are subsumed and not individually configurable when the primary interface is configured as the higher speed port. This feature allows the 7150S-24 to behave as a 4x40G switch (using 16 SFP+) and the remaining SFP+ provide 8 x 10G ports. On the 7150S-52 this allows up to 13x 40G (all 52 ports grouped as 40G) and on the 7150S-64 Agile Ports allows the switch to be deployed with up to 16 native 40G interfaces - 4 are QSFP+ and the remaining 12 as 4xSFP+ groups.

Section 10.5.11 describes the configuration of agile ports.
10.4.4 Management Interfaces

The management interface is a layer 3 host port that is typically connected to a PC for performing out of band switch management tasks. Each switch has one or two management interfaces. Only one port is needed to manage the switch; the second port, when available, provides redundancy.

Management interfaces are 10/100/1000 BASE-T interfaces. By default, auto-negotiation is enabled on management interfaces. All combinations of speed 10/100/1000 and full or half duplex is enforceable on these interfaces through `speed` commands.

Management ports are enabled by default. The switch cannot route packets between management ports and network (Ethernet interface) ports because they are in separate routing domains. When the PC is multiple hops from the management port, packet exchanges through layer 3 devices between the management port and PC may require the enabling of routing protocols.

The Ethernet management ports are accessed remotely over a common network or locally through a directly connected PC. An IP address and static route to the default gateway must be configured to access the switch through a remote connection.

10.4.5 Tunable SFP

Tuning of DWDM 10G SFP+ transceivers (10GBase-DWDM) includes:

- Tuning transceiver wavelength/frequency by channel number
- Showing wavelengths/frequencies for specified channels supported by the transceiver
- Showing current wavelength/frequency settings of the transceiver interface

For information relating to tuning the transceiver wavelength/frequency by channel number, refer to the command `transceiver channel`. To show the current wavelength/frequency settings for specified channels, refer to the command `show interfaces transceiver channels`. To show the current wavelength/frequency settings of an interface, refer to the command `show interfaces transceiver hardware`. 
10.5 **Ethernet Configuration Procedures**

These sections describe Ethernet and Management interface configuration procedures:

- Section 10.5.1: Physical Interface Configuration Modes
- Section 10.5.2: Assigning a MAC Address to an Interface
- Section 10.5.3: Port Groups (QSFP+ and SFP+ Interface Selection)
- Section 10.5.4: Referencing Modular Ports
- Section 10.5.5: Referencing Multi-lane Ports
- Section 10.5.6: QSFP+ Ethernet Port Configuration
- Section 10.5.7: QSFP100 Ethernet Port Configuration
- Section 10.5.8: CFP2 Ethernet Port Configuration
- Section 10.5.9: MXP Ethernet Port Configuration
- Section 10.5.10: Port Speed Capabilities
- Section 10.5.11: Agile Ports
- Section 10.5.12: Subinterface Configuration
- Section 10.5.13: Autonegotiated Settings
- Section 10.5.14: Displaying Ethernet Port Properties
- Section 10.5.15: Configuring Ingress Traffic-Class Counters

### 10.5.1 Physical Interface Configuration Modes

The switch provides two configuration modes for modifying Ethernet parameters:

- Interface-Ethernet mode configures parameters for specified Ethernet interfaces.
- Interface-Management mode configures parameters for specified management Ethernet interfaces.

Physical interfaces cannot be created or removed.

Multiple interfaces can be simultaneously configured. Commands are available for configuring Ethernet specific, layer 2, layer 3, and application layer parameters. Commands that modify protocol specific settings in Ethernet configuration mode are listed in the protocol chapters.

- The `interface ethernet` command places the switch in Ethernet-interface configuration mode.
- The `interface management` command places the switch in management configuration mode.

**Examples**

- This command places the switch in Ethernet-interface mode for Ethernet interfaces 5-7 and 10.
  ```
  switch(config)#interface ethernet 5-7,10
  switch(config-if-Et5-7,10)#
  ```

- This command places the switch in management-interface mode for management interface 1.
  ```
  switch(config)#interface management 1
  switch(config-if-Ma1)#
  ```
10.5.2 Assigning a MAC Address to an Interface

Ethernet and Management interfaces are assigned a MAC address when manufactured. This address is the **burn-in address**. The `mac-address` command assigns a MAC address to the configuration mode interface in place of the burn-in address. The `no mac-address` command reverts the interface's current MAC address to its burn-in address.

**Examples**
- This command assigns the MAC address of `001c.2804.17e1` to Ethernet interface 7.
  ```
  switch(config-if-Et7)#mac-address 001c.2804.17e1
  ```
- This command displays the MAC address of Ethernet interface 7. The active MAC address is `001c.2804.17e1`. The burn-in address is `001c.7312.02e2`.
  ```
  switch(config-if-Et7)#show interface ethernet 7
  Ethernet7 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.2804.17e1 (bia 001c.7312.02e2)
  Description: b.e45
  <--------OUTPUT OMITTED FROM EXAMPLE-------->
  ```

10.5.3 Port Groups (QSFP+ and SFP+ Interface Selection)

Several of Arista’s fixed switches limit the number of 10G data lanes in operation through the use of port groups. A port group is a set of interfaces that can be configured as four SFP+ interfaces or a single QSFP+ interface. When configured in SFP+ mode, the port group enables 4 standalone 10GbE interfaces using SFP+ optics. When configured in QSFP+ mode, the port group enables a single QSFP+ interface (in addition to the dedicated QSFP+ ports), which can operate as a single 40GbE port, or as four 10GbE ports with the appropriate breakout cabling.

Hardware port groups are used on the following systems:
- DCS-7050Q-16
- DCS-7050QX-32S

Use the `hardware port-group` command to select the interface mode for the specified port group.

**Important!** The `hardware port-group` command restarts the forwarding agent, which disrupts traffic on all switch ports.

**Example**
- These commands configure the DCS-7050-Q16 switch to enable four SFP+ interfaces and one extra QSFP+ interface by enabling the SFP+ interfaces in port group 1 and the QSFP+ interface in port group 2.
  ```
  switch(config)#hardware port-group 1 select Et17-20
  switch(config)#hardware port-group 2 select Et16/1-4
  ```

The `show hardware port-group` command displays the status of ports in the port groups.
Example

- This command displays the status of the flexible ports within the two port groups on a DCS-7050Q-16 switch.

```
switch# show hardware port-group
```

10.5.3.2 DCS-7050QX-32S

The DCS-7050QX-32S has 31 dedicated QSFP+ ports, plus one port group. The port group supports either one additional QSFP+ port or four SFP+ ports as shown in Table 10-4.
10.5.4 Referencing Modular Ports

Arista modular switches provide port access through installed line cards. The maximum number of line cards on a modular switch varies with the switch series and model.

Several CLI commands modify modular parameters for all ports on a specified line card or controlled by a specified chip. This manual uses these conventions to reference modular components:

- card_x refers to a line card.
- module_y refers to a QSFP+ module.
- port_z refers to a line card or module port.

Commands that display Ethernet port status use the following conventions:

- SFP ports: card_x/port_z to label the line card-port location of modular ports
- QSFP ports: card_x/module_y/port_z to label the line card-port location of modular ports

Section 10.5.6 describe QSFP+ module usage.

Example

- This command displays the status of interfaces 1 to 9 on line card 4:

```
switch> show interface ethernet 4/1-9 status
Port      Name              Status       Vlan        Duplex  Speed Type
Et4/1                       connected    1             full    10G Not Present
Et4/2                       connected    1             full    10G Not Present
Et4/3                       connected    1             full    10G Not Present
Et4/4                       connected    1             full    10G Not Present
Et4/5                       connected    1             full    10G Not Present
Et4/6                       connected    1             full    10G Not Present
Et4/7                       connected    1             full    10G Not Present
Et4/8                       connected    1             full    10G Not Present
Et4/9                       connected    1             full    10G Not Present
switch>
```

10.5.5 Referencing Multi-lane Ports

EOS supports two types of Ethernet ports:

- single-lane (also called fixed-lane)
- multi-lane (also called flexible-lane)

**Single-lane** (or “fixed-lane”) ports are always modeled as a single interface within EOS. While the speed of the interface may be configurable, the physical port can never be broken out into multiple lower-speed interfaces. Single-lane ports use the following naming scheme:

- Ethernet <port #> (for fixed switches)
- Ethernet <module #>/<port #> (for modular switches)
Multi-lane (or “flexible lane”) ports are made up of multiple parallel lanes, each served by its own laser. Multi-lane ports can be configured to combine the lanes and operate as a single native high-speed interface (a 40GbE or 100GbE interface), or to operate each lower-speed interface independently (four 10GbE or 25GbE interfaces). Multi-lane ports use the following naming scheme:

- Ethernet <port #>/<lane #> (for fixed switches)
- Ethernet <module #>/<port #>/<lane #> (for modular switches)

The operational state displayed for each lane of a multi-lane port is determined by the configuration applied to the primary lane(s), as shown in Table 10-5. When broken out into multiple lower-speed interfaces, all lanes will be active in parallel, and each will display its operational state as connected or not connected. In high-speed mode, only the primary lane(s) will be displayed as active, with the remaining lanes showing as errdisabled. The exception is the CFP2 module: when it is configured as a single 100GbE port, the primary lane is displayed as active in the CLI while the other lanes are hidden.

### Table 10-5 Lane States

<table>
<thead>
<tr>
<th>Parent Port Configured Mode</th>
<th>Primary Lane(s)</th>
<th>Secondary Lanes</th>
</tr>
</thead>
<tbody>
<tr>
<td>single high-speed interface</td>
<td>active</td>
<td>(connected/not connected)</td>
</tr>
<tr>
<td>multi-interface</td>
<td>active</td>
<td>(connected/not connected)</td>
</tr>
</tbody>
</table>

A multi-lane port is configured as a single high-speed interface or multiple breakout interfaces by using the speed command on the primary lane(s) of the port. For specific configuration instructions and details regarding the primary lane(s) of a specific interface, refer to the configuration section for the appropriate interface type:

- QSFP+ Ethernet Port Configuration
- QSFP100 Ethernet Port Configuration
- CFP2 Ethernet Port Configuration
- MXP Ethernet Port Configuration

**Important!** Use of the speed command to configure a multi-lane port is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

#### 10.5.6 QSFP+ Ethernet Port Configuration

Each QSFP+ module contains four data lanes which can be used individually or combined to form a single, higher-speed interface. This allows a QSFP+ Ethernet port to be configured as a single 40GbE interface or as four 10GbE interfaces.

When the four lanes are combined to form a 40GbE interface, display commands will show lane /1 as connected or not connected, and will show lanes /2 through /4 as errdisabled.

The following sections describe the configuration of QSFP+ ports.
10.5.6.1 Configuring a QSFP+ Module as a Single 40GbE Interface

To configure the port as a single 40GbE interface, combine the module’s four data lanes by using the \texttt{speed} command (\texttt{speed forced 40g full}) on the port’s /1 lane (the primary lane).

\begin{verbatim}
Important! The \texttt{speed} command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.
\end{verbatim}

\textbf{Step 1} Enter interface Ethernet configuration mode for lane /1 of the QSFP+ Ethernet interface.

\texttt{switch(config)#interface ethernet 5/1/1}

\textbf{Step 2} Enter the \texttt{speed forced 40g full} command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

\texttt{switch(config-if-Et5/1/1)#speed forced 40g full}

\textbf{Step 3} Use the \texttt{show interfaces status} command to confirm the change in configuration.

\texttt{switch(config-if-Et5/1/1)#show interfaces status}

\begin{verbatim}
Port       Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   40G    40GBASE-SR4
Et5/1/2                   errdisabled  1        unconf unconf 40GBASE-SR4
Et5/1/3                   errdisabled  1        unconf unconf 40GBASE-SR4
Et5/1/4                   errdisabled  1        unconf unconf 40GBASE-SR4
\end{verbatim}

10.5.6.2 Configuring a QSFP+ Module as Four 10GbE Interfaces

To configure the port as four 10GbE interfaces, use the \texttt{speed} command (\texttt{speed forced 10000full}) on the port’s /1 lane (the primary lane).

\begin{verbatim}
Important! The \texttt{speed} command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.
\end{verbatim}

\textbf{Step 1} Enter interface Ethernet configuration mode for lane /1 of the QSFP+ Ethernet interface.

\texttt{switch(config)#interface ethernet 5/1/1}

\textbf{Step 2} Enter the \texttt{speed forced 10000full} command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

\texttt{switch(config-if-Et5/1/1)#speed forced 10000full}

\textbf{Step 3} Use the \texttt{show interfaces status} command to confirm the change in configuration.

\texttt{switch(config-if-Et5/1/1)#show interfaces status}

\begin{verbatim}
Port       Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   10G    40GBASE-SR4
Et5/1/2                   connected    1        full   10G    40GBASE-SR4
Et5/1/3                   connected    1        full   10G    40GBASE-SR4
Et5/1/4                   connected    1        full   10G    40GBASE-SR4
\end{verbatim}
10.5.7 **QSFP100 Ethernet Port Configuration**

Each QSFP100 module contains four data lanes which can be used individually or combined to form a single, higher-speed interface. This allows a QSFP100 Ethernet port to be configured as a single 100GbE interface, a single 40GbE interface, or four 10GbE interfaces. The default mode is a single 100GbE interface.

The 7060X, 7260X and 7320X platforms also allow a QSFP100 port to be configured as two 50GbE interfaces or four 25GbE interfaces.

When the lanes are combined to form a higher-speed interface, display commands will show the primary lane(s) as **connected** or **not connected**, and will show the other lanes as **errdisabled**.

The following sections describe the configuration of QSFP+ ports.

### 10.5.7.1 Configuring a QSFP100 Module as a Single 100GbE Interface

By default, the QSFP100 module operates as a single 100GbE interface; using the `default speed` or `no speed` command on the primary lane restores the default behavior.

To explicitly configure the port as a single 100GbE interface, combine the module’s four data lanes by using the `speed` command (`speed forced 100gfull`) on the port’s /1 lane (the primary lane).

**Important!** The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the QSFP100 Ethernet interface.

```
switch(config)#interface ethernet 5/1/1
```

**Step 2** Enter the `speed forced 100gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 100gfull
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status
Port Name Status Vlan Duplex Speed Type Flags
Et1 connected 2 full 1G 10GBASE-T
Et5/1/1 connected 1 full 100G 100GBASE-SR4
Et5/1/2 errdisabled 1 unconf unconf 100GBASE-SR4
Et5/1/3 errdisabled 1 unconf unconf 100GBASE-SR4
Et5/1/4 errdisabled 1 unconf unconf 100GBASE-SR4
```

### 10.5.7.2 Configuring a QSFP100 Module as Two 50GbE Interfaces

To configure the port as a two 50GbE interfaces, configure the module’s four data lanes by using the `speed` command (`speed forced 50gfull`) on the port’s /1 and /3 lanes. This configuration is available on 7060X, 7260X and 7320X platforms.
Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the QSFP100 Ethernet interface.

```
switch(config)#interface ethernet 5/1
```

**Step 2** Enter the `speed forced 50gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 50gfull
```

**Step 3** Repeat the above steps for lane /3.

```
switch(config-if-Et5/1/1)#interface ethernet 5/1/3
switch(config-if-Et5/1/3)#speed forced 50gfull
```

**Step 4** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status
```

10.5.7.3 Configuring a QSFP100 Module as a Single 40GbE Interface

To configure the port as a single 40GbE interface, combine the module’s four data lanes by using the `speed` command (`speed forced 40gfull`) on the port’s /1 lane (the primary lane).

Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the QSFP100 Ethernet interface.

```
switch(config)#interface ethernet 5/1
```

**Step 2** Enter the `speed forced 40gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 40gfull
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status
```

Configuring a QSFP100 Module as Four 25GbE Interfaces

To configure the port as four 25GbE interfaces, use the `speed` command (speed forced 25gfull) on the port’s /1 lane (the primary lane). This configuration is available on 7060X, 7260X and 7320X platforms.

Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the QSFP100 Ethernet interface.

```
switch(config)#interface ethernet 5/1/1
```

**Step 2** Enter the `speed forced 25gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 25gfull
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status
Port       Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   25G    100GBASE-SR4
Et5/1/2                   errdisabled  1        unconf unconf 100GBASE-SR4
Et5/1/3                   errdisabled  1        unconf unconf 100GBASE-SR4
Et5/1/4                   errdisabled  1        unconf unconf 100GBASE-SR4
```

Configuring a QSFP100 Module as Four 10GbE Interfaces

To configure the port as four 10GbE interfaces, use the `speed` command (speed forced 10000full) on the port’s /1 lane (the primary lane).

Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the QSFP100 Ethernet interface.

```
switch(config)#interface ethernet 5/1/1
```

**Step 2** Enter the `speed forced 10000full` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 10000full
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status
Port       Name       Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   10G    100GBASE-SR4
Et5/1/2                   connected    1        full   10G    100GBASE-SR4
Et5/1/3                   connected    1        full   10G    100GBASE-SR4
Et5/1/4                   connected    1        full   10G    100GBASE-SR4
```
10.5.8 CFP2 Ethernet Port Configuration

Each CFP2 module contains ten data lanes. The configuration options available on the port depend on the optic inserted:

- **CFP2-100G-LR4** optics operate only in 100GbE mode.
- **CF2-100G-ER4** optics operate only 100GbE mode.
- **CFP2-100G-XSR10** optics can be configured as a single 100GbE interface or as ten 10GbE interfaces.

When the port is configured as ten 10GbE interface, each lane is active and visible in CLI display commands. When the lanes are combined to form a single 100GbE interface, display commands will show the primary lane as *connected* or *not connected*, all other lanes will be hidden.

The following sections describe the configuration of CFP2 ports.

10.5.8.1 Configuring a CFP2 Module as a Single 100GbE Interface

To configure the port as a single 100GbE interface (the default configuration), combine the module’s ten data lanes by using the `speed` command (`speed forced 100gfull`) on the port’s /1 lane (the primary lane).

This configuration is available for all pluggable optics.

**Important!** The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the CFP2 Ethernet interface.

```
switch(config)#interface ethernet 5/1/1
```

**Step 2** Enter the `speed forced 100gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 100gfull
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status

Port    Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                 connected    2        full   1G     10GBASE-T
<br/>&lt;--------OUTPUT OMITTED FROM EXAMPLE-------->
Et5/1/1            connected    1        full   100G   100GBASE-SR1
Et5/2/1            connected    1        full   100G   100GBASE-SR1
<br/>&lt;--------OUTPUT OMITTED FROM EXAMPLE-------->
```

10.5.8.2 Configuring a CFP2 Module as Ten 10GbE Interfaces

To configure the port as four 10GbE interfaces, use the `speed` command (`speed forced 10000full`) on the port’s /1 lane (the primary lane).

This configuration is available only for CFP2-100G-XSR10 optics.
**Important!** The speed command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the CFP2 Ethernet interface.

```
switch(config)#interface ethernet 5/1/1
```

**Step 2** Enter the speed forced 10000full command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/1/1)#speed forced 10000full
```

**Step 3** Use the show interfaces status command to confirm the change in configuration.

```
switch(config-if-Et5/1/1)#show interfaces status

Port       Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   10G    100GBASE-SR1
Et5/1/2                   connected    1        full   10G    100GBASE-SR1
Et5/1/3                   connected    1        full   10G    100GBASE-SR1
Et5/1/4                   connected    1        full   10G    100GBASE-SR1
Et5/1/5                   connected    1        full   10G    100GBASE-SR1
Et5/1/6                   connected    1        full   10G    100GBASE-SR1
Et5/1/7                   connected    1        full   10G    100GBASE-SR1
Et5/1/8                   connected    1        full   10G    100GBASE-SR1
Et5/1/9                   connected    1        full   10G    100GBASE-SR1
Et5/1/10                  connected    1        full   10G    100GBASE-SR1
```

**10.5.9 MXP Ethernet Port Configuration**

Each MXP module contains twelve data lanes which can be used individually or combined to form one or more higher-speed interfaces. This allows an MXP Ethernet port to be configured as a single 100GbE interface, up to twelve 10GbE interfaces, or a mixture of 40GbE and 10GbE ports.

MXP ports do not use pluggable optics: instead, an MTP-24 ribbon is inserted directly into the port. The remote end of the MTP 24 ribbon must then be broken out using a splitter cable or cartridge based on the operational mode and speed of the MXP port.

When four lanes of an MXP interface are combined to form a 40GbE port, CLI commands will show the primary lane of that group as connected or not connected and the other three lanes as errdisabled.

The following sections describe the configuration of MXP interfaces.

**10.5.9.1 Configuring an MXP Module as a Single 100GbE Interface**

To configure the port as a single 100GbE interface (the default configuration), enter the speed command (speed forced 100gfull) on the port’s /1 lane (the primary lane). This combines lanes 1-10 and disables lanes 11 and 12.

Under this configuration, CLI display commands will show lane /1 as connected or not connected, and show lanes /2-/12 as errdisabled.
Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the MXP Ethernet interface.

```plaintext
switch(config)#interface ethernet 5/49/1
```

**Step 2** Enter the `speed forced 100gfull` command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```plaintext
switch(config-if-Et5/49/1)#speed forced 100gfull
```

**Step 3** Use the `show interfaces status` command to confirm the change in configuration.

```plaintext
switch(config-if-Et5/49/1)#show interfaces status
```

10.5.9.2 Configuring an MXP Module With 40GbE Interfaces

Each set of four lanes on the MXP module is independently configurable as a single 40GbE interface or four 10GbE interfaces. To configure four lanes as a single 40GbE interface, enter the `speed` command (`speed forced 40gfull`) on the group’s primary lane (/1, /5, or /9). To revert a group of four lanes to functioning as four independent 10GbE interfaces, enter the `speed forced 10000full` command on the primary lane of the group.

When four lanes of an MXP interface are combined to form a 40GbE port, CLI commands will show the primary lane of that group as `connected` or `not connected` and the other three lanes as `errdisabled`. In groups of four lanes which are configured as four independent 10GbE interfaces, each lane will be displayed in the CLI as `connected` or `not connected`.

Note that a `speed forced 100gfull` command entered on the /1 lane takes precedence over `speed forced 40gfull` commands on the /5 and /9 lanes.

Important! The `speed` command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

The example below shows the steps for configuring an MXP module as three 40GbE interfaces.

**Step 1** Enter interface Ethernet configuration mode for lane /1 of the MXP Ethernet interface.

```plaintext
switch(config)#interface ethernet 5/49/1
```
Step 2  Enter the **speed forced 40gfull** command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/49/1)#speed forced 40gfull
```

Step 3  Repeat the above steps for lanes /5 and /9.

```
switch(config-if-Et5/49/1)#interface ethernet 5/49/5
switch(config-if-Et5/49/5)#speed forced 40gfull
switch(config-if-Et5/49/5)#interface ethernet 5/49/9
switch(config-if-Et5/49/9)#speed forced 40gfull
```

Step 4  Use the **show interfaces status** command to confirm the change in configuration.

```
switch(config-if-Et5/49/9)#show interfaces status
```

10.5.9.3  Configuring an MXP Module as Twelve 10GbE Interfaces

Each lane of an MXP port functions as a 10GbE interface when it is not included in a higher-speed interface configuration (either actively or as an **errdisabled** port).

To explicitly configure the port as twelve 10GbE interfaces, use the **speed** command (**speed forced 10000full**) on all twelve lanes of the port.

When each lane is configured as an independent 10GbE interface, CLI display commands show each lane as **connected** or **not connected**.

**Important!**  The **speed** command is hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, this command restarts the forwarding agent, which will result in traffic disruption.

Step 1  Enter interface Ethernet configuration mode for all twelve lanes of the MXP Ethernet interface.

```
switch(config)#interface ethernet 5/49/1-12
```

Step 2  Enter the **speed forced 10000full** command. Depending on the platform, this command may restart the forwarding agent, disrupting traffic on all ports for 60 seconds or more.

```
switch(config-if-Et5/49/1-12)#speed forced 10000full
```
Step 3 Use the `show interfaces status` command to confirm the change in configuration.

```
switch(config-if-Et5/49/1-12)#show interfaces status
Port       Name           Status       Vlan     Duplex Speed  Type         Flags
Et1                       connected    2        full   1G     10GBASE-T
Et5/1/1                   connected    1        full   10G    100GBASE-SR1
Et5/1/2                   connected    1        full   10G    100GBASE-SR1
Et5/1/3                   connected    1        full   10G    100GBASE-SR1
Et5/1/4                   connected    1        full   10G    100GBASE-SR1
Et5/1/5                   connected    1        full   10G    100GBASE-SR1
Et5/1/6                   connected    1        full   10G    100GBASE-SR1
Et5/1/7                   connected    1        full   10G    100GBASE-SR1
Et5/1/8                   connected    1        full   10G    100GBASE-SR1
Et5/1/9                   connected    1        full   10G    100GBASE-SR1
Et5/1/10                  connected    1        full   10G    100GBASE-SR1
```

10.5.10 Port Speed Capabilities

The supported speeds supported on each Arista platform per interface type are described in Table 10-6.

10.5.11 Agile Ports

An agile port is an interface that can function as a 10G port or can subsume a predefined set of 10G interfaces to form an interface with higher speed capabilities.

The set of interfaces that can be combined to form a higher speed port is restricted by the hardware configuration. Only interfaces that pass through a common PHY component can be combined. One interface within a combinable set is designated as the primary port.

- To view the set of available agile ports and the subsumable interfaces that comprise them, enter `show platform fm6000 agileport map`.
- To configure the primary port as a higher speed port, enter `speed forced 40gfull` or `speed auto 40gfull`.
- To revert the primary port and its subsumed ports to 10G interfaces, enter `no speed`. 
Example

- These commands displays the agile port map for the switch, then configures ethernet interface 13 as a 40G port.

```
switch#show platform fm6000 agileport map

-----------------------------------------------
Agile Ports       | Interfaces subsumed in 40G link
-----------------------------------------------
Ethernet1         | Ethernet3  Ethernet5  Ethernet7
Ethernet2         | Ethernet4  Ethernet6  Ethernet8
Ethernet13        | Ethernet15  Ethernet17  Ethernet19
Ethernet14        | Ethernet16  Ethernet18  Ethernet20
```

switch#config
switch(config)#interface ethernet 13
switch(config-if-Et13)#speed forced 40gfull

WARNING! Executing this command will cause the forwarding agent to be restarted. All interfaces will briefly drop links and forwarding on all interfaces will momentarily stop.

Do you wish to proceed with this command? [y/N]

Ethernet17 configured for 40G.
Ethernet15, Ethernet17 and Ethernet19 are now subsumed.
switch(config-if-Et13)#

This command reverts the agile 40G port to a 10G port and frees its subsumed ports as individual 10G ports.
switch(config-if-Et13)#no speed

WARNING! Executing this command will cause the forwarding agent to be restarted. All interfaces will briefly drop links and forwarding on all interfaces will momentarily stop.

Do you wish to proceed with this command? [y/N]

Ethernet13 no longer configured for 40G.
Ethernet15, Ethernet17 and Ethernet19 are now free.
switch(config-if-Et13)#

10.5.12 Subinterface Configuration

For a subinterface to be operational on an Ethernet or port channel interface, the parent interface must be configured as a routed port and be administratively up, and a VLAN must be configured on the subinterface. If the parent interface goes down, all subinterfaces automatically go down as well, but will come back up with the same configuration once the parent interface is up.

Note that a port channel should not contain Ethernet interfaces with subinterfaces configured on them, and that subinterfaces cannot be members of a port channel.

Subinterfaces are named by adding a period followed by a unique subinterface number to the name of the parent interface. Note that the subinterface number has no relation to the ID of the VLAN corresponding to the subinterface.

A maximum of 750 subinterfaces can be configured on a switch, and a maximum of 250 subinterfaces can be configured under a single parent interface.
Subinterfaces are available on the following platforms:

- DCS-7050X
- DCS-7060X
- DCS-7250X
- DCS-7260X
- DCS-7280E
- DCS-7300X
- DCS-7320X
- DCS-7500E

10.5.12.1 Creating a Subinterface

To create a subinterface on an Ethernet or port channel interface:

**Step 1** Bring up the parent interface and ensure that it is configured as a routed port.

```
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#no switchport
switch(config-if-Et1/1)#no shutdown
```

**Step 2** Configure a VLAN on the subinterface. The `encapsulation dot1q vlan` command is also used for VLAN translation, but in this context it associates a VLAN with the subinterface.

```
switch(config-if-Et1/1)#interface Ethernet1/1.1
switch(config-if-Et1/1.1)#encapsulation dot1q vlan 100
```

**Step 3** Configure an IP address on the subinterface (optional) and ensure that it is up.

```
switch(config-if-Et1/1)#ip address 10.0.0.1/24
switch(config-if-Et1/1)#no shutdown
```

10.5.12.2 Creating a Range of Subinterfaces

A range of subinterfaces can also be configured simultaneously. The following example configures subinterfaces 1 to 100 on Ethernet interface 1/1, and assigns VLANs 501 through 600 to them. Note that the range of interfaces must be the same size as the range of VLAN IDs.

**Example**

```
switch(config)#interface eth1/1.1-100
switch(config-if-Et1/1.1-100)#no shutdown
switch(config-if-Et1/1.1-100)#encapsulation dot1q vlan {501,600}
switch(config-if-Et1/1.1-100)#exit
switch(config)#
```

10.5.12.3 Parent Interface Configuration

For subinterfaces to function, the parent interface must be administratively up and configured as a routed port.

Some settings are inherited by subinterfaces from the parent interface. These include QoS (trust mode and default DSCP) and MTU.

Additionally, on the DCS-7050X, DCS-7250X, and DCS-7300X platforms, the parent interface may be configured with an IP address. In this case, untagged packets are treated as incoming traffic on the parent interface.
10.5.12.4 Configuring Routing Features on a Subinterface

Once a subinterface is created, the following features can be configured on it:

- Unicast and multicast routing
- BGP, OSPF, ISIS, PIM
- VRF
- VRRP
- SNMP
- Inheritance of QoS (trust mode and default DSCP) and MTU settings from the parent interface

Additionally, these features can be configured on subinterfaces on Arad (DCS-7500E and DCS-7280E) platforms:

- Subinterface counters on ingress
- VXLAN
- MPLS
- GRE
- PBR
- QoS

10.5.12.5 Displaying Subinterface Information

Subinterface information is displayed using the same show commands as for other interfaces.

**Examples**

This command displays summary information for all IP interfaces on the switch, including subinterfaces.

```
switch>show ip interfaces brief
Interface        IP Address     Status    Protocol     MTU
Ethernet1/1      10.1.1.1/24    up        up          1500
Ethernet1/1.1    10.0.0.1/24    up        up          1500
Ethernet1/2      unassigned     up        up          1500
```

This command displays information for subinterface Ethernet 1/1.1.

```
switch>show interface ethernet 1/1.1
Ethernet1/1.1 is down, line protocol is lowerlayerdown (notconnect)
   Hardware is Subinterface, address is 001c.735d.65dc
   Internet address is 10.0.0.1/24
   Broadcast address is 255.255.255.255
   Address determined by manual configuration
   IP MTU 1500 bytes, BW 10000000 kbit
   Down 59 seconds
```

This command displays status information for all subinterfaces configured on the switch.

```
switch>show interfaces status sub-interfaces
Port   Name     Status   Vlan Duplex Speed  Type                Flags
Et1.1  connect  101 full  10G    dot1q-encapsulation
Et1.2  connect  102 full  10G    dot1q-encapsulation
Et1.3  connect  103 full  10G    dot1q-encapsulation
Et1.4  connect  103 full  10G    dot1q-encapsulation
```

510
10.5.13 Autonegotiated Settings

In autonegotiation, the transmission speed, duplex setting, and flow control parameters used for Ethernet-based communication can be automatically negotiated between connected devices to establish optimized common settings.

10.5.13.1 Speed and Duplex

The `speed` command affects the transmission speed and duplex setting for the configuration mode interface. When a `speed forced` command is in effect on an interface, autonegotiation of speed and duplex settings is disabled for the interface; to enable autonegotiation, use the `speed auto` command.

The scope and effect of the `speed` command depends on the interface type; see Ethernet Interfaces and Ethernet Configuration Procedures for detailed information on the speed settings for different interfaces.

10.5.13.2 Flow Control

Flow control is a data transmission option that temporarily stops a device from sending data because of a peer data overflow condition. If a device sends data faster than the receiver can accept it, the receiver's buffer can overflow. The receiving device then sends a PAUSE frame, instructing the sending device to halt transmission for a specified period.

Flow control commands configure administrative settings for flow control packets.

- The `flowcontrol receive` command configures the port's ability to receive flow control pause frames.
  - `off`: port does not process pause frames that it receives.
  - `on`: port processes pause frames that it receives.
  - `desired`: port autonegotiates; processes pause frames if peer is set to `send` or `desired`.

- The `flowcontrol send` command configures the port's ability to transmit flow control pause frames.
  - `off`: port does not send pause frames.
  - `on`: port sends pause frames.
  - `desired`: port autonegotiates; sends pause frames if peer is set to `receive` or `desired`.

Desired is not an available parameter option. Ethernet data ports cannot be set to desired. Management ports are set to desired by default and with the `no flowcontrol receive` command.

The port linking process includes flow control negotiation. Ports must have compatible flow control settings to create a link. Table 10-7 lists the compatible flow control settings.

<table>
<thead>
<tr>
<th>local port</th>
<th>peer port</th>
</tr>
</thead>
<tbody>
<tr>
<td>receive on</td>
<td>send on or send desired</td>
</tr>
<tr>
<td>receive off</td>
<td>send off or send desired</td>
</tr>
<tr>
<td>receive desired</td>
<td>send on , send off, or send desired</td>
</tr>
<tr>
<td>send on</td>
<td>receive on or receive desired</td>
</tr>
<tr>
<td>send off</td>
<td>receive off or receive desired</td>
</tr>
<tr>
<td>send desired</td>
<td>receive on , receive off, or receive desired</td>
</tr>
</tbody>
</table>
Example

- These commands set the flow control receive and send to on on Ethernet interface 5.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#flowcontrol receive on
switch(config-if-Et5)#flowcontrol send on
```

10.5.14 Displaying Ethernet Port Properties

Show commands are available to display various Ethernet configuration and operational status on each interface. Ethernet settings that are viewable include:

- Port Type
- PHY Status
- Negotiated Settings
- Flow Control
- Capabilities

**Port Type**

The port type is viewable from the output of `show interfaces status`, `show interfaces capabilities`, and `show interfaces transceiver properties` commands.

**Example**

- This `show interfaces status` command displays the status of Ethernet interfaces 1-5.

```
switch>show interfaces status
Port      Name              Status       Vlan        Duplex  Speed Type
Et1                         connected    1             full    10G 10GBASE-SRL
Et2                         connected    1             full    10G 10GBASE-SRL
Et3                         connected    1             full    10G 10GBASE-SRL
Et4                         connected    1             full    10G 10GBASE-SRL
Et5                         notconnect   1             full    10G Not Present
switch>
```

- This `show interfaces capabilities` command displays the speed, duplex, and flow control capabilities of Ethernet interfaces 2 and 18.

```
switch>show interfaces ethernet 2,18 capabilities
Ethernet2
  Model:        DCS-7150S-64-CL
  Type:         10GBASE-CR
  Speed/Duplex: 10G/full,40G/full,auto
  Flowcontrol:  rx-(off,on,desired),tx-(off,on,desired)
Ethernet18
  Model:        DCS-7150S-64-CL
  Type:         10GBASE-SR
  Speed/Duplex: 10G/full
  Flowcontrol:  rx-(off,on),tx-(off,on)
switch>
```
Chapter 10: Ethernet Ports

Ethernet Configuration Procedures

- This command displays the media type, speed, and duplex properties for Ethernet interfaces 1.

```
switch> show interfaces ethernet 1 transceiver properties
Name : Et1
Administrative Speed: 10G
Administrative Duplex: full
Operational Speed: 10G (forced)
Operational Duplex: full (forced)
Media Type: 10GBASE-SRL
```

**PHY**

PHY information for each Ethernet interface is viewed by entering the `show interfaces phy` command.

**Example**

- This command summarizes PHY information for Ethernet interfaces 1-3.

```
switch> show interfaces ethernet 1-3 phy
Key:
  U = Link up
  D = Link down
  R = RX Fault
  T = TX Fault
  B = High BER
  L = No Block Lock
  A = No XAUI Lane Alignment
  0123 = No XAUI lane sync in lane N

<table>
<thead>
<tr>
<th>Port</th>
<th>PHY state</th>
<th>State Changes</th>
<th>Reset Count</th>
<th>PMA/PMD</th>
<th>PCS</th>
<th>XAUI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>linkUp</td>
<td>14518</td>
<td>1750 U..</td>
<td>U....</td>
<td>U....</td>
<td>U...........</td>
</tr>
<tr>
<td>Ethernet2</td>

<tr>
<td>Ethernet3</td>
<td>detectingXcvr</td>
<td>3</td>
<td>1</td>
<td>D..A0123</td>
<td>0123</td>
<td></td>
</tr>
</tbody>
</table>
```

**Negotiated Settings**

Speed, duplex, and flow control settings are displayed through the `show interfaces capabilities`, `PHY` information for each Ethernet interface is viewed by entering the `show interfaces status` commands.

**Example**

- This command displays speed/duplex and flow control settings for Ethernet interface 1.

```
switch> show interfaces ethernet 1 capabilities
Ethernet1
  Model:        DCS-7150S-64-CL
  Type:         10GBASE-SR
  Speed/Duplex: 10G/full
  Flowcontrol:  rx-(off,on),tx-(off,on)
```

Ethernet Configuration Procedures

Chapter 10: Ethernet Ports

10.5.15 Configuring Ingress Traffic-Class Counters

Ingress traffic class counter support is enabled in order to display per traffic-class counters on ingress interfaces, and supported on routed-ports and sub-interfaces. Both packet and octet counts are displayed.

Example

- This command enables traffic-class counter support.
  
  switch(config)#hardware counter feature traffic-class in
  
  switch(config)#

- This command enables TCAM profile ‘tc-counters’ if this profile is configured.
  
  switch(config)#hardware tcam profile tc-counters
  
  switch(config)#
10.6 Ethernet Configuration Commands

Global Configuration Commands
- hardware port-group
- interface ethernet
- interface ethernet create
- interface management
- transceiver qsfp default-mode
- transceiver channel

Interface Configuration Commands – Ethernet and Management Interfaces
- flowcontrol receive
- flowcontrol send
- link-debounce
- mac-address
- speed

Interface Display Commands
- show flowcontrol
- show hardware counter
- show hardware port-group
- show interfaces capabilities
- show interfaces counters
- show interfaces counters bins
- show interfaces counters errors
- show interfaces counters queue
- show interfaces counters rates
- show interfaces negotiation
- show interfaces phy
- show interfaces status
- show interfaces status errdisabled
- show interfaces transceiver
- show interfaces transceiver channels
- show interfaces transceiver hardware
- show interfaces transceiver properties
- show platform fm6000 agileport map
flowcontrol receive

The `flowcontrol receive` command configures administrative settings for inbound flow control packets. Ethernet ports use flow control to delay packet transmission when port buffers run out of space. Ports transmit a pause frame when their buffers are full, signaling their peer ports to delay sending packets for a specified period.

The `flowcontrol receive` command configures the configuration mode port's ability to receive flow control pause frames.

- **off**: port does not process pause frames that it receives.
- **on**: port processes pause frames that it receives.
- **desired**: port autonegotiates flow control; processes pause frames if the peer is set to `send desired`.

`Desired` is not an available parameter option. Ethernet data ports cannot be set to `desired`. Management ports are set to `desired` by default and with the `no flowcontrol receive` command.

The port linking process includes flow control negotiation. Ports must have compatible flow control settings to create a link. Table 10-8 lists the compatible flow control settings.

**Table 10-8 Compatible Settings for Flow Control Negotiation – Local Port Receiving**

<table>
<thead>
<tr>
<th>local port</th>
<th>peer port</th>
</tr>
</thead>
<tbody>
<tr>
<td>receive on</td>
<td>send on or send desired</td>
</tr>
<tr>
<td>receive off</td>
<td>send off or send desired</td>
</tr>
<tr>
<td>receive desired</td>
<td>send on, send off, or send desired</td>
</tr>
</tbody>
</table>

The `no flowcontrol receive` and `default flowcontrol receive` commands restore the default flow control setting for the configuration mode interface by removing the corresponding `flowcontrol receive` command from `running-config`. The default setting is `off` for Ethernet data ports and `desired` for Management ports.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

- `flowcontrol receive STATE`
- `no flowcontrol receive`
- `default flowcontrol receive`

**Parameters**

- `STATE` flow control pause frame processing setting. Options include:
  - `on`
  - `off`

**Examples**

- These commands set the flow control received on Ethernet interface 5.

  ```bash
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#flowcontrol receive on
  switch(config-if-Et5)#
  ```
**flowcontrol send**

The `flowcontrol send` command configures administrative settings for outbound flow control packets. Ethernet ports use flow control to delay packet transmission when port buffers run out of space. Ports transmit a pause frame when their buffers are full, signaling their peer ports to delay sending packets for a specified period.

The `flowcontrol send` command configures the configuration mode port's ability to transmit flow control pause frames.

- **off**: port does not send pause frames.
- **on**: port sends pause frames.
- **desired**: port autonegotiates flow control; sends pause frames if the peer is set to `receive desired`.

*Desired* is not an available parameter option. Ethernet data ports cannot be set to `desired`. Management ports are set to `desired` by default and with the `no flowcontrol send` command.

The port linking process includes flow control negotiation. Ports must have compatible flow control settings to create a link. **Table 10-9** lists the compatible flow control settings.

**Table 10-9 Compatible Settings for Flow Control Negotiation – Local Port Transmitting**

<table>
<thead>
<tr>
<th>local port</th>
<th>peer port</th>
</tr>
</thead>
<tbody>
<tr>
<td>send on</td>
<td>receive on or receive desired</td>
</tr>
<tr>
<td>send off</td>
<td>receive off or receive desired</td>
</tr>
<tr>
<td>send desired</td>
<td>receive on, receive off, or receive desired</td>
</tr>
</tbody>
</table>

The `no flowcontrol send` and `default flowcontrol send` commands restore the default flow control setting for the configuration mode interface by removing the corresponding `flowcontrol send` command from `running-config`. The default setting is `off` for Ethernet data ports and `desired` for Management ports.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
flowcontrol send STATE
no flowcontrol send
default flowcontrol send
```

**Parameters**

- **STATE**  flow control send setting. Options include
  - **on**
  - **off**

**Examples**

- These commands set the flow control sent on Ethernet interface 5.
  ```
switch(config)#interface ethernet 5
switch(config-if-Et5)#flowcontrol send on
switch(config-if-Et5)#
```
hardware port-group

The **hardware port-group** command configures a port group to activate a 40GBASE (QSFP+) interface or four 10GBASE (SFP+) interfaces, affecting QSFP+ and SFP+ availability.

The **no hardware port-group** and **default hardware port-group** commands restore a port group’s default setting by removing the corresponding **hardware port-group** command from **running-config**. The QSFP+ interface is active by default in each port group.

The **hardware port-group** command is available on DCS-7050Q-16 and DCS-7050QX-32S switches, and has different parameters on each platform.

**Command Mode**

- Global Configuration

**Command Syntax**

```
hardware port-group group_number select PORT_LIST
no hardware port-group group_number
default hardware port-group group_number
```

**Parameters**

- **group_number** label of the port group. Valid options are 1 and 2 on the 7050Q-16; only 1 is available on the 7050QX-32S.
- **PORT_LIST** ports activated by command. Options vary by platform and depend on **group_number** value.

**DCS-7050Q-16**

- **Et15/1-4** activates QSFP+ port on port group 1. Available when **group_number** is 1.
- **Et16/1-4** activates QSFP+ port on port group 2. Available when **group_number** is 2.
- **Et17-20** activates SFP+ ports on port group 1. Available when **group_number** is 1.
- **Et21-23** activates SFP+ ports on port group 2. Available when **group_number** is 2.

**DCS-7050QX-32S**

- **Et1-4** activates SFP+ ports on port group 1. Available when **group_number** is 1.
- **Et5/1-4** activates QSFP+ port on port group 1. Available when **group_number** is 1.
Example

- These commands enable the QSFP+ interface in port group 1 and SFP+ interfaces in port group 2 on a DCS-7050Q-16 switch, display the port group status, and display interface status.

```plaintext
switch(config)#hardware port-group 1 select Et15/1-4
switch(config)#hardware port-group 2 select Et21-24
switch(config)#show hardware port-group

Portgroup: 1    Active Ports: Et17-20
Port            State
-----------------------------
Ethernet17      ErrDisabled
Ethernet18      ErrDisabled
Ethernet19      ErrDisabled
Ethernet20      ErrDisabled
Ethernet15/1    Active
Ethernet15/2    Active
Ethernet15/3    Active
Ethernet15/4    Active

Portgroup: 2    Active Ports: Et16/1-4
Port            State
-----------------------------
Ethernet16/1    Active
Ethernet16/2    Active
Ethernet16/3    Active
Ethernet16/4    Active
Ethernet21      ErrDisabled
Ethernet22      ErrDisabled

Et24                      connected    in Po998      full    10G 10GBASE-SLR
```
interface ethernet

The **interface ethernet** command places the switch in Ethernet-interface configuration mode for the specified interfaces. The command can specify a single interface or multiple interfaces.

Ethernet interfaces are physical interfaces and are not created or removed.

Interface management commands include:

- `description`
- `exit`
- `load-interval`
- `mtu`
- `shutdown` (Interfaces)

Ethernet management commands include:

- `flowcontrol`
- `mac-address`
- `speed`

Chapters describing supported protocols and other features list additional configuration commands available from Ethernet interface configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

```
interface ethernet e_range
```

**Parameters**

- `e_range` Ethernet interfaces (number, range, or comma-delimited list of numbers and ranges).

  Valid Ethernet numbers depend on the switch’s available Ethernet interfaces.

**Example**

- This command enters interface configuration mode for Ethernet interfaces 1 and 2:

  ```
  switch(config)#interface ethernet 1-2
  switch(config-if-Et1-2)#
  ```

- This command enters interface configuration mode for Ethernet interface 1:

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#
  ```
interface ethernet create

The `interface ethernet create` command is used to configure a range of Ethernet subinterfaces. The command places the switch in Ethernet-interface configuration mode for the specified range of subinterfaces.

**Command Mode**
Global Configuration

**Command Syntax**

```
interface ethernet create sub_range
```

**Parameters**

- `sub_range` range of subinterfaces to be configured. Subinterfaces are named by adding a period followed by a unique subinterface number to the name of the parent interface. A maximum of 750 subinterfaces can be configured on a switch, and a maximum of 250 subinterfaces can be configured under a single parent interface.

**Example**

- This command enters interface configuration mode for Ethernet subinterfaces 1/1.1-100:

```
switch(config)#interface ethernet create 1/1.100
switch(config-if-Et1/1.1-100)#
```
interface management

The interface management command places the switch in management-interface configuration mode for the specified interfaces. The list can specify a single interface or multiple interfaces if the switch contains more than one management interface.

Management interfaces are physical interfaces and are not created or removed.

Interface management commands include:

- description
- exit
- load-interval
- mtu
- shutdown (Interfaces)

Ethernet management commands include:

- flowcontrol
- mac-address
- speed

Chapters describing supported protocols and other features list additional configuration commands available from management-interface configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

```
interface management m_range
```

**Parameters**

- **m_range** Management interfaces (number, range, or comma-delimited list of numbers and ranges).

  Valid management numbers depend on the switch's available management interfaces. A value of 0, where available, configures the virtual management interface on a dual-supervisor modular switch. Management interface 0 accesses management port 1 on the active supervisor of a dual-supervisor modular switch.

**Examples**

- This command enters interface configuration mode for management interfaces 1 and 2.
  
  ```
  switch(config)#interface management 1-2
  switch(config-if-Ma1-2)#
  ```

- This command enters interface configuration mode for management interface 1:
  
  ```
  switch(config)#interface management 1
  switch(config-if-Ma1)#
  ```
link-debounce

The **link-debounce** command configures the link debounce time for the configuration mode interface. Link debounce time is the time that advertisements for new link states are delayed after the link state is established. By default, debounce time is set to zero, disabling link debounce.

Debounce times for link-up and link-down transitions can be independently configured.

- Link-up debounce time: the delay before an interface advertises link down to link up transitions.
- Link-down debounce time: the delay before an interface advertises link up to link down transitions.

The **no link-debounce** and **default link-debounce** commands restore the default debounce setting for the configuration mode interface by removing the corresponding **link-debounce** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
link-debounce time <0 - 30000>
no link-debounce
default link-debounce
```

**Parameters**

- **WAIT_TIME**  
  - link debounce period (milliseconds). Options include
    - `<0 - 30000>`  One debounce value assigned as both link up and link down.
    - `<0 - 30000> <0 - 30000>`  Two debounce values: link up is first, link down is second.

All debounce values range from 0 (disabled) to 30000 (30 seconds).

**Examples**

- These commands set the link-up and link-down debounce period to 10 seconds on Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#link-debounce time 10000
  switch(config-if-Et5)#
  ```

- These commands set the link-up debounce to 10 seconds and the link-down debounce period to zero on Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#link-debounce time 10000 0
  switch(config-if-Et5)#
  ```

- These commands set the link-up debounce to zero and the link-down debounce period to 12.5 seconds on Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#link-debounce time 0 12500
  switch(config-if-Et5)#
  ```
mac-address

The **mac-address** command assigns a MAC address to the configuration mode interface. An interface's default MAC address is its burn-in address.

The **no mac-address** and **default mac-address** commands revert the interface to its default MAC address by removing the corresponding **mac-address** command from *running-config*.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
mac-address address
no mac-address
default mac-address
```

**Parameters**

- **address** MAC address assigned to the interface. Format is dotted hex notation (H.H.H).

  Disallowed addresses are 0.0.0 and FFFF.FFFF.FFFF.

**Example**

- This command assigns the MAC address of 001c.2804.17e1 to Ethernet interface 7, then displays interface parameters, including the assigned address.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#mac-address 001c.2804.17e1
switch(config-if-Et7)#show interface ethernet 7
Ethernet3 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.2804.17e1 (bia 001c.7312.02e2)
  Description: b.e45
  MTU 9212 bytes, BW 10000000 Kbit
  Full-duplex, 10Gb/s, auto negotiation: off
  Last clearing of "show interface" counters never
  5 seconds input rate 7.84 kbps (0.0% with framing), 10 packets/sec
  5 seconds output rate 270 kbps (0.0% with framing), 24 packets/sec
  1363799 packets input, 222736140 bytes
  Received 0 broadcasts, 290904 multicast
  0 runts, 0 giants
  0 input errors, 0 CRC, 0 alignment, 0 symbol
  0 PAUSE input
  2264927 packets output, 2348747214 bytes
  Sent 0 broadcasts, 28573 multicast
  0 output errors, 0 collisions
  0 late collision, 0 deferred
  0 PAUSE output
switch(config-if-Et7)#
```
### show flowcontrol

The `show interfaces flowcontrol` command displays administrative and operational flow control data for the specified interfaces. Administrative data is the parameter settings stored in `running-config` for the specified interface; the switch uses these settings to negotiate flow control with the peer switch. Operational data is the resolved flow control setting that controls the port’s behavior.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show flowcontrol [INTERFACE]
show [INTERFACE] flowcontrol
```

**Parameters**

- **INTERFACE**  Interface type and number for which flow control data is displayed.
  - `<no parameter>`  all interfaces.
  - `ethernet e_range`  Ethernet interfaces in the specified range.
  - `management m_range`  Management interfaces in the specified range.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command shows the settings for Ethernet interfaces 1-10.

```plaintext
switch>show flowcontrol interface ethernet 1-10
Port       Send FlowControl  Receive FlowControl  RxPause       TxPause
admin    oper     admin    oper
---------  -------- -------- -------- --------    ------------- -------------
Et1        off      off      off      off         0             0
Et2        off      off      off      off         0             0
Et3        off      off      off      off         0             0
Et4        off      off      off      off         0             0
Et5        off      off      off      off         0             0
Et6        off      off      off      off         0             0
Et7        off      off      off      off         0             0
Et8        off      off      off      off         0             0
Et9        off      off      off      off         0             0
Et10       off      off      off      off         0             0
switch>
```
**show hardware counter**

The `show hardware counter` command displays counter events across time intervals.

**Command Mode**

EXEC

**Command Syntax**

`show hardware counter`

**Example**

- This command displays counter events across all time intervals, which are currently more than one standard deviation apart from a given time interval.

```plaintext
switch(config-handler-eventHandler1-counters)#show hardware counter events
-----------------------------------------------------------------------------------------

switch(config-handler-eventHandler1-counters)#
```
show hardware port-group

The `show hardware port-group` command displays the status of DCS-7050Q-16 port-groups. Port groups contain one QSFP+ interface and a set of four SFP+ interfaces. In each port group, either the QSFP+ interface or the SFP+ interface set is enabled. The port groups are configured independent of each other.

- Port group 1 contains interface 15 (QSFP+) and interfaces 17-20 (SFP+).
- Port group 2 contains interface 16 (QSFP+) and interfaces 21-24 (SFP+).

Command Mode

EXEC

Command Syntax

`show hardware port-group`

Guidelines

The `hardware port-group` command is available on DCS-7050Q-16 switches.

Example

- This command displays the status of ports in the two port groups on a DCS-7050Q-16 switch.

```
switch>show hardware port-group

Portgroup: 1   Active Ports: Et15/1-4
Port           State
-----------------------------
Ethernet17      ErrDisabled
Ethernet18      ErrDisabled
Ethernet19      ErrDisabled
Ethernet20      ErrDisabled
Ethernet15/1    Active
Ethernet15/2    Active
Ethernet15/3    Active
Ethernet15/4    Active

Portgroup: 2   Active Ports: Et16/1-4
Port           State
-----------------------------
Ethernet16/1    Active
Ethernet16/2    Active
Ethernet16/3    Active
Ethernet16/4    Active
Ethernet21      ErrDisabled
Ethernet22      ErrDisabled
Ethernet23      ErrDisabled
Ethernet24      ErrDisabled
switch>
```
**show interfaces capabilities**

The `show interfaces capabilities` command displays the model number, interface type, duplex mode, and flow control settings of the specified interfaces. The capabilities command is available on Ethernet and management interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] capabilities
```

**Parameters**

- `INTERFACE` Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command displays the model number, interface type, duplex mode and flow control settings for Ethernet interfaces 2 and 18.

```
switch>show interfaces ethernet 2,18 capabilities
Ethernet2
  Model: DCS-7150S-64-CL
  Type: 10GBASE-CR
  Speed/Duplex: 10G/full,40G/full,auto
  Flowcontrol: rx-(off,on,desired),tx-(off,on,desired)

Ethernet18
  Model: DCS-7150S-64-CL
  Type: 10GBASE-SR
  Speed/Duplex: 10G/full
  Flowcontrol: rx-(off,on),tx-(off,on)
```

switch>
show interfaces counters

The show interfaces counters command displays packet and byte counters for the specified interfaces. Counters displayed by the command include:

- inbound bytes
- inbound unicast packets
- inbound multicast packets
- inbound broadcast packets
- outbound bytes
- outbound unicast packets
- outbound multicast packets
- outbound broadcast packets

Command Mode
EXEC

Command Syntax
   show interfaces [INTERFACE] counters

Parameters
- INTERFACE  Interface type and numbers. Options include:
  - <no parameter>  all interfaces.
  - ethernet e_range  Ethernet interface range specified by e_range.
  - management m_range  Management interface range specified by m_range.
  - port-channel p_range  Port-Channel Interface range specified by p_range.

Related Commands
- show interfaces counters bins
- show interfaces counters errors
- show interfaces counters queue
- show interfaces counters rates

Examples
- This command displays byte and packet counters for Ethernet interfaces 1 and 2.
  
  switch>show interfaces ethernet 1-2 counters

  switch>
show interfaces counters bins

The `show interfaces counters bins` command displays packet counters, categorized by packet length, for the specified interfaces. Packet length counters that the command displays include:

- 64 bytes
- 65-127 bytes
- 128-255 bytes
- 256-511 bytes
- 512-1023 bytes
- 1024-1522 bytes
- larger than 1522 bytes

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] counters bins
```

**Parameters**

- `INTERFACE` Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

**Related Commands**

- `show interfaces counters`
- `show interfaces counters errors`
- `show interfaces counters queue`
- `show interfaces counters rates`

**Examples**

- This command displays packet counter results for Ethernet interfaces 1 and 2.

```
switch#show interfaces ethernet 1-2 counters bins
Input
Port          64 Byte       65-127 Byte      128-255 Byte     256-511 Byte

switch>
```
show interfaces counters errors

The show interfaces counters errors command displays the error counters for the specified interfaces.

Command Mode

EXEC

Command Syntax

show interfaces [INTERFACE] counters errors

Parameters

- INTERFACE Interface type and numbers. Options include:
  - <no parameter> all interfaces.
  - ethernet e_range Ethernet interface range specified by e_range.
  - management m_range Management interface range specified by m_range.
  - port-channel p_range Port-Channel Interface range specified by p_range.

Display Values

The table displays the following counters for each listed interface:

- FCS: Inbound packets with CRC error and proper size.
- Align: Inbound packets with improper size (undersized or oversized).
- Symbol: Inbound packets with symbol error and proper size.
- Rx: Total inbound error packets.
- Runts: Outbound packets that terminated early or dropped because of underflow.
- Giants: Outbound packets that overflowed the receiver and were dropped.
- Tx: Total outbound error packets.

Related Commands

- show interfaces counters
- show interfaces counters bins
- show interfaces counters queue
- show interfaces counters rates

Examples

- This command displays the error packet counters on Ethernet interfaces 1-2.

```
switch>show interfaces ethernet 1-2 counters errors
Port    FCS  Align  Symbol  Rx  Runts  Giants  Tx
Et1     0     0      0       0   0      0       0
Et2     0     0      0       0   0      0       0
switch>
```
show interfaces counters queue

The **show interfaces counters queue** command displays the queue drop counters for the specified interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] counters queue
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

**Related Commands**

- `show interfaces counters`
- `show interfaces counters bins`
- `show interfaces counters errors`
- `show interfaces counters rates`

**Example**

- This command displays the queue drop counters for Ethernet interfaces 1 and 2.

  ```
  switch>show interfaces ethernet 1-2 counters queue
  Port          InDrops
  Et1           180
  Et2           169
  switch>
  ```
show interfaces counters rates

The `show interfaces counters rates` command displays the received and transmitted packet rate counters for the specified interfaces. Counter rates provided include megabits per second (Mbps), kilopackets per second (Kpps) and utilization percentage.

All port rates are calculated approximations. Note that, when displaying rate information for a port channel, the rate value for the port channel will likely differ from the sum of the rates for the member ports. The discrepancy is likely to be larger for port channels with fewer ports, and will be most obvious in single-port port channels. The rate values for individual member ports are less inaccurate than the rate values for the port channel as a whole.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] counters rates
```

**Parameters**

- `INTERFACE` Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

**Related Commands**

- `show interfaces counters`
- `show interfaces counters bins`
- `show interfaces counters errors`
- `show interfaces counters queue`

**Example**

- This command displays rate counters for Ethernet interfaces 1 and 2.

```
switch>show interfaces ethernet 1-2 counters rates
Port Intvl In Mbps % In Kpps Out Mbps % Out Kpps
Et1 0:05 53.3 0.5% 5 31.2 0.3% 2
Et2 0:05 43.3 0.4% 4 0.1 0.0% 0
switch>
```
show interfaces negotiation

The `show interfaces negotiation` command displays the speed, duplex, and flow control auto-negotiation status for the specified interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] negotiation [INFO_LEVEL]
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
    
    Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - `<no parameter>` displays status and negotiated setting of local ports.
  - `detail` displays status and negotiated settings of local ports and their peers.

**Examples**

- This command displays the negotiated status of management 1 and 2 interfaces.
  ```
  switch>show interface management 1-2 negotiation
  Port       Autoneg            Negotiated Settings
             Status   Speed     Duplex    Rx Pause  Tx Pause
  ---------  -------  --------  --------  --------  --------  --------
  Ma1        success  100M      full      off       off
  Ma2        success  auto      auto      off       off
  switch>
  ```

- This command displays the negotiated status of management 1 interface and its peer interface.
  ```
  switch>show interface management 1 negotiation detail
  Management1 :
  Auto-Negotiation Mode  10/100/1000 BASE-T (IEEE Clause 28)
  Auto-Negotiation Status Success
  Advertisements          Speed        Duplex       Pause
                         ---------------       ---------------
  Local                10M/100M/1G        half/full     Disabled

  Resolution            100Mb/s        full          Rx=off,Tx=off
  ```

```
show interfaces phy

The `show interfaces phy` command displays physical layer characteristics for the specified interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] phy [INFO_LEVEL]
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` All interfaces.
  - `ethernet e_range` Ethernet interfaces in specified range.
    - Valid `e_range` formats include number, number range, or comma-delimited list of numbers and ranges.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - `<no parameter>` command displays table that summarizes PHY data.
  - `detail` command displays data block for each specified interface.

**Examples**

- This command summarizes PHY information for Ethernet interfaces 1-5.
  ```
  switch> show interfaces ethernet 1-5 phy

`switch>`
show interfaces status

The **show interfaces status** command displays the interface name, link status, vlan, duplex, speed, and type of the specified interfaces. When the command includes a link status, the results are filtered to display only interfaces whose link status match the specified type.

**Command Mode**
EXEC

**Command Syntax**
```
show interfaces [INTERFACE] status [STATUS_TYPE]
```

**Parameters**
- **INTERFACE** Interface type and numbers. Options include:
  - <no parameter> All existing interfaces.
  - `ethernet e_range` Ethernet interfaces in the specified range.
  - `management m_range` Management interfaces in the specified range.
  - `port-channel p_range` All existing port-channel interfaces in the specified range.
  
  Valid **e_range**, **m_range**, and **p_range** formats include number, number range, or comma-delimited list of numbers and ranges.

- **STATUS_TYPE** interface status upon which the command filters output. Options include:
  - <no parameter> command does not filter on interface status.
  - `connected` interfaces connected to another port.
  - `notconnect` unconnected interfaces that are capable of connecting to another port.
  - `disabled` interfaces that have been powered down or disabled.
  - `sub-interfaces` L3 subinterfaces configured on the switch.
  
  Command may include multiple status types (**connected** **notconnect** **disabled**), which can be placed in any order.

**Example**
- This command displays the status of Ethernet interfaces 1-5.
```
switch>show interfaces ethernet 1-5 status
Port  Name              Status       Vlan        Duplex  Speed  Type                Flags
Et1   connected         1             full    10G    10GBASE-SRL
Et2   connected         1             full    10G    10GBASE-SRL
Et3   connected         1             full    10G    10GBASE-SRL
Et4   connected         1             full    10G    10GBASE-SRL
Et5   notconnect        1             full    10G    Not Present
```

This command displays status information for all subinterfaces configured on the switch.
```
switch>show interfaces status sub-interfaces
Port  Name   Status  Vlan  Duplex  Speed  Type               Flags
Et1.1  connect  101  full   10G dot1q-encapsulation
Et1.2  connect  102  full   10G dot1q-encapsulation
Et1.3  connect  103  full   10G dot1q-encapsulation
Et1.4  connect  103  full   10G dot1q-encapsulation
```
show interfaces status errdisabled

The **show interfaces status errdisabled** command displays interfaces that are in errdisabled state, including their link status and errdisable cause.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] status errdisabled
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command displays the error-disabled ports.

```
switch>show interfaces status errdisabled
                     Port     Name             Status         Reason
                     ------- ----------------- ----------------- ------------------
                           Et49/2                        errdisabled    multi-lane-intf
                           Et49/3                        errdisabled    multi-lane-intf
                           Et49/4                        errdisabled    multi-lane-intf
switch>
```
show interfaces transceiver

The `show interfaces transceiver` command displays operational transceiver data for the specified interfaces.

Command Mode

EXEC

Command Syntax

```
show interfaces [INTERFACE] transceiver [DATA_FORMAT]
```

Parameters

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range`, and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

- **DATA_FORMAT** format used to display the data. Options include:
  - `<no parameter>` table entries separated by tabs.
  - `csv` table entries separated by commas.

Related Commands

- `show interfaces transceiver properties`

Examples

- This command displays transceiver data on Ethernet interfaces 1 through 4.

```
switch>show interfaces ethernet 1-4 transceiver
```

If device is externally calibrated, only calibrated values are printed.

N/A: not applicable, Tx: transmit, Rx: receive.
mA: milliamperes, dBm: decibels (milliwatts).

switch>
show interfaces transceiver channels

The **show interfaces transceiver channels** command displays current wavelength/frequency settings for the specified channels.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE e_range] transceiver channels
```

**Parameters**

- **INTERFACE** Interface type and port numbers.
  - **ethernet e_range** Ethernet interface range specified by `e_range`.

**Related Commands**

- **transceiver channel**
- **show interfaces transceiver hardware**

**Examples**

- This command displays the supported wavelengths/frequencies and their corresponding channel numbers on Ethernet interface 4 to slot 3 through 4.

```
switch(config-as-if-Et4/1/3)#show interfaces ethernet 4 / 3 / 4 transceiver channels
Name: Et4/3/4
100GHz- 50GHz-
Wavelength Frequency spacing spacing
(nm)     (GHz)     Channel Channel
---------- --------- ------- -------
1567.95   191,200        1       1
1567.54   191,250                 2
1567.13   191,300         2       3
1566.72   191,350                 4
....
1529.16   196,050        98
1528.77   196,100       50       99
1528.38   196,150              100
switch(config-as-if-Et4/1/3)#
```
show interfaces transceiver hardware

The `show interfaces transceiver hardware` command displays current wavelength/frequency settings for the specified transceiver interfaces.

Command Mode

EXEC

Command Syntax

```
show interfaces [INTERFACE e_range] transceiver hardware
```

Parameters

- `INTERFACE` Interface type and port numbers.
- `ethernet e_range` Ethernet interface range specified by `e_range`.

Related Commands

- `transceiver channel`
- `show interfaces transceiver channels`

Examples

- This command displays the current wavelength/frequency settings on Ethernet interface 4 to slot 3 through 4.

```
switch(config-as-if-Et4/1/3)#show interfaces ethernet 4 / 3 / 4 transceiver hardware
Name: Et4/3/4
Media Type: 10GBASE-DWDM
Configured Channel : 39
Configured Grid (GHz) : 50
Computed Frequency (GHz) : 193,100
Computed Wavelength (nm) : 1552.52
Operational Channel : 39 (Default)
Operational Grid (GHz) : 50 (Default)
Operational Frequency (GHz): 193,100
Operational Wavelength (nm): 1552.52
switch(config-as-if-Et4/1/3)#
```
show interfaces transceiver properties

The show interfaces transceiver properties command displays configuration information for the specified interfaces. Information provided by the command includes the media type, interface speed-duplex settings, speed-duplex operating state.

Command Mode
EXEC

Command Syntax
show interfaces [INTERFACE] transceiver properties

Parameters
- **INTERFACE** Interface type and numbers. Options include:
  - <no parameter> Display information for all interfaces.
  - ethernet e_range Ethernet interface range specified by e_range.
  - management m_range Management interface range specified by m_range.

Valid e_range and m_range formats include number, number range, or comma-delimited list of numbers and ranges.

Related Commands
- show interfaces transceiver

Examples
- This command displays the media type, speed, and duplex properties for Ethernet interfaces 1-3.

  switch>show interfaces ethernet 1-3 transceiver properties
  Name : Et1
  Administrative Speed: 10G
  Administrative Duplex: full
  Operational Speed: 10G (forced)
  Operational Duplex: full (forced)
  Media Type: 10GBASE-SRL

  Name : Et2
  Administrative Speed: 10G
  Administrative Duplex: full
  Operational Speed: 10G (forced)
  Operational Duplex: full (forced)
  Media Type: 10GBASE-SRL

  Name : Et3
  Administrative Speed: 10G
  Administrative Duplex: full
  Operational Speed: 10G (forced)
  Operational Duplex: full (forced)
  Media Type: 10GBASE-SRL

  switch>
show platform fm6000 agileport map

The `show platform fm6000 agileport map` command displays the list of Ethernet interfaces that are combinable to form a higher speed port.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show platform fm6000 agileport map
```

**Example**
- These commands displays the agile port map for the switch, then configures Ethernet interface 13 as a 40G port, subsuming Ethernet interfaces 15, 17 and 19.

```
switch#show platform fm6000 agileport map

+-------------------------------+---------------------------------------------+---------------------------------------------+---------------------------------------------+---------------------------------------------+
| Agile Ports                   | Interfaces subsumed in 40G link             |
+-------------------------------+---------------------------------------------+---------------------------------------------+---------------------------------------------+---------------------------------------------+
| Ethernet1                    | Ethernet3                                 | Ethernet5                                 | Ethernet7                                 |
| Ethernet2                    | Ethernet4                                 | Ethernet6                                 | Ethernet8                                 |
| Ethernet13                   | Ethernet15                                | Ethernet17                                | Ethernet19                                |
| Ethernet14                   | Ethernet16                                | Ethernet18                                | Ethernet20                                |

switch(config)#interface ethernet 13

switch(config-if-Et13)#speed forced 40gfull

WARNING! Executing this command will cause the forwarding agent to be restarted. All interfaces will briefly drop links and forwarding on all interfaces will momentarily stop.

Do you wish to proceed with this command? [y/N]

Ethernet13 configured for 40G.
Ethernet15, Ethernet17 and Ethernet19 are now subsumed.
switch(config-if-Et13)#
speed

The **speed** command configures the transmission speed and duplex setting for the configuration mode interface. The scope and effect of this command depends on the interface type. Interface types include:

- **40GBASE (QSFP+):** Default is 4x10G-full. **Speed forced 40gfull** and **Speed auto 40gfull** configure interface as a 40G port.
- **10GBASE-T:** Default is 10G-full. **Speed** command affects interface.
- **10GBASE (SFP+):** Default is 10G-full. **Speed** command does not affect interface.
- **1000BASE (copper):** Default is 1G-full. **speed auto 100full** affects interface.
- **1000BASE (fiber):** Default is 1G-full. **Speed** command does not affect interface.
- **10/100/1000:** Default is **auto-negotiation. Speed** command (10/100/1000 options) affects interface.

The **speed forced 40gfull** and **auto 40gfull** commands configure a QSFP+ Ethernet interface as a 40G port. The **no speed** and **no auto 40gfull** commands configure a QSFP+ Ethernet interface as four 10G ports. These commands must be applied to the /1 port. These commands are hitless on the 7050X, 7060X, 7250X, 7260X, 7280SE, 7300X, 7320X and 7500E series platforms. On all other platforms, these commands restart the forwarding agent, which will result in traffic disruption.

The **no speed** and **default speed** commands restore the default setting for the configuration mode interface by removing the corresponding **speed** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
speed MODE
no speed
default speed
```

**Parameters**

- **MODE** transmission speed and duplex setting. Options include:
  - **auto** auto negotiation mode.
  - **auto 40gfull** auto negotiation mode with clause 73 auto negotiation.

**Important!** Interfaces using clause 73 auto negotiation must connect to a device that runs clause 73 auto negotiation.

- **sfp-1000baset auto** auto-negotiation mode (1000BASE-T interfaces only).
- **forced 10000full** 10G full duplex.
- **forced 1000full** 1G full duplex.
- **forced 1000half** 1G half duplex.
- **forced 100full** 100M full duplex.
- **forced 100gfull** 100G full duplex.
- **forced 100half** 100M half duplex.
- **forced 10full** 10M full duplex.
- **forced 10half** 10M half duplex.
• **forced 40gfull**  40G full duplex.

On 40GBase and 100GBase interfaces, options that change the SFP+ and MXP interfaces (the **auto 40gfull**, the **forced 40gfull**, and the **no speed** options) may restart the forwarding agent on some switch platforms, disrupting traffic on all ports for more than a minute.

**Examples**

• This command configures a 40GBase interface as a 40G port.

```
switch(config)#interface ethernet 49/1
switch(config-if-Et49/1)#speed forced 40gfull
switch(config-if-Et49/1)#show interface ethernet 49/1 - 49/4 status
Port   Name          Status       Vlan        Duplex  Speed Type
Et49/1                  connected    in Po999      full    40G 40GBASE-CR4
Et49/2                  errdisabled  inactive    unconf unconf 40GBASE-CR4
Et49/3                  errdisabled  inactive    unconf unconf 40GBASE-CR4
Et49/4                  errdisabled  inactive    unconf unconf 40GBASE-CR4
switch(config-if-Et49/1)#
```

• This command configures a 40GBase interface as four 10G ports (default configuration).

```
switch(config-if-Et49/1)#no speed
switch(config-if-Et49/1)#show interface ethernet 49/1 - 49/4 status
Port   Name          Status       Vlan        Duplex  Speed Type
Et49/1                  connected    routed      full    10G 40GBASE-SR4
Et49/2                  connected    routed      full    10G 40GBASE-SR4
Et49/3                  connected    routed      full    10G 40GBASE-SR4
Et49/4                  notconnect   inactive      full    10G 40GBASE-SR4
switch(config-if-Et49/1)#
```
transceiver qsfp default-mode

The transceiver qsfp default-mode command specifies the transmission mode of all QSFP transceiver modules that are not explicitly configured.

Each QSFP+ module Ethernet interface is configurable as a single 40G port or as four 10G ports. The switch displays four ports for each interface. Each port’s status depends on the interface configuration:

- The /1 port is active (connected or not connected), regardless of the interface configuration.
- The /2, /3, and /4 ports are error-disabled when the interface is configured as a single 40G port.
- all ports are active (connected or not connected), when the interface is configured as four 10G ports.

The only available default-mode value is 4x10G; QSFP modules that are not configured through a speed command are operated as four 10G ports.

The no transceiver qsfp default-mode and default transceiver qsfp default-mode commands restore the default-mode transceiver setting to its default value of 4x10G.

Command Mode
Global Configuration

Command Syntax
  transceiver qsfp default-mode 4x10G
  no transceiver qsfp default-mode
  default transceiver qsfp default-mode

Guidelines
The transceiver qsfp default-mode 4x10g statement is always in running-config and cannot be modified or removed in the current release.
transceiver channel

The **transceiver channel** command displays transceiver wavelength/frequency by channel number. The channel numbering depends on the selected grid-spacing mode. The default grid-spacing mode is 50GHz-spacing.

- If the startup configuration does not specify the channel number for the interface, the transceiver will automatically tune to the default channel (i.e. channel-39 of 50GHz-spacing grid) when it is inserted.
- If the configured wavelength/frequency is not supported by the transceiver, the transceiver will be tuned to the default channel (i.e. channel-39 of 50GHz-spacing grid).

The interface is shutdown before the channel number is configured.

**Command Mode**

Global Configuration

**Command Syntax**

```
transceiver channel CHANNEL_NUMBER grid-spacing <SPACING_GRID>
no transceiver channel CHANNEL_NUMBER [GRID_SPACING <SPACING_GRID>]
default transceiver channel CHANNEL_NUMBER [GRID_SPACING <SPACING_GRID>]
```

**Parameters**

- **CHANNEL-NUMBER**  The default channel is 39 (50GHz-spacing grid) which corresponds to a frequency of 193,100 GHz and a wavelength of 1552.52 nm.
- **GRID_SPACING**  Grid-spacing mode (optional) depends on the selected grid-spacing mode. The default grid-spacing mode is 50GHz-spacing. For example, channel 39 of 50GHz-spacing grid is equivalent to channel 20 of 100GHz-spacing grid, which corresponds to a frequency of 193,100 GHz and a wavelength of 1552.52 nm.
  - `<SPACING_GRID>`  default grid-spacing mode in GHz.

**Related Commands**

- `show interfaces transceiver channels`
- `show interfaces transceiver hardware`

**Example**

- This command tunes the transceiver on slot number 4 to slot 1 through 3 of 50GHz-spacing grid.
  
  ```
  switch(config-as)#interface ethernet 4 / 1 / 3
  switch(config-if-Et4/1/3)#transceiver channel 1 grid-spacing 50
  switch(config-if-Et4/1/3)#
  ```
Chapter 11

Port Channels and LACP

This chapter describes channel groups, port channels, port channel interfaces, and the Link Aggregation Control Protocol (LACP). This chapter contains the following sections:

- Section 11.1: Port Channel Introduction
- Section 11.2: Port Channel Conceptual Overview
- Section 11.3: Port Channel Configuration Procedures
- Section 11.4: Load Balancing Hash Algorithms
- Section 11.5: Port Channel and LACP Configuration Commands

11.1 Port Channel Introduction

Arista's switching platforms support industry standard link aggregation protocols. Arista switches optimize traffic throughput by using MAC, IP addressing and services fields to effectively load share traffic across aggregated links. Managers can configure multiple ports into a logical port channel, either statically or dynamically through the IEEE Link Aggregation Control Protocol (LACP). Various negotiation modes are supported to accommodate any variety of configurations or peripheral requirements, including LACP fallback to support devices that need simple network connectivity to retrieve images or configurations prior to engaging port channel aggregation modes.

Arista’s Multi-chassis Link Aggregation protocol (MLAG) supports LAGs across paired Arista switches to provide both link aggregation and active/active redundancy.

11.2 Port Channel Conceptual Overview

11.2.1 Channel Groups and Port Channels

A port channel is a communication link between two switches that consists of matching channel group interfaces on each switch. A port channel is also referred to as a Link Aggregation Group (LAG). Port channels combine the bandwidth of multiple Ethernet ports into a single logical link.

A channel group is a collection of Ethernet interfaces on a single switch. A port channel interface is a virtual interface that consists of a corresponding channel group and connects to a compatible interface on another switch to form a port channel. Port channel interfaces can be configured and used in a manner similar to Ethernet interfaces. Port channel interfaces are configurable as layer 2 interfaces, layer 3 (routable) interfaces, and VLAN members. Most Ethernet interface configuration options are available to port channel interfaces.
11.2.2 Port Channel Subinterfaces

Port channel subinterfaces divide a single port channel interface into multiple logical L3 interfaces based on the 802.1q tag (VLAN ID) of incoming traffic. Subinterfaces are commonly used in the L2/L3 boundary device, but they can also be used to isolate traffic with 802.1q tags between L3 peers by assigning each subinterface to a different VRF.

For further details about subinterfaces, see Subinterfaces.

11.2.3 Link Aggregation Control Protocol (LACP)

The Link Aggregation Control Protocol (LACP), described by IEEE 802.3ad, defines a method for two switches to automatically establish and maintain LAGs. When LACP is enabled, a switch can configure LACP-compatible ports into a LAG (also called a channel group); the maximum number of ports per LAG varies by platform (numbers for each platform in the latest EOS release are available here: https://www.arista.com/en/support/product-documentation/supported-features).

LACP terminology refers to the local interface as the **actor** and the remote interface as the **partner**.

- In static mode, switches create port channels without awareness of their partner’s port channels. Packets may drop when port channel static aggregate configurations differ between switches.

  The switch aggregates static links without LACP negotiation. The switches do not send LACP packets nor process inbound LACP packets.

- In dynamic mode, Link Aggregation Groups are aware of their partners’ port channel states. Interfaces configured as dynamic LAGs are designated as **active** or **passive**.

  - Active interfaces send LACP Protocol Data Units (LACP PDUs) at a rate of one per second when forming a channel with an interface on the peer switch. An aggregate forms if the peer runs LACP in active or passive mode.
  
  - Passive interfaces only send LACP PDUs in response to PDUs received from the partner. The partner switch must be in active mode and initiates negotiation by sending an LACP packet. The passive mode switch receives and responds to the packet to form a LAG.

An **active** interface can form port channels with **passive** or **active** partner interfaces. Port channels are not formed when the interface on each switch is **passive**. Table 11-1 summarizes the valid LACP mode combinations:

<table>
<thead>
<tr>
<th>Switch 1</th>
<th>Switch 2</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>active</td>
<td>Links aggregate when LACP negotiation is successful.</td>
</tr>
<tr>
<td>active</td>
<td>passive</td>
<td>Links aggregate when LACP negotiation is successful.</td>
</tr>
<tr>
<td>passive</td>
<td>passive</td>
<td>Links aggregate without LACP.</td>
</tr>
<tr>
<td>on</td>
<td>—</td>
<td>Links aggregate without LACP.</td>
</tr>
</tbody>
</table>

During synchronization, interfaces transmit one LACP PDU per second. After synchronization is complete, interfaces exchange one PDU every thirty seconds, facilitated by a default timeout of 30 seconds and a failure tolerance of three. Under these parameters, when the switch does not receive an LACP PDU for an interface during a ninety second period, it records the partner interface as **failed** and removes the interface from the port channel.

**Fallback mode** allows an active LACP interface to maintain a LAG without receiving PDUs from its peer. (An active interface that is not in fallback mode does not form a LAG until it receives PDUs from and negotiates with its peer.) The fallback timer specifies the period the LAG waits to receive a peer PDU. Upon timer expiry, the port channel reverts to its configured fallback mode if one is configured.
**Static fallback**: the port channel maintains one active port while in fallback mode; all its other member ports are in standby mode until a LACP PDU is received by the port channel. All member ports send (and can receive) LACP PDUs, but only the active port sends or receives data.

**Individual fallback**: all member ports act as individual switch ports while in fallback mode. Individual port configuration (rather than port channel configuration) is active while the port channel is in fallback mode, with the exception of ACLs. This includes VLAN membership. All member ports send and receive data, and continue to send LACP PDUs. As soon as a LACP PDU is received by a member of the port channel, all ports revert to normal port channel operation.

The switch uses a link aggregation hash algorithm to determine the forwarding path within a Link Aggregation Group. The IP and MAC header fields can be selected as components of the hash algorithm.
11.3 Port Channel Configuration Procedures

These sections describe channel group and port channel configuration procedures:

- Section 11.3.1: Configuring a Channel Group
- Section 11.3.2: Configuring a Port Channel Interface
- Section 11.3.4: Configuring LACP

11.3.1 Configuring a Channel Group

Creating a Channel Group

The `channel-group` command assigns the configuration mode Ethernet interfaces to a channel group and specifies LACP attributes for the channel.

Channel groups are associated with a port channel interface immediately upon their creation. A command that creates a new channel group also creates a port channel with a matching ID. The port channel is configured in port-channel configuration mode. Configuration changes to a port channel interface propagate to all Ethernet interfaces in the corresponding channel group.

Example

- These commands assign Ethernet interfaces 1 and 2 to channel group 10, enable LACP, and place the channel group in a negotiating state:

```plaintext
switch(config)#interface ethernet 1-2
switch(config-if-Et1-2)#channel-group 10 mode active
```

Adding an Interface to a Channel Group

The `channel-group` command adds the configuration mode interface to the specified channel group if the channel group exists. When adding channels to a previously created channel group, the LACP mode for the new channel must match the mode for the existing group.

Example

- These commands add Ethernet interfaces 7 through 10 to previously created channel group 10, using the LACP mode under which it was created.

```plaintext
switch(config)#interface ethernet 7-10
switch(config-if-Et7-10)#channel-group 10 mode active
```

Removing an Interface from a Channel Group

The `no channel-group` command removes the configuration mode interface from the specified channel group. Deleting all members of a channel group does not remove the associated port channel interface from `running-config`.

Example

- These commands remove add Ethernet interface 8 from previously created channel group 10.

```plaintext
switch(config)#interface ethernet 8
switch(config-if-Et8)#no channel-group
```

---

552
Deleting a Channel Group
A channel group is deleted by removing all Ethernet interfaces from the channel group. A channel group’s LACP mode can be changed only by deleting the channel group and then creating an equivalent group with a different LACP mode. Deleting a channel group by removing all Ethernet interfaces from the group preserves the port channel interface and its configuration settings. View running-config to verify the deletion of all Ethernet interfaces from a channel group.

11.3.2 Configuring a Port Channel Interface

Creating a Port Channel Interface
The switch provides two methods for creating port channel interfaces:
• creating a channel group simultaneously creates an associated port channel.
• the interface port-channel command creates a port channel without assigning Ethernet channels to the new interface.

The interface port-channel command places the switch in interface-port channel configuration mode.

Example
• This command creates port channel interface 8 and places the switch in port channel interface configuration mode.
  switch(config)#interface port-channel 8
  switch(config-if-Po8)#

Deleting a Port Channel Interface
The no interface port-channel command deletes the configuration mode port channel interface and removes the channel group assignment for each Ethernet channel assigned to the channel associated with the port channel. Removing all Ethernet interfaces from a channel group does not remove the associated port channel interface from running-config.

11.3.3 Configuring Port Channel Subinterfaces
When configuring subinterfaces on a port channel interface (the virtual interface associated with a port channel), the following restrictions apply:
• An L3 interface with subinterfaces configured on it should not be made a member of a port channel.
• An interface that is a member of a port channel should not have subinterfaces configured on it.
• A subinterface cannot be made a made of a port channel.

Port channel subinterfaces are otherwise configured similarly to Ethernet subinterfaces. For additional information, see Subinterfaces.

11.3.4 Configuring LACP

Configuring the LACP Mode
The LACP mode is configured when a channel group is created. A channel group’s LACP mode cannot be modified without deleting the entire channel group. A channel group’s LACP mode can be altered without deleting the port channel interface associated with the channel group.
Example

- These commands create a channel group and place it in LACP-active mode.
  
  ```
  switch(config)#interface ethernet 1-2
  switch(config-if-Et1-2)#channel-group 10 mode active
  switch(config-if-Et1-2)#
  ```

Configuring the System Priority

Each switch is assigned a globally unique system identifier by concatenating the system priority (16 bits) to the MAC address of one of its physical ports (48 bits). The system identifier is used by peer devices when forming an aggregation to verify that all links are from the same switch. The system identifier is also used when dynamically changing aggregation capabilities in response to LACP information; the system with the numerically lower system identifier is permitted to dynamically change advertised aggregation capabilities.

The `lacp system-priority` command configures the switch’s LACP system priority.

Example

- This command assigns the system priority of 8192 to the switch.
  
  ```
  switch(config)#lacp system-priority 8192
  switch(config)#
  ```

Configuring Port Priority

LACP port priority determines the port that is active in a LAG in fallback mode. Numerically lower values have higher priority. Priority is supported on port channels with LACP-enabled physical interfaces.

The `lacp port-priority` command sets the aggregating port priority for the configuration mode interface.

Example

- This command assigns the port priority of 4096 to Ethernet interface 1.
  
  ```
  switch(config-if-Et1)#lacp port-priority 4096
  switch(config-if-Et1)#
  ```

Configuring the LACP Packet Transmission Rate

The LACP transmission interval sets the rate for LACP control packets. Supported values include

- **normal**: 30 seconds on synchronized interfaces; one second on interfaces that are synchronizing.
- **fast**: one second.

The `lacp rate` command configures the LACP transmission interval on the configuration mode interface.

Example

- This command sets the LACP rate to one second on Ethernet interface 4.
  
  ```
  switch(config-if-Et4)#lacp rate fast
  switch(config-if-Et4)#
  ```
Configuring LACP Fallback

Fallback mode (static or individual) is configured on a port channel interface with the `port-channel lacp fallback` command. The fallback timeout interval is configured with the `port-channel lacp fallback timeout` command. Fallback timeout settings persist in `running-config` without taking effect for interfaces that are not configured into fallback mode. The default fallback timeout period is 90 seconds.

Examples

- These commands enable LACP static fallback mode, then configure an LACP fallback timeout of 100 seconds on port channel interface 13. If LACP negotiation fails, only the member port with the lowest LACP priority will remain active until an LACP PDU is received by one of the member ports.

  ```
  switch(config)#interface port-channel 13
  switch(config-if-Po13)#port-channel lacp fallback static
  switch(config-if-Po13)#port-channel lacp fallback timeout 100
  switch(config-if-Po13)#show active
  interface Port-Channel13
    port-channel lacp fallback static
    port-channel lacp fallback timeout 100
  switch(config-if-Po13)#
  ```

- These commands enable LACP individual fallback mode, then configure an LACP fallback timeout of 50 seconds on port channel interface 17. If LACP negotiation fails, all member ports will act as individual switch ports, using port-specific configuration, until a LACP PDU is received by one of the member ports.

  ```
  switch(config)#interface port-channel 17
  switch(config-if-Po17)#port-channel lacp fallback individual
  switch(config-if-Po17)#port-channel lacp fallback timeout 50
  switch(config-if-Po17)#show active
  interface Port-Channel17
    port-channel lacp fallback individual
    port-channel lacp fallback timeout 50
  switch(config-if-Po17)#
  ```

Configuring Minimum Links

The `port-channel min-links` command specifies the minimum number of interfaces that the configuration mode LAG requires to be active. This command is supported only on LACP ports. If there are fewer ports than specified by this command, the port channel interface does not become active.

Example

- This command sets four as the minimum number of ports required by port channel 5 to be active.

  ```
  switch(config-if-Po5)#port-channel min-links 4
  switch(config-if-Po5)#
  ```

11.3.5 Displaying Port Channel Information

Port channel information is accessed using some of the `show` commands listed under Interface Display Commands. Note that when using the `show interfaces counters rates` command to display rate information for a port channel, rate values for the individual member ports are less inaccurate than rate values for the port channel.
Both the port channel rate and the individual port rates are calculated approximations; the rate value for a port channel will likely differ from the sum of the rates for the member ports. The discrepancy is likely to be larger for port channels with fewer ports, and will be most obvious in single-port port channels.
11.4 Load Balancing Hash Algorithms

The switch balances packet load across multiple links in a port channel by calculating a hash value based on packet header fields. The hash value determines the active member link through which the packet is transmitted. This method, in addition to balancing the load in the LAG, ensures that all packets in a data stream follow the same network path.

In network topologies that include MLAGs or multiple paths with equal cost (ECMP), programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links. This uneven distribution is avoided by performing different hash calculations on each switch routing the paths.

The `port-channel load-balance` command specifies the seed for hashing algorithms that balance the load across ports comprising a port channel. Available seed values vary by switch platform.

**Example**

- This command configures the hash seed of 10 on 7150 Series (FM6000 platform) switches.

```
switch(config)# port-channel load-balance fm6000 10
```

Hashing algorithm inputs varies by switch platform. These sections describe hashing algorithm inputs for each platform.

- **Section 11.4.1: Load Balance Hash Algorithms on 7048 and 7500 Series Switches**
- **Section 11.4.2: Load Balance Hash Algorithms on 7500E Series Switches**
- **Section 11.4.3: Load Balance Hash Algorithms on 7050 Series Switches**
- **Section 11.4.4: Load Balance Hash Algorithms on 7150 Series Switches**

11.4.1 Load Balance Hash Algorithms on 7048 and 7500 Series Switches

One command configures the load balance hash algorithm on 7048 and 7500 Series switches:

- **`port-channel load-balance petraA fields ip`**: controls the hash algorithm for IP packets by specifying the algorithm’s use of IP and MAC header fields. Fields that the command can specify include source and destination IP addresses, source and destination port fields (for TCP and UDP packets), and the entire MAC address header.

The hash algorithm for non-IP packets is not configurable and always includes the entire MAC header.

**Example**

- These commands configure the load balance algorithm for IP packets by using the entire MAC header.

```
switch(config)# port-channel load-balance petraA fields ip mac-header
```

11.4.2 Load Balance Hash Algorithms on 7500E Series Switches

One command configures the load balance hash algorithm on 7500E Series switches:

- **`port-channel load-balance arad fields ip`**: controls the hash algorithm for IP packets by specifying the algorithm’s use of IP and MAC header fields. Fields that the command can specify include source and destination IP addresses, source and destination port fields (for TCP and UDP packets), and the entire MAC address header.

The hash algorithm for non-IP packets is not configurable and always includes the entire MAC header.
Example

- These commands configure the load balance algorithm for IP packets by using the entire MAC header.
  
  ```
  switch(config)#port-channel load-balance arad fields ip mac-header
  switch(config)#
  ```

11.4.3 Load Balance Hash Algorithms on 7050 Series Switches

Three commands configure the load balance hash algorithm on 7050 Series switches:

- **port-channel load-balance trident fields ip** controls the hash algorithm for IP packets by specifying the algorithm's use of IP and MAC header fields. Fields that the command can specify include source and destination IP addresses, source and destination port fields (for TCP and UDP packets), and fields specified by the `port-channel load-balance trident fields mac` command.

- **port-channel load-balance trident fields ipv6** controls the hash algorithm for IPv6 packets by specifying the algorithm's use of IP and MAC header fields. Fields that the command can specify include source and destination IP addresses, source and destination port fields (for TCP and UDP packets), and fields specified by the `port-channel load-balance trident fields mac` command.

- **port-channel load-balance trident fields mac** controls the hash algorithm for non-IP packets by specifying the algorithm’s use of MAC header fields. Fields that the command can specify include the MAC source address, MAC destination address, and Ethernet type fields.

Example

- These commands configure the switch’s port channel load balance for non IP packets by using the MAC destination and Ethernet type fields in the hashing algorithm.
  
  ```
  switch(config)#port-channel load-balance trident fields mac dst-mac eth-type
  switch(config)#
  ```

11.4.4 Load Balance Hash Algorithms on 7150 Series Switches

Load balance profiles specify parameters used by hashing algorithms that distribute traffic across ports comprising a port channel or among component ECMP routes. The switch supports 16 load balance profiles, including the default profile. The default load balance profile is configured through `port-channel load-balance fm6000 fields ip` and `port-channel load-balance fm6000 fields mac` commands.

11.4.4.1 Load Balance Profiles

Load balance profiles are managed in load-balance-policies configuration mode. Load-balance-policies mode provides commands that display the contents of all configured profiles and place the switch in load-balance-profile command. Load balance profiles are created by entering load-balance-profile mode and edited while in that mode.

The `load-balance policies` command places the switch in load-balance-policies configuration mode. Load balance profiles specify the inputs used by the hashing algorithms that distribute traffic across ports comprising a port channel or among ECMP routes.

Example

- This command places the switch in load-balance-policies configuration mode.
  
  ```
  switch(config)#load-balance policies
  switch(config-load-balance-policies)#
  ```
Chapter 11: Port Channels and LACP

This command displays the contents of the four load balance profiles configured on the switch.

```
switch(config-load-balance-policies)#show active
load-balance policies
  load-balance fm6000 profile F-01
    port-channel hash-seed 22
    fields ip dscp
    distribution random port-channel

  load-balance fm6000 profile F-02
    fields ip protocol dst-ip
    distribution random port-channel

  load-balance fm6000 profile F-03
    fields ip protocol dst-ip
    fields mac dst-mac eth-type
    distribution random ecmp port-channel

  load-balance fm6000 profile F-04
switch(config-load-balance-policies)#
```

Creating a Load Balance Profile

The `load-balance fm6000 profile` command places the switch in load-balance-profile configuration mode to configure a specified load balance profile. The command specifies the name of the profile that subsequent commands modify. It creates a profile if the profile it references does not exist.

Example

- These commands enter load-balance-profile configuration mode, creates the LB-5 profile, and lists the default settings for the profile.

```
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-5
switch(config-load-balance-profile-LB-5)#show active all
load-balance policies
  load-balance fm6000 profile LB-5
    port-channel hash-seed 0
    fields mac dst-mac src-mac eth-type vlan-priority vlan-id
    fields ip protocol dst-ip dst-port src-ip src-port dscp
    no distribution symmetric-hash
    no distribution random

switch(config-load-balance-profile-LB-5)#
```

Configuring a Load Balance Profile

These commands are available in load-balance-profile configuration mode to specify the parameters that comprise a profile.

- The `fields ip` command specifies the L3/L4 data fields used by the hash algorithm defined by the configuration mode load balance profile.

- The `fields mac` command specifies the L2 data fields used by the hash algorithm defined by the configuration mode load balance profile.

- The `distribution symmetric-hash` command enforces traffic symmetry on data distributed by the hash algorithm defined by the configuration mode load balance profile. Symmetric traffic is the flow of both directions of a data stream across the same physical link.

- The `distribution random` command specifies the random distribution of data packets handled by the hash algorithm defined by the configuration mode load balance profile.
Example

- These commands configure the following components of the hash algorithm defined by the LB-7 load balance profile:
  - L2 header fields: MAC destination address, VLAN priority
  - L3/L4 header fields: Source IP address, protocol field
  - Symmetric hash distribution of IP and non-IP packets.

```
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-7
switch(config-load-balance-profile-LB-7)#fields ip src-ip protocol
switch(config-load-balance-profile-LB-7)#fields mac dst-mac vlan-priority
switch(config-load-balance-profile-LB-7)#distribution symmetric-hash mac-ip
switch(config-load-balance-profile-LB-7)#show active
load-balance policies
  load-balance fm6000 profile LB-7
    fields mac dst-mac vlan-priority
    fields ip protocol src-ip
    distribution symmetric-hash mac-ip
switch(config-load-balance-profile-LB-7)#exit
switch(config-load-balance-policies)#exit
switch(config)#exit
```

Assigning a Load Balance Profile to an Interface

The `ingress load-balance profile` command applies a specified load-balance profile to the configuration mode interface. Load balance profiles specify parameters used by hashing algorithms that distribute traffic across ports comprising a port channel or among ECMP routes. The switch supports 16 load balance profiles, including the default profile.

Example

- This command applies the `LB-1` load balance profile to port channel interface 100.

```
switch(config)#interface port-channel 100
switch(config-if-Po100)#ingress load-balance profile LB-1
switch(config-if-Po100)#show active
interface Port-Channel100
    ingress load-balance profile LB-1
switch(config-if-Po100)#
```

11.4.4.2 Default Load Balance Profile

Two commands configure the load balance default profile on 7150 Series switches:

- `port-channel load-balance fm6000 fields ip` controls the hash algorithm for IP packets by specifying the algorithm’s use of IP and MAC header fields. Fields that the command can specify include source and destination IP addresses, source and destination port fields (for TCP and UDP packets).

- `port-channel load-balance fm6000 fields mac` controls the hash algorithm for non-IP packets by specifying the algorithm’s use of MAC header fields. Fields that the command can specify include the MAC source address, MAC destination address, and Ethernet type, VLAN-ID, and VLAN-priority fields.
Example

- These commands configure the load balance default profile for IP packets by using source and destination IP address fields, along with source and destination port fields for TCP, and UDP packets.

  switch(config)#port-channel load-balance fm6000 fields ip ip-tcp-udp-header
  switch(config)#

- This command applies the default load balance profile to port channel interface 100.

  switch(config)#interface port-channel 100
  switch(config-if-Po100)#no ingress load-balance profile
  switch(config-if-Po100)#show active
  interface Port-Channel100
  switch(config-if-Po100)#
11.5 Port Channel and LACP Configuration Commands

Global Port Channel and LACP Configuration Commands
- `interface port-channel`
- `lacp system-priority`

Interface Configuration Commands – Ethernet Interface
- `channel-group`
- `lacp port-priority`
- `lacp rate`
- `port-channel lacp fallback`
- `port-channel lacp fallback timeout`
- `port-channel min-links`

Load Balance (Default) Commands
- `port-channel load-balance`
- `port-channel load-balance arad fields ip`
- `port-channel load-balance fm6000 fields ip`
- `port-channel load-balance fm6000 fields mac`
- `port-channel load-balance petraA fields ip`
- `port-channel load-balance trident fields ip`
- `port-channel load-balance trident fields ipv6`
- `port-channel load-balance trident fields mac`

Load Balance Policies Commands
- `distribution random`
- `distribution symmetric-hash`
- `fields ip`
- `fields mac`
- `ingress load-balance profile`
- `load-balance fm6000 profile`
- `load-balance policies`
- `port-channel hash-seed`

EXEC Commands
- `show etherchannel`
- `show lacp aggregates`
- `show lacp counters`
- `show lacp interface`
- `show lacp internal`
- `show lacp neighbor`
- `show lacp sys-id`
- `show load-balance profile`
- `show port-channel`
- `show port-channel limits`
- `show port-channel load-balance fields`
- `show port-channel summary`
- `show port-channel traffic`
channel-group

The `channel-group` command assigns the configuration mode Ethernet interfaces to a channel group and specifies LACP attributes for the channel. When adding channels to a previously created channel group, the LACP mode for the new channel must match the mode for the existing group.

Channel groups are associated with a port channel interface immediately upon their creation. A command that creates a new channel group also creates a port channel with a matching ID. The port channel is configured in port-channel configuration mode. Configuration changes to a port channel interface propagate to all Ethernet interfaces in the corresponding channel group. The `interface port-channel` command places the switch in interface-port-channel configuration mode.

The `no channel-group` and `default channel group` commands remove the configuration mode interface from the specified channel group.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
channel-group number LACP_MODE
no channel-group
default channel-group
```

**Parameters**

- `number` specifies a channel group ID. Values range from 1 through 2000.
- `LACP_MODE` specifies the interface LACP mode. Values include:
  - `mode on` Interface is a static port channel, LACP disabled. Port neither verifies nor negotiates port channel membership.
  - `mode active` Interface is an active LACP port that transmits and receives LACP negotiation packets.
  - `mode passive` Interface is a passive LACP port that only responds to LACP negotiation packets.

**Guidelines: Port Channels**

You can configure a port channel to contain many ports, but only a subset may be active at a time. All active ports in a port channel must be compatible. Compatibility includes many factors and is platform-specific. For example, compatibility may require identical operating parameters such as speed and maximum transmission unit (MTU). Compatibility may only be possible between specific ports because of the internal organization of the switch.

**Guidelines: MLAG Configurations**

Static LAG is not recommended in MLAG configurations. However, these considerations apply when the channel group mode is `on` while configuring static MLAG:

- When configuring multiple interfaces on the same static port channel:
  - all interfaces must physically connect to the same neighboring switch.
  - the neighboring switch must configure all interfaces into the same port channel.

  The switches are misconfigured when these conditions are not met.
- Disable the static port channel membership before moving any cables connected to these interfaces or changing a static port channel membership on the remote switch.
Example

- These commands assign Ethernet interfaces 8 and 9 to channel group 10, and enable LACP in negotiating mode.

```plaintext
switch(config)#interface ethernet 8-9
switch(config-if-Et8-9)#channel-group 10 mode active
switch(config-if-Et8-9)#show active
interface Ethernet8
  channel-group 10 mode active
interface Ethernet9
  channel-group 10 mode active
switch(config-if-Et8-9)#
```
distribution random

The `distribution random` command specifies the random distribution of data packets handled by the hash algorithm defined by the configuration mode load balance profile. All data fields and hash seeds that are configured for the profile are used as seeds for the random number generator that defines the distribution of individual packets.

Command options allow for the random distribution of traffic across port channel links and ECMP routes. Random distribution can be enabled for either, both, or neither.

The `no distribution random` and `default distribution random` commands remove random distribution on the configuration mode load balance profile by deleting the corresponding `distribution random` command from the configuration.

Command Mode
Load-balance-profile Configuration

Command Syntax
```
distribution random BALANCE_TYPE
no distribution random
default distribution random
```

Parameters
- **SCOPE** Specifies use of random distribution for port channels and ECMP routes. Options include:
  - `<no parameter>` Random distribution is enabled for ECMP routes and port channel links.
  - `ecmp` Random distribution is enabled for ECMP routes.
  - `port-channel` Random distribution is enabled for port channel links.
  - `ecmp port-channel` Random distribution is enabled for ECMP routes and port channel links.
  - `port-channel ecmp` Random distribution is enabled for ECMP routes and port channel links.

Guidelines
The `distribution random` command takes precedence over the `distribution symmetric-hash` command when both methods are simultaneously enabled.

Related Commands
- `load-balance fm6000 profile` places the switch in load-balance-profile configuration mode.

Example
- These commands configure symmetric hashing on all traffic distributed through the algorithm defined by the LB-1 load balance profile.
```
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
switch(config-load-balance-profile-LB-1)#distribution random ecmp port-channel
switch(config-load-balance-profile-LB-1)#show active
load-balance policies
  load-balance fm6000 profile LB-1
distribution random ecmp port-channel
switch(config-load-balance-profile-LB-1)#
```
distribution symmetric-hash

The distribution symmetric-hash command enforces traffic symmetry on data distributed by the hash algorithm defined by the configuration mode load balance profile. Symmetric traffic is the flow of both directions of a data stream across the same physical link.

Two symmetric-hash options specify the traffic upon which symmetry is enforced:

- distribution symmetric-hash mac specifies that only non-IP traffic is hashed symmetrically. IP traffic is hashed normally without regard to symmetry.
- distribution symmetric-hash mac-ip specifies that all traffic is hashed symmetrically.

The no distribution symmetric-hash and default distribution symmetric-hash commands remove the specified hashing symmetry restriction on the configuration mode load balance profile by deleting the corresponding distribution symmetric-hash command from running-config.

Command Mode
Load-balance-profile Configuration

Command Syntax

distribution symmetric-hash FIELD_TYPE
no distribution symmetric-hash
default distribution symmetric-hash

Parameters

- FIELD_TYPE fields the hashing algorithm uses for layer 3 routing. Options include:
  - mac non-IP traffic is hashed symmetrically.
  - mac-ip all traffic is hashed symmetrically.

Guidelines

The distribution random command takes precedence over the distribution symmetric-hash command when both methods are simultaneously enabled.

Related Commands

- load-balance fm6000 profile places the switch in load-balance-profile configuration mode.

Example

- These commands configure symmetric hashing on all traffic distributed through the algorithm defined by the LB-1 load balance profile.

    switch(config)#load-balance policies
    switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
    switch(config-load-balance-profile-LB-1)#distribution symmetric-hash mac-ip
    switch(config-load-balance-profile-LB-1)#show active
    load-balance policies
    load-balance fm6000 profile LB-1
distribution symmetric-hash mac-ip
    switch(config-load-balance-profile-LB-1)#
fields ip

The fields ip command specifies the L3/L4 data fields used by the hash algorithm defined by the configuration mode load balance profile. When a load balance profile is assigned to a port channel or Ethernet interface, its associated hash algorithm determines the distribution of packets that ingress the interface. Profile algorithms can load balance packets across port channel links or ECMP routes.

The switch calculates a hash value by using the packet header fields to balance packets across links. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The no fields ip configures the algorithm not to use L3/L4 data fields. The default fields ip command restores the default data L3/L4 fields to the load balancing algorithm defined by the configuration mode profile by removing the corresponding fields ip or no fields ip command from running-config.

Command Mode
Load-balance-profile Configuration

Command Syntax
fields ip IP_FIELD
no fields ip
default fields ip

Parameters
- **IP_FIELD** specifies the L3/L4 fields the hashing algorithm uses. Options include:
  - **dscp** algorithm uses dscp field.
  - **dst-ip** algorithm uses destination IP address field.
  - **dst-port** algorithm uses destination TCP/UDP port field.
  - **protocol** algorithm uses protocol field.
  - **src-ip** algorithm uses source IP address field.
  - **src-port** algorithm uses source TCP/UDP port field.

Command may include from one to six fields, in any combination and listed in any order. The default setting is the selection of all fields.

Related Commands
- **load-balance fm6000 profile** places the switch in load-balance-profile configuration mode.
Example

- These commands specify the IP source and protocol fields as components of the hash algorithm defined by the LB-1 load balance profile.

```text
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
switch(config-load-balance-profile-LB-1)#fields ip src-ip protocol
switch(config-load-balance-profile-LB-1)#show active
  load-balance policies
   load-balance fm6000 profile LB-1
    fields ip protocol src-ip
switch(config-load-balance-profile-LB-1)#
```
fields mac

The `fields mac` command specifies the L2 data fields used by the hash algorithm defined by the configuration mode load balance profile. When a load balance profile is assigned to a port channel or Ethernet interface, its associated hash algorithm determines the distribution of packets that ingress the interface. Profile algorithms can load balance packets across port channel links or ECMP routes.

The switch calculates a hash value using the packet header fields to balance packets across links. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no fields mac` configures the algorithm not to use L2 data fields. The `default fields mac` command restores the default data L2 fields to the load balancing algorithm defined by the configuration mode profile by removing the corresponding `fields mac` or `no fields mac` command from `running-config`.

**Command Mode**

Load-balance-profile Configuration

**Command Syntax**

```
fields mac MAC_FIELD
no fields mac
default fields mac
```

**Parameters**

- `MAC_FIELD` specifies the L2 fields the hashing algorithm uses. Options include:
  - `dst-mac` algorithm uses MAC destination field.
  - `eth-type` algorithm uses MAC destination field.
  - `src-mac` algorithm uses MAC source field.
  - `vlan-id` algorithm uses VLAN ID field.
  - `vlan-priority` algorithm uses VLAN priority field.

**Related Commands**

- `load-balance fm6000 profile` places the switch in load-balance-profile configuration mode.

**Example**

- These commands specify the MAC destination and VLAN priority fields as components of the hash algorithm defined by the LB-1 load balance profile.

```bash
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
switch(config-load-balance-profile-LB-1)#fields mac dst-mac vlan-priority
switch(config-load-balance-profile-LB-1)#show active
load-balance policies
  load-balance fm6000 profile LB-1
    fields mac dst-mac vlan-priority
switch(config-load-balance-profile-LB-1)#
```
**ingress load-balance profile**

The **ingress load-balance profile** command applies the specified load-balance profile to the configuration mode interface. Load balance profiles specify parameters used by hashing algorithms that distribute traffic across ports comprising a port channel or among ECMP routes. The switch supports 16 load balance profiles, including the default profile.

Load balance profiles can be assigned to Ethernet and port channel interfaces. Profiles define the distribution method of traffic that ingresses the interface among the ports comprising a port channel or routes comprising an ECMP.

The default load balance profile is configured through `port-channel load-balance fm6000 fields ip` and `port-channel load-balance fm6000 fields mac` commands.

The **no ingress load-balance profile** and **default ingress load-balance profile** commands restore the default load balance profile for the configuration mode interface by removing the corresponding **ingress load-balance profile** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

- `ingress load-balance profile profile_name`
- `no ingress load-balance profile`
- `default ingress load-balance profile`

**Parameters**

- **profile_name** name of profile assigned to interface.

**Example**

- This command applies the **LB-1** load balance profile to port channel interface 100.

```plaintext
switch(config)#interface port-channel 100
switch(config-if-Po100)#show active
interface Port-Channel100
switch(config-if-Po100)#ingress load-balance profile LB-1
switch(config-if-Po100)#show active
interface Port-Channel100
  ingress load-balance profile LB-1
switch(config-if-Po100)#
```
interface port-channel

The interface port-channel command places the switch in port-channel interface configuration mode for modifying parameters of specified link aggregation (LAG) interfaces. When entering configuration mode to modify existing port channel interfaces, the command can specify multiple interfaces.

The command creates a port channel interface if the specified interface does not exist prior to issuing the command. When creating an interface, the command can only specify a single interface.

The no interface port-channel and default interface port-channel commands delete the specified LAG interfaces from running-config.

Command Mode
Global Configuration

Command Syntax
- interface port-channel p_range
- no interface port-channel p_range
- default interface port-channel p_range

Parameter
- p_range port channel interfaces (number, range, or comma-delimited list of numbers and ranges).
  Port channel numbers range from 1 to 2000.

Guidelines
When configuring a port channel, you do not need to issue the interface port-channel command before assigning a port to the port channel (see the channel-group command). The port channel number is implicitly created when a port is added to the specified port channel with the channel-group number command.

To display ports that are members of a port channel, enter show port-channel. To view information about hardware limitations for a port channel, enter show port-channel limits.

All active ports in a port channel must be compatible. Compatibility comprises many factors and is specific to a given platform. For example, compatibility may require identical operating parameters such as speed and/or maximum transmission unit (MTU). Compatibility may only be possible between specific ports because of internal organization of the switch.

You can configure a port channel with a set of ports such that more than one subset of the member ports are mutually compatible. Port channels in EOS are designed to activate the compatible subset of ports with the largest aggregate capacity. A subset with two 40 Gbps ports (aggregate capacity 80 Gbps) has preference to a subset with five active 10 Gbps ports (aggregate capacity 50 Gbps).

Example
- This example creates port channel interface 3:
  switch(config)#interface port-channel 3
  switch(config-if-Po3)#
**IACP port-priority**

The `lacp port-priority` command sets the aggregating port priority for the configuration mode interface. Priority is supported on port channels with LACP-enabled physical interfaces. LACP port priority determines the port that is active in a LAG in fallback mode. Numerically lower values have higher priority.

Each port in an aggregation is assigned a 32-bit port identifier by prepending the port priority (16 bits) to the port number (16 bits). Port priority determines the ports that are placed in standby mode when hardware limitations prevent a single aggregation of all compatible ports.

Priority numbers range from 0 to 65535. The default is 32768. Interfaces with higher priority numbers are placed in standby mode before interfaces with lower priority numbers.

The `no lacp port-priority` and `default lacp port-priority` commands restore the default port-priority to the configuration mode interface by removing the corresponding `lacp port-priority` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

- `lacp port-priority priority_value`
- `no lacp port-priority`
- `default lacp port-priority`

**Parameters**

- `priority_level` port priority. Values range from 0 to 65535. Default is 32768

**Example**

- These commands assign the port priority of 4096 to Ethernet interface 8.

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#lacp port-priority 4096
switch(config-if-Et8)#show active
interface Ethernet8
    lacp port-priority 4096
switch(config-if-Et8)#
```
**lACP rate**

The `lACP rate` command configures the LACP transmission interval on the configuration mode interface. The LACP timeout specifies the transmission rate of LACP control packets to interfaces supporting LACP. Supported rates include:

- **normal**: 30 seconds with synchronized interfaces; one second while interfaces are synchronizing.
- **fast**: one second.

This command is supported on LACP-enabled interfaces. The default value is **normal**.

The `no lACP rate` and `default lACP rate` commands restore the default value of **normal** on the configuration mode interface by deleting the corresponding lACP rate command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
  lACP rate RATE_LEVEL
  no lACP rate
  default lACP rate
```

**Parameters**

- **RATE_LEVEL**  LACP transmission interval. Options include:
  - **fast**: one second.
  - **normal**: 30 seconds for synchronized interfaces; one second while interfaces synchronize.

**Examples**

- This command sets the LACP rate to one second on Ethernet interface 4.
  
  Switch(config-if-Et4)# lACP rate fast
  Switch(config-if-Et4)#
**IACP system-priority**

The **IACP system-priority** command configures the switch’s LACP system priority. Values range between 0 and 65535. Default value is 32768.

Each switch is assigned a globally unique 64-bit system identifier by prepending the system priority (16 bits) to the MAC address of one of its physical ports (48 bits). Peer devices use the system identifier when forming an aggregation to verify that all links are from the same switch. The system identifier is also used when dynamically changing aggregation capabilities resulting from LACP data; the system with the numerically lower system identifier can dynamically change advertised aggregation parameters.

The **no IACP system-priority** and **default IACP system-priority** commands restore the default system priority by removing the IACP system-priority command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
IACP system-priority priority_value
no IACP system-priority
default IACP system-priority
```

**Parameters**

- **priority_value** system priority number. Values range from 0 to 65535. Default is 32768.

**Example**

- This command assigns the system priority of 8192 to the switch.

```
switch(config)#IACP system-priority 8192
switch(config)#
```
load-balance fm6000 profile

The `load-balance fm6000 profile` command places the switch in load-balance-profile configuration mode to configure a specified load balance profile. The command specifies the name of the profile that subsequent commands modify. It creates a profile if the profile it references does not exist.

Load balance profiles specify parameters used by hashing algorithms that distribute traffic across ports comprising a port channel or among component ECMP routes. The switch supports 16 load balance profiles, including the default profile. The default load balance profile is configured through `port-channel load-balance fm6000 fields ip` and `port-channel load-balance fm6000 fields mac` commands.

The load balance profile name is referenced when it is applied to an interface. The default profile is not associated with a name and is applied to an interface in the absence of a named profile assignment.

The `no load-balance fm6000 profile` and `default load-balance fm6000 profile` commands delete the specified load balance profile from `running-config`. Profiles that are assigned to an interface cannot be deleted. Attempts to delete an assigned profile generate a `profile in use` error messages.

The `load-balance fm6000 profile` command is accessible from load-balance-policies configuration mode. Load-balance-profile configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting load-balance-policies configuration mode does not affect the configuration. The `exit` command returns the switch to load-balance-policies configuration mode.

**Command Mode**
Load-balance-policies Configuration

**Command Syntax**

```markdown
load-balance fm6000 profile profile_name
no load-balance fm6000 profile profile_name
default load-balance fm6000 profile profile_name
```

**Parameters**

- `profile_name` name of the load-balance profile.

**Commands Available in Load-balance-profile Configuration Mode**

- `fields ip`
- `fields mac`
- `distribution random`
- `distribution symmetric-hash`
- `port-channel hash-seed`
- `show active` displays the contents of the configuration mode profile.

**Related Commands**

- `load-balance policies` places the switch in load-balance-policies configuration mode.
- `ingress load-balance profile` applies a load-balance profile to an Ethernet or port channel interface.
- `show load-balance profile` displays the contents of load balance profiles.
Example

- These commands enter load-balance-profile configuration mode, creates the LB-1 profile, and lists the default settings for the profile.

```
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
switch(config-load-balance-profile-LB-1)#show active all
load-balance policies
  load-balance fm6000 profile LB-1
    port-channel hash-seed 0
    fields mac dst-mac src-mac eth-type vlan-priority vlan-id
    fields ip protocol dst-ip dst-port src-ip src-port dscp
    no distribution symmetric-hash
    no distribution random
switch(config-load-balance-profile-LB-1)#
```
load-balance policies

The **load-balance policies** command places the switch in load-balance-policies configuration mode. Load-balance-policies configuration mode provides commands for managing load-balance profiles. Load balance profiles specify the inputs used by the hashing algorithms that distribute traffic across ports comprising a port channel or among ECMP routes.

The **no load-balance policies** and **default load-balance policies** commands delete all load balance profiles from **running-config**. The command generates an error message when at least one profile is assigned to an interface.

Load-balance-policies configuration mode is not a group change mode; **running-config** is changed immediately upon entering commands. Exiting load-balance-policies configuration mode does not affect **running-config**. The **exit** command returns the switch to global configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

```
load-balance policies
no load-balance policies
default load-balance policies
```

**Commands Available in Load-balance-policies Configuration Mode**

- **load-balance fm6000 profile** places the switch in load-balance-profile configuration mode.
- **show active** displays contents of all load balance profiles.

**Related Commands**

- **ingress load-balance profile** applies a load-balance profile to an Ethernet or port channel interface.
- **show load-balance profile** displays the contents of load balance profiles.

**Example**

- This command places the switch in load-balance-policies configuration mode.

```
switch(config)#load-balance policies
switch(config-load-balance-policies)#
```

- This command displays the contents of the three configured load balance profiles.

```
switch(config-load-balance-policies)#show active
load-balance policies
  load-balance fm6000 profile F-01
    port-channel hash-seed 22
    fields ip dscp
display random port-channel
!
  load-balance fm6000 profile F-02
    fields ip protocol dst-ip
    fields mac dst-mac eth-type
display random ecmp port-channel
!
  load-balance fm6000 profile F-03
switch(config-load-balance-policies)#
```
port-channel hash-seed

The `port-channel hash-seed` command specifies the seed used by the hash algorithm defined by the configuration mode load balance profile when distributing the load across ports comprising a port channel. When a load balance profile is assigned to a port channel or Ethernet interface, its associated hash algorithm determines the distribution of packets that ingress the interface. Profile algorithms can load balance packets across port channel links or ECMP routes.

The hash seed that the algorithm uses to select port channel links or ECMP routes is configured by the `ip load-sharing` command.

The `no port-channel hash-seed` and `default port-channel hash-seed` commands restore the default hash seed value of 0 to the load balancing algorithm defined by the configuration mode profile by removing the corresponding `port-channel hash-seed` command from `running-config`.

**Command Mode**
Load-balance-profile Configuration

**Command Syntax**
```
port-channel hash-seed number
no port-channel hash-seed
default port-channel hash-seed
```

**Parameters**
- `number` The hash seed. Value ranges from 0 to 39.

**Related Commands**
- `load-balance fm6000 profile` places the switch in load-balance-profile configuration mode.

**Example**
- These commands configure the port-channel hash seed of 22 for the hash algorithm defined by the LB-1 load balance profile.

```
switch(config)#load-balance policies
switch(config-load-balance-policies)#load-balance fm6000 profile LB-1
switch(config-load-balance-profile-LB-1)#port-channel hash-seed 22
switch(config-load-balance-profile-LB-1)#show active
load-balance policies
load-balance fm6000 profile LB-1
   port-channel hash-seed 22
switch(config-load-balance-profile-LB-1)#
```
**port-channel lacp fallback**

The `port-channel lacp fallback` command enables the LACP fallback mode on the interface.

LACP fallback is unconfigured and disabled by default. An LACP interface without fallback enabled does not form a LAG until it receives PDUs from its peer.

LACP fallback can be configured on an interface in static or individual mode:

- **static mode** the port channel member with the lowest LACP port priority is active and maintains contact with the peer (sending and receiving data) while other port channel members remain in standby mode until a LACP PDU is received. All members continue to send (and can receive) LACP PDUs.

- **individual mode** all port channel members act as individual ports, reverting to their port-specific configuration while the channel is in fallback mode, and continue to send and receive data. All members continue to send LACP PDUs until a LACP PDU is received by one of the member ports.

The `no port-channel lacp fallback` and `default port-channel lacp fallback` commands disable LACP fallback mode on the configuration mode interface by removing the corresponding `port-channel lacp fallback` command from `running-config`.

**Command Mode**

Interface-Port-Channel Configuration

**Command Syntax**

```
port-channel lacp fallback [MODE]
no port-channel lacp fallback
default port-channel lacp fallback
```

**Parameters**

- **MODE** LACP fallback mode. Options include:
  - `<no parameter>` enables static LACP fallback mode.
  - `static` enables static LACP fallback mode.
  - `individual` enables individual LACP fallback mode.

**Related Commands**

- `port-channel lacp fallback timeout` configures the fallback timeout period for a port channel interface. The default LACP fallback timeout period is 90 seconds.
- `lacp port-priority` configures the port priority for an individual interface.

**Examples**

- These commands enable LACP static fallback mode, then configure an LACP fallback timeout of 100 seconds on port channel interface 13. If LACP negotiation fails, only the member port with the lowest LACP priority will remain active until an LACP PDU is received by one of the member ports.

```
switch(config)#interface port-channel 13
switch(config-if-Po13)#port-channel lacp fallback static
switch(config-if-Po13)#port-channel lacp fallback timeout 100
switch(config-if-Po13)#show active
interface Port-Channel13
  port-channel lacp fallback static
  port-channel lacp fallback timeout 100
switch(config-if-Po13)#
```
These commands enable LACP individual fallback mode, then configure an LACP fallback timeout of 50 seconds on port channel interface 17. If LACP negotiation fails, all member ports will act as individual switch ports, using port-specific configuration, until a LACP PDU is received by one of the member ports.

```
switch(config)#interface port-channel 17
switch(config-if-Po17)#port-channel lACP fallback individual
switch(config-if-Po17)#port-channel lACP fallback timeout 50
switch(config-if-Po17)#show active
interface Port-Channel17
  port-channel lACP fallback individual
  port-channel lACP fallback timeout 50
switch(config-if-Po17)#
```
port-channel lacp fallback timeout

The `port-channel lacp fallback timeout` command specifies the fallback timeout period for the configuration mode interface.

Fallback timeout settings persist in `running-config` without taking effect for interfaces that are not configured into fallback mode. The default fallback timeout period is 90 seconds.

The `no port-channel lacp fallback timeout` and `default port-channel lacp fallback timeout` commands restore the default fallback timeout of 90 seconds for the configuration mode interface by removing the corresponding `port-channel lacp fallback timeout` command from `running-config`.

**Command Mode**
- Interface-Port-Channel Configuration

**Command Syntax**

```
port-channel lacp fallback timeout period
no port-channel lacp fallback timeout
default port-channel lacp fallback timeout
```

**Parameters**

- `period` maximum interval between receipt of LACP PDU packets (seconds). Value ranges from 1 to 300 seconds. Default value is 90.

**Related Commands**

- `port-channel lacp fallback` configures fallback mode for a port channel interface.

**Guidelines**

The fallback timeout period should not be shorter than the LACP transmission interval (`lACP rate`). The default LACP transmission interval is 30 seconds.

**Example**

- This command enables LACP fallback mode, then configures an LACP fallback timeout of 100 seconds on port channel interface 13.

```bash
switch(config)#interface port-channel 13
switch(config-if-Po13)#port-channel lacp fallback
switch(config-if-Po13)#port-channel lacp fallback timeout 100
switch(config-if-Po13)#show active
interface Port-Channel13
  port-channel lacp fallback
  port-channel lacp fallback timeout 100
switch(config-if-Po13)#
```
port-channel load-balance

The **port-channel load-balance** command specifies the seed in the hashing algorithm that balances the load across ports comprising a port channel. Available seed values vary by switch platform.

The **no port-channel load-balance** and **default port-channel load-balance** commands remove the **port-channel load-balance** command from **running-config**, restoring the default hash seed value of 0.

**Command Mode**
Global Configuration

**Command Syntax**

```
port-channel load-balance platform { hash_seed | fields ip fields | hash
hash_function }

no port-channel load-balance platform [hash_seed]
default port-channel load-balance platform [hash_seed]
```

**Parameters**

<table>
<thead>
<tr>
<th>Important! Parameter options vary by switch model. Verify available options with the ? command.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>platform</strong></td>
</tr>
<tr>
<td>• <strong>hash_seed</strong></td>
</tr>
<tr>
<td>• arad</td>
</tr>
<tr>
<td>• fm6000</td>
</tr>
<tr>
<td>• petraA</td>
</tr>
<tr>
<td>• trident</td>
</tr>
</tbody>
</table>

For trident platform switches, algorithms using hash seeds between 0 and 15 typically result in more effective distribution of data streams across the port channels.

• **fields** | Which fields will be used as inputs to the port channel hash. |
| • gre | Configure which GRE fields are inputs to the hash. |
| • ip | Configure which fields are inputs to the hash for IPv4 packets. |
| • ipv6 | Configure which fields are inputs to the hash for IPv6 packets. |
| • mac | Configure which MAC fields are inputs to the hash. |
| • mac-in-mac | Configure which MAC-in-MAC fields are inputs to the hash. |
| • mpls | Configure which MPLS fields are inputs to the hash. |
| • destination-ip | Use the layer 3 IP destination address in the hash. |
| • destination-port | Use the layer 4 TCP/UDP destination port in the hash. |
| • dst-ip | Use the destination IP address in the hash. |
| • dst-mac | Use the destination Payload MAC in the hash (or the destination MAC address in the MAC hash). |
| • eth-type | Use the Ethernet type in the MAC hash. |
| • ip-in-ip | Use the outer IP header in the hash for IPv4 over IPv4 GRE tunnel. |
| • ip-in-ipv6 | Use the outer IP header in the hash for IPv4 over IPv6 GRE tunnel. |
| • ipv6-in-ip | Use the outer IP header in the hash for IPv6 over IPv4 GRE tunnel. |
| • ipv6-in-ipv6 | Use the outer IP header in the hash for IPv6 over IPv6 GRE tunnel. |
• **ip-tcp-udp-header** Use the layer 3 and layer 4 hashes.
• **isid** Use the MAC-in-MAC ISID in the hash.
• **label** Use the MPLS label in the hash.
• **mac-header** Use the MAC hash.
• **outer-mac** Use the outer MAC of source and destination in the hash.
• **source-ip** Use the layer 3 IP source address in the hash.
• **src-ip** Use the source IP address in the hash.
• **source-port** Use layer 4 TCP/UDP source port in the hash.
• **src-mac** Use the source payload MAC in the hash (or the source MAC address in the MAC hash).

• **hash_function** Specifies the hash polynomial function. Values range from 0-2.

**Example**
• This command configures a hash seed of 10 on an FM6000 platform switch.

```
switch(config)#port-channel load-balance fm6000 10
switch(config)#
```
The `port-channel load-balance arad fields ip` command specifies the data fields that the port channel load balance hash algorithm uses for distributing IP packets on Arad platform switches. The hashing algorithm fields used for IP packets differ from the fields used for non-IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no port-channel load-balance arad fields ip` and `default port-channel load-balance arad fields ip` commands restore the default data fields for the IP packet load balancing algorithm by removing the `port-channel load-balance arad A fields ip` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
port-channel load-balance arad fields ip IP_FIELD_NAME
no port-channel load-balance arad fields ip
default port-channel load-balance arad fields ip
```

**Parameters**
- `IP_FIELD_NAME` fields the hashing algorithm uses for layer 3 routing. Options include:
  - `ip-tcp-udp-header` algorithm uses source and destination IP address fields. Source and destination port fields are included for TCP and UDP packets.
  - `mac-header` algorithm uses entire MAC header.

   A command can only specify one option. The default setting is `ip-tcp-udp-header`.

**Guidelines**
The port channel hash algorithm for non-IP packets is not configurable and always includes the entire MAC header.

**Related Commands**
- `port-channel load-balance` configures the hash seed for the algorithm.

**Example**
- These commands configure the switch’s port channel load balance hash algorithm for IP packets to use source and destination IP address (and port) fields.

```
switch(config)#port-channel load-balance fm6000 fields ip ip-tcp-udp-header
switch(config)#
```
port-channel load-balance fm6000 fields ip

The `port-channel load-balance fm6000 fields ip` command specifies the data fields that the port channel load balance hash algorithm uses for distributing IP packets on FM6000 platform switches. The hashing algorithm fields used for IP packets differ from the fields used for non-IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no port-channel load-balance fm6000 fields ip` and `default port-channel load-balance fm6000 fields ip` commands restore the default data fields for the IP packet load balancing algorithm by removing the `port-channel load-balance fm6000 fields ip` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**
```
port-channel load-balance fm6000 fields ip IP_FIELD_NAME
no port-channel load-balance fm6000 fields ip
default port-channel load-balance fm6000 fields ip
```

**Parameters**
- `IP_FIELD_NAME` specifies fields the hashing algorithm uses for layer 3 routing. Options include:
  - `ip-tcp-udp-header` algorithm uses source and destination IP address fields. Source and destination port fields are included for TCP and UDP packets.

  A command can only specify one option. The default setting is `ip-tcp-udp-header`.

**Related Commands**
- `port-channel load-balance` configures the hash seed for the algorithm.
- `port-channel load-balance fm6000 fields mac` controls the hash algorithm for non-IP packets

**Example**
- These commands configure the switch’s port channel load balance for IP packets by source and destination IP address and port fields.
  ```
  switch(config)#port-channel load-balance fm6000 fields ip ip-tcp-udp-header
  switch(config)#
  ```
port-channel load-balance fm6000 fields mac

The `port-channel load-balance fm6000 fields mac` command specifies data fields that configure the port channel load balance hash algorithm for non-IP packets on FM6000 platform switches. The hashing algorithm fields used for balancing non-IP packets differ from the fields used for IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no port-channel load-balance fm6000 fields mac` and `default port-channel load-balance fm6000 fields mac` commands restore the default data fields for the non-IP packet load balancing algorithm by removing the `port-channel load-balance fm6000 fields mac` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

- `port-channel load-balance fm6000 fields mac MAC_FIELD_NAME`
- `no port-channel load-balance fm6000 fields mac`
- `default port-channel load-balance fm6000 fields mac`

**Parameters**

- `MAC_FIELD_NAME` fields the hashing algorithm uses for layer 2 routing. Options include
  - `dst-mac`  MAC destination field
  - `eth-type`  EtherType field
  - `src-mac`  MAC source field
  - `vlan-id`  VLAN ID field
  - `vlan-priority`  VLAN priority field

  Command may include from one to five fields, in any combination and listed in any order. The default setting is the selection of all fields.

**Related Commands**

- `port-channel load-balance` configures the hash seed for the algorithm.
- `port-channel load-balance fm6000 fields ip` controls the hash algorithm for IP packets

**Example**

- These commands configure the switch’s port channel load balance for non-IP packets by using the MAC destination and Ethernet type fields in the hashing algorithm.

```
switch(config)#port-channel load-balance fm6000 fields mac dst-mac eth-type
switch(config)#
```
port-channel load-balance petraA fields ip

The `port-channel load-balance petraA fields ip` command specifies the data fields that the port channel load balance hash algorithm uses for distributing IP packets on Petra platform switches. The hashing algorithm fields used for IP packets differ from the fields used for non-IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no port-channel load-balance petraA fields ip` and `default port-channel load-balance petraA fields ip` commands restore the default data fields for the IP packet load balancing algorithm by removing the `port-channel load-balance petraA fields ip` command from `running-config`.

**Command Mode**  
Global Configuration

**Command Syntax**

```plaintext
port-channel load-balance petraA fields ip IP_FIELD_NAME  
no port-channel load-balance petraA fields ip  
default port-channel load-balance petraA fields ip
```

**Parameters**

- `IP_FIELD_NAME` fields the hashing algorithm uses for layer 3 routing. Options include:
  - `ip-tcp-udp-header` algorithm uses source and destination IP address fields. Source and destination port fields are included for TCP and UDP packets.
  - `mac-header` algorithm uses entire MAC header.

  A command can only specify one option. The default setting is `ip-tcp-udp-header`.

**Guidelines**

The port channel hash algorithm for non-IP packets is not configurable and always includes the entire MAC header.

**Related Commands**

- `port-channel load-balance` configures the hash seed for the algorithm.

**Example**

- These commands configure the switch’s port channel load balance hash algorithm for IP packets to use source and destination IP address (and port) fields.

  ```plaintext
  switch(config)# port-channel load-balance fm6000 fields ip ip-tcp-udp-header  
  switch(config)#
  ```
port-channel load-balance trident fields ip

The **port-channel load-balance trident fields ip** command specifies the data fields that the port channel load balance hash algorithm uses for distributing IP packets on Trident platform switches. The hashing algorithm fields used for IP packets differ from the fields used for non-IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The **no port-channel load-balance trident fields ip** and **default port-channel load-balance trident fields ip** commands restore the default data fields for the IP packet load balancing algorithm by removing the **port-channel load-balance trident fields ip** command from **running-config**.

**Command Mode**
- Global Configuration

**Command Syntax**
```plaintext
port-channel load-balance trident fields ip IP_FIELD_NAME
no port-channel load-balance trident fields ip
default port-channel load-balance trident fields ip
```

**Parameters**
- **IP_FIELD_NAME** specifies fields the hashing algorithm uses for layer 3 routing. Options include:
  - **destination-ip** algorithm uses destination IP address field.
  - **source-ip** algorithm uses source IP address field.
  - **destination-port** algorithm uses destination TCP/UDP port field.
  - **source-port** algorithm uses source TCP/UDP port field.
  - **ip-tcp-udp-header** algorithm uses source and destination IP address fields. Source and destination port fields are included for TCP and UDP packets. *This option can’t be used in combination with any other option.*
  - **mac-header** algorithm uses fields specified by **port-channel load-balance trident fields mac**. *This option can’t be used in combination with any other option.*

Default setting is **ip-tcp-udp-header**

**Related Commands**
- **port-channel load-balance** configures the hash seed for the algorithm.
- **port-channel load-balance trident fields ipv6** controls the hash algorithm for IPv6 packets
- **port-channel load-balance trident fields mac** controls the hash algorithm for non-IP/IPv6 packets
Example

- These commands configure the switch's port channel load balance for IP packets by using the IPv6 destination field in the hashing algorithm.

```
switch(config)#port-channel load-balance trident fields ip destination-ip
switch(config)#
```
port-channel load-balance trident fields ipv6

The `port-channel load-balance trident fields ipv6` command specifies the data fields that the port channel load balance hash algorithm uses for distributing IPv6 packets on Trident platform switches. The hashing algorithm fields used for IPv6 packets differ from the fields used for non-IPv6 packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The `no port-channel load-balance trident fields ipv6` and `default port-channel load-balance trident fields ipv6` commands restore the default data fields for the IPv6 packet load balancing algorithm by removing the `port-channel load-balance trident fields ipv6` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
port-channel load-balance trident fields ipv6 IP_FIELD_NAME
no port-channel load-balance trident fields ipv6
default port-channel load-balance trident fields ipv6
```

**Parameters**

- **IP_FIELD_NAME** specifies fields the hashing algorithm uses for layer 3 routing. Options include:
  - Command may include from one to four of the following four options, in any combination and listed in any order.
    - **destination-ip** algorithm uses destination IPv6 address field.
    - **source-ip** algorithm uses source IPv6 address field.
    - **destination-port** algorithm uses destination TCP/UDP port field.
    - **source-port** algorithm uses source TCP/UDP port field.
    - **ip-tcp-udp-header** algorithm uses source and destination IPv6 address fields. Source and destination port fields are included for TCP and UDP packets. *This option can’t be used in combination with any other option.*
    - **mac-header** algorithm uses fields specified by `port-channel load-balance trident fields mac`. *This option can’t be used in combination with any other option.*

Default setting is `ip-tcp-udp-header`

**Related Commands**

- **port-channel load-balance** configures the hash seed for the algorithm.
- **port-channel load-balance trident fields ipv6** controls the hash algorithm for non-IP packets
- **port-channel load-balance trident fields mac** controls the hash algorithm for non-IP packets
Example

- These commands configure the switch’s port channel load balance for IP packets by using the IPv6 source field in the hashing algorithm.

  switch(config)#port-channel load-balance trident fields ipv6 source-ip
  switch(config)#
port-channel load-balance trident fields mac

The **port-channel load-balance trident fields mac** command specifies data fields that the port channel load balance hash algorithm uses for distributing non-IP packets on Trident platform switches. The hashing algorithm fields used for non-IP packets differ from the fields used for IP packets.

The switch calculates a hash value using the packet header fields to load balance packets across links in a port channel. The hash value determines the link through which the packet is transmitted. This method also ensures that all packets in a flow follow the same network path. Packet flow is modified by changing the inputs to the port channel hash algorithm.

In network topologies that include MLAGs, programming all switches to perform the same hash calculation increases the risk of hash polarization, which leads to uneven load distribution among LAG and MLAG member links in MLAG switches. This problem is avoided by performing different hash calculations between the MLAG switch, and a non-peer switch connected to it.

The **no port-channel load-balance trident fields mac** and **default port-channel load-balance trident fields mac** commands restore the default data fields for the non-IP packet load balancing algorithm by removing the **port-channel load-balance trident fields mac** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
port-channel load-balance trident fields mac MAC_FIELD_NAME
no port-channel load-balance trident fields mac
default port-channel load-balance trident fields mac
```

**Parameters**

- **MAC_FIELD_NAME** fields the hashing algorithm uses for layer 2 routing. Options include
  - dst-mac  MAC destination field
  - eth-type  EtherType field
  - src-mac  MAC source field

Command may include from one to three fields, in any combination and listed in any order. The default setting is the selection of all fields.

**Related Commands**

- **port-channel load-balance** configures the hash seed for the algorithm.
- **port-channel load-balance trident fields ip** controls the hash algorithm for IP packets
- **port-channel load-balance trident fields ipv6** controls the hash algorithm for IP packets

**Example**

- These commands configure the switch’s port channel load balance for non-IP packets by using the MAC destination and Ethernet type fields in the hashing algorithm.

  `switch(config)#port-channel load-balance trident fields mac dst-mac eth-type
switch(config)#`
port-channel min-links

The **port-channel min-links** command specifies the minimum number of interfaces that the configuration mode LAG requires to be active. This command is supported only on LACP ports. If there are fewer ports than specified by this command, the port channel interface does not become active. The default min-links value is 0.

The **no port-channel min-links** and **default port-channel min-links** commands restore the default min-links setting for the configuration mode LAG by removing the corresponding **port-channel min-links** command from the configuration.

**Command Mode**
Interface-Port-Channel Configuration

**Command Syntax**

- `port-channel min-links quantity`
- `no port-channel min-links`
- `default port-channel min-links`

**Parameters**
- `quantity` minimum number of interfaces. Value range varies by platform. Default value is 0.

**Example**
- This command sets four as the minimum number of ports required by port channel 13 to be active.

```
switch(config)#interface port-channel 13
switch(config-if-Po13)#port-channel min-links 4
switch(config-if-Po13)#show active
interface Port-Channel13
  port-channel min-links 4
switch(config-if-Po13)#
```
show etherchannel

The `show etherchannel` command displays information about members of the specified port channels.

**Command Mode**

EXEC

**Command Syntax**

```
show etherchannel [MEMBERS] [PORT_LIST] [INFO_LEVEL]
```

**Parameters**

- **MEMBERS**  list of port channels for which information is displayed. Options include:
  - `<no parameter>` all configured port channels.
  - `p_range` ports in specified channel list (number, number range, or list of numbers and ranges).
- **PORT_LEVEL**  ports displayed, in terms of aggregation status. Options include:
  - `<no parameter>` Displays information on ports that are active members of the LAG.
  - `active-ports` Displays information on ports that are active members of the LAG.
  - `all-ports` Displays information on all ports (active or inactive) configured for LAG.
- **INFO_LEVEL**  amount of information that is displayed. Options include:
  - `<no parameter>` Displays information at the brief level.
  - `brief` Displays information at the brief level.
  - `detailed` Displays information at the detail level.

**Display Values**

- **Port Channel**  Type and name of the port channel.
- **Time became active**  Time when the port channel came up.
- **Protocol**  Protocol operating on the port.
- **Mode**  Status of the Ethernet interface on the port. The status value is Active or Inactive.
- **No active ports**  Number of active ports on the port channel.
- **Configured but inactive ports**  Ports configured but that are not actively up.
- **Reason unconfigured**  Reason why the port is not part of the LAG.

**Guidelines**

The `show etherchannel` and `show port-channel` commands are identical. See `show port-channel` for additional information.
show lacp aggregates

The `show lacp aggregates` command displays aggregate IDs and the list of bundled ports for all specified port channels.

**Command Mode**

EXEC

**Command Syntax**

```
show lacp [PORT_LIST] aggregates [PORT_LEVEL] [INFO_LEVEL]
```

`PORT_LEVEL` and `INFO_LEVEL` parameters can be placed in any order.

**Parameters**

- **PORT_LIST** port channels for which aggregate information is displayed. Options include:
  - <no parameter> all configured port channels.
  - `c_range` channel list (number, range, or comma-delimited list of numbers and ranges).
- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - <no parameter> ports bundled by LACP into the port channel.
  - `all-ports` all channel group ports, including channel group members not bundled into the port channel interface.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> aggregate ID and bundled ports for each channel.
  - `brief` aggregate ID and bundled ports for each channel.
  - `detailed` aggregate ID and bundled ports for each channel.
Examples

- This command lists aggregate information for all configured port channels.

  ```
  switch> show lacp aggregates
  Port Channel Port-Channel1:
  Aggregate ID:
  [(8000,00-1c-73-04-36-d7,0001,0000,0000),(8000,00-1c-73-09-a0-f3,0001,0000,0000)]
  Bundled Ports: Ethernet43 Ethernet44 Ethernet45 Ethernet46
  Port Channel Port-Channel2:
  Aggregate ID:
  [(8000,00-1c-73-01-02-1e,0002,0000,0000),(8000,00-1c-73-04-36-d7,0002,0000,0000)]
  Bundled Ports: Ethernet47 Ethernet48
  Port Channel Port-Channel3:
  Aggregate ID:
  [(8000,00-1c-73-04-36-d7,0003,0000,0000),(8000,00-1c-73-0c-02-7d,0001,0000,0000)]
  Bundled Ports: Ethernet3 Ethernet4
  Port Channel Port-Channel4:
  Aggregate ID:

  Bundled Ports: Ethernet1 Ethernet2
  Port Channel Port-Channel5:
  Aggregate ID:
  [(0001,00-22-b0-5a-0c-51,0033,0000,0000),(8000,00-1c-73-04-36-d7,0005,0000,0000)]
  Bundled Ports: Ethernet41
  switch>
  ```
show lacp counters

The **show lacp counters** command displays LACP traffic statistics.

**Command Mode**

EXEC

**Command Syntax**

```
show lacp [PORT_LIST] counters [PORT_LEVEL] [INFO_LEVEL]
```

*PORT_LEVEL* and *INFO_LEVEL* parameters can be placed in any order.

**Parameters**

- **PORT_LIST** ports for which port information is displayed. Options include:
  - *<no parameter>* all configured port channels
  - *c_range* ports in specified channel list (number, number range, or list of numbers and ranges).
  - *interface* ports on all interfaces.
  - *interface ethernet e_num* port on Ethernet interface specified by *e_num*.
  - *interface port-channel p_num* port on port channel interface specified by *p_num*.

- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - *<no parameter>* only ports bundled by LACP into an aggregate.
  - *all-ports* all ports, including LACP candidates that are not bundled.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - *<no parameter>* displays packet transmission (TX and RX) statistics.
  - *brief* displays packet transmission (TX and RX) statistics.
  - *detailed* displays packet transmission (TX and RX) statistics and actor-partner statistics.

**Example**

- This command displays transmission statistics for all configured port channels.

```
switch>show lacp counters brief
```

switch>
show lacp interface

The `show lacp interface` command displays port status for all port channels that include the specified interfaces. Within the displays for each listed port channel, the output displays sys-id, partner port, state, actor port, and port priority for each interface in the channel.

**Command Mode**

`EXEC`

**Command Syntax**

```
show lacp interface [INTERFACE_PORT] [PORT_LEVEL] [INFO_LEVEL]
```

*INTERFACE_PORT* is listed first when present. Other parameters can be listed in any order.

**Parameters**

- **INTERFACE_PORT** interfaces for which information is displayed. Options include:
  - <no parameter> all interfaces in channel groups.
  - ethernet *e_num* Ethernet interface specified by *e_num*.
  - port-channel *p_num* port channel interface specified by *p_num*.

- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - <no parameter> command lists data for ports bundled by LACP into the aggregate.
  - all-ports command lists data for all ports, including LACP candidates that are not bundled.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> displays same information as `brief` option.
  - brief displays LACP configuration data, including sys-id, actor, priorities, and keys.
  - detailed includes `brief` option information plus state machine data.
Example

- This command displays LACP configuration information for all ethernet interfaces.

```
switch>show lacp interface
State: A = Active, P = Passive; S=ShortTimeout, L=LongTimeout;
G = Aggregable, I = Individual; s+=InSync, s-=OutOfSync;

switch>
show lACP internal

The `show lACP internal` command displays the local LACP state for all specified channels. Local state data includes the state machines and LACP protocol information.

**Command Mode**

EXEC

**Command Syntax**

```
show lACP [PORT_LIST] internal [PORT_LEVEL] [INFO_LEVEL]
```

**Parameters**

- **PORT_LIST** interface for which port information is displayed. Options include:
  - `<no parameter>` all configured port channels
  - `c_range` ports in specified channel list (number, number range, or list of numbers and ranges).
  - `interface` ports on all interfaces.
  - `interface ethernet e_num` Ethernet interface specified by `e_num`.
  - `interface port-channel p_num` port channel interface specified by `p_num`.

- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - `<no parameter>` command lists data for ports bundled by LACP into an aggregate.
  - `all-ports` command lists data for all ports, including LACP candidates that are not bundled.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - `<no parameter>` displays same information as `brief` option.
  - `brief` displays LACP configuration data, including sys-id, actor, priorities, and keys.
  - `detailed` includes `brief` option information plus state machine data.

**PORT_LEVEL** and **INFO_LEVEL** parameters can be placed in any order.

**Example**

- This command displays internal data for all configured port channels.

```
switch>show lACP internal
LACP System-identifier: 8000,00-1c-73-04-36-d7
State: A = Active, P = Passive; S=ShortTimeout, L=LongTimeout;
G = Aggregable, I = Individual; s+=InSync, s-=OutOfSync;

```
show lACP neighbor

The `show lACP neighbor` command displays the LACP protocol state of the remote neighbor for all specified port channels.

**Command Mode**

EXEC

**Command Syntax**

```
show lACP [PORT_LIST] neighbor [PORT_LEVEL] [INFO_LEVEL]
```

*PORT_LEVEL* and *INFO_LEVEL* parameters can be placed in any order.

**Parameters**

- **PORT_LIST** interface for which port information is displayed. Options include:
  - <no parameter> displays information for all configured port channels
  - `c_range` ports in specified channel list (number, number range, or list of numbers and ranges).
  - `interface` ports on all interfaces.
  - `interface ethernet e_num` Ethernet interface specified by `e_num`.
  - `interface port-channel p_num` port channel interface specified by `p_num`.
- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - <no parameter> command lists data for ports bundled by LACP into an aggregate.
  - `all-ports` command lists data for all ports, including LACP candidates that are not bundled.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> displays same information as `brief` option.
  - `brief` displays LACP configuration data, including sys-id, actor, priorities, and keys.
  - `detailed` includes `brief` option information plus state machine data.
Example

- This command displays the LACP protocol state of the remote neighbor for all port channels.

```
switch>show lacp neighbor
State: A = Active, P = Passive; S=ShortTimeout, L=LongTimeout;
    G = Aggregable, I = Individual; s+=InSync, s-=OutOfSync;
    C = Collecting, X = state machine expired,
    D = Distributing, d = default neighbor state

* - Only local interfaces for MLAGs are displayed. Connect to the peer to see the state for peer interfaces.
```

switch>
show lacp sys-id

The `show lacp sys-id` command displays the System Identifier the switch uses when negotiating remote LACP implementations.

**Command Mode**

**EXEC**

**Command Syntax**

```
show lacp sys-id [INFO_LEVEL]
```

**Parameters**

- `INFO_LEVEL` amount of information that is displayed. Options include:
  - `<no parameter>` displays system identifier
  - `brief` displays system identifier.
  - `detailed` displays system identifier and system priority, including the MAC address.

**Examples**

- This command displays the system identifier.
  ```
  switch>show lacp sys-id brief
  8000,00-1c-73-04-36-d7
  ```

- This command displays the system identifier and system priority.
  ```
  switch>show lacp sys-id detailed
  System Identifier used by LACP:
  System priority: 32768  Switch MAC Address: 00:1c:73:04:36:d7
  802.11.43 representation: 8000,00-1c-73-04-36-d7
  ```
show load-balance profile

The **show load-balance profile** command displays the contents of the specified load balance profiles. Load balance profiles specify parameters used by hashing algorithms that distribute traffic across ports comprising a port channel or among component ECMP routes.

**Command Mode**

EXEC

**Command Syntax**

```
show load-balance profile [PROFILES]
```

**Parameters**

- **PROFILES**  Load balance profiles for which command displays contents. Options include:
  - `<no parameter>` displays all load balance profiles.
  - `profile_name` displays specified profile.

**Related Commands**

- **load-balance policies** places the switch in load-balance-policies configuration mode.
- **ingress load-balance profile** applies a load-balance profile to an Ethernet or port channel interface.

**Example**

- This command displays the contents of the LB-1 load balance profile.

```
switch>show load-balance profile LB-1

---------- LB-1 ----------

Source MAC address hashing        ON
Destination MAC address hashing   ON
Ethernet type hashing             ON
VLAN ID hashing                   ON
VLAN priority hashing             ON
IP source address hashing         ON
IP destination address hashing    ON
TCP/UDP source port hashing       ON
TCP/UDP destination port hashing  ON
IP protocol field hashing         ON
DSCP field hashing is             ON
Symmetric hashing for non-IP packets OFF
Symmetric hashing for IP packets  OFF
Random distribution for port-channel ON
Random distribution for ecmp      ON

Profile LB-1 is applied on the following
  Port-Channel100

switch>
```
show port-channel

The show port-channel command displays information about members the specified port channels.

Command Mode

EXEC

Command Syntax

show port-channel [MEMBERS] [PORT_LIST] [INFO_LEVEL]

Parameters

- **MEMBERS** list of port channels for which information is displayed. Options include:
  - <no parameter> all configured port channels.
  - *p_range* ports in specified channel list (number, number range, or list of numbers and ranges).
- **PORT_LEVEL** ports displayed, in terms of aggregation status. Options include:
  - <no parameter> Displays information on ports that are active members of the LAG.
  - active-ports Displays information on ports that are active members of the LAG.
  - all-ports Displays information on all ports (active or inactive) configured for LAG.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> Displays information at the brief level.
  - brief Displays information at the brief level.
  - detailed Displays information at the detail level.

Display Values

- **Port Channel** Type and name of the port channel.
- **Time became active** Time when the port channel came up.
- **Protocol** Protocol operating on the port channel.
- **Mode** Status of the Ethernet interface on the port. The status value is Active or Inactive.
- **No active ports** Number of active ports on the port channel.
- **Configured but inactive ports** Ports configured but that are not actively up.
- **Reason unconfigured** Reason why the port is not part of the LAG.

Guidelines

The show etherchannel and show port-channel commands are identical.

You can configure a port channel to contain many ports, but only a subset may be active at a time. All active ports in a port channel must be compatible. Compatibility includes many factors and is platform specific. For example, compatibility may require identical operating parameters such as speed and maximum transmission unit (MTU). Compatibility may only be possible between specific ports because of the internal organization of the switch.
Examples

- This command displays output from the `show port-channel` command:

```
switch>show port-channel 3
Port Channel Port-Channel3:
  Active Ports:
    Port                Time became active       Protocol    Mode
    -----------------------------------------------------------------------
    Ethernet3           15:33:41                 LACP        Active
    PeerEthernet3       15:33:41                 LACP        Active
```

- This command displays output from the `show port-channel active-ports` command:

```
switch>show port-channel active-ports
Port Channel Port-Channel3:
  No Active Ports
Port Channel Port-Channel11:
  No Active Ports
switch>
```

- This command displays output from the `show port-channel all-ports` command:

```
switch>show port-channel all-ports
Port Channel Port-Channel3:
  No Active Ports
  Configured, but inactive ports:
    Port            Time became inactive    Reason unconfigured
    -----------------------------------------------------------------------
    Ethernet3       Always                  not compatible with aggregate
Port Channel Port-Channel11:
  No Active Ports
  Configured, but inactive ports:
    Port            Time became inactive    Reason unconfigured
    -----------------------------------------------------------------------
    Ethernet25      Always                  not compatible with aggregate
    Ethernet26      Always                  not compatible with aggregate
```

switch>
show port-channel limits

The `show port-channel limits` command displays groups of ports that are compatible and may be joined into port channels. Each group of compatible ports is called a LAG group. For each LAG group, the command also displays `Max interfaces` and `Max ports per interface`.

- **Max interfaces** defines the maximum number of active port channels that may be formed out of these ports.
- **Max ports per interface** defines the maximum number of active ports allowed in a port channel from the compatibility group.

All active ports in a port channel must be compatible. Compatibility comprises many factors and is specific to a given platform. For example, compatibility may require identical operating parameters such as speed and/or maximum transmission unit (MTU). Compatibility may only be possible between specific ports because of internal organization of the switch.

Command Mode

EXEC

Command Syntax

```
show port-channel limits
```

Example

- This command displays `show port-channel list` output:

```
switch>show port-channel limits
LAG Group: focalpoint

Max port-channels per group: 24, Max ports per port-channel: 16
24 compatible ports: Ethernet1 Ethernet2 Ethernet3 Ethernet4
    Ethernet5 Ethernet6 Ethernet7 Ethernet8
    Ethernet9 Ethernet10 Ethernet11 Ethernet12
    Ethernet13 Ethernet14 Ethernet15 Ethernet16
    Ethernet17 Ethernet18 Ethernet19 Ethernet20
    Ethernet21 Ethernet22 Ethernet23 Ethernet24

ˆ--------------------------------------------
```

switch>
show port-channel load-balance fields

The `show port-channel load-balance fields` command displays the fields that the hashing algorithm uses to distribute traffic across the interfaces that comprise the port channels.

**Command Mode**

EXEC

**Command Syntax**

```
show port-channel load-balance fields
```

**Parameters**

- `HARDWARE`  ASIC switching device. Selection options depend on the switch model and include:
  - `arad`
  - `fm6000`
  - `petraA`
  - `trident`  

**Examples**

- This command displays the hashing fields used for balancing port channel traffic.

  ```
  switch>show port-channel load-balance fm6000 fields
  Source MAC address hashing for non-IP packets is ON
  Destination MAC address hashing for non-IP packets is ON
  Ethernet type hashing for non-IP packets is ON
  VLAN ID hashing for non-IP packets is ON
  VLAN priority hashing for non-IP packets is ON
  Source MAC address hashing for IP packets is ON
  Destination MAC address hashing for IP packets is ON
  Ethernet type hashing for IP packets is ON
  VLAN ID hashing for IP packets is ON
  VLAN priority hashing for IP packets is ON
  IP source address hashing is ON
  IP destination address hashing is ON
  IP protocol field hashing is ON
  TCP/UDP source port hashing is ON
  TCP/UDP destination port hashing is ON
  switch>
  ```
**show port-channel summary**

The **show port-channel summary** command displays the port-channels on the switch and lists their component interfaces, LACP status, and set flags.

**Command Mode**
EXEC

**Command Syntax**

```
show port-channel summary
```

**Examples**

- This command displays **show port-channel summary** output:

```
switch#show port-channel summary

Flags
-----------------------------------------------
a - LACP Active                              p - LACP Passive
U - In Use                                   D - Down
+ - In-Sync                                  - - Out-of-Sync
P - bundled in Po                            s - suspended
I - Individual                               S - ShortTimeout
                      G - Aggregable
                      w - wait for agg

Number of channels in use: 2
Number of aggregators:2

```
show port-channel traffic

The **show port-channel traffic** command displays the traffic distribution between the member ports of the specified port channels. The command displays distribution for unicast, multicast, and broadcast streams.

**Command Mode**
EXEC

**Command Syntax**
```
show port-channel [MEMBERS] traffic
```

**Parameters**
- **MEMBERS** list of port channels for which information is displayed. Options include:
  - <no parameter> all configured port channels.
  - `c_range` ports in specified channel list (number, number range, or list of numbers and ranges).

**Examples**
- This command displays traffic distribution for all configured port channels.

```
switch>show port-channel traffic
ChanId  Port  Rx-Ucst  Tx-Ucst  Rx-Mcst  Tx-Mcst  Rx-Bcst  Tx-Bcst
------ ------ -------- -------- -------- -------- -------- --------

switch>
```
Arista switches support Multi-Chassis Link Aggregation (MLAG) to logically aggregate ports across two switches. For example, two 10-gigabit Ethernet ports, one each from two MLAG configured switches, can connect to two 10-gigabit ports on a host, switch, or network device to create a link that appears as a single 20-gigabit port. MLAG-configured ports provide Layer 2 multipathing, increased bandwidth, higher availability, and other improvements on traditional active-passive or Spanning Tree governed infrastructures.

The Multi-Chassis Link Aggregation chapter contains these sections:

- Section 12.1: MLAG Introduction
- Section 12.2: MLAG Conceptual Overview
- Section 12.3: MLAG Maintenance
- Section 12.4: Configuring MLAG
- Section 12.5: MLAG Implementation Example
- Section 12.6: MLAG Commands

### 12.1 MLAG Introduction

High availability data center topologies typically provide redundancy protection at the expense of oversubscription by connecting top-of-rack (TOR) switches and servers to dual aggregation switches. In these topologies, Spanning Tree Protocol prevents network loops by blocking half of the links to the aggregation switches. This reduces the available bandwidth by 50%.

Deploying MLAG removes oversubscription by configuring an MLAG link between two aggregation switches to create a single logical switching instance that utilizes all connections to the switches. Interfaces on both devices participate in a distributed port channel, enabling all active paths to carry data traffic while maintaining the integrity of the Spanning Tree topology.

MLAG provides these benefits:

- Aggregates multiple Ethernet ports across two switches.
- Provides higher bandwidth links as network traffic increases.
- Utilizes bandwidth more efficiently with fewer links blocked by STP.
- Connects to other switches and servers by static LAG or LACP without other proprietary protocols.
- Supports normal STP operation to prevent loops.
- Supports active-active Layer-2 redundancy.

**Note**

PTP (precision timing protocol) is not supported with MLAG.
12.2 MLAG Conceptual Overview

12.2.1 MLAG Operation Process

A multi-chassis link aggregation group (MLAG) is a pair of links that terminate on two cooperating switches and appear as an ordinary link aggregation group (LAG). The cooperating switches are MLAG peer switches and communicate through an interface called a peer link. While the peer link’s primary purpose is exchanging MLAG control information between peer switches, it also carries data traffic from devices that are attached to only one MLAG peer and have no alternative path. An MLAG domain consists of the peer switches and the control links that connect the switches.

In Figure 12-1, Switch A and Switch B are peer switches in the MLAG domain and connect to each other through the peer link. Each peer switch uses the peer address to form and maintain the peer link.

The MLAG domain ID is a text string configured in each peer switch. MLAG switches use this string to identify their peers. The MLAG System ID (MSI) is the MLAG domain’s MAC address. The MSI is automatically derived when the MLAG forms and does not match the bridge MAC address of either peer. Each peer uses the MSI in STP and LACP PDUs.

The topology in Figure 12-1 contains four MLAGs: one MLAG connects each device to the MLAG domain. Each peer switch connects to the four servers through MLAG link interfaces.

In a conventional topology, with dually-attaching devices to multiple switches for redundancy, Spanning Tree Protocol (STP) blocks half of the switch-device links. In the MLAG topology, STP does not block any portion because it views the MLAG Domain as a single switch and each MLAG as a single port. The MLAG protocol facilitates the balancing of device traffic between the peer switches.

When MLAG is disabled, peer switches revert to their independent state. MLAG is disabled by any of the following:

- MLAG configuration changes.
• The TCP connection breaks.
• The peer-link or local-interface goes down.
• A switch does not receive a response to a keep alive message from its peer within a specified period.

12.2.2 MLAG Interoperability with Other Features
The following sections describe MLAG interaction with other switch features.

12.2.2.1 VLANs
VLAN parameters must be configured identically on each peer for the LAGs comprising the peer link and MLAGs. These parameters include the switchport access VLAN, switchport mode, trunk-allowed VLANs, the trunk native VLAN, and switchport trunk groups. Configuration discrepancies may result in traffic loss in certain failure scenarios. Port-specific bridging configuration originates on the switch where the port is physically located.

12.2.2.2 LACP
Link Aggregation Control Protocol (LACP) should be used on all MLAG interfaces, including the peer-link. LACP control packets reference the MLAG system ID.

12.2.2.3 Static MAC Addresses
A static MAC address configured on an MLAG interface is automatically configured on the peer’s corresponding interface. Configuring static MAC addresses on both peers prevents undesired flooding if an MLAG peer relationship fails.
If the MLAG peer relationship is broken or if all local members of an MLAG port channel go down, the peer is no longer automatically configured with the static MAC address.

12.2.2.4 STP
When implementing MLAG in a spanning tree network, spanning tree must be configured globally and on port-channels configured with an MLAG ID. Port specific spanning tree configuration comes from the switch where the port physically resides. This includes spanning-tree PortFast BPDU Guard and BPDU filter.

12.2.2.5 Port Mirroring
A port channel which is a member of an MLAG must not be used as the destination port for a port mirroring (port monitoring) session.
12.3 **MLAG Maintenance**
These sections describe tasks required for MLAG to operate on the switch:

- **Section 12.3.1: Ensuring Control Plane ACL Compatibility**
- **Section 12.3.2: MLAG Availability through a Single Functional Peer**
- **Section 12.3.3: Upgrading MLAG Peers**

12.3.1 **Ensuring Control Plane ACL Compatibility**
The control plane access control list (ACL) on any interface participating in the MLAG must be configured to allow only the peer link neighbor to generate MLAG control traffic. The required rules are included in the default control plane ACL for Ethernet ports.

Any custom control plane ACL applied to a participating port must include these two rules:

```plaintext
permit tcp any any eq mlag ttl eq 255
permit udp any any eq mlag ttl eq 255
```

MLAG peers that function as routers must each have routing enabled.

12.3.2 **MLAG Availability through a Single Functional Peer**
MLAG high availability advantages are fully realized when all devices that connect to one MLAG switch also connect to the peer switch. A switch can continue supporting MLAG when its peer is offline if the STP agent is restartable. When one peer is offline, data traffic flows from the devices through the MLAG component link that connects to the functioning switch. When a switch is offline, its interfaces and ports do not appear in `show mlag` and `show spanning tree protocol` commands of the functioning peer.

To view the restartability status of the STP agent, issue the `show spanning-tree bridge detail` command:

```
switch-1#show spanning-tree bridge detail | grep agent
Stp agent is restartable
```

STP agent restartability requires consistent configuration between the peers of STP, LACP, MLAG, and switchport parameters. Events triggering an STP state machine change may also briefly prevent the STP agent from being restartable.

12.3.2.1 **Reload Delay**
If an MLAG peer reboots, all ports except those in the peer-link port-channel remain in `errdisabled` state for a specified time, called the reload-delay period. This period allows all topology states to stabilize before the switch begins forwarding traffic. Each Arista switch defaults to the recommended reload-delay value, which varies by switch platform:

- **fixed configuration switches**: 300 seconds
- **Trident-2 modular switches**: 900 seconds
  - 7304
  - 7308
  - 7316
  - 7300X series
- **Sand platform modular switches**: 1800 seconds
  - 7504
  - 7508
  - 7500E series
In those cases where network topology requires additional time to stabilize or where a shorter delay can be tolerated, the reload-delay period can be configured using the `reload-delay mlag` command.

Severing the physical connection (cable) that establishes the peer-link between MLAG peers may result in a *split brain* state where each peer independently enters spanning tree state to prevent topology loops. Sessions established through one interface of a dual attached device may fail if its path is disrupted by the STP reconvergence, possibly resulting in temporarily lost connectivity. Sessions can be reestablished if permitted by the resulting topology.

### 12.3.3 Upgrading MLAG Peers

MLAG ISSU (In-Service Software Upgrade) upgrades EOS software on one MLAG peer with minimal traffic disruptions on active MLAG interfaces and without changing the network topology.

### 12.3.3.1 Verifying Configuration Compatibility

A seamless EOS upgrade on an MLAG peer requires that the following features are configured consistently on each switch:

- VLANs
- Switchport configuration on port channel interfaces that are configured with an MLAG ID
- STP configuration (global)

### 12.3.3.2 Version Compatibility

A switch running MLAG can be upgraded without disrupting MLAG traffic when the upgrade EOS version is compatible with the version on the peer switch. Refer to the Release Notes for a list of compatible EOS versions.

### 12.3.3.3 Reload Warning Conditions

Entering an EOS reload command while MLAG is active generates warning messages if conditions that can result in packet loss during the upgrade are present. All warnings should be resolved before confirming the reload request. Table 12-1 displays the reload conditions and a common resolution method for each condition.

<table>
<thead>
<tr>
<th>Reload Condition</th>
<th>Resolution Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compatibility check</td>
<td>Refer to the Release Notes to verify that the new version is compatible with the currently installed version</td>
</tr>
<tr>
<td>Active-partial MLAG warning</td>
<td>Bring up the remote port-channel. If the MLAG is not actively used, then this warning can be ignored.</td>
</tr>
<tr>
<td>STP is not restartable</td>
<td>Wait for STP to be restartable: typically 30 seconds, up to 120 seconds for a newly started STP agent. Refer to Section 12.3.2 for information on checking restartability.</td>
</tr>
<tr>
<td>Reload delay too low</td>
<td>Configure a reload delay value greater than or equal to the default. Recommend delay is 300 seconds for TOR switches and 900 seconds for modulars.</td>
</tr>
<tr>
<td>Peer has error-disabled interfaces</td>
<td>Wait for reload-delay to expire on the peer.</td>
</tr>
</tbody>
</table>
Example

- The following `reload` command generates MLAG warning conditions that should be addressed before confirming the *proceed with reload* prompt.

```plaintext
switch(config)#reload
```

If you are performing an upgrade, and the Release Notes for the new version of EOS indicate that MLAG is not backwards-compatible with the currently installed version (4.9.2), the upgrade will result in packet loss.

The following MLAGs are not in Active mode. Traffic to or from these ports will be lost during the upgrade process.

```
<table>
<thead>
<tr>
<th>mlag</th>
<th>desc</th>
<th>state</th>
<th>local</th>
<th>remote</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>active-partial</td>
<td>Po14</td>
<td>Po14</td>
<td>up/down</td>
<td></td>
</tr>
<tr>
<td>15</td>
<td>active-partial</td>
<td>Po15</td>
<td>Po15</td>
<td>up/down</td>
<td></td>
</tr>
</tbody>
</table>
```

STP is not restartable. Topology changes will occur during the upgrade process.

The configured reload delay of 100 seconds is below the default value of 300 seconds. A longer reload delay allows more time to rollback an unsuccessful upgrade due to incompatibility.

The other MLAG peer has errdisabled interfaces. Traffic loss will occur during the upgrade process.

Proceed with reload? [confirm]

### 12.3.3.4 Performing an MLAG ISSU Upgrade

The following procedure performs an MLAG ISSU upgrade:

**Step 1** Very configuration consistency on each peer ([Section 12.3.3.1](#)).

**Step 2** Verify version compatibility between the new and existing images ([Section 12.3.3.2](#)).

**Step 3** Configure `reload-delay mlag` ([Section 12.3.2](#)) if needed. Recommended delay period varies by switch type, and each switch defaults to its recommended delay period.

**Step 4** Install the new image onto one of the peers:

a. Upload the new image to the switch.

b. Set the boot path to the new image.

c. Enter the `reload` command.

**Step 5** Resolve all reload warnings.

**Step 6** Confirm the reload.

**Step 7** Wait for MLAG peers to renegotiate to the active state and reload-delay expiry on rebooted peer; until reload-delay period has expired, ports on the rebooted peer (except the peer-link) will be in *errdisabled* state with err-disabled reason being *mlag-issu*.

Avoid configuration changes on both peers until after this step.

**Step 8** Repeat the upgrade process for the other peer.

When upgrading modular switches with dual supervisors, upgrade the standby supervisors first, then upgrade the active supervisors.
12.4 Configuring MLAG

These sections describe the basic MLAG configuration steps:

- Section 12.4.1: Configuring the MLAG Peers
- Section 12.4.2: Configuring MLAG Services

12.4.1 Configuring the MLAG Peers

Connecting two switches as MLAG peers requires the establishment of the peer link and an SVI that defines local and peer IP addresses on each switch.

The peer link is composed of a LAG between the switches. When all devices that connect to the MLAG domain are dually connected to the switches through an MLAG, a peer link of two Ethernet interfaces is sufficient to handle MLAG control data and provide N+1 redundancy. When the domain connects to devices through only one MLAG peer, the peer link may require additional Ethernet interfaces to manage data traffic.

Disruptions to peer link connectivity due to forwarding agent restarts may cause an extended MLAG outage. Forwarding agent restart event include some configuration changes, such as port speed change or UFT mode change). The following precautions can reduce the risk of losing peer-link connectivity:

- all switches: constructing peer-links from port-channels in preference to a single Ethernet interface.
- modular systems: peer-link port-channel members should span multiple line cards.
- multi-chip systems: peer-link port-channel member should span multiple chips.

Section 3.6 describes modular systems.

The steps that configure two switches as MLAG peers include:

- Configuring the Port Channels, VLAN Interfaces, and IP addresses
- Configure Peer Parameters
- Configuring MLAG Peer Gateway

12.4.1.1 Configuring the Port Channels, VLAN Interfaces, and IP addresses

The peer link is a normal port channel. The local address is the SVI that maps to the peer link port channel. The port channel and SVI must be configured on each peer switch. The port channel should be an active LACP port. The local and peer addresses must be located on the same IP address subnet. Autostate should be disabled on the SVI configured as the local interface.

Examples

- These commands create an active mode LACP port channel interface from two Ethernet interfaces and configure it as part of a trunk group on each switch.

  The `switchport mode trunk` command permits all VLANs on the interface by default, so all VLANs are permitted on port channel 10 in the following example. The configuration of a trunk group for a VLAN restricts only that specific VLAN to the associated ports: VLAN 4094 is only permitted on port channel 10, and not on any other ports on the switch. It is important to remember that all VLANs must be permitted between the peers on the peer link for correct operation.
Switch 1

switch1#config
switch1(config)#vlan 4094
switch1(config-vlan-4094)#trunk group mlpeer
switch1#config
switch1(config)#interface ethernet 1-2
switch1(config-if-et1-2)#channel-group 10 mode active
switch1(config-if-et1-2)#interface port-channel 10
switch1(config-if-po10)#switchport mode trunk
switch1(config-if-po10)#switchport trunk group mlpeer
switch1(config-if-po10)#exit
switch1(config)#

Switch 2

switch2#config
switch2(config)#vlan 4094
switch2(config-vlan-4094)#trunk group m2peer
switch2(config-vlan-4094)#exit
switch2(config)#interface ethernet 1-2
switch2(config-if-et1-2)#channel-group 10 mode active
switch2(config-if-et1-2)#interface port-channel 10
switch2(config-if-po10)#switchport mode trunk
switch2(config-if-po10)#switchport trunk group m2peer
switch2(config-if-po10)#exit
switch2(config)#

- These commands create an SVI for the local interface and associate it to the trunk group assigned to the peer link port channel.

The SVI creates a Layer 3 endpoint in the switch and enables MLAG processes to communicate via TCP. The IP address can be any unicast address that does not conflict with other SVIs. STP is disabled for the peer link VLAN 4094 to prevent any potential STP disruption of inter peer communications. Recall that the VLAN has been restricted to port-channel 10 by the earlier trunk group configuration thus preventing potential Layer 2 loop conditions within VLAN 4094.

Switch 1

switch1#config
switch1(config)#interface vlan 4094
switch1(config-if-vl4094)#ip address 10.0.0.1/30
switch1(config-if-vl4094)#no autostate
switch1(config-if-vl4094)#exit
switch1(config)#

Switch 2

switch2#config
switch2(config)#interface vlan 4094
switch2(config-if-vl4094)#ip address 10.0.0.2/30
switch2(config-if-vl4094)#no autostate
switch2(config-if-vl4094)#exit
switch2(config)#

12.4.1.2 Configure Peer Parameters

Peer connection parameters configure the connection between the MLAG peer switches. This section describes the following peer configuration parameters.

- MLAG Configuration Mode
MLAG Configuration Mode

Peer connection parameters are configured in MLAG-configuration mode. The `mlag configuration (global configuration)` command places the switch in MLAG configuration mode.

Example

- This command places the switch in MLAG configuration mode.

```
switch(config)# mlag configuration
switch(config-mlag)#
```

Local VLAN Interface

The local interface specifies the SVI upon which the switch sends MLAG control traffic. The local IP address is specified within the definition of the VLAN associated with the local interface. The Peer Address configures the control traffic destination on the peer switch.

The `local-interface` command specifies a VLAN interface as the peer link SVI.

Example

- This command configures VLAN 4094 as the local interface.

```
switch(config-mlag)# local-interface vlan 4094
switch(config-mlag)#
```

Peer Address

The peer address is the destination address on the peer switch for MLAG control traffic. If the peer IP address is unreachable, MLAG peering fails and both peer switches revert to their independent state.

The `peer-address` command specifies the peer address.

Example

- This command configures a peer address of 10.0.0.2.

```
switch(config-mlag)# peer-address 10.0.0.2
switch(config-mlag)#
```

Peer Link

An MLAG is formed by connecting two switches through an interface called a peer link. The peer link carries MLAG advertisements, keepalive messages, and data traffic between the switches. This information keeps the two switches working together as one. While interfaces comprising the peer links on each switch must be compatible, they need not use the same interface number. Ethernet and Port-channel interfaces can be configured as peer links.

The `peer-link` command specifies the interface the switch uses to communicates MLAG control traffic.
Example
- This command configures port-channel 10 as the peer link.
  ```
  switch(config-mlag)#peer-link port-channel 10
  switch(config-mlag)#
  ```

Domain ID
The MLAG domain ID is a unique identifier for an MLAG domain. The MLAG domain ID must be the identical on each switch to facilitate MLAG communication.

The **domain-id** command configures the MLAG domain ID.

Example
- This command configures `mlagDomain` as the domain ID:
  ```
  switch(config-mlag)#domain-id mlagDomain
  switch(config-mlag)#
  ```

Heartbeat Interval and Timeout
The heartbeat interval specifies the period between the transmission of successive keepalive messages. Each MLAG switch transmits keepalive messages and monitors message reception from its peer. The heartbeat timeout is reset when the switch receives a keepalive message. If the heartbeat timeout expires, the switch disables MLAG under the premise that the peer switch is not functioning.

The **heartbeat-interval (MLAG)** command configures the heartbeat interval between 1 and 30 seconds, with a default value of 2 seconds. The heartbeat timeout expiry is 30 seconds.

**Important!** On 7500 and 7500E Series Switches, Arista recommends setting the heartbeat interval to 10 seconds.

Example
- This command configures the heartbeat interval as 2.5 seconds (2500 ms).
  ```
  switch(config-mlag)#heartbeat-interval 2500
  switch(config-mlag)#
  ```

Reload Delay Period
The reload delay period specifies the interval that non-peer links are disabled after an MLAG peer reboots. This interval allows non-peer links to learn multicast and OSPF states and synchronize ARP caches before the ports start handling traffic. Each Arista switch defaults to the recommended reload-delay value, which varies by switch platform

- fixed configuration switches: 300 seconds (five minutes)
- Trident-2 platform modular switches: 1200 seconds (twenty minutes)
- Sand platform modular switches: 1800 seconds (thirty minutes)

In those cases where network topology requires additional time to stabilize or where a shorter delay can be tolerated, the reload-delay period can be configured using the **reload-delay mlag** command.

Example
- This command configures the reload delay interval as 2.5 minutes (150 seconds).
  ```
  switch(config-mlag)#reload-delay 150
  switch(config-mlag)#```
Chapter 12: Multi-Chassis Link Aggregation

Configuring MLAG

Shutdown

The **shutdown (MLAG)** command disables MLAG operations without disrupting the MLAG configuration. The **no mlag configuration** command (global configuration mode) disables MLAG and removes the MLAG configuration. The **no shutdown** command resumes MLAG activity.

Examples

- This command disables MLAG activity on the switch.
  ```
  switch(config-mlag)#shutdown
  switch(config-mlag)#
  ```

- This command resumes MLAG activity on the switch.
  ```
  switch(config-mlag)#no shutdown
  switch(config-mlag)#
  ```

12.4.1.3 Configuring MLAG Peer Gateway

In an MLAG setup, routing on a MLAG peer switch is possible using its own bridge system MAC, VARP MAC, or VRRP MAC. On a peer receiving an IP packet with destination MAC set to one of these MACs, a packet gets routed if its hardware has enough information to route the packet. Configuring sending traffic to a cached MAC involves routing the session table and MLAG peer traffic if packets are received with the MAC peer.

Examples

- This command enables the MLAG peer gateway.
  ```
  switch(config)#ip virtual-router mac-address mlag-peer
  switch1(config)#
  ```

- This command disables the MLAG peer gateway.
  ```
  switch(config)#no ip virtual-router mac-address mlag-peer
  switch1(config)#
  ```
Configuring MLAG

Chapter 12: Multi-Chassis Link Aggregation

12.4.1.4 Configuring Ingress Replication to LAGs

Hardware support for ingress replication to LAGs is enabled by default when the user configures ingress replication. When multicast traffic is sent over the LAG, the hardware uses its built-in algorithm, based on the L2/L3/L4 headers, to load balance traffic over ports in the LAG. When a port goes down in a LAG, the hardware quickly hashes the multicast traffic over the remaining ports in the LAG, resulting in fewer drops than software based LAG support.

Examples

- This command enables ingress replication.
  ```
  switch(config)#platform sand multicast replication default ingress
  switch(config)#
  ```

- This command configures the maximum members for ingress only replication in a multicast group.
  ```
  switch(config)#platform sand multicast replication ingress maximum 32
  switch(config)#
  ```

12.4.2 Configuring MLAG Services

An MLAG is a pair of links that originate on a network attached device and terminate on the two MLAG peer switches. The MLAG switches coordinate traffic to the device through a common `mlag (port-channel interface configuration)` command on the interfaces that connect to the device.

The MLAG ID differs from the MLAG domain ID. The MLAG domain ID is assigned globally per switch in MLAG configuration mode, and the same MLAG domain ID must be on both switches.

It is not recommended that MLAGs are used with static LAGs. Configure the downstream switch or router connected to the MLAG peers to negotiate a LAG with LACP. For Arista Networks switches, this is in respect to a configuration such as `channel-group group-number mode on`.

Port channels configured as an MLAG must have identical port channel numbers. Although the MLAG ID is a distinct parameter from the port channel number, best practices recommend assigning the MLAG ID to match the port channel number.

The following example does not follow this convention to emphasize the parameters that are distinct. The example in Section 12.5 follows the best practices convention.

Examples

- These Switch1 commands bundle Ethernet interfaces 3 and 4 in port channel 20, then associate that port channel with MLAG 12.
  ```
  switch1(config)#interface ethernet 3-4
  switch1(config-if-et3-4)#channel-group 20 mode active
  switch1(config-if-et3-4)#interface port-channel 20
  switch1(config-if-po20)#mlag 12
  switch1(config-if-po20)#exit
  switch1(config)#
  ```

- These Switch2 commands bundle Ethernet interfaces 9 and 10 in port channel 15, then associate that port channel with MLAG 12.
  ```
  switch2(config)#interface ethernet 9-10
  switch2(config-if-et9-10)#channel-group 15 mode active
  switch2(config-if-et9-10)#interface port-channel 20
  switch2(config-if-po20)#mlag 12
  switch2(config-if-po20)#exit
  switch2(config)#
  ```
• These commands configure the port channels that attach to the MLAG on network attached device:

NAD(config)#interface ethernet 1-4
NAD(config-if-Et1-4)#channel-group 1 mode active
NAD(config-if-Et1-4)#exit
NAD(config)#

Figure 12-2 displays the result of the interface MLAG configuration.

Figure 12-2: MLAG Interface Configuration
12.5 MLAG Implementation Example

This example creates an MLAG Domain, then configures MLAG connections between the peer switches and four Network Attached Devices (NADs). The MLAG switches connect through a LAG and communicate with the NADs through MLAGs. Although the NADs can be any device that supports LACP LAGs, the devices in this example are Arista switches.

Figure 12-3: MLAG Implementation Example

12.5.1 Topology

Figure 12-3 displays the MLAG topology. Switch 1 and Switch 2 are MLAG peers that logically represent a single Layer 2 switch. The peer link between the switches contains the following interfaces:

- Switch 1: Ethernet 47, Ethernet 48
- Switch 2: Ethernet 23, Ethernet 24

The example configures MLAGs from the MLAG Domain to four network attached devices (NAD-1, NAD-2, NAD-3, NAD-4).

12.5.2 Configuring the Peer Switch Connections

To configure the switches in the described topology, perform the tasks in these sections:

- Section 12.5.2.1: Configuring the Peer Switch Port Channels
- Section 12.5.2.2: Configuring the Peer Switch SVIs
- Section 12.5.2.3: Configuring the Peer Links

12.5.2.1 Configuring the Peer Switch Port Channels

These commands create the port channels the switches use to establish the peer link.
These commands create port channels on Switch1

```
switch1(config)#interface ethernet 47-48
switch1(config-if-et47-48)#channel-group 101 mode active
switch1(config-if-et47-48)#interface port-channel 101
switch1(config-if-po101)#switchport mode trunk
switch1(config-if-po101)#switchport trunk group peertrunk
switch1(config-if-po101)#exit
switch1(config)#
```

These commands create port channels on Switch2

```
switch2(config)#interface ethernet 23-24
switch2(config-if-et23-24)#channel-group 201 mode active
switch2(config-if-et23-24)#interface port-channel 201
switch2(config-if-po201)#switchport mode trunk
switch2(config-if-po201)#switchport trunk group trunkpeer
switch2(config-if-po201)#exit
switch2(config)#
```

12.5.2.2 Configuring the Peer Switch SVIs

For each peer switch, these commands create an SVI and associate it to the trunk group assigned to the peer link port channel. STP is disabled on the VLAN.

These commands configure the SVI on Switch1

```
switch1(config)#vlan 4094
switch1(config-vlan-4094)#trunk group peertrunk
switch1(config-vlan-4094)#interface vlan 4094
switch1(config-if-vl4094)#ip address 172.17.0.1/30
switch1(config-if-vl4094)#no autostate
switch1(config-if-vl4094)#exit
switch1(config)#no spanning-tree vlan 4094
switch1(config)#
```

These commands configure the SVI on Switch2

```
switch2(config)#vlan 4094
switch2(config-vlan-4094)#trunk group trunkpeer
switch2(config-vlan-4094)#interface vlan 4094
switch2(config-if-vl4094)#ip address 172.17.0.2/30
switch2(config-if-vl4094)#no autostate
switch2(config-if-vl4094)#exit
switch2(config)#no spanning-tree vlan 4094
switch2(config)#
```

12.5.2.3 Configuring the Peer Links

These commands create the peer links on each MLAG switch.
These commands create peer links on Switch1

switch1(config)#mlag configuration
switch1(config-mlag)#local-interface vlan 4094
switch1(config-mlag)#peer-address 172.17.0.2
switch1(config-mlag)#peer-link port-channel 101
switch1(config-mlag)#domain-id mlag_01
switch1(config-mlag)#heartbeat-interval 2500
switch1(config-mlag)#reload-delay 150
switch1(config-mlag)#exit
switch2(config)#

These commands create peer links on Switch2

switch2(config)#mlag configuration
switch2(config-mlag)#local-interface vlan 4094
switch2(config-mlag)#peer-address 172.17.0.1
switch2(config-mlag)#peer-link port-channel 201
switch2(config-mlag)#domain-id mlag_01
switch2(config-mlag)#heartbeat-interval 2500
switch2(config-mlag)#reload-delay 150
switch2(config-mlag)#exit
switch2(config)#

12.5.3 Configuring Peer Switch MLAGs

These commands create the MLAGs that connect the MLAG domain to the network attached devices.

These commands configure MLAG 1 on Switch1

switch1(config)#interface ethernet 17-18
switch1(config-if-et17-18)#channel-group 1 mode active
switch1(config-if-et17-18)#interface port-channel 1
switch1(config-if-po1)#mlag 1
switch1(config-if-po1)#exit
switch1(config)#

These commands configure MLAG 1 on Switch2

switch2(config)#interface ethernet 1-2
switch2(config-if-et1-2)#channel-group 1 mode active
switch2(config-if-et1-2)#interface port-channel 1
switch2(config-if-po1)#mlag 1
switch2(config-if-po1)#exit
switch2(config)#

These commands configure MLAG 2 on Switch1

switch1(config)#interface ethernet 19-20
switch1(config-if-et19-20)#channel-group 2 mode active
switch1(config-if-et19-20)#interface port-channel 2
switch1(config-if-po2)#mlag 2
switch1(config-if-po2)#exit
switch1(config)#
These commands configure MLAG 2 on Switch2

```
switch2(config)#interface ethernet 3-4
switch2(config-if-et3-4)#channel-group 2 mode active
switch2(config-if-et3-4)#interface port-channel 2
switch2(config-if-po2)#mlag 2
switch2(config-if-po2)#exit
switch2(config)#
```

These commands configure MLAG 3 on Switch1

```
switch1(config)#interface ethernet 23
switch1(config-if-et23)#channel-group 3 mode active
switch1(config-if-et23)#interface port-channel 3
switch1(config-if-po3)#mlag 3
switch1(config-if-po3)#exit
switch1(config)#
```

These commands configure MLAG 3 on Switch2

```
switch2(config)#interface ethernet 7
switch2(config-if-et7)#channel-group 3 mode active
switch2(config-if-et7)#interface port-channel 3
switch2(config-if-po3)#mlag 3
switch2(config-if-po3)#exit
switch2(config)#
```

These commands configure MLAG 4 on Switch1

```
switch1(config)#interface ethernet 25
switch1(config-if-et25)#channel-group 4 mode active
switch1(config-if-et25)#interface port-channel 4
switch1(config-if-po4)#mlag 4
switch1(config-if-po4)#exit
switch1(config)#
```

These commands configure MLAG 4 on Switch2

```
switch2(config)#interface ethernet 9
switch2(config-if-et9)#channel-group 4 mode active
switch2(config-if-et9)#interface port-channel 4
switch2(config-if-po4)#mlag 4
switch2(config-if-po4)#exit
switch2(config)#
```

12.5.4 Configuring the Network Attached Devices

These commands create the LAGs on the Network Attached Devices that connect to the MLAG domain.

These commands configure the port channels on NAD-1

```
NAD-1(config)#interface ethernet 7-10
NAD-1(config-if-Et7-10)#channel-group 1 mode active
NAD-1(config-if-Et7-10)#exit
NAD-1(config)#
```
These commands configure the port channels on NAD-2

```
NAD-2(config)#interface ethernet 25-28
NAD-2(config-if-Et25-28)#channel-group 7 mode active
NAD-2(config-if-Et25-28)#exit
NAD-2(config)#
```

These commands configure the port channels on NAD-3

```
NAD-3(config)#interface ethernet 3-4
NAD-3(config-if-Et3-4)#channel-group 5 mode active
NAD-3(config-if-Et3-4)#exit
NAD-3(config)#
```

These commands configure the port channels on NAD-4

```
NAD-4(config)#interface ethernet 1-2
NAD-4(config-if-Et1-2)#channel-group 2 mode active
NAD-4(config-if-Et1-2)#exit
NAD-4(config)#
```
12.5.5 Verification

The following tasks verify the MLAG peer and connection configuration:

- Section 12.5.5.1: Verify the Peer Switch Connection
- Section 12.5.5.2: Verify the MLAGs
- Section 12.5.5.3: Verify Spanning Tree Protocol (STP)
- Section 12.5.5.4: Verify the MLAG Port Channel
- Section 12.5.5.5: Verify the VLAN Membership

12.5.5.1 Verify the Peer Switch Connection

To display the MLAG configuration and the MLAG status on Switch 1, use the `show mlag` command:

```
Switch1#show mlag
MLAG Configuration:
domain-id : mlag_01
local-interface : Vlan4094
peer-address : 172.17.0.2
peer-link : Port-Channel101

MLAG Status:
state : Active
peer-link status : Up
local-int status : Up
system-id : 02:1c:FF:00:15:38

MLAG Ports:
Disabled : 0
Configured : 0
Inactive : 0
Active-partial : 0
Active-full : 4
```

To display the MLAG configuration and the MLAG status on Switch 2, use the `show mlag` command:

```
Switch2#show mlag
MLAG Configuration:
domain-id : mlag_01
local-interface : Vlan4094
peer-address : 172.17.0.1
peer-link : Port-Channel102

MLAG Status:
state : Active
peer-link status : Up
local-int status : Up
system-id : 02:1c:FF:00:15:41

MLAG Ports:
Disabled : 0
Configured : 0
Inactive : 0
Active-partial : 0
Active-full : 4
```
12.5.5.2 Verify the MLAGs

The `show mlag interfaces` command displays MLAG connections between the MLAG switches and the Network Attached Devices.

- **This show mlag interfaces command displays MLAG connections between the MLAG peer Switch 1 and the network attached devices:**

  ```
  Switch1#show mlag interfaces
  mlag  desc                   state     local     remote         status
  ----------------------------------------------------------------------------
  1     sw1.po1          active-full       Po1        Po1          up/up
  2     sw1.po2          active-full       Po2        Po2          up/up
  3     sw1.po3          active-full       Po3        Po3          up/up
  4     sw1.po4          active-full       Po4        Po4          up/up
  ```

- **The following show mlag interfaces command, with the `detail` option, displays MLAG connections between the MLAG peer Switch 1 and the network attached devices**

  ```
  Switch2#show mlag interfaces detail
  mlag state local remote    oper   config          last change  changes
  ----------------------------------------------------------------------------
  1 active-full    Po1    Po1  up/up  ena/ena  6 days, 2:08:28 ago        5
  2 active-full    Po2    Po2  up/up  ena/ena  6 days, 2:08:30 ago        5
  3 active-full    Po3    Po3  up/up  ena/ena  6 days, 2:08:33 ago        5
  4 active-full    Po4    Po4  up/up  ena/ena  6 days, 2:08:41 ago        5
  ```

12.5.5.3 Verify Spanning Tree Protocol (STP)

STP functions can be displayed from each peer switch. MLAG interfaces are displayed as a single entry. Configured interfaces on each switch that are not included in an MLAG are displayed. Local interfaces have the normal notation; remote interfaces are preceded by `P` or `Peer`.

**VLAN Output 1: Assume VLAN 3903 includes MLAG 1**

```
Switch1#show spanning-tree vlan 3903
Spanning tree instance for vlan 3903
VL3903
  Spanning tree enabled protocol rapid-pvst
  Root ID Priority    36671
  Address 001c.730c.3009
  Cost 1999 (Ext) 0 (Int)
  Port 105 (Port-Channel5)
  Hello Time 2.000 sec  Max Age 20 sec  Forward Delay 15 sec
  Bridge ID Priority    36671 (priority 32768 sys-id-ext 3903)
  Address 021c.7300.1319
  Hello Time 2.000 sec  Max Age 20 sec  Forward Delay 15 sec
  Interface Role State   Cost     Prio.Nbr Type
  ----------------- --------- ------- ---------- ------------------
  Po1 root forwarding 1999 128.105 P2p
Switch1#
```

The output displays MLAG 1 under its local interface name (Po1). A peer interface is not displayed because spanning tree considers the local and remote Port Channels as a single MLAG interface.
VLAN Output 2: Assume VLAN 3908 does not include any MLAGs

Switch1# show spanning-tree vlan 3908
Spanning tree instance for vlan 3908
VL3908
  Spanning tree enabled protocol rapid-pvst
  Root ID  Priority    36676
  Address     021c.7300.1319
  This bridge is the root

  Bridge ID  Priority    36676  (priority 32768 sys-id-ext 3908)
  Address     021c.7300.1319
  Hello Time  2.000 sec  Max Age 20 sec  Forward Delay 15 sec

  Interface        Role       State      Cost      Prio.Nbr Type
  ---------------- ---------- ---------- --------- -------- ----------------------
  Et17             designated forwarding 2000      128.217  P2p
  Et18             designated forwarding 2000      128.218  P2p
  PEt17            designated forwarding 2000      128.17   P2p
  PEt18            designated forwarding 2000      128.18   P2p

The output displays all interfaces from both switches. Each interface is explicitly displayed because they are individual units that STP must consider when selecting ports to block.

- Et17 and Et18 are located on the switch where the show spanning-tree command is issued.
- PEt17 and PEt18 are located on the remote switch from where the command was issued

An identical command issued on the peer switch displays similar information.

Verify the MLAG does not create topology loops (show spanning-tree blocked)

Switch1# show spanning-tree blocked
Name       Blocked Interfaces List
---------- -------------- --------------------------------------------

Number of blocked ports (segments) in the system : 0
Switch1#

12.5.5.4 Verify the MLAG Port Channel

Issue the command show port-channel for channels 1-4 from Switch 1:

Switch1# show port-channel 1-4
Port Channel Port-Channel1:
  Active Ports: Ethernet17     Ethernet18     PeerEthernet1 PeerEthernet2
Port Channel Port-Channel2:
  Active Ports: Ethernet19     Ethernet20     Ethernet21     Ethernet22
  PeerEthernet3 PeerEthernet4 PeerEthernet5 PeerEthernet6
Port Channel Port-Channel3:
  Active Ports: Ethernet23     Ethernet24     PeerEthernet7 PeerEthernet8
Port Channel Port-Channel4:
  Active Ports: Ethernet25     Ethernet26     PeerEthernet9 PeerEthernet10
Issue the command `show port-channel load-balance fields detailed` command for channel 1 from Switch 2:

```
Switch# show port-channel 1 detailed
Port Channel Port-Channel1:
  Active Ports:
                      Port          Time became active          Protocol    Mode
---------------------------------------------------------------------------------
  Ethernet17          7/7/11 15:27:36          LACP        Active
  Ethernet18          7/7/11 15:27:36          LACP        Active
  PeerEthernet1       7/7/11 15:27:36          LACP        Active
  PeerEthernet2       7/7/11 15:27:36          LACP        Active
```

12.5.5.5 Verify the VLAN Membership

The `show vlan` command displays VLAN member ports, including MLAG ports and ports on each peer not bundled in an MLAG.

```
Switch1# show vlan 3903, 3908
VLAN Name                             Status    Ports
----- -------------------------------- --------- -------------------------------
  3903  ar.mg.rn.172.17.254.16/29        active    Cpu, Po1
  3908  po.ra.ar.mg.172.17.254.64/29     active    Cpu, Et17, Et18, PEt17, PEt18
```
Chapter 12: Multi-Chassis Link Aggregation

12.6 MLAG Commands

MLAG and Port Channel Commands – Global Configuration Mode

- `mlag configuration (global configuration)`

Interface Configuration Commands – Interface Configuration Mode

- `mlag (port-channel interface configuration)`

MLAG Configuration Commands

- `domain-id`
- `heartbeat-interval (MLAG)`
- `local-interface`
- `peer-address`
- `peer-link`
- `reload-delay mlag`
- `reload-delay mode`
- `reload-delay non-mlag`
- `shutdown (MLAG)`

Display Commands

- `show mlag`
- `show mlag interfaces`
- `show mlag interfaces members`
- `show mlag interfaces states`
- `show mlag issu warnings`
**domain-id**

The `domain-id` command specifies a name for the multi-chassis link aggregation (MLAG) domain. The `no domain-id` and `default domain-id` commands remove the MLAG domain name by deleting the `domain-id` statement from `running-config`.

**Command Mode**
MLAG Configuration

**Command Syntax**
```
domain-id identifier
no domain-id
default domain-id
```

**Parameters**
- `identifier` alphanumeric string that names the MLAG domain.

**Examples**
- This command names the MLAG domain `mlag1`.
  ```
  switch(config)#mlag
  switch(config-mlag)#domain-id mlag1
  switch(config-mlag)#
  ```
heartbeat-interval (MLAG)

The heartbeat-interval command configures the interval at which heartbeat messages are issued in a multi-chassis link aggregation (MLAG) configuration.

The no heartbeat-interval and default heartbeat-interval commands revert the heartbeat interval to the default setting (2 seconds) by removing the heartbeat-interval command from running-config.

**Command Mode**

MLAG Configuration

**Command Syntax**

- `heartbeat-interval period`
- `no heartbeat-interval`
- `default heartbeat-interval`

**Parameters**

- **period** Interval duration (ms). Value ranges from 1000 through 30000. Default interval is 2000 ms.

**Guidelines**

Heartbeat messages flow independently in both directions between the MLAG peers. If a peer stops receiving heartbeat messages within the expected time frame (30 seconds), the other peer can assume it no longer functions and without intervention or repair, the MLAG becomes disabled. Both switches revert to their independent state.

**Important!** On 7500 and 7500E Series Switches, Arista recommends setting the heartbeat interval to 10 seconds.

**Examples**

- This command configures the heartbeat interval to 15000 milliseconds:

```
switch(config)#mlag
switch(config-mlag)#heartbeat-interval 15000
switch(config-mlag)#
```
**local-interface**

The `local-interface` command assigns a VLAN interface for use in multi-chassis link aggregation (MLAG) configurations. The VLAN interface is used for both directions of communication between the MLAG peers.

The `no local-interface` and `default local-interface` commands delete the VLAN interface assignment by removing the `local-interface` command from `running-config`.

**Command Mode**

MLAG Configuration

**Command Syntax**

```
local-interface vlan vlan_number
no local-interface
default local-interface
```

**Parameters**

- `vlan_number` VLAN number, in the range from 1 through 4094.

**Guidelines**

When configuring the local interface, the VLAN interface must exist already. To configure a VLAN interface, issue the command `interface vlan`.

**Example**

- This command assigns VLAN 4094 as the local interface.

```
switch(config)#mlag
switch(config-mlag)#local-interface vlan 4094
switch(config-mlag)#
```
mlag (port-channel interface configuration)

The `mlag` command assigns an MLAG ID to a port-channel. MLAG peer switches form an MLAG when each switch configures the same MLAG ID to a port-channel interface. Only one MLAG ID can be assigned to an interface. An individual MLAG number cannot be assigned to more than one interface.

The `no mlag` and `default mlag` commands remove the MLAG ID assignment from the configuration mode interface by deleting the corresponding `mlag` command from `running-config`.

**Command Mode**

- Interface-Port Channel Configuration

**Command Syntax**

```
mlag number
no mlag
default mlag
```

**Parameters**

- `number` Number used as MLAG ID. Value ranges from 1 to 2000.

**Example**

- These commands configures a port channel and assigns it MLAG 4.

```
switch(config)#interface ethernet 5-10
switch(config-if-Et5-10)#channel-group 1 mode active
switch(config-if-Et5-10)#interface port-channel 4
switch(config-if-Po4)#switchport trunk group group4
switch(config-if-Po4)#mlag 4
switch(config-if-Po4)#exit
switch(config)#
```
mlag configuration (global configuration)

The `mlag configuration` command enters MLAG configuration mode to configure multi-chassis link aggregation (MLAG) features. MLAG configuration mode is not a group change mode; `running-config` is changed immediately after commands are executed. The `exit` command does not affect the configuration.

The `no mlag configuration` and `default mlag configuration` commands remove all MLAG configuration commands from `running-config`.

The `exit` command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
`mlag [configuration]`
`no mlag configuration`
`default mlag configuration`

mlag and mlag configuration are identical commands.

Guidelines
An MLAG is formed by connecting two switches through an interface called a peer link. The peer link carries control and data traffic between the switches, including advertisements and keepalive messages. This information coordinates the switches. Functioning peers are in the active state.

Each peer switch uses IP-level connectivity between their local addresses and the MLAG peer IP address to form and maintain the peer link.

Commands Available in MLAG Configuration Mode
- `domain-id`
- `heartbeat-interval (MLAG)`
- `local-interface`
- `peer-address`
- `peer-link`
- `reload-delay mlag`
- `shutdown (MLAG)`

Example
- These commands enter MLAG configuration mode and configure MLAG parameters:

  switch(config)#mlag
  switch(config-mlag)#local-interface vlan 4094
  switch(config-mlag)#peer-address 10.0.0.2
  switch(config-mlag)#peer-link port-channel 10
  switch(config-mlag)#domain-id mlagDomain
  switch(config-mlag)#heartbeat-interval 2500
  switch(config-mlag)#reload-delay 2000
  switch(config-mlag)#exit
  switch(config)#
peer-address

The `peer-address` command specifies the peer IPv4 address for a multi-chassis link aggregation (MLAG) domain. MLAG control traffic, including keepalive messages, is sent to the peer IPv4 address. If the peer IPv4 address is unreachable, then MLAG peering fails and both peer switches revert to their independent state.

The `no peer-address` and `default peer-address` commands remove the MLAG peer's IPv4 address assignment by deleting the peer-address command from `running-config`.

**Command Mode**
MLAG Configuration

**Command Syntax**
```
peer-address ipv4_addr
no peer-address
default peer-address
```

**Parameters**
- `ipv4_addr`  MLAG peer IPv4 address.

**Example**
- These commands configure the MLAG peer address.
  ```
  switch(config)#mlag
  switch(config-mlag)#peer-address 10.0.0.2
  switch(config-mlag)#
  ```
peer-link

The *peer-link* command specifies the interface that connects multi-chassis link aggregation (MLAG) peers. To form an MLAG, two switches are connected through an interface called a peer link. The peer link carries control and data traffic between the two switches. Control traffic includes MLAG-related advertisements and keepalive messages. This information keeps the two switches working as one.

The *no peer-link* and *default peer-link* command remove the peer link by deleting the *peer-link* command from *running-config*.

**Command Mode**
MLAG Configuration

**Command Syntax**

```
peer-link INT_NAME
no peer-link
default peer-link
```

**Parameters**
- *INT_NAME* denotes the interface type and number of the interface. Values include:
  - *ethernet e_num* Ethernet interface range specified by e_num.
  - *port-channel p_num* Channel group interface range specified by p_num.

**Example**
- These commands creates a peer link.

```
switch(config)#mlag configuration
switch(config-mlag)#peer-link port-channel 10
switch(config-mlag)
```
reload-delay mlag

The `reload-delay mlag` command configures the reload delay period for MLAG links. The command also specifies the reload delay period for non-MLAG links when the `reload-delay non-mlag` command is not configured.

Each Arista switch defaults to the recommended reload-delay value, which varies by switch platform:

- **fixed configuration switches**: 300 seconds
- **Trident-2 modular switches**: 900 seconds
  - 7304
  - 7308
  - 7316
  - 7300X series
- **Sand platform modular switches**: 1800 seconds
  - 7504
  - 7508
  - 7500E series
  - 7548S

The `no reload-delay mlag` and `default reload-delay mlag` commands restore the default value by deleting the `reload-delay mlag` statement from `running-config`.

**Command Mode**

MLAG Configuration

**Command Syntax**

```
reload-delay [mlag] PERIOD
no reload-delay [mlag]
default reload-delay [mlag]
```

**Parameters**

- **PERIOD**: Period that non-peer links are disabled after an MLAG peer reboots. Options include:
  - `infinity`: link is not enabled after reboot.
  - `<0 to 86400>`: disabled link interval (seconds). Default varies by switch platform as described above.

**Guidelines**

The `reload-delay` and `reload-delay mlag` commands are equivalent.

**Example**

- These commands configure the reload-delay interval to 15 minutes.

```
switch(config)#mlag configuration
switch(config-mlag)#reload-delay mlag 900
switch(config-mlag)#
```
**reload-delay mode**

The `reload-delay mode` command specifies the state of LACP LAG ports during the MLAG reload delay period. By default, MLAG ports remain in the errdisabled state during reload delay. This command configures MLAG ports to come up to standby mode before the expiration of the reload delay period.

The `no reload-delay mode` and `default reload-delay mode` commands restore the default behavior of MLAG ports by deleting the `reload-delay mode` statement from `running-config`. The default behavior is for the MLAG ports to remain in the errdisabled state until the expiration of the reload delay period.

**Command Mode**

MLAG Configuration

**Command Syntax**

```
reload-delay mode lacp standby
no reload-delay mode
default reload-delay mode
```

**Related Commands**

- `reload-delay mlag` configures the MLAG reload delay period.

**Example**

- These commands configure the MLAG port to come up to standby state before the end of the reload delay period.

```
switch(config)#mlag configuration
switch(config-mlag)#reload-delay mode lacp standby
switch(config-mlag)#
```
**reload-delay non-mlag**

The `reload-delay non-mlag` command specifies the period that non-MLAG links are disabled after an MLAG peer reboots. This interval allows non peer links to learn multicast and OSPF states before the ports start handling traffic. The recommended minimum value required to ensure the forwarding hardware is initialized with the topology state depends on the switch platform:

- fixed configuration switches: 300 seconds (five minutes)
- modular switches: 1200 seconds (20 minutes)

When the `reload-delay non-mlag` command is not configured, the `reload-delay mlag` command specifies the reload delay time for non-MLAG and MLAG links.

The `no reload-delay non-mlag` and `default reload-delay non-mlag` command restores the default behavior by deleting the `reload-delay non-mlag` statement from `running-config`.

**Command Mode**
MLAG Configuration

**Command Syntax**

```
reload-delay non-mlag PERIOD
no reload-delay non-mlag
default reload-delay non-mlag
```

**Parameters**

- **PERIOD** Period that non-MLAG links are disabled after an MLAG peer reboots. Options include:
  - infinity links are not enabled after reboot.
  - `<0 to 86400>` disabled link interval (seconds). Values range from 0 to 86400 (24 hours).

**Example**

- These commands configure the reload-delay interval of non-MLAG links to 20 minutes.

  ```
  switch(config)#mlag configuration
  switch(config-mlag)#reload-delay non-mlag 1200
  switch(config-mlag)#
  ```
**show mlag**

The **show mlag** command displays information about the multi-chassis link aggregation (MLAG) configuration on bridged Ethernet interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show mlag [INFO_LEVEL]
```

**Parameters**

- **INFO_LEVEL** specifies information displayed by command. Options include:
  - `<no parameter>` command displays MLAG configuration, status, and ports.
  - **detail** command displays MLAG configuration, status, ports, and detailed status.

**Example**

- This command displays output from the **show mlag** command:

```plaintext
switch>show mlag
MLAG Configuration:
domain-id         :         ar.mg.mlag
local-interface   :           Vlan3901
peer-address      :       172.17.254.2
peer-link         :      Port-Channel1

MLAG Status:
state             :             Active
peer-link status  :                 Up
local-int status  :                 Up
system-id         :  02:1c:73:00:13:19

MLAG Ports:
Disabled          :   0
Configured        :   0
Inactive          :   0
Active-partial    :   0
Active-full       :   5

switch>
```
show mlag interfaces

The `show mlag interfaces` command displays information about the multi-chassis link aggregation (MLAG) configuration on bridged Ethernet interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show mlag interfaces [MLAGS] [INFO_LEVEL]
```

**Parameters**

- **MLAGS**  
  MLAG channels for which command displays data. Options include:
  - `<no parameter>` command displays data for all MLAGs.
  - `mlag_id` specifies MLAG for which command displays data. Value ranges from 1 to 2000.

- **INFO_LEVEL**  
  specifies information displayed by command. Options include:
  - `<no parameter>` command displays basic MLAG interface parameters
  - `detail` command displays detailed MLAG interface parameters.

**Example**

- This command displays output from the `show mlag interfaces detail` command:

```
switch>show mlag interfaces detail

        mlag  state   local   remote     oper   config     last change     changes
---------------------------------------------------------------
  4 active-full   Po4    Po4  up/up     ena/ena 6 days, 1:19:26 ago        5
  5 active-full   Po5    Po5  up/up     ena/ena 6 days, 1:19:24 ago        5
  6 active-full   Po6    Po6  up/up     ena/ena 6 days, 1:19:23 ago        5
  7 active-full   Po7    Po7  up/up     ena/ena 6 days, 1:19:23 ago        5
```
show mlag interfaces members

The `show mlag interfaces members` command displays information about the multi-chassis link aggregation (MLAG) members on bridged Ethernet interfaces.

**Command Mode**

EXEC

**Command Syntax**

`show mlag interfaces members`

**Example**

- This command displays the MLAG interface members.

```
switch#show mlag interface members
Mlag4 is Port-Channel4
  Active Ports: Ethernet3 PeerEthernet3
Mlag5 is Port-Channel5
  Active Ports: Ethernet14
Mlag7 is Port-Channel7
  Active Ports: Ethernet5 PeerEthernet5
Mlag8 is Port-Channel8
  Active Ports: Ethernet10 PeerEthernet10
Mlag9 is Port-Channel9
  Active Ports: Ethernet15 Ethernet21 PeerEthernet19 PeerEthernet20
Mlag10 is Port-Channel10
  Active Ports: Ethernet19 Ethernet20 PeerEthernet21 PeerEthernet22
switch#
```
show mlag interfaces states

The `show mlag interfaces states` command displays information about the multi-chassis link aggregation (MLAG) states on bridged Ethernet interfaces.

**Command Mode**

EXEC

**Command Syntax**

```
show mlag interfaces [MLAGS] states [STATE_NAMES] [INFO_LEVEL]
```

**Parameters**

- **MLAGS** MLAG channels for which command displays data. Options include:
  - <no parameter> command displays data for all MLAGs.
  - `mlag_id` specifies MLAG for which command displays data. Value ranges from 1 to 2000.
- **STATE_NAMES** MLAG channels for which command displays data. Parameter may specify more than one name, which can be listed in any order. Valid state names include:
  - `active-full` includes active-full interfaces.
  - `active-partial` includes active-partial interfaces.
  - `configured` includes configured interfaces.
  - `disabled` includes disabled interfaces.
  - `inactive` includes inactive interfaces.
- **INFO_LEVEL** specifies information displayed by command. Options include:
  - <no parameter> command displays basic MLAG interface parameters
  - `detail` command displays detailed MLAG interface state parameters.

**Example**

- This command displays the MLAG interface states that are active-full.
  
  ```
  switch# show mlag interfaces states active-full
  mlag desc       state       local    remote    local/remote
  ------- -------- -------------- --------- ----------- ---------------
  4        b.po1   active-full   Po4     Po4          up/up          
  7        ar.mg.au.po1 active-full Po7     Po7          up/up          
  8        co.po1   active-full   Po8     Po8          up/up          
  9        k.po5    active-full   Po9     Po9          up/up          
  10       ar.mg.pt.ir.po10 active-full Po10    Po10        up/up          
  switch#  
  ```

show mlag issu warnings

The `show mlag issu warnings` command displays a warning message regarding the backward-compatibility of this feature before you upgrade.

**Command Mode**

EXEC

**Command Syntax**

`show mlag issu warnings`

**Example**

- This command displays the MLAG backward-compatibility warning message. Refer to the latest version of the release notes for additional information before you upgrade.

  switch##show mlag issu warnings

If you are performing an upgrade, and the Release Notes for the new version of EOS indicate that MLAG is not backwards-compatible with the currently installed version, the upgrade will result in packet loss.

Stp is not restartable. Topology changes will occur during the upgrade process.

switch#
shutdown (MLAG)

The `shutdown` command disables MLAG on the switch without modifying the MLAG configuration. The `no shutdown` and `default shutdown` commands re-enable MLAG by removing the `shutdown` command from `running-config`.

**Command Mode**

MLAG Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Example**

- These commands disable MLAG on the switch.

```
switch(config)#mlag configuration
switch(config-mlag)#shutdown
switch(config-mlag)#
```
Chapter 13

802.1x Port Security

This section explains the basic concepts behind 802.1x port security, including switch roles, how the switches communicate, and the procedure used for authenticating clients.

- Section 13.1: 802.1x Port Security Introduction
- Section 13.2: 802.1x Port Security Description
- Section 13.3: Configuring 802.1x Port Security
- Section 13.4: Displaying 802.1x information
- Section 13.5: IEEE 802.1x Configuration Commands

13.1 802.1x Port Security Introduction

Port security control who can send or receive traffic from an individual switch port. An end node is not allowed to send or receive traffic through a port until the node is authenticated by a RADIUS server. This prevents unauthorized individuals from connecting to a switch port to access your network. Only designated valid users on a RADIUS server will be allowed to use the switch to access the network.
13.2 802.1x Port Security Description

13.2.1 Switch Roles for 802.1x Configurations

The 802.1x standard specifies the roles of Supplicant (client), Authenticator, and Authentication Server in a network. Figure 11-1 illustrates these roles.

Figure 13-1: Authenticator, Supplicant, and Authentication Server in an 802.1x configuration

Authentication server – The switch that validates the client and specifies whether or not the client may access services on the switch. The switch supports Authentication Servers running RADIUS.

Authenticator – The switch that controls access to the network. In an 802.1x configuration, the switch serves as the Authenticator. As the Authenticator, it moves messages between the client and the Authentication Server. The Authenticator either grants or does not grant network access to the client based on the identity data provided by the client, and the authentication data provided by the Authentication Server.

Supplicant/Client – The client provides a username or password data to the Authenticator. The Authenticator sends this data to the Authentication Server. Based on the supplicant’s information, the Authentication Server determines whether the supplicant can use services given by the Authenticator. The Authentication Server gives this data to the Authenticator, which then provides services to the client, based on the authentication result.

13.2.2 Authentication Process

The authentication that occurs between a supplicant, authenticator, and authentication server include the following processes.

- Either the authenticator (a switch port) or the supplicant starts an authentication message exchange. The switch starts an exchange when it detects a change in the status of a port, or if it gets a packet on the port with a source MAC address that is not included in the MAC address table.
- An authenticator starts the negotiation by sending an EAP-Request/Identity packet. A supplicant starts the negotiation with an EAPOL-Start packet, to which the authenticator answers with an EAP-Request/Identity packet.
- The supplicant answers with an EAP-Response/Identity packet to the authentication server via the authenticator.
- The authentication server responds with an EAP-Request packet to the supplicant via the authenticator.
- The supplicant responds with an EAP-Response.
- The authentication server transmits either an EAP-Success packet or EAP-Reject packet to the supplicant.
- If an EAP-Reject is received, the supplicant will receive an EAP-Reject message and their traffic will not be forwarded.

13.2.3 Communication Between the Switches

For communication between the switches, 802.1x port security uses the Extensible Authentication Protocol (EAP), defined in RFC 2284 and the RADIUS authentication protocol.

The 802.1x standard defines a method for encapsulating EAP messages so they can be sent over a LAN. This encapsulated kind of EAP is known as EAP over LAN (EAPOL). The standard also specifies a means of transferring the EAPOL information between the client or Supplicant, Authenticator, and Authentication Server.

EAPOL messages are passed between the Supplicant’s and Authenticator’s Port Access Entity (PAE). Figure 13-2 shows the relationship between the Authenticator PAE and the Supplicant PAE.

Figure 13-2: Authenticator PAE and Supplicant PAE
**Authenticator PAE**: The Authenticator PAE communicates with the Supplicant PAE to receive the Supplicant’s identifying information. Behaving as a RADIUS client, the Authenticator PAE passes the Supplicant’s information to the Authentication Server, which decides whether to grant the Supplicant access. If the Supplicant passes authentication, the Authenticator PAE allows it access to the port.

**Supplicant PAE** – The Supplicant PAE provides information about the client to the Authenticator PAE and replies to requests from the Authenticator PAE. The Supplicant PAE may initiate the authentication procedure with the Authenticator PAE, as well as send logoff messages.

### 13.2.4 Controlled and Uncontrolled Ports

A physical port on the switch used with 802.1x has two virtual access points that include a controlled port and an uncontrolled port. The controlled port grants full access to the network. The uncontrolled port only gives access for EAPOL traffic between the client and the Authentication Server. When a client is authenticated successfully, the controlled port is opened to the client.

*Figure 13-3: Ports before and after client authentication*

The uncontrolled port on the Authenticator is the only one open before a client is authenticated. The uncontrolled port permits only EAPOL frames to be swapped between the client and the Authentication Server. No traffic is allowed to pass through the controlled port in the unauthorized state.

During authentication, EAPOL messages are swapped between the Supplicant PAE and the Authenticator PAE, and RADIUS messages are swapped between the Authenticator PAE and the Authentication Server. If the client is successfully authenticated, the controlled port becomes authorized, and traffic from the client can flow through the port normally.
All controlled ports on the switch are placed in the authorized state, allowing all traffic, by default. When authentication is initiated, the controlled port on the interface is initially set in the unauthorized state. If a client connected to the port is authenticated successfully, the controlled port is set in the authorized state.

**13.2.5 Message Exchange During Authentication**

Figure 13-4 illustrates an exchange of messages between an 802.1x-enabled client, a switch operating as Authenticator, and a RADIUS server operating as an Authentication Server.

**Figure 13-4: Message exchange during authentication**

Arista switches support MD5-challenge TLS and any other EAP-encapsulated authentication types in EAP Request or Response messages. In other words, the switches are transparent to the authentication scheme used.

**13.2.6 Authenticating Multiple Clients Connected to the Same Port**

Arista switches support 802.1x authentication for ports with more than one client connected to them (multi-host mode). Figure 13-5 illustrates a sample configuration where multiple clients are connected to a single 802.1x port.

If there are multiple clients connected to a single 802.1x-enabled port, the switch authenticates each individually. Each client’s authentication state is independent of the others, so that if one authenticated client disconnects from the network, it won’t impact the authentication status of any of the other authenticated clients.
Figure 13-5: Multiple clients connected to a 802.1x-enabled port
13.3 Configuring 802.1x Port Security

Basic steps to implementing 802.1x Port-based Network Access Control and RADIUS accounting on the switch:

**Step 1** A RADIUS server is required on one or more of your network servers or management stations.

802.1x is not supported with the TACACS+ authentication protocol.

**Step 2** You must create supplicant accounts on the RADIUS server:

- The account for a supplicant connected to an authenticator port must have a username and password combination when set to the 802.1x authentication mode. The maximum username length is 38 alphanumeric characters and spaces, and the maximum length for a password is 16 alphanumeric characters and spaces.

- An account for the supplicant connected to an authenticator port and placed in the MAC address-based authentication mode needs use the MAC address of the node as both the username and password.

- Connected clients to an 802.1x authenticator port will require 802.1x client software.

**Step 3** The RADIUS client must be configured by entering the IP addresses and encryption keys of the authentication servers on your network.

**Step 4** The port access control settings must be configured on the switch. This includes the following:

- Specifying the port roles.
- Configuring 802.1x port parameters.
- Enabling 802.1x Port-based Network Access Control.

**Guidelines**

- Do not set a port that is connected to a RADIUS authentication server to the authenticator role as an authentication server cannot authenticate itself.

- A supplicant connected to an authenticator port set to the 802.1x username and password authentication method must have 802.1x client software.

- To prevent unauthorized individuals from accessing the network through unattended network workstations, end users of 802.1x port-based network access control should always log off when they are finished with a work session.

- The RADIUS client should be configured on the switch before activating port-based access control.

13.3.1 Configuring 802.1x Authentication Methods

IEEE 802.1x port security relies on external client-authentication methods, which must be configured for use. The method currently supported on Arista switches is RADIUS authentication. To configure the switch to use a RADIUS server for client authentication, use the `aaa authentication dot1x` command.

**Example**

- The `aaa authentication dot1x` command configures the authentication, authorization, and accounting (AAA) methods to be used on interfaces running IEEE 802.1X. The following configures the switch to use RADIUS authentication.

```bash
switch(config)# aaa authentication dot1x default group radius
switch(config)#
```
13.3.2 Globally Enable IEEE 802.1x
To enable IEEE 802.1X port authentication globally on the switch, use the `dot1x system-auth-control` command.

- This command enables IEEE 802.1X globally on the switch.
  ```
  switch(config)#dot1x system-auth-control
  switch(config)
  ```

13.3.3 Designating Authenticator Ports
For ports to act as authenticator ports to connected supplicants, those ports must be designated using the `dot1x port-control` command.

The `auto` option of the `dot1x port-control` command designates an authenticator port for immediate use, blocking all traffic that is not authenticated by the RADIUS server.

**Example**

- This command configures Ethernet 1 to immediately begin functioning as an authenticator port.
  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x port-control auto
  switch(config-if-Et1)#
  ```

The `force-authorized` option of the `dot1x port-control` command sets the state of the port to `authorized` without authentication, allowing traffic to continue uninterrupted.

**Example**

- These commands designate Ethernet 1 as an authenticator port that will forward packets without authentication.
  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x port-control force-authorized
  switch(config-if-Et1)#
  ```

To designate a port as an authenticator but prevent it from authorizing any traffic, use the `force-unauthorized` option of the `dot1x port-control` command.

**Example**

- The `force-unauthorized` option of the `dot1x port-control` command places the specified port in the `unauthorized` state, which will deny any access requests from users of the ports.
  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x port-control force-authorized
  switch(config-if-Et1)#
  ```

13.3.4 Configuring Re-authentication
The `dot1x reauthentication` and `dot1x timeout reauth-period` commands configure authenticator ports to require re-authentication from clients at regular intervals.
Example
- These commands configure the Ethernet interface 1 authenticator to require re-authentication from clients every 6 hours (21600 seconds).
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x reauthentication
  switch(config-if-Et1)#dot1x timeout reauth-period 21600
  switch(config-if-Et1)#
- These commands deactivate re-authentication on Ethernet interface 1.
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#no dot1x reauthentication
  switch(config-if-Et1)#

13.3.5 Setting the EAP Request Maximum
The `dot1x max-reauth-req` command configures the number of times the switch retransmits an 802.1x Extensible Authentication Protocol (EAP) request packet before ending the conversation and restarting authentication.

Example
- These commands set the number of times the authenticator sends an EAP request packet to the client before restarting authentication.
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x max-reauth-req 4
  switch(config-if-Et1)#

13.3.6 Disabling Authentication on a Port
To disable authentication on an authenticator port, use the `no dot1x port-control` command.

Example
- These commands disable authentication on Ethernet interface 1.
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#no dot1x port-control
  switch(config-if-Et1)#

13.3.7 Setting the Quiet Period
If the switch fails to immediately authenticate the client, the time the switch waits before trying again is specified by the `dot1x timeout quiet-period` command. This timer also indicates how long a client that failed authentication is blocked.

Example
- These commands set the 802.1x quiet period for Ethernet interface 1 to 30 seconds.
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#dot1x timeout quiet-period 30
13.3.8 Setting the Transmission Timeout

Authentication and re-authentication are accomplished by the authenticator sending an Extensible Authentication Protocol (EAP) request to the supplicant and the supplicant sending a reply which the authenticator forwards to an authentication server. If the authenticator doesn’t receive a reply to the EAP request, it waits a specified period of time before retransmitting. To configure that wait time, use the \texttt{dot1x timeout tx-period} command.

\textbf{Example}

- These commands configure Ethernet interface 1 to wait 30 seconds before retransmitting EAP requests to the supplicant.

  switch(config)#interface Ethernet 1  
  switch(config-if-Et1)#dot1x timeout tx-period 30  
  switch(config-if-Et1)#

13.3.9 Clearing 802.1x Statistics

The \texttt{clear dot1x statistics} command resets the 802.1x counters.

\textbf{Example}

- This command clears the 802.1x counters on all interfaces.

  switch#clear dot1x statistics all  
  switch#

- This command clears the 802.1x counters on Ethernet interface 1.

  switch#clear dot1x statistics interface ethernet 1  
  switch#

13.4 Displaying 802.1x information

You can display information about 802.1x on the switch and on individual ports.

13.4.1 Displaying port security configuration information

The \texttt{show dot1x} command shows information about the 802.1x configuration on the specified port or ports.

\textbf{Example}

- This commands displays IEEE 802.1x configuration information for Ethernet interface 5.

  switch#show dot1x interface ethernet 5  
  Dot1X Information for Ethernet5  
  --------------------------------------------  
  PortControl : auto  
  QuietPeriod : 60 seconds  
  TxPeriod : 5 seconds  
  ReauthPeriod : 3600 seconds  
  MaxReauthReq : 2  
  switch#

13.4.2 Displaying 802.1x summary information

Use the \texttt{show dot1x all summary} command to display IEEE 802.1x status for all ports.
Example

- The following commands display a summary of IEEE 802.1x status.

```
switch#show dot1x all summary
Interface     Client                     Status
-------------------------------------------------------------
Ethernet5     None                       Unauthorized
```

13.4.3 Displaying 802.1x statistics

Use the `show dot1x statistics` command to display 802.1x statistics for the specified port or ports.

Example

- This command displays IEEE 802.1x statistics for Ethernet interface 5.

```
switch#show dot1x interface ethernet 5 statistics
Dot1X Authenticator Port Statistics for Ethernet5
-------------------------------------------------
RxStart = 0      RxLogoff = 0    RxRespId = 0
RxResp = 0       RxInvalid = 0   RxTotal = 0
TxReqId = 0      TxReq = 0       TxTotal = 0
RxVersion = 0    LastRxSrcMAC = 0000.0000.0000
```
13.5 IEEE 802.1x Configuration Commands

Global Configuration Commands
- `dot1x system-auth-control`

Interface Configuration Commands – Ethernet Interface
- `dot1x max-reauth-req`
- `dot1x pae authenticator`
- `dot1x port-control`
- `dot1x reauthentication`
- `dot1x timeout quiet-period`
- `dot1x timeout reauth-period`
- `dot1x timeout tx-period`

Privileged EXEC Commands
- `clear dot1x statistics`
- `show dot1x`
- `show dot1x statistics`
- `show dot1x all summary`
clear dot1x statistics

The clear dot1x statistics command resets the 802.1x counters on the specified interface or all interfaces.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear dot1x statistics INTERFACE_NAME
```

**Parameters**
- **INTERFACE_NAME** Interface type and number. Options include:
  - **all** Display information for all interfaces.
  - **interface ethernet e_num** Ethernet interface specified by e_num.
  - **interface loopback l_num** Loopback interface specified by l_num.
  - **interface management m_num** Management interface specified by m_num.
  - **interface port-channel p_num** Port-Channel Interface specified by p_num.
  - **interface vlan v_num** VLAN interface specified by v_num.

**Example**
- This command resets the 802.1x counters on all interfaces.
```
switch# clear dot1x statistics all
switch#
```
**dot1x system-auth-control**

The **dot1x system-auth-control** command enables 802.1X authentication on the switch.

The **no dot1x system-auth-control** and **default dot1x system-auth-control** commands disables 802.1X authentication by removing the **dot1x system-auth-control** command from *running-config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
dot1x system-auth-control
no dot1x system-auth-control
default dot1x system-auth-control
```  

**Example**

- This command enables 802.1X authentication on the switch.
  
  switch(config)#dot1x system-auth-control
  switch(config)#

- This command disables 802.1X authentication on the switch.
  
  switch(config)#no dot1x system-auth-control
  switch(config)#
**dot1x max-reauth-req**

The `dot1x max-reauth-req` command configures how many times the switch retransmits an 802.1x Extensible Authentication Protocol (EAP) request packet before ending the conversation and restarting authentication.

The `no dot1x max-reauth-req` and `default dot1x max-reauth-req` commands restore the default value of 2 by deleting the corresponding `dot1x max-reauth-req` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
dot1x max-reauth-req attempts
no dot1x max-reauth-req
default dot1x max-reauth-req
```

**Parameters**

- `attempts` maximum number of attempts. Values range from 1 to 10; default value is 2.

**Examples**

- This command sets the 802.1x EAP-request retransmit limit to 6.

  ```
  switch(config-if-Et1)#dot1x max-reauth-req 6
  switch(config-if-Et1)#
  ```

- This command restores the default request repetition value of 2.

  ```
  switch(config-if-Et1)#no dot1x max-reauth-req
  switch(config-if-Et1)#
  ```
**dot1x pae authenticator**

The **dot1x pae authenticator** command sets the port access entity (PAE) type of the configuration mode interface to **authenticator**.

The **no dot1x pae authenticator** and **default dot1x pae authenticator** commands restore the switch default by deleting the corresponding **dot1x pae authenticator** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
dot1x pae authenticator
no dot1x pae authenticator
default dot1x pae authenticator
```

**Example**

- These commands configure on Ethernet interface 2 as a port access entity (PAE) authenticator, which enables IEEE 802.1x on the port.

  ```
  switch(config-if-Et1)#interface ethernet 2
  switch(config-if-Et1)#dot1x pae authenticator
  switch(config-if-Et1)#
  ```

- These commands disable IEEE 802.1x authentication on Ethernet interface 2.

  ```
  switch(config-if-Et1)#interface ethernet 2
  switch(config-if-Et1)#no dot1x pae authenticator
  switch(config-if-Et1)#
  ```
**dot1x port-control**

The `dot1x port-control` command configures the configuration mode interface as an authenticator port and specifies whether it will authenticate traffic.

The **no dot1x port-control** and **default dot1x port-control** commands configure the port to pass traffic without authorization by removing the corresponding `dot1x port-control` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
dot1x port-control STATE
no dot1x port-control
default dot1x port-control
```

**Parameters**
- **STATE** specifies whether the interface will authenticate traffic. The default value is `force-authorized`. Options include:
  - **auto** configures the port to authenticate traffic using Extensible Authentication Protocol messages.
  - **force-authorized** configures the port to pass traffic without authentication.
  - **force-unauthorized** configures the port to block all traffic regardless of authentication.

**Examples**
- These commands configure Ethernet interface 1 to pass traffic without authentication. This is the default setting.
  
  ```
  switch(config)#interface Ethernet 1
  switch(config-if-Et1)#dot1x port-control force-authorized
  switch(config-if-Et1)#
  ```

- These commands configure Ethernet interface 1 to block all traffic.
  
  ```
  switch(config)#interface Ethernet 1
  switch(config-if-Et1)#dot1x port-control force-unauthorized
  switch(config-if-Et1)#
  ```

- These commands configure Ethernet interface 1 to authenticate traffic using EAP messages.
  
  ```
  switch(config)#interface Ethernet 1
  switch(config-if-Et1)#dot1x port-control auto
  switch(config-if-Et1)#
  ```
The `dot1x reauthentication` command configures the configuration mode interface to require re-authentication from clients at regular intervals. The interval is set by the `dot1x timeout reauth-period` command.

The `no dot1x reauthentication` and `default dot1x reauthentication` commands restore the default setting by deleting the corresponding `dot1x reauthentication` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**
- `dot1x reauthentication`
- `no dot1x reauthentication`
- `default dot1x reauthentication`

**Example**
- These commands configure the Ethernet interface 1 authenticator to require periodic re-authentication from clients.

```
switch(config)#interface Ethernet 1
switch(config-if-Et1)#dot1x reauthentication
switch(config-if-Et1)#
```
**dot1x timeout quiet-period**

If the switch fails to immediately authenticate the client, the time the switch waits before trying again is specified by the `dot1x timeout quiet-period` command. This timer also indicates how long a client that failed authentication is blocked.

The `no dot1x timeout quiet-period` and `default dot1x timeout quiet-period` commands restore the default quiet period of 60 seconds by removing the corresponding `dot1x timeout quiet-period` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**
```
dot1x timeout quiet-period quiet_time
no dot1x timeout quiet-period
default dot1x timeout quiet-period
```

**Parameters**
- `quiet_time` interval in seconds. Values range from 1 to 65535. Default value is 60.

**Example**
- These commands set the 802.1x quiet period for Ethernet interface 1 to 30 seconds.

```
switch(config)#interface Ethernet 1
switch(config-if-Et1)#dot1x timeout quiet-period 30
switch(config-if-Et1)#
```
dot1x timeout reauth-period

The `dot1x timeout reauth-period` command specifies the time period that the configuration mode interface waits before requiring re-authentication from clients.

The `no dot1x timeout reauth-period` and `default dot1x timeout reauth-period` commands restore the default period of 60 minutes by removing the corresponding `dot1x timeout reauth-period` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**
- `dot1x timeout reauth-period reauth_time`
- `no dot1x timeout reauth-period`
- `default dot1x timeout reauth-period`

**Parameters**
- `reauth_time` the number of seconds the interface passes traffic before requiring re-authentication. Values range from 1 to 65535. Default value is 3600.

**Example**
- These commands configure the Ethernet interface 1 authenticator to require re-authentication from clients every 6 hours (21600 seconds).

```
switch(config)#interface Ethernet 1
switch(config-if-Et1)#dot1x reauthentication
switch(config-if-Et1)#dot1x timeout reauth-period 21600
switch(config-if-Et1)#
```
**dot1x timeout tx-period**

Authentication and re-authentication are accomplished by the authenticator sending an Extensible Authentication Protocol (EAP) request to the supplicant and the supplicant sending a reply which the authenticator forwards to an authentication server. If the authenticator does not get a reply to the EAP request, it waits a specified period of time before retransmitting. The `dot1x timeout tx-period` command configures that wait time.

The `no dot1x timeout tx-period` and `default dot1x timeout tx-period` commands restore the default wait time by removing the corresponding `dot1x timeout tx-period` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
dot1x timeout tx-period tx_time
no dot1x timeout tx-period
default dot1x timeout tx-period
```

**Parameters**

- `tx_time` Values range from 1 to 65535. Default value is 5.

**Example**

- These commands configure Ethernet interface 1 to wait 30 seconds before retransmitting EAP requests to the supplicant.

```
switch(config)#interface Ethernet 1
switch(config-if-Et1)#dot1x timeout tx-period 30
switch(config-if-Et1)#
```
show dot1x

The show dot1x command displays 802.1x information for the specified interface.

Command Mode
EXEC

Command Syntax
show dot1x INTERFACE_NAME INFO

Parameters
- INTERFACE_NAME Interface type and number. Options include:
  - all Display information for all interfaces.
  - ethernet e_num Ethernet interface specified by e_num.
  - loopback l_num Loopback interface specified by l_num.
  - management m_num Management interface specified by m_num.
  - port-channel p_num Port-Channel Interface specified by p_num.
  - vlan v_num VLAN interface specified by v_num.
- INFO Type of information the command displays. Values include:
  - <no parameter> displays summary of the specified interface.
  - detail displays all 802.1x information for the specified interface.

Example
- This command displays 802.1X summary information for Ethernet interface 5.
  switch#show dot1x interface ethernet 5
  Dot1X Information for Ethernet5
  --------------------------------------------
  PortControl             : auto
  QuietPeriod             : 60 seconds
  TxPeriod                : 5 seconds
  ReauthPeriod            : 3600 seconds
  MaxReauthReq            : 2
  switch#

- This command displays detailed 802.1X information for Ethernet interface 5.
  switch#show dot1x interface ethernet 5 detail
  Dot1X Information for Ethernet5
  --------------------------------------------
  PortControl             : auto
  QuietPeriod             : 60 seconds
  TxPeriod                : 5 seconds
  ReauthPeriod            : 3600 seconds
  MaxReauthReq            : 2

  Dot1X Authenticator Client
  Port Status             : Unauthorized
  switch#
show dot1x statistics

The **show dot1x statistics** command displays 802.1X statistics for the specified port or ports.

**Command Mode**

EXEC

**Command Syntax**

```
show dot1x  INTERFACE_NAME  statistics
```

**Parameters**

- **INTERFACE_NAME** Interface type and number. Options include:
  - `all` Display information for all interfaces.
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-Channel Interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.

**Output Fields**

- `RxStart` Number of EAPOL-Start frames received on the port.
- `TxReqId` Number of EAP-Request/Identity frames transmitted on the port.
- `RxVersion` Version number of the last EAPOL frame received on the port.
- `RxLogoff` Number of EAPOL-Logoff frames received on the port.
- `RxInvalid` Number of invalid EAPOL frames received on the port.
- `TxReq` Number of transmitted EAP-Request frames that were not EAP-Request/Identity.
- `LastRxSrcMAC` The source MAC address in the last EAPOL frame received on the port.
- `RxRespId` The number of EAP-Response/Identity frames received on the port.
- `RxTotal` The total number of EAPOL frames transmitted on the port.
- `TxTotal` The total number of EAPOL frames transmitted on the port.

**Example**

- This command displays the 802.1X statistics for ethernet 5

```
switch#show dot1x  interface  ethernet  5  statistics
Dot1X Authenticator Port Statistics for Ethernet5
---------------------------------------------
RxStart = 0       RxLogoff = 0       RxRespId = 0
RxStart= 0        RxInvalid = 0      RxTotal = 0
TxReqId = 0       TxReq = 0          TxTotal = 0
RxVersion = 0     LastRxSrcMAC = 0000.0000.0000
switch#
```
show dot1x all summary

The **show dot1x all summary** command displays the IEEE 802.1X status for all ports.

**Command Mode**

EXEC

**Command Syntax**

`show dot1x all summary`

**Example**

- This command displays the IEEE 802.1X status.

```
switch# show dot1x all summary
Interface               Client                  Status
-----------------------------------------------------------------
Ethernet5               None                    Unauthorized
switch#
```

Chapter 14

DCBX and Flow Control

This chapter describes Data Center Bridging Capability Exchange (DCBX) configuration tasks. Sections in this chapter include:

- Section 14.1: Introduction
- Section 14.2: DCBX and Priority-Based Flow Control Overview
- Section 14.3: DCBX and PFC Configuration and Verification Procedures
- Section 14.4: DCBX and Flow Control Configuration Commands

14.1 Introduction

EOS implements Link Layer Discovery Protocol (LLDP) and the Data Center Bridging Capability Exchange (DCBX) protocol to help automate the configuration of Data Center Bridging (DCB) parameters, including the Priority-Based Flow Control (PFC) standard, which allows an end-to-end flow-control feature.

This feature enables a switch to recognize when it is connected to an iSCSI device and automatically configure the switch link parameters (such as priority flow control) to provide optimal support for that device. DCBX can be used to prioritize the handling of iSCSI traffic to help ensure that packets are not dropped or delayed. DCBX is off by default.
14.2 DCBX and Priority-Based Flow Control Overview

14.2.1 DCBX Description

DCBX works with LLDP to allow switches to exchange information about their data center bridging (DCB) capabilities and configuration and automatically negotiate common Priority-Based Flow Control (PFC) parameters. Data is exchanged in type-length-value (TLV) format. For DCBX to function on an interface LLDP must be enabled on that interface as well.

14.2.2 Priority-Based Flow Control (PFC) Description

PFC uses a new control packet defined in IEEE 802.1Qbb and is not compatible with 802.3x flow control (FC). An interface that is configured for PFC will be disabled for FC. When PFC is disabled on an interface, the FC configuration for the interface becomes active. Any FC frames received on a PFC configured interface are ignored.

Each priority is configured as either drop or no-drop. If a priority that is designated as no-drop is congested, the priority is paused. Drop priorities do not participate in pause.

When PFC is disabled, the interface defaults to the IEEE 802.3x flow control setting for the interface. PFC is disabled by default.
14.3 DCBX and PFC Configuration and Verification Procedures

14.3.1 Set the Priority Rank to the Traffic Class

The `dcbx application priority` command assigns a priority rank to the specified traffic class in the application priority table. This table is transmitted on each DCBX-enabled interface.

**Examples**

- These commands tell the DCBX peer that iSCSI frames (TCP ports 860 and 3260) should be assigned the given priority of 5.

  ```
  switch(config)#dcbx application tcp-sctp 860 priority 5
  switch(config)#dcbx application tcp-sctp 3260 priority 5
  ```

- These commands specify a different priority for the two iSCSI traffic ports.

  ```
  switch(config)#dcbx application tcp-sctp 860 priority 3
  switch(config)#dcbx application tcp-sctp 3260 priority 4
  ```

- This command is equivalent to the `dcbx application tcp-sctp` command. The DCBX peer that iSCSI frames are assigned are the given the priority 5.

  ```
  switch(config)#dcbx application iscsi priority 5
  ```

- These commands prevent the peers from sending anything about the iSCSI frames.

  ```
  switch(config)#no dcbx application tcp-sctp 860 priority 5
  switch(config)#no dcbx application tcp-sctp 3260 priority 5
  ```

14.3.2 Enable Priority-Flow-Control (PFC)

The `priority-flow-control mode` command enables Priority-Flow-Control (PFC) on an individual port.

**Examples**

- The `priority-flow-control mode` command in DCBX mode enables PFC on an interface.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control mode on
  ```

14.3.3 Set the Priority Flow Control Priority

The `priority-flow-control priority` command in DCBX mode creates a priority group that pauses priority. Each priority is configured as either drop or no-drop. If a priority that is designated as no-drop is congested, the priority is paused. Drop priorities do not participate in pause.

**Examples**

- The `priority-flow-control priority` command in DCBX mode creates a priority group that pauses priority 5 on Ethernet 2.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control priority 5 no-drop
  switch(config-if-Et2)# priority-flow-control priority 5 no-drop
  ```

- To enable lossy behavior, use the drop option of the `priority-flow-control priority` command.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control mode on
  switch(config-if-Et2)#priority-flow-control priority 5 drop
  ```
14.3.4 Disable Priority-Flow-Control (PFC)

To disable priority flow control (PFC) on the configuration mode interface and restore the default packet drop setting on the interface, use the `no priority-flow-control` command.

**Example**

- To disable PFC, use the `no priority-flow-control` command.

```
switch (config)#interface ethernet 2
switch(config-if-Et2)#no priority-flow-control
```

14.3.5 DCBX Verification

To display the DCBX status and the interfaces on which DCBX is enabled, use the `show dcbx` command.

**Examples**

- This command displays the DCBX status for Ethernet 50.

```
switch#show dcbx Ethernet 50
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:06:01 2013
  No priority flow control configuration TLV received
  No application priority configuration TLV received
switch#
```
14.4 DCBX and Flow Control Configuration Commands

Global Configuration Commands
- dcbx application priority
- platform fm6000 pfc-wm

Interface Configuration Commands – Ethernet Interface
- dcbx mode
- no priority-flow-control
- priority-flow-control mode
- priority-flow-control priority

Privileged EXEC Commands
- show dcbx
- show dcbx application-priority-configuration
- show dcbx priority-flow-control-configuration
- show dcbx status
- show interfaces priority-flow-control
- show platform fm6000 pfc-wm
- show priority-flow-control
**dcbx application priority**

The **dcbx application priority** command assigns a priority rank to the specified traffic class in the application priority table. This table is transmitted on each DCBX-enabled interface.

The **no dcbx application priority** and **default dcbx application priority** commands remove the specified DCBX traffic class – priority assignment by deleting the corresponding **dcbx application priority** command from **running-config**. When the command does not specify a traffic class, all DCBX traffic class priority assignments are removed.

**Command Mode**
- Global Configuration

**Command Syntax**

```
dcbx application APPLICATION_TYPE priority rank
no dcbx application [APPLICATION_TYPE priority]
default dcbx application [APPLICATION_TYPE priority]
```

**Parameters**

- **APPLICATION_TYPE** traffic class receiving the priority assignment. Options include:
  - **ether ethertype_number** Ethernet traffic. *Ethertype_number* varies from 1536 to 65535.
  - **iscsi** iSCSI traffic. Maps to TCP/SCTP ports 860 and 3260.
  - **tcp-sctp port_number** TCP/SCTP traffic. Port number varies from 1 to 65535.
  - **tcp-sctp-udp port_number** TCP/SCTP/UDP traffic. Port number varies from 1 to 65535.
  - **udp port_number** UDP traffic. Port number varies from 1 to 65535.
  - **rank** priority assigned to traffic class. Values range from 0 to 7.

**Examples**

- These commands tell the DCBX peer that iSCSI frames (TCP ports 860 and 3260) should be assigned the given priority of 5.
  
  ```
  switch(config)#dcbx application tcp-sctp 860 priority 5
  switch(config)#dcbx application tcp-sctp 3260 priority 5
  ```

- These commands specify a different priority for the two iSCSI traffic ports.
  
  ```
  switch(config)# dcbx application tcp-sctp 860 priority 3
  switch(config)# dcbx application tcp-sctp 3260 priority 4
  ```

- This command is equivalent to the **dcbx application tcp-sctp** command. The DCBX peer that iSCSI frames are assigned to is given priority 5.
  
  ```
  switch(config)#dcbx application iscsi priority 5
  switch(config)#
  ```

- These commands prevent the peers from sending anything about the iSCSI frames.
  
  ```
  switch(config)#no dcbx application tcp-sctp 860 priority
  switch(config)#no dcbx application tcp-sctp 3260 priority
  ```
**dcbx mode**

The `dcbx mode` command enables DCBX mode on the configuration mode interface. The switch supports IEEE P802.1Qaz. When DCBX is enabled, two TLVs are added to outgoing LLDPDUs, which instruct the peer on the interface to configure PFC (priority flow control) and the application priority table in the same way as the switch.

The `no dcbx mode`, `default dcbx mode`, and `dcbx mode none` commands disable DCBX on the configuration mode interface by removing the corresponding `dcbx mode` command from running-config.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
dcbx mode MODE_NAME
no dcbx mode
default dcbx mode
```

**Parameters**

- **MODE_NAME** Specifies the DCBX version. Options include:
  - `ieee` IEEE version.
  - `cee` Converged Enhanced Ethernet version.
  - `none` DCBX is disabled.

**Examples**

- These commands enable interface Ethernet 2 to use IEEE DCBX.
  
  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#dcbx mode ieee
  switch(config-if-Et2)#
  ```

- These commands disable DCBX on interface Ethernet 5.
  
  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#dcbx mode none
  switch(config-if-Et2)#
  ```
no priority-flow-control

The no priority-flow-control and default priority-flow-control commands disable the priority flow control (PFC) on the configuration mode interface and restore the default packet drop setting on the interface, which takes effect when PFC is re-enabled. The commands delete all corresponding priority-flow-control mode commands from running-config.

Command Mode

Interface-Ethernet Configuration

Command Syntax

no priority-flow-control
default priority-flow-control

Examples

- These commands disable priority flow control (PFC) on Ethernet interface 3.

  switch(config)#interface Ethernet 3
  switch(config-if-Et3)#no priority-flow-control
  switch(config-if-Et3)#
platform fm6000 pfc-wm

The platform fm6000 pfc-wm command configures the hardware buffer space allocated to the PFC (Priority Flow Control) RX-Private buffer. The command provides options to configure the buffer size and specify when PFC frames are sent to request that a neighbor stop sending traffic. The default values are as follows:

- RX-Private: 18400 bytes
- on (watermark): 9280 bytes
- off (watermark): 1600 bytes

Values that are entered in the command are rounded up to the closest multiple of 160. The RX-Private value must be greater than the off value, which must be larger than the on value.

The no platform fm6000 pfc-wm and default platform fm6000 pfc-wm commands restore the default settings by removing the platform fm6000 pfc-wm command from running-config.

Command Mode
Global Configuration

Command Syntax
```
platform fm6000 pfc-wm [RX-PRIVATE_SIZE] [PFC-ON_WM] [PFC-OFF_WM]
no platform fm6000 pfc-wm
default platform fm6000 pfc-wm
```

The platform fm6000 pfc-wm command must explicitly configure at least one parameter.

Parameters

- **RX-PRIVATE_SIZE** Specifies size of rx-private buffer. Options include:
  - <no parameter> rx-private buffer retains previously configured size.
  - rx-private <18268 to 102400> Size of rx-private buffer (bytes).
- **PFC-ON_WM** Buffer capacity that triggers the switch to send PFC frames. Options include:
  - <no parameter> Parameter retains previously configured value.
  - on <9134 to 102400> Buffer capacity that triggers PFC frames (bytes).
- **PFC-OFF_WM** Buffer capacity that triggers the switch to stop PFC frame transmissions. Options include:
  - <no parameter> Parameter retains previously configured value.
  - off <1536 to 102400> Buffer capacity that turns off PFC frames.

Related Commands
- show platform fm6000 pfc-wm displays the PFC RX-Private buffer memory allocations

Example
- This command configures the rx-private hardware buffer.
  ```
  switch(config)#platform fm6000 pfc-wm rx-private 24800 on 16000 off 3200
  switch(config)#
  ```
priority-flow-control mode

The **priority-flow-control mode** command enables priority flow control (PFC) on the configuration mode interface to pause selected traffic classes.

The **no priority-flow-control mode** and **default priority-flow-control mode** commands disable PFC on the configuration mode interface by deleting the corresponding **priority-flow-control mode** command from **running-config**. The **no priority-flow-control** command also disables PFC on the configuration mode interface.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```plaintext
priority-flow-control mode [on]
no priority-flow-control [on]
default priority-flow-control [on]
```

**Example**

- These commands enable PFC on Ethernet interface 3.
  ```plaintext
  switch(config)# interface Ethernet 3
  switch(config-if-Et3)# priority-flow-control mode on
  switch(config-if-Et3)#
  ```

- These commands disable PFC on Ethernet interface 3.
  ```plaintext
  switch(config)# interface Ethernet 3
  switch(config-if-Et3)# no priority-flow-control mode
  switch(config-if-Et3)#
  ```
priority-flow-control priority

The `priority-flow-control priority` command configures the packet resolution setting on the configuration mode interface. This setting determines if packets are dropped when priority flow control (PFC) is enabled on the interface. Packets are dropped by default.

The `no priority-flow-control priority` and `default priority-flow-control priority` commands restore the default packet drop setting on the configuration mode interface by deleting the corresponding `priority-flow-control priority` command from `running-config`. The `no priority-flow-control` command also restores the default setting on the configuration mode interface.

**Command Mode**
- Interface-Ethernet Configuration

**Command Syntax**

```
priority-flow-control priority pack-drop
no priority-flow-control priority
default priority-flow-control priority
```

**Parameters**

- `pack-drop` denotes the interfaces. Options include:
  - `drop`  Packets are dropped. Default setting.
  - `no drop`  Packets are not dropped.

**Examples**

- These commands in DCBX mode create a priority group that pauses dot1p priority 5 on Ethernet 2.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control mode on
  switch(config-if-Et2)# priority-flow-control priority 5 no-drop
  ```

- These commands enable lossy behavior.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control mode on
  switch(config-if-Et2)#priority-flow-control priority 5 drop
  ```

- These commands remove the priority group that pauses dot1p priority 5 on Ethernet 2.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)# priority-flow-control mode on
  switch(config-if-Et2)# no priority-flow-control priority
  ```
**show dcbx**

The `show dcbx` command lists DCBX status and the interfaces on which DCBX is enabled.

**Command Mode**

EXEC

**Command Syntax**

```
show dcbx [INTERFACE]
```

**Parameters**

- **INTERFACE** Interface type and number. Options include:
  - `<no parameter>` all configured DCBX interfaces.
  - `ethernet e-num` Ethernet interface specified by `e-num`.

**Examples**

- This command displays the DCBX status for Ethernet 50.
  ```
  switch#show dcbx Ethernet 50
  Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:06:01 2013
  No priority flow control configuration TLV received
  No application priority configuration TLV received
  switch#
  ```

- This command displays the DCBX status for Ethernet 50 when Priority Flow Control (PFC) is not enabled.
  ```
  switch#show dcbx Ethernet 50
  Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:08:29 2013
  - PFC configuration: willing
  not capable of bypassing MACsec
  supports PFC on up to 4 traffic classes
  PFC enabled on priorities: 5 7
  WARNING: peer PFC configuration does not match the local PFC configuration
  - Application priority configuration:
  2 application priorities configured:
  tcp-sctp 860 priority 5
  tcp-sctp 3260 priority 5
  switch#
  ```
show dcbx application-priority-configuration

The show dcbx application-priority-configuration command displays the DCBX peer application priority configuration.

Command Mode

EXEC

Command Syntax

show dcbx [INTERFACE] application-priority-configuration

Parameters

• INTERFACE Interface type and number. Options include:
  • <no parameter> All configured DCBX interfaces.
  • ethernet e-num Ethernet interface specified by e-num.

Guidelines

This command and the show priority-flow-control command function identically.

Examples

• This command displays the DCBX peer application priority configuration for all DCBX-enabled interfaces.

  switch# show dcbx application-priority-configuration
  Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No application priority configuration TLV received
  Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No application priority configuration TLV received
  ...
  Ethernet50:
  Last LLDPDU received on Thu Feb 14 12:08:29 2013
  - Application priority configuration:
    2 application priorities configured:
    tcp-sctp 860 priority 5
    tcp-sctp 3260 priority 5
  switch#
show dcbx priority-flow-control-configuration

The `show dcbx priority-flow-control-configuration` command displays the IEEE DCBX peer priority flow control configurations.

**Command Mode**

EXEC

**Command Syntax**

```
show dcbx [INTERFACE] priority-flow-control-configuration
```

**Parameters**

- **INTERFACE** Interface type and number. Options include:
  - `<no parameter>` all configured DCBX interfaces.
  - `ethernet e-num` Ethernet interface specified by `e-num`.

**Examples**

This command displays the DCBX peer priority flow control configuration for the DCBX-enabled interfaces on the device.

```
switch#show dcbx priority-flow-control-configuration
Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No priority flow control configuration TLV received
Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No priority flow control configuration TLV received
...
Ethernet50:
  Last LLDPDU received on Thu Feb 14 12:11:29 2013
  - PFC configuration: willing
    - not capable of bypassing MACsec
    - supports PFC on up to 4 traffic classes
    - PFC enabled on priorities: 5 7
  WARNING: peer PFC configuration does not match the local PFC configuration
switch#
```
**show dcbx status**

The `show dcbx status` command displays the DCBX status on the interfaces on which DCBX is enabled.

**Command Mode**
EXEC

**Command Syntax**
```
show dcbx [INTERFACE] status
```

**Parameters**
- **INTERFACE** Interface type and number. Options include:
  - `<no parameter>` all configured DCBX interfaces.
  - `ethernet e-num` Ethernet interface specified by `e-num`.

**Examples**
- This command displays the DCBX status for the DCBX-enabled interfaces.
  ```
switch#show dcbx status
Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:11:54 2013
switch#
```
show interfaces priority-flow-control

The `show interfaces priority-flow-control` command displays the status of PFC on all interfaces.

**Command Mode**
EXEC

**Command Syntax**

```
show interfaces [INTERFACE] priority-flow-control [INFO_LEVEL]
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.
  - `vxlan vx_range` VXLAN interface range specified by `vx_range`.

  Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

- **INFO_LEVEL** specifies the type of information displayed. Options include:
  - `<no parameter>` Displays information about all DCBX neighbor interfaces.
  - `status` Displays the DCBX status.
  - `counters` Displays the DCBX counters.

**Guidelines**
This command and the `show priority-flow-control` command function identically.

**Examples**

- This command displays the PFC for all interfaces.

  ```
  switch#show interfaces priority-flow-control
  The hardware supports PFC on priorities 0 1 2 3 4 5 6 7

  Port   Enabled Priorities Active Note
  Et1    No       No
  Et2    No       No
  ...
  Et50   Yes      5  Yes
  ...
  Port       RxPfc    TxPfc
  Et1        0        0
  Et2        0        0
  ...
  Et50       0        0
  ...
  switch#
  ```
show platform fm6000 pfc-wm

The `show platform fm6000 pfc-wm` command displays the buffer space allocated to the RX-Private buffer and buffer levels that trigger PFC frame transmission activities.

**Command Mode**

Privileged EXEC

**Command Syntax**

`show platform fm6000 pfc-wm`

**Related Commands**

- `platform fm6000 pfc-wm` specifies the PFC RX-Private buffer memory allocation.

**Example**

- This command displays the rx-private hardware buffer memory allocation.

```
switch# show platform fm6000 pfc-wm
Pfc_Rx_Private_WM: 24800 Bytes
Pfc_On_WM: 16000 Bytes
Pfc_Off_WM: 3200 Bytes
switch#
```
show priority-flow-control

The `show priority-flow-control` command displays the status of PFC on all interfaces.

Command Mode

EXEC

Command Syntax

```
show priority-flow-control [INT_NAME] [INFO_LEVEL]
```

Parameters

- **INT_NAME**
  - Denotes the interfaces to be configured. Options include:
    - `<no parameter>` Displays information for all interfaces.
    - `interface ethernet e_range` Ethernet interface range.
    - `interface loopback l_range` Loopback interface range.
    - `interface management m_range` Management interface range.
    - `interface port-channel c_range` Channel group interface range.
    - `interface vlan v_range` VLAN interface range.
  
  Valid `e_range`, `l_range`, `m_range`, `c_range`, and `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges.

- **INFO_LEVEL**
  - Specifies level of information detail provided by the command.
    - `<no parameter>` Displays information about all DCBX neighbor interfaces.
    - `status` Displays the DCBX status.
    - `counters` Displays the DCBX counters.
    - `counters detail` Displays the DCBX counters for each priority class. This option is available only on Trident switches.

Guidelines

This command and the `show interfaces priority-flow-control` command function identically.

Examples

- This command displays the status of PFC on all interfaces.

  ```
  switch#show priority-flow-control
  The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
  
  Port  Enabled Priorities Active Note
  Et1   No                No
  Et2   No                No
  ...  
  Et50  Yes              5    Yes
  ...
  
  Port  RxPfc  TxPfc
  Et1   0       0
  Et2   0       0
  ...  
  Et50  0       0
  ...
  switch#
  ```
LLDP

This chapter describes initial configuration and recovery tasks. Refer to the Command Descriptions for information about commands used in this chapter.

This chapter contains these sections:

- Section 15.1: LLDP Introduction
- Section 15.2: LLDP Overview
- Section 15.3: LLDP Configuration Procedures
- Section 15.4: LLDP Configuration Commands

15.1 LLDP Introduction

Link Layer Discovery Protocol (LLDP) lets Ethernet network devices advertise details about themselves, such as capabilities, identification, and device configurations to directly connected devices on the network that are also using LLDP.

15.2 LLDP Overview

LLDP is a discovery protocol that allows devices to advertise information about themselves to peer devices that are on the same physical LAN and store information about the network. LLDP allows a device to learn higher layer management reachability and connection endpoint information from adjacent devices.

Each switch with an active LLDP agent sends and receives messages on all physical interfaces enabled for LLDP transmission. These messages are sent periodically and are typically configured for short time intervals to ensure that accurate information is always available. These messages are then stored for a configurable period of time, and contained within the received packet. The message information expires and is discarded when the configured value is met. The only other time an advertisement is sent is when a relevant change takes place in the switch. If information changes for any reason, the LLDP agent is notified and will send out and update the new values.
15.2.1 LLDP Data Units

A single LLDP Data Unit (LLDPDU) is transmitted in a single 802.3 Ethernet frame. The basic LLDPDU includes a header and a series of type-length-value elements (TLVs). Each TLV advertises different types of information, such as its device ID, type, or management addresses.

LLDP advertises the following TLVs by default:

- port-description
- system-capabilities
- system-description
- system-name
- management-address
- port-vlan

15.2.2 Transmission and Reception

Every device that uses LLDP has its own LLDP agent. The LLDP agent is responsible for the reception, transmission, and management of LLDP. When LLDP is enabled on a port, transmission and reception of LLDPDUs are both enabled by default, but the agent can be configured to only transmit or only receive.

Transmission

When LLDP transmission is enabled, the LLDP agent advertises information about the switch to neighbors at regular intervals. Each transmitted LLDPDU contains the mandatory TLVs, and any enabled optional TLVs.

Reception

When LLDP reception is enabled, the LLDP agent receives and stores advertised information from neighboring devices.

15.2.3 Storing LLDP Information

Whenever the switch receives a valid and current LLDP advertisement from a neighbor, it stores the information in a Simple Network Management Protocol (SNMP) management information base (MIB).

15.2.4 Guidelines and Limitations

LLDP has the following configuration limitations:

- LLDP must be enabled globally before it can be enabled on an interface.
- LLDP is not supported on virtual interfaces.
- LLDP can discover only one device per port.
15.3 LLDP Configuration Procedures

These sections describe the following configuration processes:

- Section 15.3.1: Enabling LLDP Globally
- Section 15.3.2: Enabling LLDP on an Interface
- Section 15.3.3: Optional LLDP Parameters
- Section 15.3.4: Clearing LLDP Statistics
- Section 15.3.5: Displaying LLDP Information

15.3.1 Enabling LLDP Globally

The `lldp run` command globally enables LLDP on the Arista switch. Once LLDP is enabled, the switch will transmit advertisements from the ports that are configured to send TLVs. The neighbor information table is populated as advertisements from the neighbors arrive on the ports.

Example

- This command enables LLDP globally on the Arista switch.
  
  ```
  switch(config)# lldp run
  switch(config)#
  ```

15.3.2 Enabling LLDP on an Interface

When enabling LLDP, it is enabled on all interfaces by default. By using the `lldp transmit` and `lldp receive` commands, LLDP can be enabled or disabled on individual interfaces or configured to only send or only receive LLDP packets.

Examples

- These commands enable Ethernet port 3/1 to transmit LLDP packets.
  
  ```
  switch(config)# interface ethernet 3/1
  switch(config-if-Et3/1)# lldp transmit
  switch(config-if-Et3/1)#
  ```

- These commands enable Ethernet port 3/1 to receive LLDP packets.
  
  ```
  switch(config)# interface ethernet 3/1
  switch(config-if-Et3/1)# lldp receive
  switch(config-if-Et3/1)#
  ```

15.3.3 Optional LLDP Parameters

The following sections describe these tasks:

- Section 15.3.3.1: Setting the LLDP Timer
- Section 15.3.3.2: Setting the LLDP Hold Time
- Section 15.3.3.3: Setting the LLDP Re-initialization Timer
- Section 15.3.3.4: Setting the IP Management Address to be used in the TLV
- Section 15.3.3.5: Selecting the LLDP TLV

15.3.3.1 Setting the LLDP Timer

The `lldp timer` command specifies the time in seconds between LLDP updates sent by the switch.
Examples

- This command specifies that the LLDP updates should be sent every 120 seconds.
  
  
  ```
  switch(config)# lldp timer 120
  switch(config)#
  ```

- This command reverts the LLDP timer to its default value of 30 seconds.
  
  ```
  switch(config)# no lldp timer 120
  switch(config)#
  ```

15.3.3.2 Setting the LLDP Hold Time

The `lldp holdtime` command sets the amount of time a receiving device should retain the information sent by the device.

Examples

- This command specifies that the receiving device should retain the information for 180 seconds before discarding it.
  
  ```
  switch(config)# lldp holdtime 180
  switch(config)#
  ```

- This command reverts the LLDP hold time and to the default value of 120 seconds.
  
  ```
  switch(config)# no lldp holdtime 180
  switch(config)#
  ```

15.3.3.3 Setting the LLDP Re-initialization Timer

The `lldp reinit` command specifies the amount in time in seconds to delay the re-initialization attempt by the switch.

Example

- This command specifies that the switch waits 10 seconds before attempting to re-initialize.
  
  ```
  switch(config)# lldp reinit 10
  switch(config)#
  ```

15.3.3.4 Setting the IP Management Address to be used in the TLV

The `lldp management-address` command specifies the IP management address or the IP address of the VRF interface in LLDP type-length-value (TLV) triplets.

Example

- This command specifies the IP management address to be used in the TLV.
  
  ```
  switch(config)# lldp management-address ethernet 3/1
  switch(config)#
  ```

15.3.3.5 Selecting the LLDP TLV

The `lldp tlv-select` command configures the type, length, and value (TLV) to send and receive in LLDP packets. The `no lldp tlv-select` command removes the TLV configuration.

Example

- This command enables the system descriptions to be included in the TLVs.
  
  ```
  switch(config)# lldp tlv-select system-description
  switch(config)#
  ```
15.3.4 Clearing LLDP Statistics

- Section 15.3.4.1: Clear LLDP Counters
- Section 15.3.4.2: Clear LLDP Table

15.3.4.1 Clear LLDP Counters

The `clear lldp counters` command resets the LLDP traffic counters to zero.

**Example**

- This command resets the traffic counters to zero.
  
  ```
  switch# clear lldp counters
  switch#
  ```

15.3.4.2 Clear LLDP Table

The `clear lldp table` command clears neighbor information from the LLDP table.

**Example**

- This command clears neighbor information from the LLDP table.
  
  ```
  switch# clear lldp table
  switch#
  ```

15.3.5 Displaying LLDP Information

- Section 15.3.5.1: Viewing LLDP Global Information
- Section 15.3.5.2: Viewing LLDP Local Information
- Section 15.3.5.3: Viewing LLDP Neighbors
- Section 15.3.5.4: Viewing LLDP Traffic

15.3.5.1 Viewing LLDP Global Information

The `show lldp` command displays LLDP information.
Examples

- This command displays global information about LLDP.

```bash
switch# show lldp
LLDP transmit interval : 60 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : default

Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
  Management Address (Management0)
  IEEE802.1 Port VLAN ID
  IEEE802.3 Link Aggregation
  IEEE802.3 Maximum Frame Size

  Port       Tx Enabled  Rx Enabled
  Et3/1      Yes         Yes

<--------OUTPUT OMITTED FROM EXAMPLE-------->
```

- This command displays LLDP information.

```bash
switch# show lldp ethernet interface 3/1
LLDP transmit interval : 30 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : default

Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
```

15.3.5.2 Viewing LLDP Local Information

The `show lldp local-info` command displays the information contained in the LLDP TLVs to be sent about the local system.
Example

- This command displays information contained in the TLVS about the local systems.

  switch# show lldp local-info management 1

  Local System:
  - Chassis ID type: MAC address (4)
  - Chassis ID: 001c.730f.11a8
  - System Name: "switch.aristanetworks.com"
  - System Description: "Arista Networks EOS version 4.13.2F running on an Arista Networks DCS-7150S-64-CL"
  - System Capabilities: Bridge, Router
  
  Enabled Capabilities: Bridge

  Interface Management1:
  - Port ID type: Interface name (5)
  - Port ID: "Management1"
  - Port Description: ""
  - Management Address Subtype: IPv4 (1)
  - Management Address: 172.22.30.154
  - Interface Number Subtype: ifIndex (2)
  - Interface Number: 999001
  - OID String:
  - IEEE802.1 Port VLAN ID: 0
  - IEEE802.1/IEEE802.3 Link Aggregation
    - Link Aggregation Status: Not Capable (0x00)
    - Port ID: 0
  - IEEE802.3 Maximum Frame Size: 1518 bytes

switch(config)#

15.3.5.3 Viewing LLDP Neighbors

The `show lldp neighbors` command displays information about LLDP neighbors.

Example

- This command shows information about LLDP neighbors.

  switch# show lldp neighbor

  Last table change time : 0:12:33 ago
  Number of table inserts : 33
  Number of table deletes : 0
  Number of table drops : 0
  Number of table age-outs : 0

<table>
<thead>
<tr>
<th>Port</th>
<th>Neighbor Device ID</th>
<th>Neighbor Port ID</th>
<th>TTL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et3/1</td>
<td>tg104.sjc.aristanetworks.com</td>
<td>Ethernet3/2</td>
<td>120</td>
</tr>
<tr>
<td>Ma1/1</td>
<td>dcl-rack11-tor1.sjc</td>
<td>1/1</td>
<td>120</td>
</tr>
</tbody>
</table>

switch#
Example

- This command displays detailed information about the neighbor Ethernet 3/1.

  switch# show lldp neighbor ethernet 3/1
  Last table change time : 0:16:24 ago
  Number of table inserts : 33
  Number of table deletes  : 0
  Number of table drops   : 0
  Number of table age-outs: 0

  Port   Neighbor Device ID             Neighbor Port ID           TTL
  Et3/1  tg104.sjc.aristanetworks.com   Ethernet3/2             120

switch#

15.3.5.4 Viewing LLDP Traffic

The **show lldp traffic** command displays the LLDP traffic information for the switch.

Example

- This command displays the LLDP counters on the switch.

  switch# show lldp traffic
  Port   Tx Frames  Tx Length Exceeded
  Et20   69485       0
  Et21   69394       0
  Et22   69203       0
  Et23   57546       0
  Et24   0           0
  Ma1    69665       0

  Port   Rx Frames  Rx Errors  Rx Discard TLVs Discard TLVs Unknown
  Et20   69470       0         0          0          0          0
  Et21   69383       0         0          0          0          0
  Et22   69143       0         0          0          0          0

15.4 LLDP Configuration Commands

Global Configuration Commands
- lldp holdtime
- lldp management-address
- lldp management-address vrf
- lldp reinit
- lldp run
- lldp timer
- lldp tlv-select

Interface Configuration Commands – Ethernet Interface
- lldp receive
- lldp transmit

Privileged EXEC Commands
- clear lldp counters
- clear lldp table

EXEC Commands
- show lldp
- show lldp local-info
- show lldp neighbors
- show lldp traffic
clear lldp counters

The `clear lldp counters` command resets the LLDP counters to zero.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
clear lldp counters [SCOPE]
```

**Parameters**

- `SCOPE` Session affected by command. Options include:
  - `<no parameter>` command affects counters on all CLI sessions.
  - `session` clears LLDP counters for the current CLI session only.

**Examples**

- This command resets all the LLDP counters to zero.
  ```
  switch(config)# clear lldp counters
  switch(config)#
  ```

- This command resets only the LLDP counters for the current CLI session.
  ```
  switch(config)# clear lldp counters session
  switch(config)#
  ```
clear lldp table

The `clear lldp table` command clears neighbor information from the LLDP table.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear lldp table
```

**Example**
- This command clears neighbor information from the LLDP table.
  ```
  switch(config)# clear lldp table
  switch(config)#
  ```
**lldp holdtime**

The `lldp holdtime` command specifies the amount of time a receiving device should maintain the information sent by the device before discarding it.

**Command Mode**

Global Configuration

**Command Syntax**

```
lldp holdtime period
no lldp holdtime
default lldp holdtime
```

**Parameters**

- **period**  The amount of time a receiving device should hold LLDPDU information before discarding it. Value ranges from 10 to 65535 second; default value is 120 seconds.

**Examples**

- This command sets the amount of time before the receiving device discards LLDPDU information to 180 seconds.

```
switch(config)# lldp holdtime 180
switch(config)#
```

- This command restores the hold time to its default value of 120 seconds.

```
switch(config)# no lldp holdtime 180
switch(config)#
```
lldp management-address

The **lldp management-address** command enables the user to add the IP management address used for LLDP type-length-value (TLV).

**Command Mode**
- Global Configuration

**Command Syntax**

```
lldp management-address INTERFACE
no lldp management-address [INTERFACE]
default lldp management-address [INTERFACE]
```

**Parameters**
- **INTERFACE**  Interface type and number. Options include:
  - **all**  all interfaces.
  - **ethernet e_num**  Ethernet interface specified by *e_num*.
  - **loopback l_num**  Loopback interface specified by *l_num*.
  - **management m_num**  Management interface specified by *m_num*.
  - **port-channel p_num**  Port-Channel Interface specified by *p_num*.
  - **vlan v_num**  VLAN interface specified by *v_num*.

**Examples**

- This command specifies the IP management address to be used in the TLV.
  ```
switch(config)# lldp management-address ethernet 3/1
switch(config)#
```

- This command removes the IP management address used in the TLV.
  ```
switch(config)# no lldp management-address ethernet 3/1
switch(config)#
```

- This command specifies that VLAN 200 is used in the TLV.
  ```
switch(config)# lldp management-address vlan 200
switch(config)#
```

- This command removes the VLAN ID used in the TLV.
  ```
switch(config)# no lldp management-address vlan 200
switch(config)#
```
lldp management-address vrf

The lldp management-address vrf command enables the user to add the IP address of the VRF interface used in LLDP type-length-value (TLV).

Command Mode
Global Configuration

Command Syntax

lldp management-address vrf VRF_INSTANCE
no lldp management-address vrf VRF_INSTANCE
default lldp management-address vrf VRF_INSTANCE

Parameters

- **VRF_INSTANCE** specifies the VRF instance.

Examples

- This command specifies the management address VRF to be used in the TLV.

  ```
  switch(config)# lldp management-address vrf test 1
  switch(config)#
  ```

- This command removes the management VRF used in the TLV.

  ```
  switch(config)# no lldp management-address vrf test 1
  switch(config)#
  ```
**lldp receive**

The `lldp receive` command enables LLDP packets on an interface. The `no lldp receive` command disables the acceptance of LLDP packets.

**Command Mode**
- Interface-Ethernet configuration
- Interface-Management configuration

**Command Syntax**
```
lldp receive
no lldp receive
default lldp receive
```

**Examples**
- These commands enable the reception of LLDP packets on Ethernet interface 4/1.
  ```
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)#lldp receive
  switch(config-if-Et4/1)#
  ```
- These commands disable LLDP the reception of LLDP packets on Ethernet interface 4/1.
  ```
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)# no lldp receive
  switch(config-if-Et4/1)#
  ```
lldp reinit

The `lldp reinit` command sets the time delay in seconds for LLDP to initialize.

**Command Mode**

Global Configuration

**Command Syntax**

```
lldp reinit delay
no lldp reinit
default lldp reinit
```

**Parameters**

- `delay` the amount of time the device should wait before re-initialization is attempted. Value ranges from 1 to 20 seconds; default value is 2 seconds.

**Examples**

- This command specifies that the switch should wait 10 seconds before attempting to re-initialize.
  ```
  switch(config)# lldp reinit 10
  switch(config)#
  ```

- This command restores the default initialization delay of 2 seconds.
  ```
  switch(config)# no lldp reinit 10
  switch(config)#
  ```
**lldp run**

The `lldp run` command enables LLDP on the Arista switch.

**Command Mode**

Global Configuration

**Command Syntax**

```
lldp run
no lldp run
default lldp run
```

**Examples**

- This command enables LLDP globally on the Arista switch.
  
  switch(config)# lldp run
  switch(config)#

- This command disables LLDP globally on the Arista switch.
  
  switch(config)# no lldp run
  switch(config)#
**lldp timer**

The `lldp timer` command specifies the amount of time a receiving device should maintain the information sent by the device before discarding it. The `no lldp timer` command removes the configured LLDP timer.

**Command Mode**

Global Configuration

**Command Syntax**

```
  lldp timer transmission_time  
  no lldp timer               
  default lldp timer          
```

**Parameters**

- `transmission_time` the period of time at which LLDPDUs are transmitted. Values range from 5 to 32768 seconds; the default is 30 seconds.

**Examples**

- This command configures a period of 80 seconds at which the LLDPDUs are transmitted.

  ```
  switch(config)# lldp timer 180
  switch(config)#
  ```

- This command removes the configured period of time at which the LLDPDUs are transmitted.

  ```
  switch(config)# no lldp timer 180
  switch(config)#
  ```
lldp tlv-select

The **lldp tlv-select** command allows the user to specify the type-length-values (TLVs) to include in LLDP packets.

**Command Mode**

Global Configuration

**Command Syntax**

```
lldp tlv-select **TLV_NAME**
no lldp tlv-select **TLV_NAME**
default lldp tlv-select **TLV_NAME**
```

**Parameters**

- **TLV_NAME** Options include:
  - `link-aggregation` specifies the link aggregation TLV.
  - `management-address` specifies the management address TLV.
  - `max-frame-size` specifies the Frame size TLV.
  - `port-description` specifies the port description TLV.
  - `port-vlan` specifies the port VLAN ID TLV.
  - `system-capabilities` specifies the system capabilities TLV.
  - `system-description` specifies the system description TLV.
  - `system-name` specifies the system name TLV.

**Example**

- This command enables the system description TLV:
  ```
switch(config)# lldp tlv-select system-description
switch(config)#
  ```

- This command disables the system description TLV:
  ```
switch(config)# no lldp tlv-select system-description
switch(config)#
  ```

- This command enables the max-frame-size TLV:
  ```
switch(config)# lldp tlv-select max-frame-size
switch(config)#
  ```

- This command disables the max-frame-size TLV:
  ```
switch(config)# no lldp tlv-select max-frame-size
switch(config)#
  ```
Illdp transmit

The Illdp transmit command enables the transit of LLDP packets on an interface.

Command Mode

Interface-Ethernet configuration
Interface-Management configuration

Command Syntax

illdp transmit
no illdp transmit
default illdp transmit

Examples

• These commands enable the transmission of LLDP packets.
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)#illdp transmit
  switch(config-if-Et4/1)#

• These commands disable the transmission of LLDP packets.
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)#no illdp transmit
  switch(config-if-Et4/1)#
show lldp

The `show lldp` command displays LLDP information.

Command Mode
EXEC

Command Syntax
```
show lldp [INTERFACE]
```

Parameters
- `INTERFACE` Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

Examples
- This command displays all LLDP information.
  ```
  switch# show lldp
  LLDP transmit interval : 60 seconds
  LLDP transmit holdtime : 120 seconds
  LLDP reinitialization delay : 2 seconds
  LLDP Management Address VRF : test
  
  Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
  Management Address (Management0)
  IEEE802.1 Port VLAN ID
  IEEE802.3 Link Aggregation
  IEEE802.3 Maximum Frame Size
  
  Port       Tx Enabled  Rx Enabled
  Et3/1      Yes         Yes
  <-------OUTPUT OMITTED FROM EXAMPLE-------->
  switch#
  ```
- This command displays specific information about LLDP for Ethernet interface 3/1.
  ```
  switch# show lldp ethernet 3/1
  LLDP transmit interval : 30 seconds
  LLDP transmit holdtime : 120 seconds
  LLDP reinitialization delay : 2 seconds
  LLDP Management Address VRF : default
  
  Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
  switch#
  ```
• This command displays specific information about LLDP for management interface 1/1.

```bash
switch# show lldp management 1/1
LLDP transmit interval : 60 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : default

Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
  Management Address (Management0)
  IEEE802.1 Port VLAN ID
  IEEE802.3 Link Aggregation
  IEEE802.3 Maximum Frame Size

<td>Ma1/1</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

switch#
```
show lldp local-info

The `show lldp local-info` command displays LLDP errors and overflows.

Command Mode

EXEC

Command Syntax

```
show lldp local-info [INTERFACE]
```

Parameters

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

Example

- This command displays the specific LLDP errors and overflows on management interface 1.

```
switch# show lldp local-info management 1
Local System:
  - Chassis ID type: MAC address (4)
    Chassis ID : 001c.730f.11a8qqq

se505.16:01:44#
switch#
```
show lldp neighbors

The `show lldp neighbors` command displays information about the switch’s LLDP neighbors.

Command Mode
EXEC

Command Syntax
```
show lldp neighbors [INTERFACE] [INFO_LEVEL]
```

Parameters
- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` displays information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - `<no parameter>` Displays information for all interfaces.
  - `detailed` LLPDP information for all the adjacent LLDP devices.

Examples
- This command displays the neighbor’s information about LLDP.

```
switch(config)# show lldp neighbor

switch#
show lldp traffic

The `show lldp traffic` command displays LLDP traffic information for the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show lldp traffic [INTERFACE]
```

**Parameters**

- `INTERFACE` Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays the LLDP counters on the switch.

  ```
  switch# show lldp traffic
  Port          Tx Frames Tx Length Exceeded
  Et20              69485                  0

  switch#
  ```
Arista switches support the transfer of packets (network layer) and frames (data link layer). This chapter describes concepts and processes that are referenced by routing and switching protocols that Arista switches support.

Sections in this chapter include:

- Section 16.1: Data Transfer Introduction
- Section 16.2: Data Transfer Methods
- Section 16.3: MAC Address Table
- Section 16.4: Configuring Ports
- Section 16.5: Monitoring Links
- Section 16.6: Data Transfer Command Descriptions

### 16.1 Data Transfer Introduction

Arista switches transfer data through switching, routing, and layer 3 switching. This chapter provides an introduction to these transfer methods.

Data structures and processes that support data transfer methods and referenced in specific protocol chapters are also described, including:

- routed ports
- switched ports
- MAC address table
- port mirroring
- storm control
- loopback interfaces
- route redistribution
- null0 interfaces
- MTUs
16.2 Data Transfer Methods

This section describes these data transfer methods:

- **Section 16.2.1: Switching and Bridging**
- **Section 16.2.2: Routing**
- **Section 16.2.3: Layer 3 Switching**

16.2.1 Switching and Bridging

Switching and bridging operations transmit data link layer frames between devices within a single subnet. Each port is assigned a 48 bit Media Access Control (MAC) address. Frames arriving at a hub are bridged, or sent to all other ports on the subnet. Switches can associate ports with their MAC addresses, obviating the need to flood the subnet when sending a frame.

Subnets in the switch are defined by VLANs. A virtual local area network (VLAN) is a group of devices that are configured to communicate as if they are attached to the same network regardless of their physical location. Chapter describes VLANS.

Four MAC address types identify the scope of LAN interfaces that an address represents:

- unicast: represents a single interface.
- broadcast: represents all interfaces.
- multicast: represents a subset of all interfaces.
- reserved: assigned to nodes that have no configured MAC address.

The Individual/Group (I/G) bit distinguishes unicast MAC addresses from multicast addresses. As shown in Figure 16-1, the I/G bit is the least significant bit of the most significant byte in a MAC address.

![Figure 16-1: MAC Address Format](image)

- Unicast address: the I/G bit is 0: 1234.1111.1111 is a unicast MAC address (the most significant byte is an even number).
- Reserved address: all bits set to 0 (0000.0000.0000).
- Multicast address: the I/G bit is 1: 1134.1111.1111 is a multicast MAC address (the most significant byte is an odd number).
- Broadcast address: all bits set to 1 (FFFF.FFFF.FFFF).

**Example**

- The following are unicast MAC addresses:
  - 0200.0000.0000
  - 1400.0000.0000
Chapter 16: Data Transfer

Data Transfer Methods

- The following are multicast MAC addresses:
  0300.0000.0000
  2500.0000.0000

The following sections describe MAC address functions and data structures.
- Section 10.5.2 describes the process of assigning a MAC address to an interface.
- Section 16.3 describes the MAC Address table.

16.2.2 Routing

Routing transmits network layer packets over connected independent subnets. Each subnet is assigned an IP address range and each device on the subnet is assigned an IP address from that range. Connected subnets have IP address ranges that do not overlap. A router connects multiple subnets. Routers forward inbound packets to the subnet whose address range includes the packets’ destination address.

IPv4 and IPv6 are internet layer protocols that facilitate packet-switched networking, including transmissions across multiple networks.

These chapters describe available IP features:
- IPv4
- IPv6

16.2.2.1 Static Routing

Static routes are entered through the CLI and are typically used when dynamic protocols are unable to establish routes to a specified destination prefix. Static routes are also useful when dynamic routing protocols are not available or appropriate.

Creating a static route associates a destination IP address with a local interface. The routing table refers to these routes as connected routes that are available for redistribution into routing domains defined by dynamic routing protocols.

These sections describe static route configuration commands:
- Section 24.1.2: IPv4 Address Configuration
- Section 25.3.1.2: Configuring Default and Static IPv6 Routes

16.2.2.2 Dynamic Routing

Dynamic routes are established by dynamic routing protocols. These protocols also maintain the routing table and modify routes to adjust for topology or traffic changes. Routing protocols assist the switch in communicating with other devices to exchange network information, maintaining routing tables, and establishing data paths.

The switch supports these dynamic routing protocols:
- Open Shortest Path First – Version 2
- Open Shortest Path First – Version 3
- Border Gateway Protocol (BGP)
- Routing Information Protocol
- IS-IS
16.2.3 Layer 3 Switching

Layer 3 switches establish data paths through routing processes (Layer 3) and transfer data as a switch (Layer 2) through speed-optimized hardware. Layer 3 switches use a control plane (routing) and data plane (switching) to manage these processes.

16.2.3.1 Control plane

The control plane builds and maintains the IP routing table, which identifies IP packet routes in terms of destination addresses. The routing table defines a route by its next hop address and the egress interface that accesses the next hop.

The control plane derives routing information from three sources:

- Status of physical and virtual interfaces on the switch.
- Static routes entered through the CLI.
- Routes established through dynamic routing protocols.

Applying an ACL to the Control Plane

The control plane supports routing and management functions, handling packets that are addressed to the switch without regard to any switch interface.

To apply an IP ACL to the control plane, enter \texttt{ip access-group (Control Plane mode)} in control-plane mode. The \texttt{control-plane} command places the switch in control-plane mode.

Example

- These commands place the switch in control-plane mode and assigns \texttt{CP-Test1} to the control plane.

  \begin{verbatim}
  switch(config)#control-plane
  switch(config-cp)#ip access-group CP-Test1 in
  switch(config-cp)#
  \end{verbatim}

16.2.3.2 Data plane

The data plane routes IP packets based on information derived by the control plane. Each packet's path includes Layer 2 addresses that reach its next hop destination. The data plane also performs other operations required by IP routing, such as recalculating IP header checksums and decrementing the time-to-live (TTL) field.

Arista data planes support these packet forwarding modes:

- Store and forward: the switch accumulates entire packets before forwarding them.
- Cut through: the switch begins forwarding frames before their reception is complete.

Cut through mode reduces switch latency at the risk of decreased reliability. Packet transmissions can begin immediately after the destination address is processed. Corrupted frames may be forwarded because packet transmissions begin before CRC bytes are received.

Packet forwarding mode availability varies by switch platform:

- Arad: store and forward mode only
- FM6000: both modes are available.
- Petra: store and forward mode only
- Trident: both modes are available.
• Trident-II: both modes are available.

The data plane is also referred to as the forwarding plane.

**Data Plane Forwarding Mode Configuration**

The `switch forwarding-mode` command specifies the forwarding mode of the switch's data plane. This command is available on Trident, Trident-II, and FM6000 platform switches. The forwarding mode is `store-and-forward` on Arad and Petra platform switches.

**Example**

• This command changes the forwarding mode to `store-and-forward`.

```
switch(config)#switch forwarding-mode store-and-forward
switch(config)#
```

The `show switch forwarding-mode` command displays the switch's forwarding mode.

**Example**

• This command displays the switch's forwarding mode.

```
switch(config)#show switch forwarding-mode
Current switching mode: store and forward
Available switching modes: cut through, store and forward
```
16.3 MAC Address Table

The switch maintains a MAC address table for switching frames efficiently between ports. The MAC address table contains static and dynamic MAC addresses.

- Static MAC addresses are entered into the table through a CLI command.
- Dynamic MAC addresses are entered into the table when the switch receives a frame whose source address is not listed in the MAC address table. The switch builds the table dynamically by referencing the source address of frames it receives.

16.3.1 MAC Address Table Configuration

These sections describe MAC address table configuration tasks.

- Section 16.3.1.1: Static MAC Address Table Entries
- Section 16.3.1.2: Dynamic MAC Address Table Entries

16.3.1.1 Static MAC Address Table Entries

The MAC address table accepts static MAC addresses, including multicast entries. Each table entry references a MAC address, a VLAN, and a list of layer 2 (Ethernet or port channel) ports. The table supports three entry types: unicast drop, unicast, and multicast.

- A drop entry does not include a port.
- A unicast entry includes one port.
- A multicast entry includes at least one port.

Packets with a MAC address (source or destination) and VLAN specified by a drop entry are dropped. Drop entries are valid for only unicast MAC addresses.

The `mac address-table static` command adds a static entry to the MAC address table.

**Example**

- This command adds a static entry for unicast MAC address 0012.3694.03ec to the MAC address table.

```
switch(config)#mac address-table static 0012.3694.03ec vlan 3 interface Ethernet 7
switch(config)#show mac address-table static
```

```
Vlan | Mac Address     | Type   | Ports | Moves | Last Move
-----|-----------------|--------|-------|-------|----------
  3   | 0012.3694.03ec  | STATIC | Et7   |       |----------
```

Total Mac Addresses for this criterion: 1

```

```

```
Vlan | Mac Address | Type | Ports | Moves | Last Move
-----|-------------|------|-------|-------|----------
```

Total Mac Addresses for this criterion: 0
Chapter 16: Data Transfer

MAC Address Table

This command adds the static entry for the multicast MAC address 0112.3057.8423 to the MAC address table.

```
switch(config)#mac address-table static 0112.3057.8423 vlan 4 interface port-channel 10 port-channel 12
```

```
switch(config)#show mac address-table
Mac Address Table
-----------------------------
Vlan  | Mac Address       | Type        | Ports      | Moves | Last Move
----  | ------------------ | ----        | -----      | ----- | ---------
Total Mac Addresses for this criterion: 0

Multicast Mac Address Table
-----------------------------
Vlan  | Mac Address       | Type        | Ports
----  | ------------------ | ----        | -----      | ----- | ---------
4     | 0112.3057.8423    | STATIC      | Po10 Po12
Total Mac Addresses for this criterion: 1
```

16.3.1.2 Dynamic MAC Address Table Entries

Learning Mode

The switch maintains a MAC address table for switching frames efficiently between VLAN ports. When the switch receives a frame, it associates the MAC address of the transmitting interface with the recipient VLAN and port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is not enabled, the entry is not added to the table.

The `switchport mac address learning` command enables MAC address learning for the configuration mode interface. MAC address learning is enabled by default on all Ethernet and port channel interfaces.

Example

```
These commands disables MAC address learning for Ethernet interface 8, then displays the active configuration for the interface.
```

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#no switchport mac address learning
switch(config-if-Et8)#show active
interface Ethernet8
no switchport mac address learning
switch(config-if-Et8)#
```

Aging Time

Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry's VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.

Aging time ranges from 10 to 1,000,000 seconds with a default of 300 seconds (five minutes).
Example

- This command sets the MAC address table aging time to two minutes (120 seconds).

  switch(config)#mac address-table aging-time 120
  switch(config)#

The `mac address-table aging-time` command configures the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.

Clearing Dynamic Addresses

The `clear mac address-table dynamic` command removes specified dynamic entries from the MAC address table. Entries are identified by their VLAN and layer 2 (Ethernet or port channel) interface.

Example

- This command clears all dynamic mac address table entries for port channel 5 on VLAN 34.

  switch(config)#clear mac address-table dynamic vlan 34 interface port-channel 5
  switch(config)#

16.3.2 Displaying the MAC Address Table

The `show mac address-table` command displays the specified MAC address table entries.
### Example
- This command displays the MAC address table.

```
switch# show mac address-table
```

---

16.4 Configuring Ports

This section describes these port properties:

- Section 16.4.1: Port Mirroring
- Section 16.4.2: Storm Control
- Section 16.4.3: Switched and Routed Ports
- Section 16.4.4: Loopback Ports
- Section 16.4.5: MAC Security
- Section 16.4.6: Null0 Interface
- Section 16.4.7: Maximum Transmission Units (MTU)

16.4.1 Port Mirroring

Port mirroring, also known as port monitoring, is the duplication of traffic from a collection of source ports to a destination port. A mirror session correlates a set of source ports to a destination port.

Valid mirror sources are Ethernet or port channel interfaces, including port channels which are part of an MLAG. Mirror destination ports are usually Ethernet interfaces; port channel destination ports are also supported on some platforms. Mirror ports cannot be routed ports or Ethernet ports that are port channel members. Mirroring is deactivated on Ethernet mirror ports that are subsequently added to a port channel. Layer 2 control protocols run normally on source ports; PDU traffic is mirrored identically to data traffic. Layer 2 control protocols do not run on destination ports.

An interface cannot be in a more than one mirror session and cannot be simultaneously a source and destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from only one direction.

- **Ingress Mirroring:** Packets received by a source port are duplicated, including all valid data frames and L2 control PDUs. Ports mirror data before forwarding logic is applied. Packets subsequently dropped because of forwarding decisions are mirrored.
- **Egress Mirroring:** Packets transmitted by a source port are duplicated, with these exceptions:
  - **Flooded/Multicast Packets:** Packets sent to multiple mirror ports generate one copy, except in multi-chip devices when the mirror source and destination ports are on different chips; in this case, an extra copy is generated.
  - **Dropped Packets:** Packets dropped by forwarding decisions (such as output STP state checks) on egress sources are not duplicated. Packets dropped because of congestion may be duplicated.

VLAN tags on duplicate packets from an egress source are identical to tags on inbound source packets.

When a packet’s path through the switch includes multiple mirror source ports in different mirror sessions, the traffic is duplicated once and sent to the destination of the highest numbered session.

16.4.1.1 Port Mirroring Capacity

Port mirroring capacity varies by platform. This section describes session limits for each platform.

**FM6000 Platform Switches**

- **Maximum Number of Sessions:** 4
- **Session Sources:** Ethernet interfaces (any number), Port channel interfaces (any number)
Chapter 16: Data Transfer

### Configuring Ports

- **Session Destinations:** Ethernet interfaces (any number), Port channel interfaces (any number), CPU
- Egress IP ACL on destination port is supported
  - Sessions can mirror Rx, Tx, or both ways without impacting the number of available sessions.
  - Implementing any of the following reduces the number available sessions by one: ACL Logging, MLAG Peer Link, sFlow, VTEP Learning (VXLAN), LANZ Sampling

#### Arad Platform Switches
- **Maximum Number of Sessions:** 16
- **Session Sources:** Ethernet interfaces (any number), Port channel interfaces (any number)
- **Session Destinations:** Ethernet interfaces (one)
- Egress IP ACL on Destination Port is supported for Rx sessions
  - Sessions can mirror Rx, Tx, or both ways without impacting number of available sessions.
  - Although the number of configured source interfaces is unlimited, the number of interfaces that can be effectively mirrored is restricted by the destination port speed.

#### Petra Platform Switches
- **Maximum Number of Sessions:** 16
- **Session Sources:** Ethernet interfaces (eight for Rx or Tx sessions; four for both ways)
- **Session Destinations:** Ethernet interfaces (eight for Rx or Tx sessions; four for both ways)
- Egress IP ACL on Destination Port is not supported
  - Sessions can mirror Rx, Tx, or both ways without impacting number of available sessions.

#### Trident Platform Switches
- **Maximum Number of Sessions:** 4
- **Session Sources:** Ethernet interfaces (any number), Port channel interfaces (any number)
- **Session Destinations:** Ethernet interfaces (one)
- Egress IP ACL on Destination Port is supported
  - Mirroring Rx or Tx requires one session. Mirroring both ways requires two sessions.

#### Trident-II Platform Switches
- **Maximum Number of Sessions:** 4 per chip
- **Session Sources:** Ethernet interfaces (any number), Port channel interfaces (any number)
- **Session Destinations:** Ethernet interfaces (one)
- Egress IP ACL on Destination Port is supported
  - Mirroring Rx or Tx requires one session. Mirroring both ways requires two sessions.

### 16.4.1.2 Configuring Mirror Ports

Mirror sessions associate a set of source ports to a destination port using the `monitor session source` and `monitor session destination` commands. An interface cannot be used in more than one mirror session and cannot be simultaneously a source and a destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from one direction. On Trident and Trident-II platform switches (DCS-7050, DCS-7050X, DCS-7250X, and DCS-7300X series), all frames...
Configuring Ports Chapter 16: Data Transfer

mirrored on egress are prefixed with an 802.1Q VLAN tag, even when the egress port is configured as an access port. If the capture device cannot process VLAN tags properly, mirroring should be configured exclusively for ingress traffic by specifying `rx` in the `monitor session source` command.

Filtering on TX traffic in a mirror session is not supported.

**Example**

- These commands configure Ethernet interface 7 as the source port and Ethernet interface 8 as the destination port for the redirect_1 mirroring session. The session mirrors ingress and egress traffic.

```
switch(config)#monitor session redirect_1 source ethernet 7
switch(config)#monitor session redirect_1 destination ethernet 8
```

The `show monitor session` command displays the configuration of the specified port mirroring session.

**Example**

- This command shows the configuration of the `redirect_1` mirroring session.

```
switch(config)#show monitor session

Session redirect_1
------------------------
Source Ports
  Both: Et7

Destination Port: Et8
```

The `monitor session ip access-group` command configures an ACL to filter the traffic being mirrored to the destination port.

**Example**

- These commands create an ACL and apply it to filter the traffic mirrored to the destination port by session “redirect_1.”

```
switch(config)#ip access-list allow-host
switch(config-acl-allow-host)#10 permit ip host 192.168.11.24 host 10.0.215.23
switch(config-acl-allow-host)#20 deny ip any any
switch(config-acl-allow-host)#exit
switch(config)#monitor session redirect_1 ip access-group allow-host
switch(config)#
```

16.4.1.3 Filtered Mirroring to CPU

Filtered mirroring to CPU adds a special destination to port mirroring that allows mirrored traffic to be sent to the switch supervisor. The traffic can then be monitored and analyzed locally without the need of a remote port analyzer. Filtered mirroring to CPU can also be used for debugging and troubleshooting, configured to mirror RX traffic, TX traffic or both, with up to 14 mirroring profiles used simultaneously. In addition, mirroring to CPU uses control plane protection to limit the rate of the traffic sent to the CPU.
Examples

- These commands configure the source for normal mirroring and the destination to CPU.

  ```
  switch(config)#monitor session mySession source ethernet 3/1 both
  switch(config)#monitor session mySession destination cpu
  switch(config)#
  ```

- These commands configure reserved bandwidth and shape rate of mirrored traffic.

  ```
  switch(config)#policy-map type control-plane copp-system-policy
  switch(config-pmap-control-plane-copp-system-policy)#class opp-system-mirroring
  switch(config-pmap-c-copp-system-policy-copp-system-mirroring)#bandwidth kbps 2000
  switch(config-pmap-c-copp-system-policy-copp-system-mirroring)#shape kbps 4000
  switch(config-pmap-c-copp-system-policy-copp-system-mirroring)#
  ```

- These commands show the current status of mirroring to CPU from the CLI, and display the control plane protection configuration for mirroring to CPU.

  ```
  switch(config)#show monitor session
  Session mySession
  ---------------
  Source Ports:
  Both : Et3/1
  Destination Ports:
  Cpu : active (mirror0)
  switch(config)#
  ```

- These commands show the current status of mirroring to CPU from the CLI, and display the control plane protection configuration for mirroring to CPU.

  ```
  switch(config)#show policy-map type control-plane copp-system-policy class opp-system-mirroring
  Class-map: copp-system-mirroring (match-any)
  shape : None
  bandwidth : None
  switch(config)#
  ```

16.4.2 Storm Control

A traffic storm is a flood of packets entering a network, resulting in excessive traffic and degraded performance. Storm control prevents network disruptions by limiting traffic beyond specified thresholds on individual physical LAN interfaces.

Storm control monitors inbound traffic levels over one-second intervals and compares the traffic level with a specified benchmark.

Storm control has three modes:

- **Storm control all**: When inbound traffic exceeds the specified threshold within a one-second control interval, all traffic is dropped until the end of the interval.

- **Storm control broadcast**: When inbound broadcast traffic exceeds the specified threshold within a one-second control interval, broadcast traffic is dropped until the end of the interval.

- **Storm control multicast**: When inbound multicast traffic exceeds the specified threshold within a one-second control interval, multicast traffic is dropped until the end of the interval.

Broadcast and multicast storm control are independent features and can be enabled simultaneously. The **storm control all** threshold overrides broadcast and multicast thresholds.
Storm Control Configuration

The `storm-control` command configures and enables broadcast or multicast storm control on the configuration mode interface. The command provides three mode options:

- `storm-control all` unicast, multicast, and broadcast inbound packet control.
- `storm-control broadcast` broadcast inbound packet control.
- `storm-control multicast` multicast inbound packet control.

An interface configuration can contain three storm-control statements, one with each mode setting. The `storm-control all` threshold overrides broadcast and multicast thresholds.

When storm control is enabled, the switch monitors inbound traffic levels over one second intervals and compares the traffic level with a specified threshold. The threshold is a percentage of the total available port bandwidth and is configurable on each interface for each transmission mode.

Example

- These commands enable multicast storm control on Ethernet interfaces 2 through 4 and set a threshold of 65%. During each one second interval, the interface drops inbound multicast traffic in excess of 65% of capacity.
  
  ```
  switch(config)#interface ethernet 2 / 3 / 4
  switch(config-if-Et4/4/4)#storm-control multicast level 65
  switch(config-if-Et4/4/4)#
  ```

Example

- These commands clear multicast storm control on Ethernet interfaces 2 through 4.

  ```
  switch(config)#interface ethernet 2 / 3 / 4
  switch(config-if-Et2/3/4)#no storm-control multicast
  switch(config-if-Et2/3/4)#
  ```

Example

- These commands enable broadcast storm control on Ethernet interfaces 2 through 4 and set broadcast traffic to 50%. During each one second interval, the interface drops inbound multicast traffic in excess of 50% of capacity.

  ```
  switch(config)#interface ethernet 2 / 3 / 4
  switch(config-if-Et2/3/4)#storm-control broadcast level 50
  switch(config-if-Et2/3/4)#
  ```

Example

- These commands enable broadcast storm control on Ethernet interfaces 2 through 4 and set a threshold of 5000 packets per second (pps).

  ```
  switch(config)#interface ethernet 2 / 3 / 4
  switch(config-if-Et2/3/4)#storm-control broadcast level pps 5000
  switch(config-if-Et2/3/4)#
  ```

Example

- These commands clear broadcast storm control on Ethernet interfaces 2 through 4.

  ```
  switch(config)#interface ethernet 2 / 3 / 4
  switch(config-if-Et2/3/4)#no storm-control broadcast
  switch(config-if-Et2/3/4)#
  ```

The `show storm-control` command displays the storm-control level and interface inbound packet capacity for the specified interface.
Example

- This command displays the storm control configuration for Ethernet ports 2 through 4.

```plaintext
switch(config-if-Et2/3/4)#show storm-control
Port            Type     Level   Units Rate(Mbps)   Status   Drops Reason
Et2/3/4          all     75.00       %       7500   active       0
multicast     55.00       %       5500   active       0
broadcast     50.00       %       5000   active       0

switch(config-if-Et2/3/4)#
```

16.4.3 Switched and Routed Ports

A switched port is an Ethernet or port channel interface that is configured as a layer 2 interface. Switched ports bridge frames and are assigned to at least one VLAN. Switched ports are not associated with any IP addresses. By default, Ethernet and port channel interfaces are in switched port mode.

A routed port is an Ethernet or port channel interface that is configured as a layer 3 interface. Routed ports do not bridge frames and are not members of any VLANs. Routed ports can have IP addresses assigned to them and packets are routed directly to and from the port.

Configuring an interface as a routed port is similar to creating a VLAN with spanning-tree disabled, making the port the only member of that VLAN and configuring the IP address on the switch virtual interface (SVI) associated with the VLAN.

All IP-level interface configuration commands, except `autostate` and `ip virtual-router`, can be used to configure a routed interface. If the interface is reverted to switched port mode, `running-config` maintains IP level interface configuration statements. These changes become active again if the interface is configured back to routed port mode.

A LAG that is created with the `channel-group` command inherits the mode of the member port. A LAG created from a routed port becomes a routed LAG. IP-level configuration is not propagated to the LAG from its component members.

The broadcast queue towards the CPU is shared among all interfaces of the forwarding chip. Broadcast storm on a single port adversely impacts other interfaces of the same chip by potentially dropping even low rate broadcast frames. Routed port storm control attempts to mitigate this effect by performing storm control on the broadcast frames for routed ports.

Routed Port Configuration

The switching-routing configuration of Ethernet and port channel interfaces is specified by the `switchport` and `no switchport` commands. These commands only toggle the interface between switched and routed modes. They have no effect on other configuration states.

The `no switchport` command places the configuration mode interface in `routed port` mode. Routed ports behave as Layer 3 interfaces. They do not bridge packets and are not VLAN members. An IP address can be assigned to a routed port for the direct routing of packets to and from the interface.

When an interface is configured as a routed port, the switch transparently allocates an internal VLAN whose only member is the routed interface. Internal VLANs are created in the range from 1006 to 4094. VLANs that are allocated internally for a routed interface cannot be directly created or configured. Section 18.3.4: Allocating Internal VLANs describes VLAN allocation configuration procedures.

Example

- This command places Ethernet interface 5 in routed port mode.

```plaintext
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
```
Switched Port Configuration

The `switchport` command places the configuration mode interface in **switched port** (Layer 2) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments. By default, Ethernet and port channel interfaces are switched ports.

**Example**

- This command places Ethernet interface 5 in switched port mode.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport
  ```

The `switchport default mode routed` command places the configuration mode interface for a switch with all ports in **switched port** (Layer 3) routed mode, changing the switch with all ports from **switchport default mode access**.

**Examples**

- This command places a switch with all ports in routed mode.
  ```
  switch(config)#switchport default mode routed
  ```

- This command places a switch with all ports in access mode.
  ```
  switch(config)#switchport default mode access
  ```

### 16.4.4 Loopback Ports

A loopback interface is a virtual network interface implemented in software and does not connect to any hardware. Traffic sent to the loopback interface is immediately received on the sending interface. The switch provides loopback configuration mode for creating loopback interfaces and modifying their operating parameters.

Internet protocols reserve specific addresses for loopback network segments:

- IPv4 designates 127/8 as loopback subnet, which includes 127.0.0.0 through 127.255.255.255.
- IPv6 designates ::1/128 as the loopback address, which includes 0:0:0:0:0:0:0:1 (also written as ::1).

Arista switches support the configuration of 1001 loopback interfaces, numbered from 0 to 1000.

**Loopback Interface Configuration**

Loopback ports are instantiated by entering loopback interface mode for the desired port number. Loopback interface mode also provides access to loopback configuration commands. Previously instantiated ports are edited by entering loopback interface mode for the specified port.

The `interface loopback` command places the switch in interface-loopback configuration mode for the specified interfaces, creating loopback interfaces for each specified port not previously created.

**Example**

- These commands instantiate loopback interface 2 and assigns it IP address 10.1.1.42/24.
  ```
  switch(config)#interface loopback 2
  switch(config-if-Lo2)#ip address 10.1.1.42
  switch(config-if-Lo2)#show active
  interface Loopback2
    ip address 10.1.1.42/24
  switch(config-if-Lo2)#
  ```
16.4.5 MAC Security

MAC security restricts input to a switched port by limiting the number of MAC addresses that can access the port. Ports with MAC security enabled restrict traffic to a limited number of hosts, as determined by their MAC addresses. When the limit is exceeded, the port becomes errdisabled.

Port Security Configuration

MAC address security is enabled by `switchport port-security`. The default MAC address limit on an interface where port security is enabled is one; to change that default limit, use the `switchport port-security maximum` command.

Example

- These commands enable MAC security on Ethernet interface 7, set the maximum number of assigned MAC addresses to 2, assign two static MAC addresses to the interface, and clear the dynamic MAC addresses for the interface.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#switchport port-security
switch(config-if-Et7)#switchport port-security maximum 2
switch(config-if-Et7)#exit
switch(config)#mac address-table static 0034.24c2.8f11 vlan 10 interface ethernet 7
switch(config)#mac address-table static 4464.842d.17ce vlan 10 interface ethernet 7
switch(config)#clear mac address-table dynamic interface ethernet 7
switch(config)#show port-security

```

16.4.6 Null0 Interface

The null0 interface is a virtual interface that drops all inbound packets. A null0 route is a network route whose destination is `null0 interface`. Inbound packets to a null0 interface are not forwarded to any valid address. Many interface configuration commands provide `null0` as an interface option.

16.4.7 Maximum Transmission Units (MTU)

The MTU of a communications protocol refers to the size in bytes of the largest frame (Ethernet) or packet (IP) that can be sent on the network. Different protocols support a variety of MTU sizes. Most IP over Ethernet implementations use the Ethernet V2 frame format, which specifies an MTU of 1500 bytes. Jumbo frames are Ethernet frames containing more than 1500 bytes.
16.4.7.1 Switching interface MTU size

On Arista devices, layer two interfaces (either trunk or access ports) are set with a default ethernet MTU of 9236 bytes. This value cannot be changed and is derived as follows: 9214 + 6 (source MAC) + 6 (dst MAC) + 4 (VLAN tag) + 2 (ether type) + 4 (crc) totals 9236 bytes.

The output of a `show interface` command for a layer two interface displays the following:

**Trunk**

```
Ethernet1 is up, line protocol is up (connected)
Hardware is Ethernet, address is 001c.731c.5073 (bia 001c.731c.5073)
  Ethernet MTU 9214 bytes, BW 1000000 kbit
```

**Access**

```
Ethernet3 is up, line protocol is up (connected)
Hardware is Ethernet, address is 001c.731c.5075 (bia 001c.731c.5075)
  Ethernet MTU 9214 bytes, BW 1000000 kbit
```

**Important!** The value 9214 displayed here is NOT the maximum frame size but rather the maximum size of the IP packet that can be encapsulated within a frame leaving the interface.

16.4.7.2 Routing Interface MTU Size

The MTU size on layer 3 interfaces varies between a minimum of 68 to the maximum 9214 bytes. The default size is 1500 bytes. The `show interface` output for a layer three interface displays the following:

**VLAN routed interface**

```
Vlan100 is up, line protocol is up (connected)
Hardware is Vlan, address is 001c.731c.5072 (bia 001c.731c.5072)
  Internet address is 10.1.1.2/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 9214 bytes
```

**Physical routed interface**

```
Ethernet4 is down, line protocol is down (connect)
Hardware is Ethernet, address is 001c.731c.5072
  Internet address is 10.10.10.10/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 9214 bytes
```

**Important!** The value 9214 in these outputs is the maximum *IP packet* size that the interface can transmit or receive.

**Important!** Some protocols, such as OSPF, may require that neighbor interfaces on physically disparate systems are configured with the same IP MTU.

A routed interface fragments packets that exceed the configured IP MTU on the interface. For example, if a 2000 byte packet is received on routed interface 1 and is forwarded from routed interface 2 then routed interface 2 fragments the packet into a 1500 byte packet plus an additional packet containing the remaining data. This fragmentation should be avoided by configuring a consistent IP MTU across all systems within the operational domain.
The IP MTU set on a routed interface is valid for both IPv4 and IPv6 packets.

**MTU Configuration**

The `mtu` command configures the IPv4 and IPv6 Maximum Transmission Unit (MTU) size for the configuration mode interface. An interface’s MTU value is displayed with the `show interface` command. The command is valid for all routable interfaces.

**Example**

- This command sets the MTU size of 1492 bytes on VLAN interface 20.
  
  switch(config-if-Vl20)#mtu 1492
  switch(config-if-Vl20)#

- This command displays status for a routed interface.
  
  switch(config-if-Et3)#show interface e3

  Ethernet3 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.731c.5072
  Internet address is 10.1.1.2/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 1500 bytes , BW 1000000 kbit
  Full-duplex, 1Gb/s, auto negotiation: on, uni-link: unknown
  Up 22 days, 7 hours, 47 minutes, 58 seconds
  switch(config)#

- Using ping on a Linux host, you can test the maximum transmission through the interface.
  
  [user@linux ~]$ ping -M do -s 1472 10.1.1.2
  PING 10.1.1.2 (10.1.1.2) 1472(1500) bytes of data.
  1480 bytes from 10.1.1.2: icmp_seq=1 ttl=64 time=0.206 ms
  1480 bytes from 10.1.1.2: icmp_seq=2 ttl=64 time=0.191 ms
  --- 10.1.1.2 ping statistics ---
  2 packets transmitted, 2 received, 0% packet loss, time 999ms
  rtt min/avg/max/mdev = 0.191/0.198/0.206/0.015 ms

The size 1472 has 8 bytes of ICMP information added and 20 bytes of IP headers added, generating a total packet size of 1500 bytes.

- The option ‘-M do’ specifies that fragmentation is prohibited for this test.
- The option ‘-s’ specifies the size of the packet being generated.
- A capture of the frame displays total length of 1514 bytes on the wire which includes the Ethernet headers and type field.
16.5 Monitoring Links

These section describes link monitoring and object tracking processes:

- **Section 16.5.1: Object Tracking**
- **Section 16.5.2: Errdisabled Ports**
- **Section 16.5.3: Link Flap Monitoring**
- **Section 16.5.4: Fabric Link Monitoring**
- **Section 16.5.5: Rapid Automated Indication of Link-Loss**

16.5.1 Object Tracking

Object tracking makes it possible for the switch to take action in response to changes in specific switch properties by creating an object to track those properties. When the tracked property changes, the object then changes state, allowing configured agents to react accordingly.

**Object Tracking Configuration**

The `track` command creates an object that changes state to reflect changes in a specific switch property. Agents configured to track that object are then able to react to the change.

**Example**

- These commands create an object that tracks the line protocol state on Ethernet interface 8, then configure Ethernet interface 5 to disable VRRP when that tracked object changes state to `down`.

  ```
  switch(config)# track ETH8 interface ethernet 8 line-protocol
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# vrrp 1 track ETH8 shutdown
  switch(config-if-Et5)#
  ```

- These commands use object tracking:
  - `link state track`
  - `vrrp track`

16.5.2 Errdisabled Ports

The switch places an Ethernet or management interface in `error-disabled` state when it detects an error on the interface. *Error-disabled* is an operational state that is similar to link-down state. Conditions that error-disable an interface include:

- `bpduguard`
- `link-flap`
- `no-internal-vlan`
- `portchannelguard`
- `portsec`
- `tapagg`
- `uplink-failure-detection`
- `xcvr_unsupported`

Most conditions are programmed by the configuration of other features, such as Spanning Tree protocol (`bpduguard`). Link flap error-disabling is configured through errdisable commands or link flap monitor commands (Section 16.5.3).
Error-disabled interfaces are recovered either through manual or automated methods.

To manually recover an interface, enter its configuration mode and execute `shutdown` and `no shutdown` commands.

**Example**
- These commands manually recover Ethernet interface 30 from the errdisable state.

```
switch(config)#interface ethernet 30
switch(config-if-Et30)#shutdown
switch(config-if-Et30)#no shutdown
switch(config-if-Et30)#
```

Automated recovery of Ethernet interfaces that are error-disabled by a specified condition is enabled by `errdisable recovery cause`. The `errdisable recovery interval` specifies the period that an interface remains disabled until it is enabled and begins operating normally. When the disabling condition persists, recovered interfaces eventually return to the error-disabled state.

**Example**
- These commands configure automated recovery for all interfaces that are error-disabled from link flap and bpduguard conditions. Automated recovery begins five minutes after the port is disabled.

```
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery cause bpduguard
switch(config)#errdisable recovery interval 300
switch(config)#
```

### 16.5.3 Link Flap Monitoring

Link flap frequency is the quantity of link flaps (connection state changes) over a specified period. Excessive link flaps result in network stability issues, including spanning tree and routing recalculations. Link flaps are often caused by layer 1 issues, such as a bad cable or duplex mismatch. Link flap monitoring specifies link flap thresholds and disables a port when a threshold is exceeded.

Link flap monitoring can be enabled on all interfaces through `errdisable link flap` commands or on individual interfaces with the `link flap monitor`.

#### 16.5.3.1 Global Link Flap Monitor

Global link flap detection is configured through two global configuration mode commands:

- `errdisable flap-setting cause link-flap` configures the link-flap frequency that defines link-flap errors on an Ethernet interface.
- `errdisable detect cause link-flap` enables the error-disabling of Ethernet interfaces that exceed the threshold link flap frequency.

Link-flap detection is enabled by default.

**Example**
- These commands sets the link flap error criteria of 15 connection state changes over a 30 second period, then enables error detection on all interfaces.

```
switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
switch(config)#errdisable detect cause link-flap
switch(config)#
```
16.5.3.2 Interface Link Flap Monitor

An interface is monitored for link flap errors with link flap profiles. A link flap profile specifies conditions that define a link-flap error. Profiles are assigned to Ethernet interfaces. Multiple profiles can be assigned to an interface to monitor a set of error conditions.

The global link flap monitor is used by interfaces that are not individually monitored for link flap errors.

Configuring Link Flap Profiles

Link flap profiles are configuration statements that define a link flap error in terms of these criteria:

- **flaps**  Threshold number of interface state changes.
- **period**  Interval when link flaps accumulate to trigger an error condition.
- **violations**  Number of link flap errors (threshold exceeded over specified period).
- **intervals**  Quantity of periods.

The *monitor link-flap policy* command places the switch in link-flap configuration mode for configuring link flap profiles and compiling a default-profile set. The *profile max-flaps (Link Flap Configuration)* command configures link flap profiles.

The default-profile set is a list of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled but link-flap profiles are not assigned. The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, *errdisable flap-setting cause link-flap* specifies default error-disable criteria. When the default-profile set contains multiple profiles, the criteria is satisfied when conditions match any profile.

Example

- These commands enter link flap configuration mode and create four link flap profiles.

```plaintext
switch(config)#monitor link-flap policy
switch(config-link-flap)#profile LF01 max-flaps 15 time 60 violations 1 intervals 10
switch(config-link-flap)#profile LF02 max-flaps 10 time 30 violations 5 intervals 10
switch(config-link-flap)#profile LF03 max-flaps 20 time 75 violations 2 intervals 6
switch(config-link-flap)#profile LF04 max-flaps 30 time 100 violations 4 intervals 7
switch(config-link-flap)#show active
monito link-flap policy
profile LF01 max-flaps 15 time 60 violations 1 intervals 1
profile LF02 max-flaps 10 time 30 violations 5 intervals 10
profile LF02 max-flaps 20 time 75 violations 2 intervals 6
profile LF02 max-flaps 30 time 100 violations 4 intervals 7
switch(config-link-flap)#
```

The *default-profiles* command specifies the set of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled without a link flap profile assignment. Entering a *default-profile* command replaces the current default-profile statement in *running-config*.

The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, *errdisable flap-setting cause link-flap* specifies default error-disable criteria. When the default-profile set contains multiple profiles, error-disable criteria is satisfied when conditions match any profile. Multiple profiles are assigned to the default-profile set through a single *default-profiles* command.
Example

- This command assigns configures LF01 and LF02 as the default-profile set.

```bash
switch(config)#monitor link-flap policy
switch(config-link-flap)#default-profiles LF01 LF02
switch(config-link-flap)#show active
monitor link-flap policy
  profile LF01 max-flaps 15 time 60 violations 1 intervals 1
  profile LF02 max-flaps 10 time 30 violations 5 intervals 10
  profile LF02 max-flaps 20 time 75 violations 2 intervals 6
  profile LF02 max-flaps 30 time 100 violations 4 intervals 7
default-profiles LF01 LF02
```

Interface Link Flap Profile Assignments

Link flap monitoring is enabled on individual Ethernet interfaces and can optionally specify one or more profiles to define link-flap error-disabling criteria. When link flap monitoring is enabled on an interface, the link-flap conditions determine when the interface is error-disabled. Multiple profiles can be assigned to an interface to monitor a set of error conditions; a port is disabled when conditions match any of the profiles assigned to an interface.

The **monitor link-flap profiles** command controls link-flap monitoring on a configuration mode interface. The command provides these link flap detection options:

- **monitor link-flap (no profiles listed)**: Interface detects link flaps using default-profile set criteria.
- **monitor link-flap (at least one profile listed)**: Interface detects link flaps using listed profile criteria.
- **default monitor link-flap**: The interface uses global link flap monitor commands (Section 16.5.3.1).
- **no monitor link-flap**: The interface does not detect link flaps.

Examples

- This command assigns LF03 and LF04 link flap profiles to Ethernet interface 33.

```bash
switch(config)#interface ethernet 33
switch(config-if-Et33)#monitor link-flap profiles LF03 LF04
switch(config-if-Et33)#show active
interface Ethernet33
  monitor link-flap profiles LF04 LF03
```

- This command disables link-flap monitoring on Ethernet interface 34.

```bash
switch(config)#interface ethernet 34
switch(config-if-Et34)#no monitor link-flap
switch(config-if-Et34)#show active
interface Ethernet34
  no monitor link-flap
```

- This command assigns the default-profile set to Ethernet interface 35.

```bash
switch(config)#interface ethernet 35
switch(config-if-Et35)#monitor link-flap
switch(config-if-Et35)#show active
interface Ethernet35
  monitor link-flap
```

741
This command configures Ethernet interface 36 to use the global link flap monitoring commands:

```
switch(config)#interface ethernet 36
switch(config-if-Et36)#default monitor link-flap
switch(config-if-Et36)#show active
```

**16.5.4 Fabric Link Monitoring**

Fabric link monitoring enables EOS to monitor low error rate errors on all fabric links for long durations, and automatically isolates fabric links on consistent error detection over an extended time interval. Isolated fabric links are restored when the error rate drops below a configured threshold.

The error rate over each configurable polling interval is derived by comparing the number of cells with CRC errors against the total number of received cells. Links are automatically isolated when the error rate is above the configured threshold for the configured consecutive number of polling intervals.

On an isolated fabric link, control cells (but not data cells) are sent. Once the error rate drops below a set threshold for the configured consecutive number of polling intervals, EOS revives the fabric link to continue sending data traffic.

**16.5.4.1 Configuring Fabric Link Monitoring**

Configuration mode commands globally enable and disable fabric link monitoring and syslog messages for the settings described below.

The `no platform sand monitor` command disables fabric link monitoring.

**Generate Serdes Error Syslog**

The `platform sand monitor serdes error log` command generates syslog fabric link monitoring for serdes error logging.

**Example**

- This command enables the serdes error log for fabric link monitoring.
  
```
switch(config)#platform sand monitor serdes error log
switch(config)#
```

The following syslog messages are not enabled by default. Fabric link monitoring syslog is enabled by configuring the `platform sand monitor serdes error log` command.

**Examples**

- The following syslog message is generated when a fabric link for serdes is automatically withdrawn:
  
  `%SAND-4-SERDES_WITHDRAWN_FROM_FABRIC: Serdes withdrawn from the switch fabric.`

- Here is another instance where a syslog message is generated when a fabric link is automatically withdrawn:
  
  `%SAND-4-SERDES_WITHDRAWN_FROM_FABRIC: Serdes Arad10/5-FabricSerdes-11 withdrawn from the switch fabric.`

- The following syslog message is generated when a fabric link is restored:
  
  `%SAND-4-SERDES_RESTORED_TO_FABRIC: Serdes restored to the switch fabric.`

- Here is another instance where a syslog message is generated when a fabric link is restored:
  
  `%SAND-4-SERDES_RESTORED_TO_FABRIC: Serdes Arad10/5-FabricSerdes-11 restored to the switch fabric.`
Generate Serdes Error Threshold

The `platform sand monitor serdes error threshold` command generates a fabric link monitoring serdes error threshold.

**Example**

- This command monitors serdes error thresholds over the specified number of received cells, resulting in the isolation of a fabric link between 200 and 30,000 received cells.

  ```
  switch(config)#platform sand monitor serdes error threshold 200 30000
  switch(config)#
  ```

Enable Serdes Poll Period

The `platform sand monitor serdes poll period` command sets the serdes poll period.

**Example**

- This command changes the serdes polling period for fabric link monitoring to 6 seconds.

  ```
  switch(config)#platform sand monitor serdes poll period 6
  switch(config)#
  ```

Monitor Serdes Poll Threshold Isolation

The `platform sand monitor serdes poll threshold isolation` command sets and enables fabric link monitoring for serdes poll threshold isolation.

**Example**

- This command changes the number of consecutive polls in which the threshold needs to be detected to isolate a link. In this case the number is 5 consecutive polls.

  ```
  switch(config)#platform sand monitor serdes poll threshold isolation 5
  switch(config)#
  ```

Monitor Serdes Poll Threshold Recovery

The `platform sand monitor serdes poll threshold recovery` command sets and enables fabric link monitoring for serdes poll threshold recovery.

**Example**

- This command changes the number of consecutive serdes polls used for threshold recovery to 6 seconds.

  ```
  switch(config)#platform sand monitor serdes poll threshold recovery 6
  switch(config)#
  ```

Show Fabric Monitoring Health

The `show fabric monitoring health` command displays the fabric monitoring connected state status with isolated links.
Example

- When fabric links are isolated, their connected state status is shown with isolated links.

```
switch(config)#show platform sand health
Fabric serdes isolated by fabric monitoring: (36 total)
Arad5/0 serdes [0-1, 10-19, 2, 20-29, 3, 30-35, 4-9]
```

Top fabric serdes list by number of times isolated by monitoring:
- Arad5/0 serdes 0: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 1: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 10: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 11: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 12: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 13: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 14: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 15: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 16: 1 (last occurred: 0:01:04 ago)
- Arad5/0 serdes 17: 1 (last occurred: 0:01:04 ago)

```
switch(config)#
```

16.5.5 Rapid Automated Indication of Link-Loss

Rapid Automated Indication of Link-Loss (RAIL) is a software feature that reduces the wait time of applications on hosts that are blocked due to a failed link. When a link goes down because of link-flapping or the unavailability of a directly connected server, the switch drops all traffic to servers whose next-hop destination was learned on the port connected to the link. Applications that drive the traffic (clients on source hosts) are blocked because of the dropped edge-switch traffic. Connection timeout varies by application and is usually measured in seconds or minutes.

RAIL is functional on a switch if it is routing-enabled and available for servers that set the switch as the default router.

16.5.5.1 RAIL Method

When a link monitored by RAIL goes down, the switch performs these steps for servers that the switch proxies:

**Step 1** IP addresses of servers on the failed link are extracted from ARP cache. The interface that accesses the server is determined by searching for the MAC address in the hardware MAC address tables.

**Step 2** Upon link shutdown, a dynamic MAC entry is added in the MAC address table for each server that was learned on the failed interface. Each new entry lists its interface as **CPU**.

**Figure 16-2** depicts three switch-server scenarios: link is up, link is down with RAIL disabled, and link is down with RAIL enabled. A failed link with RAIL enabled results in these behaviors:

**Step 1** All ingress packets whose destination MAC address matches an address added to the MAC address table are sent to the CPU.

**Step 2** For packets scheduled to be forwarded to the source address, the switch sends one of the following, based on the type of received segment:

- TCP: TCP RST segment to the source IP address and port.
- UDP: ICMP unreachable segment to the source IP address and port.
Step 3  The client closes the socket associated with the transmitted segment and notifies the application. The application reacts immediately instead of maintaining the block until connection timeout expiry.

**Figure 16-2: RAIL Scenarios**

![RAIL Scenarios Diagram](image)

16.5.5.2 RAIL Implementation

RAIL defines a state machine that manages the RAIL activity level relative to a specified server. The state machine consists of four states:

- **Up**: Transitions to this state from *Inactive* when ARP and MAC entries are added for the server.
- **Proxying**: Transitions to this state from *Up* when Link Down is detected and RAIL proxying is enabled. The switch is a proxy for messages to the server.
- **Down**: Transitions to this state from *Up* when Link Down is detected and RAIL proxying is not enabled. Messages from the client remain unanswered and the application recovers only after timeout expiry.
- **Inactive**: Transitions to this state upon any of the following conditions:
  - Server’s MAC address or ARP entry is deleted (from any state).
  - Proxy timeout expiry (from *Proxying* state)
  - Link down timeout expiry (from *Down* state).

16.5.5.3 RAIL Configuration

Server-failure configuration mode commands globally enable RAIL and configure RAIL parameters. RAIL is functional on individual interfaces only when it is globally enabled and enabled on the interface. RAIL monitors an interface for link errors when RAIL is globally enabled and enabled on the interface.

**Entering Server-failure Configuration Mode**

The `monitor server-failure` command places the switch in server-failure configuration mode. The `exit` command returns the switch to global configuration mode. Server-failure mode is not a group change mode; `running-config` is changed when commands are entered and not affected by exiting the mode.

The `no monitor server-failure` deletes all server-failure mode commands from `running-config`.

**Examples**

- These commands place the switch in server-failure configuration mode.

```
switch(config)#monitor server-failure
switch(config-server-failure)#
```
This command deletes all server-failure configuration mode commands from `running-config`.

```
switch(config)#no monitor server-failure
switch(config)#
```

### Enabling RAIL on the Switch

RAIL is disabled by default and is enabled by `no shutdown (server-failure configuration mode)`. The `shutdown` command disables RAIL without removing RAIL commands from `running-config`.

#### Examples

- **These commands enable RAIL globally.**
  ```
  switch(config)#monitor server
  switch(config-server-failure)#no shutdown
  switch(config-server-failure)#show active
  monitor server-failure
  no shutdown
  switch(config-server-failure)#
  ```

- **This command disables RAIL globally.**
  ```
  switch(config-server-failure)#shutdown
  switch(config-server-failure)#
  ```

### Enabling Proxy Mode

The `proxy (server-failure configuration mode)` command sets the RAIL proxy setting to `enabled` and specifies the interval that RAIL responds to messages sent to servers on failed links. The proxy timeout is measured individually for each server whose link has failed. The switch enters RAIL proxy state only when the proxy setting is enabled.

When RAIL is enabled but the proxy setting is disabled, the switch maintains a list of unavailable servers without responding to messages sent to the servers. The RAIL proxy setting is `disabled` by default. When RAIL proxy is enabled, the default period is three minutes.

The `no proxy` and `default proxy` commands return the RAIL proxy setting to `disabled`. The `no proxy lifetime` and `default proxy lifetime` commands set the proxy timeout to its default of three minutes if the RAIL proxy setting is `enabled`. The lifetime commands have no effect if RAIL proxy is `disabled`.

#### Examples

- **These commands enable the RAIL proxy and sets the proxy timeout period of 10 minutes.**
  ```
  switch(config)#monitor server
  switch(config-server-failure)#proxy lifetime 10
  switch(config-server-failure)#show active
  monitor server-failure
  proxy lifetime 10
  switch(config-server-failure)#
  ```

- **This command sets the proxy timeout period to its default value of 3 minutes.**
  ```
  switch(config-server-failure)#no proxy lifetime
  switch(config-server-failure)#show active
  monitor server-failure
  proxy
  switch(config-server-failure)#
  ```

- **This command disables the RAIL proxy.**
  ```
  switch(config-server-failure)#no proxy
  switch(config-server-failure)#show active
  switch(config-server-failure)#
  ```
Selecting Networks to Monitor

The `network (server-failure configuration mode)` command specifies the IPv4 network space that Rapid Automated Indication of Link-Loss (RAIL) monitors for failed links to connected servers. 

*Running-config* can contain multiple *network* statements, allowing RAIL to monitor multiple disjoint network spaces.

When a server on the specified network is blocked because of a failed Ethernet or port channel link, the switch becomes a proxy for the unavailable server and responds with *TCP RST* or *ICMP Unreachable* segments to devices sending packets to the unavailable server.

**Example**

- These commands specify two IPv4 network spaces that RAIL monitors for server failures.

```plaintext
switch(config)#monitor server
switch(config-server-failure)#network 10.1.1.0/24
switch(config-server-failure)#network 10.2.1.96/28

switch(config-server-failure)#show active
monitor server-failure
    network 10.2.1.96/28
    network 10.1.1.0/24
switch(config-server-failure)#
```

Enabling RAIL on an Interface

RAIL monitors an interface for link errors only when RAIL is globally enabled and enabled for the interface. The `monitor server-failure link` command enables RAIL on the configuration mode interface. Configuration settings are effective for all Ethernet and port channel interfaces that enable RAIL.

**Example**

- These commands enable RAIL on port channel interface 100.

```plaintext
switch(config)#interface port-channel 100
switch(config-if-Po100)#monitor server-failure link
switch(config-if-Po100)#show active
interface Port-Channel100
    monitor server-failure link
switch(config-if-Po100)#
```

16.5.5.4 Displaying RAIL Status

The switch provides commands to display RAIL configuration and status information:

**Displaying RAIL Configuration settings**

The `show monitor server-failure` command displays Rapid Automated Indication of Link-Loss (RAIL) configuration settings and the number of servers on each monitored network.
Example

- This command displays RAIL configuration status and lists the number of servers that are on each monitored network.

```
switch> show monitor server-failure
Server-failure monitor is enabled
Proxy service: disabled
Networks being monitored: 3
  10.2.1.96/28    : 0 servers
  10.1.1.0/24     : 0 servers
  10.3.0.0/16     : 3 servers
switch>
```

Displaying RAIL History for All Connected Servers

The `show monitor server-failure history` command displays the time of all link failures detected by Rapid Automated Indication of Link-Loss (RAIL) and includes the interface name for each failure.

Example

- This command displays the link failure history from the time RAIL is instantiated on the switch.

```
switch> show monitor server-failure history
Total server failures: 4

<table>
<thead>
<tr>
<th>Server IP</th>
<th>Server MAC</th>
<th>Interface</th>
<th>Last Failed</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.11.11.7</td>
<td>ad:3e:5f:dd:64:cf</td>
<td>Ethernet23</td>
<td>2013-02-10 00:07:56</td>
</tr>
<tr>
<td>10.1.8.13</td>
<td>01:33:df:ee:39:91</td>
<td>Port-Channel5</td>
<td>2013-02-10 00:03:39</td>
</tr>
</tbody>
</table>

switch>
```

Displaying Server Configuration and Status

The `show monitor server-failure servers` command displays status and configuration data about each server that RAIL monitors. The display format depends on the parameter specified by the command:

Example

- This command displays RAIL information for the server at IP address 10.11.11.7

```
switch> show monitor server-failure servers 10.11.11.7
Server information:
Server Ip Address : 10.11.11.7
MAC Address      : ad:3e:5f:dd:64:cf
Current state    : down
Interface        : Ethernet23
Last Discovered  : 2013-01-06 06:47:39
Last Failed      : 2013-02-10 00:07:56
Last Proxied     : 2013-02-10 00:08:33
Last Inactive    : 2013-02-09 23:52:21
Number of times failed : 3
Number of times proxied : 1
Number of times inactive : 18

switch>
```
This command displays RAIL information for all servers on configured interfaces.

```plaintext
switch> show monitor server-failure servers all
Total servers monitored: 5

<table>
<thead>
<tr>
<th>Server IP</th>
<th>Server MAC</th>
<th>Interface</th>
<th>State</th>
<th>Last Failed</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.1.67.92</td>
<td>01:22:ab:cd:ee:ff</td>
<td>Ethernet17</td>
<td>inactive</td>
<td>7 days, 12:47:48 ago</td>
</tr>
<tr>
<td>44.11.11.7</td>
<td>ad:3e:5f:dd:64:cf</td>
<td>Ethernet23</td>
<td>down</td>
<td>0:06:14 ago</td>

<tr>
<td>132.23.23.1</td>
<td>00:11:aa:bb:32:ad</td>
<td>Ethernet1</td>
<td>up</td>
<td>never</td>
</tr>
</tbody>
</table>
```

switch>

16.6 Data Transfer Command Descriptions

Control Plane and Data Plane Commands
- control-plane
- ip access-group (Control Plane mode)
- switch forwarding-mode
- show switch forwarding-mode

Errdisable Commands
- errdisable detect cause link-flap
- errdisable flap-setting cause link-flap
- errdisable recovery cause
- errdisable recovery interval

Fabric Link Monitoring Commands
- platform sand monitor serdes error log
- platform sand monitor serdes error threshold
- platform sand monitor serdes poll period
- platform sand monitor serdes poll threshold isolation
- platform sand monitor serdes poll threshold recovery
- show fabric monitoring health

RAIL Commands
- clear server-failure servers inactive
- monitor server-failure
- monitor server-failure link
- network (server-failure configuration mode)
- proxy (server-failure configuration mode)
- show monitor server-failure
- show monitor server-failure history
- show monitor server-failure servers
- shutdown (server-failure configuration mode)

Link Flap Monitor Commands
- default-profiles
- monitor link-flap policy
- monitor link-flap profiles
- profile max-flaps (Link Flap Configuration)

MAC Address Table Commands
- clear mac address-table dynamic
- mac address-table aging-time
- mac address-table static
- switchport mac address learning
- show mac address-table
- show mac address-table aging time
- show mac address-table count
- show mac address-table mlag-peer
- show mac address-table multicast
- show mac address-table multicast brief
Port Configuration Commands
- clear counters
- description
- interface loopback
- load interval
- switchport
- mtu
- show interfaces
- show interfaces description
- switchport default mode access
- switchport default mode routed

Port Mirroring Commands
- monitor session destination
- monitor session destination cpu
- monitor session ip access-group
- monitor session source
- monitor session source ip access-group
- monitor session truncate
- no monitor session
- show monitor session

Port Security Commands
- switchport port-security
- switchport port-security maximum
- switchport port-security violation protect
- show port-security
- show port-security address
- show port-security interface

Storm Control Commands
- storm-control
- show storm-control

Tracking Commands
- link state group
- link state track
- links minimum
- track
- show link state group
- show track
clear counters

The clear counters command resets the counters to zero for the specified interfaces. The command provides the following options:

- No parameter: When no option is selected, the counters are reset on the switch.
- Session parameter: The command resets the counters in software for the current CLI session, establishing a baseline upon which subsequent show interfaces or show interfaces counters commands are relative. Counters are not affected for other CLI sessions.

Command Mode

Privileged EXEC

Command Syntax

clear counters [INTERFACE] [SCOPE]

Parameters

- **INTERFACE** Interface type and number. Options include:
  - <no parameter> Display information for all interfaces.
  - ethernet e_range Ethernet interface range specified by e_range.
  - loopback l_range Loopback interface specified by l_range.
  - management m_range Management interface range specified by m_range.
  - port-channel p_range Port-Channel Interface range specified by p_range.
  - vlan v_range VLAN interface range specified by v_range.
  - vxlan vx_range VXLAN interface range specified by vx_range.

  Valid e_range, l_range, m_range, p_range, v_range, and vx_range formats include number, number range, or comma-delimited list of numbers and ranges.

- **SCOPE** Duration of the reset results. Options include:
  - <no parameter> counters are cleared on the switch.
  - session counters are reset only for the current session.
Examples

- These commands display interface counters, clear the counters, then display the counters again.

```
switch# show interfaces ethernet 1
Ethernet1 is up, line protocol is up (connected)
   Hardware is Ethernet, address is 001c.7302.2fff (bia 001c.7302.2fff)
   MTU 9212 bytes, BW 10000000 Kbit
   Full-duplex, 10Gb/s, auto negotiation: off
   Last clearing of "show interface" counters never
   5 minutes input rate 301 bps (0.0% with framing), 0 packets/sec
   5 minutes output rate 0 bps (0.0% with framing), 0 packets/sec
   2285370854005 packets input, 225028582832583 bytes
   Received 29769609741 broadcasts, 3073437605 multicast
   113 runts, 1 giants
   118 input errors, 11 CRC, 0 alignment, 18 symbol
   27511409 PAUSE input
   335031607678 packets output, 27845413138330 bytes
   Sent 14282316688 broadcasts, 54045824072 multicast
   108 output errors, 0 collisions
   0 late collision, 0 deferred
   0 PAUSE output

switch#
clear mac address-table dynamic

The `clear mac address-table dynamic` command removes specified dynamic entries from the MAC address table. Entries are identified by their VLAN and layer 2 (Ethernet or port channel) interface.

- To remove a specific entry, include its VLAN and interface in the command.
- To remove all dynamic entries for a VLAN, do not specify an interface.
- To remove all dynamic entries for an interface, do not specify a VLAN.
- To remove all dynamic entries, do not specify a VLAN or an interface.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear mac address-table dynamic [VLANS] [INTERFACE]
```

**Parameters**
- **VLANS**  Table entries are cleared for specified VLANs. Options include:
  - `<no parameter>`  all VLANs.
  - `vlan v_num`  VLAN specified by `v_num`.
- **INTERFACE**  Table entries are cleared for specified interfaces. Options include:
  - `<no parameter>`  all Ethernet and port channel interfaces.
  - `interface ethernet e_range`  Ethernet interfaces specified by `e_range`.
  - `interface port-channel p_range`  port channel interfaces specified by `p_range`.
  - `vxlan vx_range`  VXLAN interfaces specified by `vx_range`.

Valid range formats include number, range, or comma-delimited list of numbers and ranges.

**Example**
- This command clears all dynamic mac address table entries for port channel 5 on VLAN 34.

  ```
  switch# clear mac address-table dynamic vlan 34 interface port-channel 5
  switch#
  ```
clear server-failure servers inactive

The `clear server-failure servers inactive` command removes all inactive server entries from the server failed history list. The switch maintains this list, even after a server's ARP entry is removed, to maintain a list of servers that are connected to the switch and log the most recent time of the failure of the link that connects the switch to the server.

**Command Mode**

Privileged EXEC

**Command Syntax**

`clear server-failure servers inactive`

**Related Commands**

- `show monitor server-failure history`

**Example**

- This command clears the inactive servers from the server failed history list.
  
  ```
  switch#clear server-failure servers inactive
  switch#
  ```
control-plane

The `control-plane` command places the switch in control-plane configuration mode. Control-plane mode is used for assigning an ACL (access control list) to the control plane.

Control-plane configuration mode is not a group change mode; `running-config` is changed immediately after commands are executed. Exiting control-plane configuration mode does not affect the configuration.

The `exit` command returns the switch to global configuration mode.

**Command Mode**
- Global Configuration

**Command Syntax**

```
control-plane
```

**Commands Available in control-plane Configuration Mode**

- `ip access-group (Control Plane mode)`

**Examples**

- This command places the switch in control plane mode.
  ```
  switch(config)#control-plane
  switch(config-cp)
  ```

- This command assigns the `control-plane-2` ACL to the control plane.
  ```
  switch(config-cp)#ip access-group control-plane-2
  switch(config-cp)
  ```

- This command exits control plane mode.
  ```
  switch(config-cp)#exit
  switch(config)
  ```
**default-profiles**

The **default-profiles** command specifies the set of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled without a link flap profile assignment. Entering a **default-profile** command replaces the current default-profile statement in *running-config*.

The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, **errdisable flap-setting cause link-flap** specifies default error-disable criteria. When the default-profile set contains multiple profiles, error-disable criteria is satisfied when conditions match any profile. Multiple profiles are assigned to the default-profile set through a single **default-profiles** command.

The **no default-profiles** and **default default-profiles** commands restore the empty default-profile set by deleting the **default-profiles** command from *running-config*.

**Command Mode**

Link-flap Configuration

**Command Syntax**

```
default-profiles [LF_PROFILES]
no default-profiles
default default-profiles
```

**Parameters**

- **LF_PROFILES** Name of link-flap profiles assigned to default profile set. Parameter may contain zero, one, or multiple link-flap profile names:
  - <no parameter> default-profile set is empty.
  - **profile** name of single link-flap profile.
  - **profile_1 profile_2 ... profile_N** list of link-flap profile names.

**Related Commands**

- **monitor link-flap policy** places the switch in link-flap-profiles configuration mode.
- **profile max-flaps (Link Flap Configuration)** configures link flap profiles.

**Guidelines**

The **errdisable flap-setting cause link-flap** statement is also configurable through the **profile max-flaps (Link Flap Configuration)** command.

**Example**

- This command assigns configures LF01 and LF02 as the default-profile set.

```
switch(config)#monitor link-flap policy
switch(config-link-flap)#default-profiles LF01 LF02
switch(config-link-flap)#show active
monitor link-flap policy
  profile LF01 max-flaps 15 time 60 violations 1 intervals 1
  profile LF02 max-flaps 10 time 30 violations 5 intervals 10
  profile LF03 max-flaps 25 time 100 violations 2 intervals 12
  profile LF04 max-flaps 5 time 15 violations 1 intervals 3
default-profiles LF01 LF02
switch(config-link-flap)#
```
description

The `description` command adds comment text for the configuration mode interface. The text provides information about the interface and has no effect on interface functions. The `show interfaces description` command displays interface description text.

The `no description` command removes the description text for the configuration mode interface from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration
Interface-VXLAN Configuration

**Command Syntax**

```
description label_text
no description
default description
```

**Parameters**

- `label_text` character string assigned to description attribute.

**Examples**

- These commands add description text to Ethernet interface 23, then displays the text through a `show interfaces description` command.

```
switch(config)#interface ethernet 23
switch(config-if-Et23)#description external line
switch(config-if-Et23)#show interfaces ethernet 23 description

Interface                      Status         Protocol Description     
Et23                           up             up       external line
```

errdisable detect cause link-flap

The `errdisable detect cause link-flap` command enables the error-disabling of Ethernet interfaces when the switch detects a link flap error on the interface. The `errdisable flap-setting cause link-flap` command defines a link flap error in terms of the frequency of connection state changes.

The switch places an interface in `error-disabled` state when it detects an error on the interface. `Error-disabled` is an operational state that is similar to `link-down` state. To re-enable an error-disabled interface, enter `shutdown` and `no shutdown` command in the configuration mode for the interface.

By default, link flap detection is enabled. The `no errdisable detect cause link-flap` command disables the triggering of error-disable actions. The `errdisable detect cause link-flap` and `default errdisable detect cause link-flap` commands enable the triggering of error-disable actions by removing the `no errdisable detect cause link-flap` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

- `errdisable detect cause link-flap`
- `no errdisable detect cause link-flap`
- `default errdisable detect cause link-flap`

**Examples**

- This command disables error detection on the switch.
  ```
  switch(config)#no errdisable detect cause link-flap
  switch(config)#
  ```

- These commands sets the link flap error criteria of 15 connection state changes over a 30 second period, then enables error detection on the switch.
  ```
  switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
  switch(config)#errdisable detect cause link-flap
  switch(config)#
  ```
errdisable flap-setting cause link-flap

The `errdisable flap-setting cause link-flap` command configures the link-flap frequency that defines an link-flap error on an Ethernet interface. The `errdisable detect cause link-flap` command uses this criteria to trigger an error-disable action.

The link-flap frequency is defined by the quantity of link flaps (connection state changes) over a specified period. The default settings are five link flaps and ten seconds.

The `no errdisable flap-setting cause link-flap` and `default errdisable flap-setting cause link-flap` commands restore the default link flap cause settings by removing the `errdisable flap-setting cause link-flap` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
errdisable flap-setting cause link-flap max-flaps quantity time period
no errdisable flap-setting cause link-flap
default errdisable flap-setting cause link-flap
```

**Parameters**
- `quantity` Number of link flaps. Value ranges from 1 to 100. Default value is 5.
- `period` Interval over which link flaps accumulate to trigger an error condition (seconds). Value ranges from 1 to 1800. Default value is 10.

**Examples**
- This command sets the link flap error criteria of 15 connection state changes over 30 second periods.
  ```
  switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
  switch(config)#
  ```
**errdisable recovery cause**

The **errdisable recovery cause** command enables the automated recovery of error-disabled Ethernet interfaces. An interface that is disabled as a result of a specified condition attempts normal operation after a specified interval. When the disabling condition persists, recovered interfaces eventually return to the error-disabled state.

When automated recovery is not enabled, interfaces are recovered manually by entering **shutdown** and **no shutdown** from the interface's configuration mode.

**Running-config** can simultaneously store **errdisable recovery cause** statements for each error-disable condition. By default, error-disable recovery is disabled for all conditions.

The **no errdisable recovery cause** and **default errdisable recovery cause** commands disable automated recovery for interfaces disabled by the specified condition by removing the corresponding **errdisable recovery cause** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
errdisable recovery cause CONDITION
no errdisable recovery cause CONDITION
default errdisable recovery cause CONDITION
```

**Parameters**

- **CONDITION** Disabling condition for which command automates recovery. Options include:
  - arp-inspection
  - bpduguard
  - link-flap
  - no-internal-vlan
  - portchannelguard
  - portsec
  - tapagg
  - uplink-failure-detection
  - xcvr_unsupported

**Related Commands**

- **errdisable recovery interval** configures the period that an ethernet interface remains disabled before automated recovery begins.
Examples

- This command enables error-disable recovery for interfaces that are disabled by link-flap and bpduguard conditions and sets the errdisable recovery period at 10 minutes.

```
switch(config)#errdisable recovery cause bpduguard
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery interval 600
switch(config)#show running-config
! Command: show running-config
  <--------OUTPUT OMITTED FROM EXAMPLE-------->
  errdisable recovery cause bpduguard
  errdisable recovery cause link-flap
  errdisable recovery interval 600
!
  <--------OUTPUT OMITTED FROM EXAMPLE-------->
switch(config)#
```
The `errdisable recovery interval` command specifies the period that an error-disabled Ethernet interface remains disabled before automated errdisable recovery begins. This command affects only interfaces whose automated recovery is enabled for the disabling condition (`errdisable recovery cause`). When automated recovery is not enabled, interfaces are recovered manually by entering `shutdown` and `no shutdown` from the interface's configuration mode.

The no `errdisable recovery interval` and `default errdisable recovery interval` commands restore the default error recovery period of 300 seconds by removing the `errdisable recovery interval` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**
```
errdisable recovery interval period
no errdisable recovery interval
default errdisable recovery interval
```

**Parameters**
- `period` Error disable recovery period (seconds). Value ranges from 30 to 86400. Default value is 300

**Related Commands**
- `errdisable recovery cause` enables the automated recovery of error-disabled Ethernet interfaces.

**Examples**
- This command enables error-disable recovery for interfaces that are disabled by link-flap conditions and sets the errdisable recovery period at 10 minutes.

```
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery interval 600
switch(config)#show running-config
! Command: show running-config
     <--------OUTPUT OMITTED FROM EXAMPLE-------->
     
     !
     errdisable recovery cause link-flap
erdisable recovery interval 600
     !
     <--------OUTPUT OMITTED FROM EXAMPLE-------->
     
     !
     i
switch(config)#
```
interface loopback

The interface loopback command places the switch in loopback-interface configuration mode for the specified interfaces. The command creates loopback interfaces for previously unconfigured interfaces.

The command can specify a single interface or multiple interfaces:

- Single interface: Command creates an interface if it specifies one that was not previously created.
- Multiple interfaces: Command is valid only if all specified interfaces were previously created.

The no interface loopback command removes the specified interfaces from running-config, including all interface configuration statements. The default interface loopback command removes all configuration statements for the specified loopback interface without deleting the loopback interface from running-config.

The following commands are available in loopback configuration mode:

- description
- exit
- ip address
- ip proxy-arp
- ipv6 address
- ipv6 enable
- load interval
- logging event
- mtu
- shutdown (Interfaces)
- snmp trap

Command Mode
Global Configuration

Command Syntax

```
interface loopback l_range
no interface loopback l_range
default interface loopback l_range
```

Parameters

- **l_range**  
  Loopback interfaces (number, range, or comma-delimited list of numbers and ranges).
  
  Loopback number ranges from 0 to 1000.

Examples

- This command enters interface configuration mode for loopback interfaces 1 through 5.
  
  ```
  switch(config)#interface loopback 1-5
  switch(config-if-Lo1-5)#
  ```

- This command creates interface 23 and enters interface configuration mode:
  
  ```
  switch(config)#interface loopback 23
  switch(config-if-Lo23)#
  ```

- This command removes loopback interfaces 5 through 7 from running-config.
  
  ```
  switch(config)#no interface loopback 5-7
  switch(config)#
  ```
ip access-group (Control Plane mode)

The ip access-group command applies an IPv4 or standard IPv4 access control list (ACL) to the control plane.

The no ip access-group and default ip access-group commands remove the corresponding ip access-group command from running-config.

Command Mode

  Control-plane Configuration

Command Syntax

  ip access-group list_name \[VRF_INSTANCE\] DIRECTION
  no ip access-group [list_name] \[VRF_INSTANCE\] DIRECTION
  default ip access-group [list_name] \[VRF_INSTANCE\] DIRECTION

Parameters

  - list_name    name of ACL assigned to interface.
  - VRF_INSTANCE specifies the VRF instance being modified.
    - <no parameter> changes are made to the default VRF.
    - vrf vrf_name changes are made to the specified user-defined VRF.
  - DIRECTION    transmission direction of packets, relative to interface. Valid options include:
    - in    inbound packets.

Example

  These commands apply the IPv4 ACL named test2 to the control plane.

  switch(config)#control-plane
  switch(config-cp)#ip access-group test2 in
  switch(config-cp)#
link state group

The link state group command adds the configuration mode interface to a link-state group and specifies whether it is upstream or downstream.

The no link state group and default link state group commands remove the specified link-state group assignment for the configuration mode interface.

Command Mode
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration
- Interface-VXLAN Configuration

Command Syntax

- link state group group_name DIRECTION
- no link state group [group_name]
- default link state group [group_name]

Parameters
- group_name link state tracking group name.
- DIRECTION position of the interface in the link-state group. Valid options include:
  - upstream
  - downstream

Example
- These commands create link-state group “xyz” and add VLAN interface 100 to the group as an upstream interface.

  switch(config)#link state track xyz
  switch(config-link-state-xyz)#show active
  link state track xyz
  switch(config-link-state-xyz)#exit
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#link state group xyz upstream
  switch(config-if-Vl100)#show active
  interface Vlan100
    link state group xyz upstream
  switch(config-if-Vl100)#
link state track

The `link state track` command creates and enables a link-state group and places the switch in link-state-group configuration mode. A link-state group consists of “upstream” interfaces (connections to servers) and “downstream” interfaces (connections to switches and clients). In the event of a failure of all upstream interfaces in the link-state group, the downstream interfaces are shut down.

The `no link state track` and `default link state track` commands delete the `link state track` from `running-config`.

Command Mode
Global Configuration

Command Syntax

  - `link state track` `group_name`
  - `no link state track` `group_name`
  - `default link state track` `group_name`

Parameters
- `group_name` link-state group name.

Commands available in link-state Configuration Mode
- `links minimum` configures the minimum number of links that the link-state group requires.

Example
- This command creates and enables link-state group 1.

```
switch(config)#link state track 1
switch(config-link-state-1)#
```
links minimum

The **links minimum** command specifies the minimum number of links the configuration mode link-state group requires.

The **no links minimum** and **default links minimum** commands restore the default minimum value of 1 by deleting the corresponding **links minimum** statement from **running-config**.

**Command Mode**
Link-State Configuration

**Command Syntax**

```
links minimum quantity
no links minimum
default links minimum
```

**Parameters**
- **quantity** Minimum number of links. Value ranges from 1 to 100000. Default value is 1.

**Related Commands**
- **link state track** creates and enables a link-state group and places the switch in link-state configuration mode.
- **link state group** adds the configuration mode interface to the specified link-state group.

**Examples**
- These commands configure link-state tracking group **link-a** to have at least 60 links.

```
switch(config)#link state track link-a
switch(config-link-state-link-a)links minimum 60
switch(config-link-state-link-a)
```
load interval

The `load-interval` command changes the load interval for the configuration mode interface. Load interval is the time period over which data is used to compute interface rate counters. Interface rates are exponentially weighted moving averages; recent data samples have greater influence than older samples. Statistics calculated with shorter load intervals are usually more sensitive to short traffic bursts.

The `no load-interval` and `default load-interval` commands restore the default value of 300 seconds by removing the corresponding `load-interval` statement from `running-config`.

Command Mode
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration
- Interface-VXLAN Configuration

Command Syntax
- `load-interval delay`
- `no load-interval`
- `default load-interval`

Parameters
- `delay` Load interval delay. Values range from 5 to 600 (seconds). Default value is 300 (five minutes).

Example
- These commands set the load interval for Ethernet interface 7 at 60 seconds.

  switch(config)#interface ethernet 7
  switch(config-if-Et7)#load-interval 60
  switch(config-if-Et7)#
mac address-table aging-time

The `mac address-table aging-time` command configures the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.

Aging time ranges from 10 to 1,000,000 seconds with a default of 300 seconds (five minutes).

The `no mac address-table aging-time` and `default mac address-table aging-time` commands reset the aging time to its default by removing the `mac address-table aging-time` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
mac-address-table aging-time period
no mac-address-table aging-time
default mac-address-table aging-time
```

**Parameters**
- `period` MAC address table aging time. Default is 300 seconds. Options include:
  - `0` disables deletion of table entries on the basis of aging time.
  - `10` through `1000000` (one million) aging period (seconds).

**Example**
- This command sets the MAC address table aging time to two minutes (120 seconds).
```
switch(config)#mac address-table aging-time 120
switch(config)#
```
mac address-table static

The **mac address-table static** command adds a static entry to the MAC address table. Each table entry references a MAC address, a VLAN, and a list of layer 2 (Ethernet or port channel) ports. The table supports three entry types: unicast drop, unicast, and multicast.

- A drop entry does not include a port.
- A unicast entry includes one port.
- A multicast entry includes at least one port.

Packets with a MAC address (source or destination) and VLAN specified by a drop entry are dropped. Drop entries are valid for only unicast MAC addresses.

The command replaces existing dynamic or static table entries with the same VLAN-MAC address. Static entries are not removed by aging (**mac address-table aging-time**). Static MAC entries for mirror destinations or LAG members are typically avoided.

The most important byte of a MAC address distinguishes it as a unicast or multicast address:

- Unicast: most significant byte is an even number. Examples: 0200.0000.0000  1400.0000.0000
- Multicast: most significant byte is an odd number. Examples: 0300.0000.0000  2500.0000.0000

The **no mac address-table static** and **default mac address-table static** commands remove corresponding **mac address-table static** commands from **running-config** and MAC address table entries.

**Command Mode**

Global Configuration

**Command Syntax**

```
mac address-table static mac_address vlan v_num DESTINATION
no mac address-table static mac_address vlan v_num [DESTINATION]
default mac address-table static mac_address vlan v_num [DESTINATION]
```

**Parameters**

- **mac_address** Table entry’s MAC address (dotted hex notation – H.H.H).
- **v_num** Table entry’s VLAN.
- **DESTINATION** Table entry’s port list.

For multicast MAC address entries, the command may contain multiple ports, listed in any order. The CLI accepts only one interface for unicast entries.

- **drop** creates drop entry in table. Valid only for unicast addresses.
- **interface ethernet e_range** Ethernet interfaces specified by **e_range**.
- **interface port-channel p_range** Port channel interfaces specified by **p_range**.
- **<no parameter>** Valid for **no** and **default** commands that remove multiple table entries.

**e_range** and **p_range** formats include number, range, comma-delimited list of numbers and ranges.
Example

- This command adds a static entry for unicast MAC address 0012.3694.03ec to the MAC address table.

```
switch(config)# mac address-table static 0012.3694.03ec vlan 3 interface Ethernet 7
switch(config)# show mac address-table static

Mac Address Table

<table>
<thead>
<tr>
<th>Vlan</th>

```
switch(config)#
```
monitor link-flap policy

The `monitor link-flap policy` command places the switch in link-flap configuration mode for configuring link flap profiles and compiling a default-profile set. Link-flap configuration mode is not a group change mode; `running-config` is changed immediately after commands are executed. The `exit` command does not affect the configuration.

Link flap profiles are assigned to Ethernet interfaces and specify conditions that define a link-flap error. When link flap monitoring is enabled on an interface, the link-flap conditions determine when the interface is error-disabled. Multiple profiles can be assigned to an interface to monitor a set of error conditions.

**Command Mode**

Global Configuration

**Command Syntax**

`monitor link-flap policy`

**Commands Available in link-flap Configuration Mode**

- `default-profiles` configures the set of profiles that define the default-profile set.
- `profile max-flaps (Link Flap Configuration)` configures a link-flap profile

**Example**

- These commands place the switch in link-flap configuration mode.
  
  `switch(config)#monitor link-flap policy`
  `switch(config-link-flap)#`

- This command returns the switch to global configuration mode.
  
  `switch(config-link-flap)#exit`
  `switch(config)#`
monitor link-flap profiles

The `monitor link-flap profiles` command enables link-flap monitoring on the configuration mode interface and specifies the error-disable criteria for the interface. Entering a `monitor link-flap profiles` command replaces the corresponding statement in `running-config`.

The command enables the following link flap detection options:

- **monitor link-flap** *(no profiles listed)*: The interface detects link flaps using the criteria defined by the default-profile set *(default-profiles)*.
- **monitor link-flap profiles** *(at least one profile listed)*: The interface detects link flaps using the criteria of the listed profiles. Error-disable criteria require conditions that match at least one profile.
- **default monitor link-flap**: The interface detects link flaps using the `errdisable flap-setting cause link-flap` and `errdisable recovery cause` commands.
- **no monitor link-flap**: The interface does not detect link flaps.

Default monitor link flap is the default setting.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Management Configuration

**Command Syntax**

```
monitor link-flap [LF_PROFILES]
no monitor link-flap
default monitor link-flap
```

**Parameters**

- **LF_PROFILES**  Name of link-flap profiles assigned to interface. Parameter may contain zero, one, or multiple link-flap profile names:
  - *(no parameter)*  Link flap criteria determined by default-profile set.
  - **profiles profile_name**  Name of single link-flap profile.
  - **profiles profile_name_1 profile_name_2 ... profile_name_N**  List of link-flap profile names.

**Example**

- This command applies the LF03 and LF04 link flap profiles to Ethernet interface 33.

```
switch(config)#interface ethernet 33
switch(config-if-Et33)#monitor link-flap profiles LF03 LF04
switch(config-if-Et33)#show active
interface Ethernet33
  monitor link-flap profiles LF03 LF04
switch(config-if-Et33)#
```

- This command disables link-flap monitoring on Ethernet interface 34.

```
switch(config)#interface ethernet 34
switch(config-if-Et34)#no monitor link-flap
switch(config-if-Et34)#show active
interface Ethernet34
  no monitor link-flap
switch(config-if-Et34)#
```
monitor server-failure

The `monitor server-failure` command places the switch in server-failure configuration mode. Rapid Automated Indication of Link-Loss (RAIL) settings are configured in server-failure configuration mode. RAIL is disabled by default and is enabled by the `no shutdown` command in server-failure configuration mode.

The `no monitor server-failure` and `default monitor server-failure` commands disable RAIL and restore all settings to their default state by removing all server-failure configuration mode statements from `running-config`.

Server-failure configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting server-failure configuration mode does not affect `running-config`. The `exit` command returns the switch to global configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

```
monitor server-failure
no monitor server-failure
default monitor server-failure
```

**Commands Available in server-failure Configuration Mode**

- `network (server-failure configuration mode)`
- `proxy (server-failure configuration mode)`
- `shutdown (server-failure configuration mode)`

**Example**

- These commands place the switch in server-failure configuration mode and enables RAIL.
  ```
  switch(config)#monitor server-failure
  switch(config-server-failure)#show active
  switch(config-server-failure)#no shutdown
  switch(config-server-failure)#show active
  monitor server-failure
  no shutdown
  switch(config-server-failure)#
  ```

- This command deletes all server-failure configuration mode commands from `running-config`.
  ```
  switch(config)#no monitor server-failure
  switch(config)#
  ```
**monitor server-failure link**

The `monitor server-failure link` command enables Rapid Automated Indication of Link-Loss (RAIL) on the configuration mode interface. RAIL must be properly configured globally or this command has no effect on switch operation.

When an interface monitored by RAIL goes down, the switch performs these steps for servers that the switch accesses from the interface:

**Step 1**  IP addresses of the servers are removed from ARP cache.

**Step 2**  A dynamic MAC entry is added to the MAC address table for each server. The port for each entry is listed as **CPU**.

The `no monitor server-failure link` and `default monitor server-failure link` commands disable RAIL on the configuration mode interface by deleting the corresponding `monitor server-failure link` command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```plaintext
monitor server-failure link
no monitor server-failure link
default monitor server-failure link
```

**Related Commands**

- `monitor server-failure` places the switch in server-failure configuration mode for configuring RAIL.

**Example**

- These commands enable RAIL on port channel interface 100.

```plaintext
switch(config)#interface port-channel 100
switch(config-if-Po100)#monitor server-failure link
switch(config-if-Po100)#show active
interface Port-Channel100
    monitor server-failure link
switch(config-if-Po100)#
```
monitor session destination

The monitor session destination command configures an interface as the destination port of a specified port mirroring session. The destination is usually an Ethernet interface, but other options are available on certain platforms (see Restrictions). The monitor session source command configures the source port of the mirroring session.

An interface cannot be used in more than one mirror session and cannot be simultaneously a source and destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from only one direction.

Note
On platforms which support the use of port channels as mirror destinations, a port channel must not be used as a mirror destination if it is a member of an MLAG.

The no monitor session destination and default monitor session destination commands remove the mirroring session destination assignment by deleting the corresponding monitor session destination command from running-config. The no monitor session removes the entire mirroring session.

Command Mode
Global Configuration

Command Syntax

```
monitor session session_name destination INT_NAME
no monitor session session_name destination INT_NAME
default monitor session session_name destination INT_NAME
```

Parameters
- `session_name` Label assigned to port mirroring session.
- `INT_NAME` Destination interface for the mirroring session
  - `ethernet e_range` Ethernet interfaces specified by `e_range`.
  - `port-channel p_range` Port channel interfaces specified by `p_range`.

Restrictions
Port mirroring capacity varies by platform. Session destination capacity for switches on each platform is listed below:
- **Arad Platform:** Ethernet interfaces (one)
- **FM6000 Platform:** Ethernet interfaces (any number), Port channel interfaces (any number), CPU
- **Petra Platform:** Ethernet interfaces (eight for Rx or Tx sessions; four for both ways)
- **Trident Platform:** Ethernet interfaces (one)
- **Trident-II Platform:** Ethernet interfaces (one)

Mirrored frames use Tx properties of the lowest numbered Tx mirror source configured, when there are multiple Tx sources in a monitor session. Packets are modified based on properties.

Example
- For two source interfaces, ethernet8 and ethernet9, the allowed VLANs on ethernet8 is 10, 20, 30 and allowed VLANs on ethernet9 30, 40, and 50. The frames going out of ethernet9 tagged with 10, 20, and 30 will appear at the mirrored destination as tagged frames. The tagged frames with 40 or 50 on ethernet9 will appear at the mirrored destination as untagged frames. Since ethernet8 is the lowest numbered source interface, all Tx frames on ethernet8 will appear as tagged in the mirrored destination.
Example

- This command configures Ethernet interface 8 as the destination port for the `redirect_1` mirroring session.

  ```
  switch(config)#monitor session redirect_1 destination ethernet 8
  switch(config)#
  ```
**monitor session destination cpu**

The `monitor session destination cpu` command configures the CPU as the destination port of a specified port mirroring session. The `monitor session source` command configures the source port of the mirroring session. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from one direction.

The CPU can only be configured as a destination for a mirroring session, not as a source. However, the CPU can serve as the destination for multiple mirroring sessions. Traffic mirrored to the CPU can be viewed using tcpdump.

The `no monitor session destination cpu` and `default monitor session destination cpu` commands remove the mirror session destination assignment by deleting the corresponding `monitor session destination cpu` command from `running-config`. The `no monitor session` command removes the entire mirror session.

**Command Mode**

- Global Configuration

**Command Syntax**

```
monitor session session_name destination cpu
no monitor session session_name destination cpu
default monitor session session_name destination cpu
```

**Parameters**

- `session_name` Label assigned to port mirroring session.

**Guidelines**

To view the traffic mirrored to the CPU from a source port, use tcpdump from the Bash shell, with the source interface as an argument. This causes tcpdump to capture packets from the kernel interface of the source port.

**Examples**

- These commands configure Ethernet interface 35 as the source and the CPU as the destination port for the `redirect_1` mirroring session, then display the mirror interface.

```bash
switch(config)#monitor session redirect_1 destination cpu
switch(config)#monitor session redirect_1 source ethernet 35
switch(config)#show monitor session
```

```
Session redirect_1
------------------------
Source Ports:
  Both:        Et35

Destination Ports:
  Cpu :  active (mirror0)
```

switch(config)#
This command uses tcpdump to view the traffic mirrored by the redirect_1 mirroring session. The CPU mirror interface specified in the previous output must be used in the tcpdump expression (in this case, mirror0).

```
switch#bash tcpdump -i mirror0
tcpdump: WARNING: mirror0: no IPv4 address assigned
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on mirror0, link-type EN10MB (Ethernet), capture size 65535 bytes
09:51:12.478363 00:1c:73:27:a6:d3 (oui Arista Networks) > 01:80:c2:00:00:00 (oui Unknown), 802.3, length 119: LLC, dsap STP (0x42) Individual, ssap STP (0x42) Command, ctrl 0x03: STP 802.1s, Rapid STP, CIST Flags [Proposal, Learn, Forward, Agreement], length 102
09:51:14.478235 00:1c:73:27:a6:d3 (oui Arista Networks) > 01:80:c2:00:00:00 (oui Unknown), 802.3, length 119: LLC, dsap STP (0x42) Individual, ssap STP (0x42) Command, ctrl 0x03: STP 802.1s, Rapid STP, CIST Flags [Proposal, Learn, Forward, Agreement], length 102
switch#
```
monitor session ip access-group

The `monitor session ip access-group` command configures an ACL to filter the traffic being mirrored to the destination port.

**Note**

ACLs applied to a source port affect the RX side of the interface, and do not impact the TX side of the interface. TX mirrored packets cannot be filtered, and will continue to be sent to the mirror destination.

The `no monitor session ip access-group` and `default monitor session ip access-group` commands remove the filter from the specified mirror session by deleting the corresponding `monitor session ip access-group` command from `running-config`. The `no monitor session` command removes the entire mirror session.

**Command Mode**

Global Configuration

**Command Syntax**

```
monitor session session_name ip access-group acl_name
no monitor session session_name ip access-group
default monitor session session_name ip access-group
```

**Parameters**

- `session_name`  Label assigned to port mirroring session.
- `acl_name`  The ACL to be applied to filter traffic for the specified session.

**Examples**

- These commands create an ACL and apply it to filter the traffic mirrored to the destination port by session “redirect_1.”

  ```
  switch(config)#ip access-list allow-host
  switch(config-acl-allow-host)#10 permit ip host 192.168.11.24 host 10.0.215.23
  switch(config-acl-allow-host)#20 deny ip any any
  switch(config-acl-allow-host)#exit
  switch(config)#
  switch(config)#monitor session redirect_1 ip access-group allow-host
  switch(config)#
  ```

- Use the `show monitor session` command to verify the configuration.

  ```
  switch#show monitor session
  Session redirect_1
  ------------------------
  Source Ports:
  Both: Et35(Acl:allow-host)
  Destination Ports:
  Cpu : active (mirror0)
  ip access-group: allow-host
  switch#
  ```
monitor session source

The monitor session source command configures the source port of a specified port mirroring session. The monitor session destination or monitor session destination cpu command configures the destination port of the mirroring session.

An interface cannot be used in more than one mirror session and cannot be simultaneously a source and a destination. An interface which is part of a port channel cannot be used as a source, but a port channel which is a member of an MLAG can be used. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from only one direction.

The no monitor session source and default monitor session source commands remove the mirroring session source assignment by deleting the corresponding monitor session source command from running-config. The no monitor session removes entire the mirroring session.

Command Mode
Global Configuration

Command Syntax

```
monitor session session_name source INT_NAME DIRECTION
no monitor session session_name source INT_NAME DIRECTION
default monitor session session_name source INT_NAME DIRECTION
```

Parameters
- **session_name** Label assigned to port mirroring session.
- **INT_NAME** Source interface for the mirroring session.
  - **ethernet e_range** Ethernet interfaces specified by e_range.
  - **port-channel p_range** Port channel interfaces specified by p_range.
- **DIRECTION** transmission direction of traffic to be mirrored.
  - <no parameter> mirrors transmitted and received traffic.
  - **both** mirrors transmitted and received traffic.
  - **rx** mirrors received traffic only.
  - **tx** mirrors transmitted traffic only.

Guidelines
On DCS-7050, DCS-7050X, DCS-7250X, and DCS-7300X series, due to limitations of the switch ASIC, all frames mirrored on egress are prefixed with an 802.1Q VLAN tag, even when the egress port is configured as an access port. If the capture device is unable to process VLAN tags in a desirable manner mirroring should be configured exclusively for ingress traffic by specifying rx.

Restrictions
Port mirroring capacity varies by platform. Session source capacity for each platform is listed below:

- **FM6000 Platform**: Ethernet interfaces (any number), port channel interfaces (any number)
- **Arad Platform**: Ethernet interfaces (any number), port channel interfaces (any number).
- **Petra Platform**: Ethernet interfaces (eight for Rx or Tx sessions; four for both ways)
- **Trident Platform**: Ethernet interfaces (any number), port channel interfaces (any number)
- **Trident-II Platform**: Ethernet interfaces (any number), port channel interfaces (any number)

The number of interfaces that can be effectively mirrored is restricted by the destination port speed.
Example

- This command configures Ethernet interface 7 as the source port for redirect_1 mirroring session.

```
switch(config)#monitor session redirect_1 source ethernet 7
switch(config)#
```
**monitor session source ip access-group**

The `monitor session source ip access-group` command configures an ACL to filter the traffic being mirrored from a specific source port. This enables the ability to filter traffic using a different ACL on each source port and have the combined matched traffic sent to the destination port.

The `no monitor session source ip access-group` and `default monitor session source ip access-group` commands remove the filter from the specified mirror session by deleting the corresponding `monitor session source ip access-group` command from `running-config`. The `no monitor session` command removes the entire mirror session.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
[54x37]monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
no monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
default monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
```

**Parameters**

- `s_name`  Label assigned to port mirroring session.
- `INT_NAME`  Source interface for the mirroring session.
  - `ethernet e_range`  Ethernet interfaces specified by `e_range`.
  - `port-channel p_range`  Port channel interfaces specified by `p_range`.
- `DIRECT`  Transmission direction of traffic to be mirrored. Options include:
  - `<no parameter>`  Mirrors received traffic only.
  - `rx`  Mirrors received traffic only.
- `acl_name`  The ACL to be applied to filter traffic for the specified session.

**Examples**

- These commands create ACLs and apply them to filter the traffic mirrored from two source ports by session “redir_1.”

  ```plaintext
  switch(config)#ip access-list allow-host-x
  switch(config-acl-allow-host-x)#10 permit ip host 192.168.11.24 host 10.0.215.23
  switch(config-acl-allow-host-x)#20 deny ip any any
  switch(config-acl-allow-host-x)#exit
  switch(config)#ip access-list allow-host-y
  switch(config-acl-allow-host-y)#10 permit ip host 172.16.233.80 host 10.0.215.23
  switch(config-acl-allow-host-y)#20 deny ip any any
  switch(config-acl-allow-host-y)#exit
  switch(config)#monitor session redir_1 source ethernet 5,9 rx
  switch(config)#monitor session redir_1 source ethernet 5 ip access-group allow-host-x
  switch(config)#monitor session redir_1 source ethernet 9 ip access-group allow-host-y
  ```
monitor session truncate

The monitor session truncate command configures a port mirroring session to truncate mirrored packets, retaining only the first 160 bytes. Packet truncation can be used to prevent oversubscription of the session’s destination port.

Packet truncation applies to the mirroring session as a whole, and cannot be applied to individual source ports.

The no monitor session truncate and default monitor session truncate commands restores mirroring of full packets by deleting the corresponding monitor session truncate command from running-config. The no monitor session removes the entire mirroring session.

Command Mode
    Global Configuration

Command Syntax
    monitor session session_name truncate
    no monitor session session_name truncate
    default monitor session session_name truncate

Parameters
    • session_name    Label assigned to port mirroring session.

Examples
    • This command configures mirroring session redirect_1 to truncate mirrored packets.
      switch(config)#monitor session redirect_1 truncate
      switch(config)#
The `mtu` command configures the IPv4 and IPv6 Maximum Transmission Unit (MTU) size for the configuration mode interface. The switch fragments IP packets that are larger than the MTU value for the outbound interface. An interface's MTU value is displayed with the `show interfaces` command.

MTU is independently configurable on all routable interfaces. The switch supports MTU sizes ranging from 68 to 9214 bytes. The default MTU size is 1500 bytes.

The `no mtu` and `default mtu` commands restore the interface's MTU to the default value by removing the corresponding `mtu` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
- `mtu bytes`
- `no mtu`
- `default mtu`

**Parameters**
- `bytes` MTU size (bytes). Values range from 68 to 9214.

**Examples**
- This command sets the MTU size of 1492 bytes on VLAN interface 20.

```bash
switch(config)#interface vlan 20
switch(config-if-Vl20)#mtu 1492
switch(config-if-Vl20)#
```
network (server-failure configuration mode)

The **network** command specifies the IPv4 network space that Rapid Automated Indication of Link-Loss (RAIL) monitors for failed links to connected servers. RAIL reduces the wait time for applications on directly connected servers that are blocked due to a failed link. **Running-config** supports simultaneous network command, allowing RAIL to monitor multiple disjoint network spaces.

When a server on the specified network is blocked because of a failed Ethernet or port channel link, the switch becomes a proxy for the unavailable server and responds with **TCP RST** or **ICMP Unreachable** segments to devices sending packets to the unavailable server.

The **no network** and **default network** commands terminate the RAIL monitoring of the specified IPv4 address space by deleting the corresponding **network** command from **running-config**.

**Command Mode**
- Server-failure Configuration

**Command Syntax**
```
 network netv4_address
no network netv4_address
default network netv4_address
```

**Parameters**
- **netv4_addr** IPv4 subnet address to be monitored (CIDR or address-mask notation).

**Related Commands**
- **monitor server-failure** places the switch in server-failure configuration mode.

**Example**
- This command specifies two IPv4 network spaces that RAIL monitors for server failures.

```
switch(config)#monitor server
switch(config-server-failure)#network 10.1.1.0/24
switch(config-server-failure)#network 10.2.1.96/28
switch(config-server-failure)#show active
monitor server-failure
  network 10.2.1.96/28
  network 10.1.1.0/24
switch(config-server-failure)#
```
no monitor session

The no monitor session and default monitor session commands remove the specified monitor session from the switch by deleting all corresponding monitor commands from running-config. Commands that remove or alter individual commands within a session configuration are described in the monitor session destination and monitor session source commands.

Command Mode
Global Configuration

Command Syntax

no monitor session session_name
default monitor session session_name

Parameters
- session_name Label assigned to port mirroring session.

Example
- This command displays the configuration of the redirect_1 mirroring session, deletes the session, then confirms that the session was removed.

```
switch(config)#show monitor session redirect_1

Session redirect_1
------------------------
Source Ports
  Both: Et7

Destination Port: Et8
switch(config)#no monitor session redirect_1
switch(config)#show monitor session redirect_1

Session not created
```

switch(config)#

platform sand monitor serdes error log

The platform sand monitor serdes error log command is used for enabling the serdes error log for fabric link monitoring.

**Command Mode**

Global Configuration

**Command Syntax**

platform sand monitor serdes error log

**Example**

- This command enables the serdes error log for fabric link monitoring.

```
switch(config)#platform sand monitor serdes error log
switch(config)#
```
**platform sand monitor serdes error threshold**

The **platform sand monitor serdes error threshold** command is used for generating a fabric link monitoring serdes error threshold.

**Command Mode**

- Global Configuration

**Command Syntax**

- `platform sand monitor serdes error threshold`

**Example**

- This command monitors serdes error thresholds over the specified number of received cells, resulting in the isolation of a fabric link between 200 and 30,000 received cells.
  
  `switch(config)#platform sand monitor serdes error threshold 200 30000`
  
  `switch(config)#`
platform sand monitor serdes poll period

The platform sand monitor serdes poll period command is used to enable the serdes poll period.

Command Mode
Global Configuration

Command Syntax
platform sand monitor serdes poll period

Example
• This command changes the serdes polling period for fabric link monitoring to 6 seconds.

switch(config)#platform sand monitor serdes poll period 6
switch(config)#
platform sand monitor serdes poll threshold isolation

The platform sand monitor serdes poll threshold isolation command is used to set and enables fabric link monitoring for serdes poll threshold isolation.

Command Mode

Global Configuration

Command Syntax

platform sand monitor serdes poll threshold isolation

Example

- This command changes the number of consecutive polls in which the threshold needs to be detected to isolate a link. In this case the number is 5 consecutive polls.

  switch(config)#platform sand monitor serdes poll threshold isolation 5
  switch(config)#
platform sand monitor serdes poll threshold recovery

The platform sand monitor serdes poll threshold recovery command is used to set and enable fabric link monitoring for serdes poll threshold recovery.

Command Mode

Global Configuration

Command Syntax

platform sand monitor serdes poll threshold recovery

Example

- This command changes the number of consecutive serdes polls used for threshold recovery to 6 seconds.

```
switch(config)#platform sand monitor serdes poll threshold recovery 6
switch(config)#
```
profile max-flaps (Link Flap Configuration)

The `profile max-flaps` command creates a link flap profile that, when assigned to an Ethernet interface, specifies the conditions that result in an error-disable action. Link flap profile parameters include:

- **flaps**  Threshold number of interface state changes.
- **period**  Interval when link flaps accumulate to trigger an error condition.
- **violations**  Number of link flap errors (threshold exceeded over specified period).
- **intervals**  Quantity of periods.

By default, `violations` and `intervals` are each set to one, resulting in a profile that triggers a link-flap error when the specified frequency is exceeded once. By configuring violations and intervals, link-flap errors are defined when the frequency is exceeded multiple times over a specified set of intervals.

**Default** is a reserved profile name that modifies the `errdisable flap-setting cause link-flap` statement in `running-config`. When configuring the `default` profile, `violations` and `intervals` are disregarded.

The `no profile max-flaps` command removes the specified profile by deleting the corresponding `profile max-flaps` command from `running-config`. The `no profile max-flaps default` command restores default `errdisable flap-setting cause link-flap` values by removing that command from `running-config`.

**Command Mode**

Link-flap Configuration

**Command Syntax**

```
profile PROFILE_NAME max-flaps flap_max time period [EXTENSIONS]
no profile LF_PROFILE
```

**Parameters**

- **PROFILE_NAME**  Name of link flap profile. Options include:
  - `default`  command modifies default values (`errdisable flap-setting cause link-flap`).
  - `profile_name`  command modifies specified link-flap profile.
- **flap_max**  Threshold number of interface state changes. Value ranges from 1 to 100.
- **period**  Interval when flaps accumulate toward threshold (seconds). Value ranges from 1 to 1800.
- **EXTENSIONS**  Configures multi-flap triggers. Options include:
  - `<no parameter>`  Sets errors and episodes to default values (one).
  - `violations errors intervals episodes`  Link flap errors (`errors`) and number of periods (`episodes`).
    - **Errors**  range is 1 to 1000. Default value is one.
    - **Episodes**  range is 1 to 1000. Default value is one.

**Related Commands**

- `monitor link-flap policy` places the switch in link-flap configuration mode.
Example

- These commands create two link flap profiles with various trigger settings.

```plaintext
switch(config)#monitor link-flap policy
switch(config-link-flap)#profile LF01 max-flaps 15 time 60
switch(config-link-flap)#profile LF02 max-flaps 10 time 30 violations 5 intervals 10
switch(config-link-flap)#show active
monitor link-flap policy
  profile LF01 max-flaps 15 time 60 violations 1 intervals 1
  profile LF02 max-flaps 10 time 30 violations 5 intervals 10
switch(config-link-flap)#
```
proxy (server-failure configuration mode)

The `proxy` command enables the Rapid Automated Indication of Link-Loss (RAIL) proxy setting and specifies the interval that RAIL responds to messages sent to servers on failed links, starting from when the switch detects the failed link. The RAIL state machine is in the proxying state during the timeout interval this command specifies. When RAIL proxy is not enabled, the switch maintains a list of unavailable servers without responding to messages sent to the servers. The switch can enter RAIL proxy state only when this command is enabled.

The RAIL proxy setting is `disabled` by default. When RAIL proxy is enabled, the default period is three minutes.

The `no proxy` and `default proxy` commands return the RAIL proxy setting to disabled by removing the proxy statement from `running-config`.

The `no proxy lifetime` and `default proxy lifetime` command sets the proxy time setting to its default value of three minutes if the RAIL proxy setting is `enabled`. These commands have no effect if the RAIL proxy setting is `disabled`.

**Command Mode**

Server-failure Configuration

**Command Syntax**

```
proxy [lifetime time_span]
no proxy
no proxy [lifetime]
default proxy
default proxy [lifetime]
```

**Parameters**

- `timespan` proxy timeout period (minutes). Value ranges from 1 to 10080. Default value is 3.

**Related Commands**

- `monitor server-failure` places the switch in server-failure configuration mode.

**Example**

- These commands enable the RAIL proxy and sets the proxy timeout period of 10 minutes.

  ```
  switch(config)#monitor server
  switch(config-server-failure)#proxy lifetime 10
  switch(config-server-failure)#show active
  monitor server-failure
  proxy lifetime 10
  switch(config-server-failure)#
  ```

- This command sets the proxy timeout period to its default value of 3 minutes.

  ```
  switch(config-server-failure)#no proxy lifetime
  switch(config-server-failure)#show active
  monitor server-failure
  proxy
  switch(config-server-failure)#
  ```

- This command disables the RAIL proxy.

  ```
  switch(config-server-failure)#no proxy
  switch(config-server-failure)#show active
  monitor server-failure
  switch(config-server-failure)#
  ```
show fabric monitoring health

The **platform sand monitor health** command is used to display the fabric monitoring connected state status with isolated links.

**Command Mode**
- Global Configuration

**Command Syntax**
```
platform sand monitor health
```

**Example**
- This command displays the connected state status with isolated links.

```
switch(config)#show platform sand health
Fabric serdes isolated by fabric monitoring: (36 total)

Arad5/0 serdes [0-1, 10-19, 2, 20-29, 3, 30-35, 4-9]

Top fabric serdes list by number of times isolated by monitoring:
Arad5/0 serdes 0: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 1: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 10: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 11: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 12: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 13: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 14: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 15: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 16: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 17: 1 (last occurred: 0:01:04 ago)

switch(config)#
```
show interfaces

The `show interfaces` command displays operational status and configuration information of specified interfaces. The output includes speed, duplex, flow control information and basic interface statistics.

The input and output bit rates, as displayed, do not include framing bits that are part of the Ethernet standard, the inter-frame gap and preamble that total 20 bytes per packet. The percentage number includes those framing bits to provide a better link utilization estimate.

**Command Mode**
EXEC

**Command Syntax**

```
show interfaces [INT_NAME]
```

**Parameters**
- **INT_NAME** Interface type and numbers. Options include:
  - <no parameter> all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.
  - `vxlan vx_range` VXLAN interface range specified by `vx_range`.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.
Example

- This command display configuration and status information for Ethernet interface 1 and 2.

```plaintext
switch>show interfaces ethernet 1-2
Ethernet1 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.2481.7647 (bia 001c.2481.7647)
  Description: mkt.1
  MTU 9212 bytes, BW 10000000 Kbit
  Full-duplex, 10Gb/s, auto negotiation: off
  Last clearing of "show interface" counters never
  5 seconds input rate 33.5 Mbps (0.3% with framing), 846 packets/sec
  5 seconds output rate 180 kbps (0.0% with framing), 55 packets/sec
    76437268 packets input, 94280286608 bytes
    Received 2208 broadcasts, 73358 multicast
    0 runts, 0 giants
    0 input errors, 0 CRC, 0 alignment, 0 symbol
    0 PAUSE input
    6184281 packets output, 4071319140 bytes
    Sent 2209 broadcasts, 345754 multicast
    0 output errors, 0 collisions
    0 late collision, 0 deferred
    0 PAUSE output

Ethernet2 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.2481.7648 (bia 001c.2481.7648)
  Description: mkt.2
  MTU 9212 bytes, BW 10000000 Kbit
  Full-duplex, 10Gb/s, auto negotiation: off
  Last clearing of "show interface" counters never
  5 seconds input rate 711 kbps (0.0% with framing), 271 packets/sec
  5 seconds output rate 239 kbps (0.0% with framing), 65 packets/sec
    73746370 packets input, 78455101010 bytes
    Received 11 broadcasts, 83914 multicast
    0 runts, 0 giants
    0 input errors, 0 CRC, 0 alignment, 0 symbol
    0 PAUSE input
    5687714 packets output, 4325064454 bytes
    Sent 15 broadcasts, 107279 multicast
    0 output errors, 0 collisions
    0 late collision, 0 deferred
    0 PAUSE output

switch>
```
show interfaces description

The `show interfaces description` command displays the status and description text of the specified interfaces. The `description` command configures an interface's description parameter.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INT_NAME] description
```

**Parameters**

- `INT_NAME` Interface type and labels. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.
  - `vxlan vx_range` VXLAN interface range specified by `vx_range`.

Range formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays description text and status of ethernet interfaces 1-10.

```
switch>show interfaces ethernet 1-10 description
Interface     Status   Protocol Description
Et1           up        up       ctar_01
Et2           up        up       ctar_02
Et3           up        up       ctar_03
Et4           up        up       fobd_01
Et5           up        up       fobd_02
Et6           up        up       yzrq_01
Et7           up        up       yzrq_02
Et8           down      down     yzrq_03
Et9           up        up       yzrq_04
Et10          up        up       yzrq_05
switch>
```
show link state group

The **show link state group** command displays information about a specified link-state group or about all groups.

**Command Mode**
EXEC

**Command Syntax**
```
show link state group [DATA_LEVEL] [GROUPS]
```

**Parameters**
- **DATA_LEVEL** device for which the command provides data. Options include:
  - <no parameter> information about all groups in group list.
  - `detail` detailed information about all groups in group list.
- **GROUPS**
  - <no parameter> all link-state groups.
  - `group_name` link-state group name.

**Example**
- This command displays all the link-state group information.

```
switch# show link state group detail
Link State Group: 1 Status: up
Upstream Interfaces : Vlan100
Downstream Interfaces : Vlan200
Number of times disabled : 2
Last disabled 0:10:29 ago

Link State Group: group3 Status: down
Upstream Interfaces : Ethernet24
Downstream Interfaces : Ethernet8
Number of times disabled : 2
Last disabled 0:30:35 ago

Link State Group: 2 Status: up
Upstream Interfaces : Ethernet5 Ethernet5
Downstream Interfaces : Ethernet12
Number of times disabled : 0
Last disabled never
switch#
```
show mac address-table

The show mac-address-table command displays the specified MAC address table entries.

Command Mode
EXEC

Command Syntax
show mac address-table [ENTRY_TYPE] [MAC_ADDR] [INTF_1 ... INTF_N] [VLANS]

Parameters
- **ENTRY_TYPE** command filters display by entry type. Entry types include mlag-peer, dynamic, static, unicast, multicast entries, and configured.
  - <no parameter> all table entries.
  - **configured** static entries; includes unconfigured VLAN entries.
  - **dynamic** entries learned by the switch.
  - **static** entries entered by CLI commands and include a configured VLAN.
  - **unicast** entries with unicast MAC address.
- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - <no parameter> all MAC addresses table entries.
  - **address mac_address** displays entries with specified address (dotted hex notation – H.H.H).
- **INTF_X** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - <no parameter> all Ethernet and port channel interfaces.
  - **ethernet e_range** Ethernet interfaces specified by e_range.
  - **port-channel p_range** Port channel interfaces specified by p_range.
- **VLANS** command filters display by VLAN.
  - <no parameter> all VLANs.
  - **vlan v_num** VLANs specified by v_num.

Related Commands
- show mac address-table mlag-peer
- show mac address-table multicast
Example

- This command displays the MAC address table.

```
switch>show mac address-table

switch>
```
**show mac address-table aging time**

The *show mac-address-table aging time* command displays the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries that exceed the aging time.

Aging time ranges from 10 seconds to 1,000,000 seconds with a default of 300 seconds (five minutes).

**Command Mode**

EXEC

**Command Syntax**

```
show mac address-table aging-time
```

**Examples**

- This command shows the MAC address table aging time

  ```
  switch>show mac address-table aging-time
  Global Aging Time: 120
  switch>
  ```
show mac address-table count

The `show mac-address-table count` command displays the number of entries in the MAC address table for the specified VLAN or for all VLANs.

**Command Mode**

EXEC

**Command Syntax**

```
show mac address-table count [VLANs]
```

**Parameters**

- **VLANs**  The VLANs for which the command displays the entry count.
  - `<no parameter>`  all configured VLANs.
  - `vlan v_num`  VLAN interface specified by `v_num`.

**Examples**

- This command displays the number of entries on VLAN 39
  ```
  switch>show mac address-table count vlan 39
  ```

  Mac Entries for Vlan 39:
  --------------------------
  Dynamic Address Count : 1
  Unicast Static Address Count : 1
  Multicast Static Address Count : 0
  Total Mac Addresses : 2

  switch>
show mac address-table mlag-peer

The **show mac-address-table mlag-peer** command displays the specified MAC address table entries learned from the MLAG peer switch.

**Command Mode**

EXEC

**Command Syntax**

```
show mac address-table mlag-peer [ENTRY_TYPE][MAC_ADDR][INTF_1 ... INTF_N][VLANS]
```

**Parameters**

- **ENTRY_TYPE** command filters display by entry type. Entry types include mlag-peer, dynamic, static, unicast, multicast entries, and configured.
  - **<no parameter>** all MLAG peer entries.
  - **configured** static entries on MLAG peer; includes unconfigured VLAN entries.
  - **dynamic** entries learned on MLAG peer.
  - **static** MLAG entries entered by CLI commands and include a configured VLAN.
  - **unicast** MLAG entries with unicast MAC address.

- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - **<no parameter>** all MAC addresses table entries.
  - **address mac_address** displays entries with specified address (dotted hex notation – H.H.H).

- **INTF_X** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - **<no parameter>** all Ethernet and port channel interfaces.
  - **ethernet e_range** Ethernet interfaces specified by e_range.
  - **port-channel p_range** Port channel interfaces specified by p_range.

- **VLANS** command filters display by VLAN.
  - **<no parameter>** all VLANS.
  - **vlan v_num** VLANS specified by v_num.

**Related Commands**

- **show mac address-table**
- **show mac address-table multicast**
show mac address-table multicast

The show mac-address-table command displays the specified multicast MAC address table entries.

Command Mode

EXEC

Command Syntax

show mac address-table multicast [MAC_ADDR] [INTF] [VLANS]

Parameters

- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - <no parameter> all MAC addresses table entries.
  - address mac_address displays entries with specified address (dotted hex notation – H.H.H).
- **INTF** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - <no parameter> all Ethernet and port channel interfaces.
  - ethernet e_range Ethernet interfaces specified by e_range.
  - port-channel p_range Port channel interfaces specified by p_range.
- **VLANS** command filters display by VLAN.
  - <no parameter> all VLANs.
  - vlan v_num VLANs specified by v_num.

Related Commands

- show mac address-table
- show mac address-table multicast brief
show mac address-table multicast brief

The `show mac-address-table` command displays a summary of multicast MAC address table entries.

**Command Mode**

EXEC

**Command Syntax**

```
show mac address-table multicast [VLANS] brief
```

**Parameters**

- **VLANS** command filters display by VLAN.
  - `<no parameter>` all VLANs.
  - `vlan v_num` VLANs specified by `v_num`.

**Related Commands**

- `show mac address-table multicast`
show monitor server-failure

The `show monitor server-failure` command displays Rapid Automated Indication of Link-Loss (RAIL) configuration settings and the number of servers on each monitored network.

**Command Mode**
- EXEC

**Command Syntax**
- `show monitor server-failure`

**Example**
- This command displays RAIL configuration status and lists the number of servers that are on each monitored network.

```
switch>show monitor server-failure
Server-failure monitor is enabled
Proxy service: disabled
Networks being monitored: 3
  10.2.1.96/28    : 0 servers
  10.1.1.0/24     : 0 servers
  10.3.0.0/16     : 3 servers
switch>
```
show monitor server-failure history

The `show monitor server-failure history` command displays the time of all link failures detected by Rapid Automated Indication of Link-Loss (RAIL) and includes the interface name for each failure.

The history is cleared by removing RAIL from the switch (`no monitor server-failure`).

**Command Mode**
EXEC

**Command Syntax**
```
show monitor server-failure history
```

**Related Commands**
- `clear server-failure servers inactive`

**Example**
- This command displays the Fast Server Failure link failure history from the time RAIL is instantiated on the switch.
```
switch> show monitor server-failure history
Total server failures: 4

 Server IP   Server MAC              Interface           Last Failed
----------- -----------------       -----------         -------------------
44.11.11.7  ad:3e:5f:dd:64:cf       Ethernet23          2013-02-10 00:07:56
10.1.8.13   01:33:df:ee:39:91       Port-Channel5       2013-02-10 00:03:39
```

switch>
**show monitor server-failure servers**

The `show monitor server-failure servers` command displays status and configuration information about each server that RAIL is monitoring. The display format depends on the parameter specified by the command:

- **single IP address**: command displays information about the server at the specified address, including IP address, MAC address, RAIL state, the time of most recent entry of all RAIL states, and the number of failed, proxied, and inactive state entries.
- **no parameter, key specifying a server list**: command displays a table. Each row corresponds to a monitored server. Information that the command displays includes IP address, MAC address, RAIL state, the time of most recent link failure.

**Command Mode**

EXEC

**Command Syntax**

`show monitor server-failure servers [SERVER_LIST]`

**Parameters**

- **SERVER_LIST**  Servers for which command displays information. Valid options include:
  - `<no parameter>` all servers in up, down, and proxying states.
  - `ipv4_addr`  individual server; command displays detailed information.
  - `all`  all servers on monitored networks.
  - `inactive`  all servers in inactive state.
  - `proxying`  all servers in proxying state.

**Example**

- This command displays RAIL information for the server at IP address 10.11.11.7
  
  `switch>show monitor server-failure servers 10.11.11.7`
  
  Server information:
  
  Server Ip Address : 10.11.11.7
  MAC Address       : ad:3e:5f:dd:64:cf
  Current state     : down
  Interface         : Ethernet23
  Last Discovered   : 2013-01-06 06:47:39
  Last Failed       : 2013-02-10 00:07:56
  Last Proxied      : 2013-02-10 00:08:33
  Last Inactive     : 2013-02-09 23:52:21
  Number of times failed : 3
  Number of times proxied : 1
  Number of times inactive : 18

  `switch>`

- This command displays RAIL data for all servers in monitored networks that are in inactive state.
  
  `switch>show monitor server-failure servers inactive`
  
  Inactive servers: 1
  
  Server IP | Server MAC | Interface | State     | Last Failed
  ----------|------------|-----------|-----------|-------------
  10.1.67.92| 01:22:ab:cd:ee:ff | Ethernet17 | inactive   | 7 days, 12:48:06 ago

  `switch>`
• This command displays RAIL information for all servers in monitored networks that are in up, down, and proxying states.

```
switch>show monitor server-failure servers
Active servers: 4
```

```
show monitor session

The `show monitor session` command displays the configuration of the specified port mirroring session. The command displays the configuration of all mirroring sessions on the switch when the session name parameter is omitted.

**Command Mode**

EXEC

**Command Syntax**

`show monitor session SESSION_NAME`

**Parameters**

- `SESSION_NAME` Port mirroring session identifier. Options include:
  - `<no parameter>` displays configuration for all sessions.
  - `label` command displays configuration of the specified session.

**Example**

- This command displays the mirroring configuration of the specified monitor session.

  `switch>show monitor session redirect_1`  

  Session redirect_1
  ------------------------
  
  Source Ports
  
  Both:  Et7
  
  Destination Port: Et8

  `switch(config)>`
show port-security

The **show port-security** command displays a summary of MAC address port security configuration and status on each interface where switchport port security is enabled.

**Command Mode**

EXEC

**Command Syntax**

```text
show port-security
```

**Display Values**

Each column corresponds to one physical interface. The table displays interfaces with port security enabled.

- **Secure Port**: Interface with switchport port-security enabled.
- **MaxSecureAddr**: Maximum quantity of MAC addresses that the specified port can process.
- **CurrentAddr**: Static MAC addresses assigned to the interface.
- **SecurityViolation**: Number of frames with unsecured addresses received by port.
- **Security Action**: Action triggered by a security violation.

**Examples**

- This command displays switchport port security configuration and status data.

```text
switch>show port-security
Secure Port    MaxSecureAddr  CurrentAddr  SecurityViolation  Security Action
(Count)        (Count)      (Count)
-----------------------------------------------------------------------------------------------------------------
 Et7            5             3            0            Shutdown
 Et10           1             0            0            Shutdown
-----------------------------------------------------------------------------------------------------------------
Total Addresses in System: 3
switch>
```
show port-security address

The **show port-security address** command displays static unicast MAC addresses assigned to interfaces where switchport port security is enabled.

**Command Mode**

EXEC

**Command Syntax**

```
show port-security address
```

**Example**

- This command displays MAC addresses assigned to port-security protected interfaces.

```
switch>show port-security address
Secure Mac Address Table

Vlan  Mac Address       Type                     Ports   Remaining Age (mins)
----  -----------       ----                     -----   -------------

Total Mac Addresses for this criterion: 3
switch>
```
show port-security interface

The show port-security interface command displays the switchport port-security status of all specified interfaces.

Command Mode
EXEC

Command Syntax
show port-security interface [INT_NAME]

Parameters
- **INT_NAME** Interface type and numbers. Options include:
  - <no parameter> Display information for all interfaces.
  - ethernet e_range Ethernet interface range specified by e_range.
  - loopback l_range Loopback interface specified by l_range.
  - management m_range Management interface range specified by m_range.
  - port-channel p_range Port-Channel Interface range specified by p_range.
  - vlan v_range VLAN interface range specified by v_range.
  - vxlan vx_range VXLAN interface range specified by vx_range.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

Examples
- This command display port-security configuration and status for the specified interfaces.
  
  switch>show port-security interface ethernet 7-8
  Interface : Ethernet7
  Port Security : Enabled
  Port Status : Secure-down
  Violation Mode : Shutdown
  Maximum MAC Addresses : 5
  Aging Time : 5 mins
  Aging Type : Inactivity
  SecureStatic Address Aging : Disabled
  Total MAC Addresses : 3

  Learn/Move/Age Events : 5
  Last Source Address:Vlan : 164f.29ae.4e14:10
  Last Address Change Time : 0:39:47 ago
  Security Violation Count : 0

  Interface : Ethernet8
  Port Security : Disabled
  Port Status : Secure-down
  Violation Mode : Shutdown
  Maximum MAC Addresses : 1
  Aging Time : 5 mins
  Aging Type : Inactivity
  SecureStatic Address Aging : Disabled
  switch>
show storm-control

The `show storm-control` command displays the storm-control level and interface inbound packet capacity for the specified interface.

The configured value (`storm-control`) differs from the programmed threshold in that the hardware accounts for Interframe Gaps (IFG) based on the minimum packet size. This command displays the broadcast or multicast rate after this adjustment.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show storm-control [INT_NAME]
```

**Parameters**

- `<no parameter>` Command returns data for all interfaces configured for storm control.
- `INT_NAME` interface type and port range. Settings include:
  - `ethernet e_range` Ethernet interfaces that `e_range` denotes.
  - `port-channel p_range` Port channel interfaces that `p_range` denotes.

When storm control commands exist for a port-channel and an Ethernet port that is a member of the port channel, the command for the port-channel takes precedence.

Valid `range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

This command displays the storm control configuration for Ethernet ports 1 through 5.

```
switch# show storm-control
Port          Type  Level Rate(Mbps)   Status      Drops Reason
Et10/2         all     75       7500   active          0
Et10/3   multicast     55       5500   active          0
Et10/4   broadcast     50       5000   active          0
switch#
```
**show switch forwarding-mode**

The *show switch forwarding-mode* command displays the switch’s current and available forwarding plane hardware modes.

**Command Mode**

EXEC

**Command Syntax**

```
show switch forwarding-mode
```

**Related Commands**

- *switch forwarding-mode* configures the switch’s forwarding mode setting.

**Example**

- This command changes the switch’s forward mode to *store-and-forward*, then displays the forwarding mode.

```
switch(config)#switch forwarding-mode store-and-forward
switch(config)#show switch forwarding-mode
Current switching mode:    store and forward
Available switching modes: cut through, store and forward
```
show track

The **show track** command displays information about tracked objects configured on the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show track [OBJECT] [INFO_LEVEL]
```

**Parameters**

- **OBJECT** tracked object for which information is displayed. Options include:
  - <no parameter> displays information for all tracked objects configured on the switch.
  - object_name displays information for the specified object.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> displays complete information including object status, number of status changes, time since last change, and client process tracking the object (if any).
  - brief displays brief list of all tracked objects and their current status.

**Examples**

- This command displays all information for tracked object ETH8.
  ```
  switch#show track ETH8
  Tracked object ETH8 is up
  Interface Ethernet8 line-protocol
  4 change, last change time was 0:36:12 ago
  Tracked by:
  Ethernet5/1 vrrp instance 50
  switch#
  ```
- This command displays summary information for all tracked objects.
  ```
  switch#show track brief
  Tracked object ETH2 is up
  Tracked object ETH4 is down
  Tracked object ETH6 is up
  Tracked object ETH8 is up
  switch#
  ```
shutdown (server-failure configuration mode)

The `shutdown` command disables Rapid Automated Indication of Link-Loss (RAIL). By default, RAIL is disabled.

After entering server-failure configuration mode, a `no shutdown` command is required to enable RAIL.

The `no shutdown` command enables RAIL on the switch. The `shutdown` and `default shutdown` commands disable RAIL by removing the shutdown command from `running-config`.

**Command Mode**

Server-failure Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Examples**

- This command enables RAIL on the switch.
  ```
  switch(config)#monitor server
  switch(config-server-failure)#no shutdown
  switch(config-server-failure)#show active
  monitor server-failure
    no shutdown
  switch(config-server-failure)#
  ```

- This command disables RAIL on the switch.
  ```
  switch(config-server-failure)#shutdown
  switch(config-server-failure)#show active
  monitor server-failure
  switch(config-server-failure)#
  ```
storm-control

The **storm-control** command configures and enables storm control on the configuration mode physical interface. The command provides three mode options:

- **storm-control all**  unicast, multicast, and broadcast inbound packet control.
- **storm-control broadcast**  broadcast inbound packet control.
- **storm-control multicast**  multicast inbound packet control.

An interface configuration can contain three storm-control statements, one with each mode setting. The **storm-control all** threshold overrides broadcast and multicast thresholds.

The threshold is a percentage of the available port bandwidth and is configurable on each interface for each transmission mode.

The **no storm-control** and **default storm-control** commands remove the corresponding **storm-control** statement from **running-config**, disabling storm control for the specified transmission type on the configuration mode interface.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
storm-control MODE level threshold
no storm-control mode
default storm-control mode
```

**Parameters**

- **MODE**  packet transmission type. Options include:
  - all
  - broadcast
  - multicast
- **threshold**  Inbound packet level that triggers storm control, as a percentage of port capacity. Value ranges from 0.01 to 100. Storm control is suppressed by a level of 100.

  The configured value differs from the programmed threshold in that the hardware accounts for Interframe Gaps (IFG) based on the minimum packet size. The **show storm-control** command displays the broadcast or multicast rate after this adjustment.

**Restrictions**

The **storm-control all** option is not available on Arad platform switches.

**Example**

- These commands enable multicast and broadcast storm control on Ethernet port 20 and sets thresholds of 65% (multicast) and 50% (broadcast). During each one second interval, the interface drops inbound multicast traffic and broadcast traffic in excess of the specified thresholds.

```
switch(config)#interface ethernet 20
switch(config-if-Et20)#storm-control multicast level 65
switch(config-if-Et20)#storm-control broadcast level 50
switch(config-if-Et20)#show active
interface Ethernet20
  storm-control broadcast level 50
  storm-control multicast level 65
switch(config-if-Et20)#
```
switch forwarding-mode

The `switch forwarding-mode` command specifies the mode of the switch's forwarding plane hardware. The default forwarding mode is `cut through`.

The `no switch forwarding-mode` and `default switch forwarding-mode` commands restore the default forwarding mode by removing the `switch forwarding-mode` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
switch forwarding-mode MODE_SETTING
no switch forwarding-mode
default switch forwarding-mode
```

**Parameters**
- `MODE_SETTING` Specifies the switch's forwarding plane hardware mode. Options include:
  - `cut-through` the switch begins forwarding frames before their reception is complete.
  - `store-and-forward` the switch accumulates entire packets before forwarding them.

**Guidelines**
The forwarding plane mode is `store-and-forward` on Petra and Arad platform switches.

**Related Commands**
- `show switch forwarding-mode` displays the current forwarding mode.

**Examples**
- This command changes the forwarding mode to `store-and-forward`.
  ```
  switch(config)#switch forwarding-mode store-and-forward
  switch(config)#
  ```
switchport

The switchport command places the configuration mode interface in **switched port** (Layer 2) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

The no switchport command places the configuration mode interface in **routed port** (Layer 3) mode. Routed ports are not members of any VLANs and do not switch or bridge packets. All IP level configuration commands, including IP address assignments, apply directly to the routed port interface.

By default, Ethernet and Port Channel interfaces are in switched port mode. The default switchport command also places the configuration mode interface in switched port mode by removing the corresponding no switchport command from running-config.

These commands only toggle the interface between switched and routed modes. They have no effect on other configuration states.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
switchport
no switchport
default switchport
```

**Guidelines**

When an interface is configured as a routed port, the switch transparently allocates an internal VLAN whose only member is the routed interface. Internal VLANs are created in the range from 1006 to 4094. VLANs that are allocated internally for a routed interface cannot be directly created or configured. The vlan internal allocation policy command specifies the method that VLANs are allocated.

All IP-level configuration commands, except autostate and ip virtual-router, can be used to configure a routed interface. Any IP-level configuration changes made to a routed interface are maintained when the interface is toggled to switched port mode.

A LAG that is created with the channel-group command inherits the mode of the member port. A LAG created from a routed port becomes a routed LAG. IP-level configuration statements are not propagated to the LAG from its component members.

**Examples**

- These commands put Ethernet interface 5 in routed port mode.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no switchport
  switch(config-if-Et5)#
  ```

- These commands returns Ethernet interface 5 to switched port mode.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport
  switch(config-if-Et5)#
  ```
**switchport default mode access**

The `switchport default mode access` command places the configuration mode interface in **switched port default access** (Layer 3) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

**Command Mode**
- Global Configuration

**Command Syntax**

```
switchport default mode access
```

**Related Commands**
- `switchport default mode routed` puts a switch with all ports in routed port mode.

**Examples**
- This command puts a switch with all ports in access port mode.
  ```
  switch(config)#switchport default mode access
  ```
**switchport default mode routed**

The **switchport default mode routed** command places the configuration mode interface in **switched port default routed** (Layer 3) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

By default, on a switch with default startup config or no config, all ports come up in access mode. By adding the CLI command **switchport default mode routed** to kickstart config, all ports will come up in routed mode after boot up. On boot up, Zero Touch Provisioning (ZTP) is enabled by default if the startup config (/mnt/flash/startupconfig) is deleted. ZTP can be disabled by setting DISABLE=True in ZTP config (/mnt/flash/zerotouchconfig). Kickstart config (/mnt/flash/kickstart-config) is used when startup config is missing and ZTP is disabled.

**Command Mode**

Global Configuration

**Command Syntax**

`switchport default mode routed`

**Related Commands**

- **switchport default mode access** puts a switch with all ports in access port mode.

**Examples**

- This command puts a switch with all ports in routed port mode.

  `switch(config)#switchport default mode routed`
**switchport mac address learning**

The `switchport mac address learning` command enables MAC address learning for the configuration mode interface. MAC address learning is enabled by default on all Ethernet and port channel interfaces.

The switch maintains a MAC address table for switching frames between VLAN ports. When the switch receives a frame, it associates the MAC address of the transmitting interface with the recipient VLAN and port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is not enabled, the entry is not added to the table.

The `no switchport mac address learning` command disables MAC address learning for the configuration mode interface. The `switchport mac address learning` and `default switchport mac address learning` commands enable MAC address learning for the configuration mode interface by deleting the corresponding `no switchport mac address learning` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
switchport mac address learning
no switchport mac address learning
default switchport mac address learning
```

**Example**

- These commands disables MAC address learning for Ethernet interface 8, then displays the active configuration for the interface.

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#no switchport mac address learning
switch(config-if-Et8)#show active
interface Ethernet8
    no switchport mac address learning
switch(config-if-Et8)#
```
**switchport port-security**

The `switchport port-security` command enables MAC address port security on the configuration mode interface. Ports with port security enabled restrict traffic to a limited number of hosts, as determined by their MAC addresses. The `switchport port-security maximum` command specifies the maximum number of MAC addresses. The `switchport port-security violation protect` command enables port security in protect mode.

The `no switchport port-security` and `default switchport port-security` commands disable port security on the configuration mode interface by removing the corresponding `switchport port-security` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
switchport port-security
no switchport port-security
default switchport port-security
```

**Examples**

- These commands enable port security on ethernet interface 7.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#switchport port-security
switch(config-if-Et7)#
```
switchport port-security maximum

The `switchport port-security maximum` command specifies the maximum MAC address limit for the configuration mode interface when configured as a secure port. When port security is enabled, the port accepts traffic and adds source addresses to the ARP table until the maximum is reached. Once the maximum is reached, if any traffic arrives from a source not already in the ARP table for the secure port, the port becomes errdisabled. The `switchport port-security` command configures an interface as a secure port.

The `no switchport port-security maximum` and `default switchport port-security maximum` commands restore the maximum MAC address limit of one on the configuration mode interface by removing the corresponding `switchport port-security maximum` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

- `switchport port-security maximum max_addr`
- `no switchport port-security maximum`
- `default switchport port-security maximum`

**Parameters**
- `max_addr` maximum number of MAC addresses. Value ranges from 1 to 1000. Default value is 1.

**Examples**
- These commands configure a maximum of five incoming addresses for secure port channel interface 14.

```
switch(config)#interface port-channel 14
switch(config-if-Po14)#switchport port-security maximum 5
switch(config-if-Po14)#
```
switchport port-security violation protect

The `switchport port-security violation protect` command enables port security in protect mode (with the option of enabling logging). When port security is enabled, the port accepts traffic and adds source addresses to the ARP table until the maximum is reached. Once the maximum is reached, if any traffic arrives from a source not already in the ARP table for the secure port, the port becomes errdisabled. The `switchport port-security` command configures an interface as a secure port.

The `no switchport port-security` and `no switchport port-security violation protect log` commands disable port security protect mode and port security protect mode logging on the configuration mode interface.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
- `switchport port-security violation protect`
- `switchport port-security violation protect log`
- `no switchport port-security`
- `no switchport port-security violation protect log`

**Examples**
- These commands configure port security violation protect mode for secure port channel interface 14.
  ```
  switch(config)#interface port-channel 14
  switch(config-if-Po14)#switchport port-security violation protect
  switch(config-if-Po14)#
  ```
- These commands configure port security violation protect logging mode for secure port channel interface 14.
  ```
  switch(config)#interface port-channel 14
  switch(config-if-Po14)#switchport port-security violation protect log
  switch(config-if-Po14)#
  ```
track

The `track` command creates an object whose state changes to provide information to a client process. The client process must be separately configured for object tracking to have an effect on the switch.

The `no track` and `default track` commands remove the specified tracked object by removing the corresponding `track` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
track object_name interface INTERFACE_NAME PROPERTY
no track object_name
default track object_name
```

**Parameters**

- `object_name` User-created name for the tracked object.
- `INTERFACE_NAME` Interface associated with the tracked object. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.
  - `vxlan vx_num` VXLAN interface specified by `vx_num`.
- `PROPERTY` Tracked property. Options include:
  - `line-protocol` Object changes when the state of the associated interface changes.

**Example**

- This command creates a tracked object which tracks the state of the line protocol on Ethernet interface 8.
  ```
  switch(config)#track ETH8 interface ethernet 8 line-protocol
  switch(config)#
  ```
Chapter 17

Tap Aggregation

This chapter describes tap aggregation and the data structures that it requires. Sections in this chapter include:

- Section 17.1: Tap Aggregation Introduction
- Section 17.2: Tap Aggregation Description
- Section 17.3: Tap Aggregation Configuration
- Section 17.4: Tap Aggregation Traffic Steering
- Section 17.5: Tap Aggregation GUI
- Section 17.6: Keyframe and Timestamp Configuration
- Section 17.7: Tap Aggregation Command Descriptions

Port mirroring is described in Port Mirroring.

17.1 Tap Aggregation Introduction

Ethernet based switches are commonly deployed in dedicated networks to support tap and mirror port traffic towards one or more analysis applications. Ports configured to mirror data can simultaneously switch traffic to its primary destination while directing a copy of that traffic to analysis or test devices. Tap ports are typically part of a dedicated environment that allows for the aggregation of data streams from multiple sources that can be directed to multiple destinations.

Arista switches support port mirroring and tap aggregation and the data structures required by these functions.
17.2 Tap Aggregation Description

These sections describe tap aggregation, timestamps, and keyframes:

- Section 17.2.1: Tap Aggregation
- Section 17.2.2: Timestamps and Keyframes

17.2.1 Tap Aggregation

Tap aggregation is the accumulation of data streams and subsequent dispersal of these streams to devices and applications that analyze, test, verify, parse, detect, or store data. Tap aggregation requires an environment free from switching operations. Arista switches operate in one of two device modes:

- Switching mode: The switch performs normal switching and routing operations. Data mirroring is supported in switching mode. Tap aggregation is not available in switching mode.
- Tap aggregation mode: The switch is a data monitoring device and does not provide normal switching and routing services. Data mirroring is not available in tap aggregation mode.

Access control lists, port channels, LAGs, QoS, and VLANs function normally in both modes. Ethernet and port channel interfaces are configured as tap and tool ports to support tap aggregation.

- Tap ports: A tap port is an interface that receives a data stream that two network ports exchange. Tap ports prohibit egress traffic. MAC learning is disabled. All control plane interaction is prevented. Traps for inbound traffic are disabled. Tap ports are in STP forwarding mode.
- Tool ports: A tool port is an interface that replicates data streams received by one or more tap ports. Tool ports connect to devices that process the monitored data streams. Tool ports prohibit ingress traffic. MAC learning is disabled. All control plane interaction is prevented. Tool ports are in STP forwarding mode.

Tap and tool ports are configured with the `switchport mode` command. These ports are active when the switch is in tap aggregation mode and error-disabled when the switch is in switching mode.

Tap aggregation groups are data structures that map a set of tap ports to a set of tool ports. Both tap and tool ports may belong to multiple tap aggregation groups, and a tap aggregation group may contain multiple tap and tool ports.

Tap and tool ports are designated through switchport mode commands and act similar to trunk ports, in that they can allow access to VLANs specified through allowed-VLAN lists. Tap ports also specify a native VLAN for handling untagged frames.

- Access, trunk, and dot1q-tunnel mode ports are active when the switch is in switching mode and error-disabled when the switch is in tap aggregation mode.
- Tap and tool mode ports are active when the switch is in tap aggregation mode and error-disabled when the switch is in switching mode.

17.2.2 Timestamps and Keyframes

FM6000 platform switches support packet timestamping of packets sent from any port at line rate. Timestamps are used to correlate network events and in performance analysis. Keyframes provide information to assist in the interpretation of timestamps.

The switch contains two 64-bit counters to maintain ASIC time and UTC time. ASIC time is based on an internal 350 MHz counter. UTC is absolute time that is maintained by a precision oscillator and synchronized through PTP.
Timestamps are derived from the least significant 31 bits of ASIC time. Based on the 350 MHz counter period and 31-bit resolution, timestamp values repeat every 6.135 seconds.

Keyframes are periodically inserted into the data stream to provide context for interpreting timestamps. Keyframes contain the 64-bit value of the ASIC time counter, the corresponding 64-bit value of the UTC time counter, and the elapsed time since the last PTP synchronization of the UTC counter. Inserting one keyframe every second into the data stream assures that the timestamp value in each egress packet can be associated with values of the complete 64-bit ASIC time counter and the corresponding UTC counter.

17.2.2.1 Timestamps

Timestamps are based on a frame’s ingress time and applied to frames sent on egress ports, ensuring that timestamps on monitored traffic reflect ingress timing of the original frames. Timestamping is configured on the egress port where the timestamp is applied to the frame.

A timestamp consists of the least significant 31 bits of the ASIC time counter. The most significant bit of the least significant byte is a 0 pad, resulting in a 32 bit timestamp with 31 bits of data. The keyframe mechanism provides recovery of the most significant 33 bits of the ASIC counters and a map to UTC time. Applications use this mechanism to determine the absolute time of the frame timestamp.

The switch supports three timestamp modes, which are configurable on individual Ethernet ports. The modes differ in the management of the egress frame’s 32-bit frame check sequence (FCS):

- Disabled: Timestamping is disabled.
- FCS Replacement Mode: The original FCS is discarded, the ingress timestamp is appended to frame data, followed by a new FCS that is based on the appended timestamp. The result is a valid Ethernet frame, but the headers of all nested protocols are not updated to reflect the timestamp.
- FCS Appending Mode: The original FCS is discarded and replaced by the ingress timestamp. The size of the original frame is maintained without any latency impact, but the FCS is not valid.

17.2.2.2 Keyframes

Keyframes contain routable IP packets that provide information to relate timestamps with the complete ASIC counter and absolute UTC time. Keyframes have valid L2 and L3 headers. Keyframes contain these header fields:

- MAC fields (12 bytes):
  - Source MAC address is the address of the egress interface transmitting the keyframe.
  - Destination MAC address is configured through a CLI command.
- IP Header (20 bytes):
  - Source IP address is configured through CLI; default is management interface IP address.
  - Destination IP address is configured through a CLI command.
  - TTL is set to 64.
  - TOS is set to 0.
  - Protocol field is set to 253.
  - IP header’s ID field is set to 0.

Keyframes contain these payload fields:

- ASIC time: (64 bits) ASIC time counter. (2.857 ns resolution).
- UTC time: (64 bits) Unix time that corresponds to ASIC time (ns).
- Last sync time: (64 bits) ASIC time of most recent PTP synchronization.
- Keyframe time: (64 bits) ASIC time of the keyframe’s egress (ns).
- Egress interface drops: (64 bits) Number of dropped frames on keyframe’s egress interface.
- Device ID: (16 bits) device ID (user defined).
- Egress interface: (16 bits) Keyframe’s egress switchport.
- FCS type (8 bits): Timestamping mode configured on keyframe’s egress port.
  - 0: timestamping disabled.
  - 1: timestamp is appended to payload; new FCS is added to the frame.
  - 2: timestamp overwrites the existing FCS.
- Reserved (8 bits): Reserved for future use.
- Skew numerator/skew denominator: Form a ratio indicating the ASIC clock skew. If the ratio is greater than 1, the clock is skewed fast; if the ratio is less than 1, the clock is skewed slow.

Last sync time equals 0 when there was no previous synchronization or the time since the last synchronization is greater than 8 hours.

The 31-bit frame timestamp provides high-resolution timing, rolling over about every 6.135 seconds (31 bits at 2.857ns per tick). To obtain the full ASIC time and to correlate the timestamp to an absolute UTC time, the switch sends keyframes. Each keyframe contains the current ASIC time and UTC time; hence an application can compute the high order bits of the ASIC time (for precise, relative timing) from the ASIC to UTC time mapping, and then determine absolute time.

ASIC to UTC time conversion is not quite immediate, so the UTC time in the frame will not be the ‘current’ time. A keyframe timestamp is provided for this purpose. The frame also includes the timestamping mode (FCS type) so applications can dynamically determine the timestamp’s byte offset. Each field is described in the following table.
### Figure 17-1: Key frame payload

17.3 Tap Aggregation Configuration

These sections describe tap aggregation configuration tasks:

- Section 17.3.1: Enabling Tap Aggregation Mode
- Section 17.3.2: Tap Port Configuration
- Section 17.3.3: Tool Port Configuration
- Section 17.3.4: Identity VLAN Tagging
- Section 17.3.5: Tap Aggregation Group Configuration

17.3.1 Enabling Tap Aggregation Mode

The switch supports switching mode and tap aggregation mode. In switching mode, normal switching and routing functions are supported while tap aggregation functions are disabled. In tap aggregation mode, tap aggregation functions are enabled while normal switching and routing functions are disabled. By default, the switch is in switching mode.

A port’s switchport status depends on its switchport mode and the switch’s tap aggregation mode.

- Tap aggregation mode enabled: Tap and tool ports are enabled. Switching ports are errdisabled.
- Tap aggregation mode disabled: Tap and tool ports are errdisabled. Switching ports are enabled.

To enable the switch to carry out tap aggregation, first enter tap aggregation configuration mode and then set the mode.

**Example**

- These commands enter tap-agg configuration mode, then place the switch in tap aggregation mode.

```plaintext
switch(config)#tap aggregation
switch(config-tap-agg)#mode exclusive
switch(config-tap-agg)#show active
tap aggregation
  mode exclusive
switch(config-tap-agg)#
```

To return the switch to switching mode, remove the mode command from `running-config`.

**Examples**

- These commands enter tap-agg configuration mode, then place the switch in switching mode.

```plaintext
switch(config)#tap aggregation
switch(config-tap-agg)#no mode
switch(config-tap-agg)#show active
switch(config-tap-agg)#
```

- These commands enter switching mode and remove all tap-agg configuration mode statements.

```plaintext
switch(config)#no tap aggregation
switch(config)#
```

17.3.2 Tap Port Configuration

Tap ports function when the switch is in tap aggregation mode. Tap ports receive traffic for replication to one or more tool ports. In tap aggregation mode, tap ports are in STP forwarding state and prohibit egress traffic. MAC learning, control plane interaction and traps for inbound traffic are disabled.
Tap mode ports are configured through switchport mode commands. Tap mode command settings persist in `running-config` without taking effect when the switch is not in tap aggregation mode or the interface is not in tap aggregation mode.

This section describes the following tap port configuration steps.

- **Configuring an interface as a Tap Mode Port**
- **Tap Port Allowed VLAN List Configuration**
- **Tap Port Native VLAN**
- **Tap Port Packet Truncation**

### Configuring an interface as a Tap Mode Port

Ethernet and port channel interfaces are configured as tap ports with the `switchport mode` command.

**Example**

- These commands configure ethernet interfaces 41 through 43 as tap mode ports.

```
switch(config)#interface ethernet 41-43
switch(config-if-Et41-43)#switchport mode tap
switch(config-if-Et41-43)#show interface ethernet 41-43 tap
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured Mode</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et41</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
<tr>
<td>Et42</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
<tr>
<td>Et43</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>

```
switch(config-if-Et41-43)#
```

### Tap Port Allowed VLAN List Configuration

By default, tap mode interfaces handle tagged traffic for all VLANs. The `switchport tap allowed vlan` command creates or modifies the set of VLANs for which a tap port handles tagged traffic.

**Example**

- These commands create tap mode allowed VLAN lists for Ethernet interface 41 through 43.

```
switch(config)#interface ethernet 41
switch(config-if-Et41)#switchport tap allowed vlan 401-410
switch(config-if-Et41)#interface ethernet 42
switch(config-if-Et42)#switchport tap allowed vlan 411-420
switch(config-if-Et41)#interface ethernet 41-42
switch(config-if-Et41-42)#show active
```

```
interface Ethernet41
switchport mode tap
switchport tap allowed vlan 401-410
interface Ethernet42
switchport mode tap
switchport tap allowed vlan 411-420
switch(config-if-Et41-42)#
```

### Tap Port Native VLAN

Tap mode Interfaces associate untagged frames with the tap mode native VLAN. The `switchport tap native vlan` command specifies the tap mode native VLAN for the configuration mode interface. The default tap mode native VLAN for all interfaces is VLAN 1.

```
switch(config)#interface ethernet 41
switch(config-if-Et41)#switchport mode tap
switch(config-if-Et41)#switchport tap native vlan 1
```

```
switch(config-if-Et41)#
```
Example

- These commands assign VLAN 400 as the tap mode native VLAN for Ethernet interface 41.

```
switch(config)#interface ethernet 41
switch(config-if-Et41)#switchport tap native vlan 400
switch(config-if-Et41)#show interface ethernet 41-43 tap
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et41</td>
<td>tap</td>
<td>tap</td>
<td>400</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
<tr>
<td>Et42</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
<tr>
<td>Et43</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>

```
switch(config-if-Et41)#
```

**Tap Port Packet Truncation**

Tap ports can be configured to truncate inbound packets. The `switchport tap truncation` command configures the configuration mode interface, as a tap port, to truncate inbound packets to the specified packet size. By default, tap ports do not truncate packets.

Example

- These commands configure ethernet interface 41 to truncate packets to 150 bytes.

```
switch(config)#interface ethernet 41
switch(config-if-Et41)#switchport tap truncation 150
switch(config-if-Et41)#show interface ethernet 41-43 tap
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et41</td>
<td>tap</td>
<td>tap</td>
<td>400</td>
<td>1</td>
<td>150</td>
<td>---</td>
</tr>
<tr>
<td>Et42</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
<tr>
<td>Et43</td>
<td>tap</td>
<td>tap</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>

```
switch(config-if-Et41)#
```

- These commands configure ethernet interface 41 to send complete packets for replication.

```
switch(config-if-Et41)#no switchport tap truncation
switch(config-if-Et41)#show interface ethernet 41 tap
```

```
<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Native Vlan</th>

<td>tap</td>
<td>tap</td>
<td>400</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>
```

```
switch(config-if-Et41)#
```

**17.3.3 Tool Port Configuration**

Tool ports replicate traffic received by tap ports. Tool ports are mapped to the tap ports through tap aggregation groups. A tool port may belong to multiple aggregation groups and an aggregation group may contain multiple tool ports.

Tool ports function when the switch is in tap aggregation mode. In this switch mode, tool ports are in STP forwarding state and ingress traffic is prohibited. MAC learning, control plane interaction and traps for inbound traffic are disabled. All control plane interaction is prevented and L2 agents do not send PDUs to tool mode interfaces. When the switch is in switching mode, tool ports are error-disabled.

Tool mode ports are configured through switchport commands. Tool mode command settings persist in `running-config` without taking effect when the switch is not in tap aggregation mode or the interface is not in tap aggregation mode.

This section describes the following tool port configuration steps.
• Configuring an interface as a Tool Mode Port
• Tool Port Allowed VLAN List Configuration
• Tool Port Packet Truncation

Configuring an interface as a Tool Mode Port

Ethernet and port channel interfaces are configured as tool ports with the `switchport mode` command.

Example

• These commands configure port channel interfaces 101 through 103 as tool mode ports.

```
switch(config)#interface port-channel 101-103
switch(config-if-Po101-103)#switchport mode tool
switch(config-if-Po101-103)#show interface port-channel 101-103 tool
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Allowed Vlans</th>
<th>Tag</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Po101</td>
<td>tool</td>
<td>tool</td>
<td>All</td>
<td>Off</td>
<td>---</td>
</tr>
<tr>
<td>Po102</td>
<td>tool</td>
<td>tool</td>
<td>All</td>
<td>Off</td>
<td>---</td>
</tr>
<tr>
<td>Po103</td>
<td>tool</td>
<td>tool</td>
<td>All</td>
<td>Off</td>
<td>---</td>
</tr>
</tbody>
</table>

switch(config-if-Po101-103)#

Tool Port Allowed VLAN List Configuration

By default, tool mode interfaces handle tagged traffic for all VLANs. The `switchport tool allowed vlan` command creates or modifies the set of VLANs for which a tool port handles tagged traffic.

Example

• These commands create tool mode allowed VLAN lists for port channel interfaces 101 through 103.

```
switch(config)#interface port-channel 101-103
switch(config-if-Po101-103)#switchport tool allowed vlan 1010-1020
switch(config-if-Po101-103)#interface port-channel 101
switch(config-if-Po101)#switchport tool allowed vlan add 1001-1009
switch(config-if-Po101)#interface port-channel 102
switch(config-if-Po102)#switchport tool allowed vlan remove 1016-1020
switch(config-if-Po102)#interface port-channel 103
switch(config-if-Po103)#switchport tool allowed vlan add 1021-1030
switch(config-if-Po103)#show interface port-channel 101-103 tool
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Allowed Vlans</th>
<th>Id</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Po101</td>

<td>tool</td>
<td>tool</td>
<td>1010-1015</td>
<td>Off</td>
<td>---</td>
</tr>
<tr>
<td>Po103</td>
<td>tool</td>
<td>tool</td>
<td>1010-1030</td>
<td>Off</td>
<td>---</td>
</tr>
</tbody>
</table>

switch(config-if-Po103)#

Tool Port Packet Truncation

Tool ports can be configured to truncate outbound packets. The `switchport tool truncation` command configures the configuration mode interface, as a tool port, to truncate outbound packets to 160 bytes. By default, tool ports do not truncate packets.

Tool port packet truncation is supported only on the 7150 series platform.
Examples

- These commands configure ethernet interface 41, as a tool port, to truncate packets on egress to 160 bytes.

  ```
  switch(config)#interface ethernet 41
  switch(config-if-Et41)#switchport mode tool
  switch(config-if-Et41)#switchport tool truncation 160
  switch(config-if-Et41)#
  ```

- These commands configure ethernet interface 41 to send complete packets.

  ```
  switch(config-if-Et41)#no switchport tool truncation
  switch(config-if-Et41)#
  ```

17.3.4 Identity VLAN Tagging

By default, tool port output packets are identical to the replicated packets they receive from the tap ports to which they are associated. Identity tagging modifies packets sent by tool ports by adding a dot1q VLAN tag that identifies the originating tap port. Each tap port is associated with an identity number. Tool ports that are configured to add an identity tag append the originating tap port’s identity number in the outer layer (or s-VLAN) tag.

These procedures describe commands that support identity VLAN tagging

- Tap Port Identity Value Configuration
- Tool Port Identity Tag Configuration

Tap Port Identity Value Configuration

The `switchport tap identity` command configures the tap port identity value for the configuration mode interface. The default identity value for all tap ports is 1.

Example

- These commands configure 1042 as the identity value for Ethernet interface 42.

  ```
  switch(config)#interface ethernet 42
  switch(config-if-Et42)#switchport tap identity 1042
  switch(config-if-Et42)#show interface ethernet 41-43 tap
  Port  Mode  Configured Status  Native Vlan  Id  Truncation Default Group
  Et41  tap  tap          400   1   0  ---
  Et42  tap  tap          1   1042  0  ---
  Et43  tap  tap          1   1   0  ---
  switch(config-if-Et42)#
  ```

Tool Port Identity Tag Configuration

The `switchport tool identity` command configures the configuration mode interface to include a tier 1 VLAN tag (dot1q) to packets it transmits. The VLAN number on the dot1q tag is specified by identity value configured for the tap port that supplies the packets. By default, tool ports do not encapsulate packets with the tier 1 VLAN tag.
Example

- These commands configure port channel 102 to include the identity tag in packets it transmits.

```
switch(config)#interface port-channel 102
switch(config-if-Po102)#switchport tool identity dot1q
```

```
switch(config-if-Po102)#show interface port-channel 101-103 tool
```

<table>
<thead>
<tr>

<td>1010-1015</td>
<td>On ---</td>
</tr>
<tr>
<td>Po103</td>
<td>tool</td>
<td>tool</td>
<td>1010-1030</td>
<td>Off ---</td>
</tr>
</tbody>
</table>

```
switch(config-if-Po102)#
```

17.3.5 Tap Aggregation Group Configuration

Tap aggregation groups associate a set of tap ports with a set of tool ports. Tool port replicates packets it receives from tap ports that are in the aggregation groups to which it belongs. A tap port can be assigned to a maximum of one tap aggregation group. Tool ports may belong to multiple tap aggregation groups. Tap aggregation groups may contain multiple tap ports and multiple tool ports.

These procedures describe commands that configure tap aggregation groups:

- Assigning a Tool Port to Tap Aggregation Groups
- Assigning Tap Ports to a Tap Aggregation Group
- Viewing Tap Aggregation Groups Assignments
- Replication to LAGs in Tool Groups with Multiple Members

Assigning a Tool Port to Tap Aggregation Groups

Tool ports are assigned to tap aggregation group through the `switchport tool group` command. Each command either creates a list or alters the existing list of groups to which a tool port belongs.

```
Example
```

- These commands create the list of tap aggregation groups for port channel interface 101.

```
switch(config)#interface port-channel 101
switch(config-if-Po101)#switchport tool group set analyze1 analyze2 analyze3
```

```
interface Port-Channel101
switchport mode tool
switchport tap identity 2101
switchport tool allowed vlan 1001-1020
switchport tap default group tag-9
switchport tool group set analyze3 analyze1 analyze2
```

```
switch(config-if-Po101)#
```

- These commands remove analyze-1 from port channel 101’s tap aggregation group list.

```
switch(config-if-Po101)#switchport tool group remove analyze1
```

```
interface Port-Channel101
switchport mode tool
switchport tap identity 2101
switchport tool allowed vlan 1001-1020
switchport tap default group tag-9
switchport tool group set analyze3 analyze2
```

```
switch(config-if-Po101)#
```

843
Assigning Tap Ports to a Tap Aggregation Group

Tap ports are assigned to a tap aggregation group through the `switchport tap default group` command. Multiple ports are added to a group by entering interface configuration mode for all interfaces.

Example

- These commands assign Ethernet interface 41 through 43 to tap aggregation groups analyze2 (41 and 42) and analyze3 (43).

```
switch(config)#interface ethernet 41-42
switch(config-if-Et41-42)#switchport tap default group analyze2
switch(config-if-Et41-42)#interface ethernet 43
switch(config-if-Et43)#switchport tap default group analyze3
switch(config-if-Et43)#show interface ethernet 41-43 tap
```

<table>
<thead>

Viewing Tap Aggregation Groups Assignments

Tap aggregation group membership is displayed by `show tap aggregation groups`. Options facilitate the display of individual groups or all configured groups. The command displays active tool and tap ports by default and provides an option to display configured ports that are not active.

Example

- This command displays the contents of all configured tap aggregation groups.

```
switch>show tap aggregation groups
```

<table>
<thead>
<tr>
<th>Group Name</th>
<th>Tool Members</th>
<th>Tap Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>analyze2</td>

<td>Et41, Et42</td>
</tr>
<tr>
<td>analyze3</td>
<td>Po101, Po103</td>
<td>Et43</td>
</tr>
</tbody>
</table>

Replication to LAGs in Tool Groups with Multiple Members

Replication to LAGs in tool groups with multiple members results in traffic load balanced out of all LAG members, regardless whether the LAG is the only member of a tool group.

- This commands changes the system-wide default multicast replication mode.

```
switch(config)#platform sand multicast replication default ingress
switch(config)#
```
17.4 Tap Aggregation Traffic Steering

Traffic steering is a tap aggregation process that uses class maps and policy maps to direct data streams at tool ports that are not otherwise associated to the ingress tap port. A policy map is a data structure that filters data streams upon which identity VLAN tagging or tap aggregation group assignment is implemented.

Tapagg class maps and policy maps are similar to QoS and control plane maps. However, policy maps and their components are not interchangeable among function types.

17.4.1 Tapagg Policies

A policy map filters data packets by using classes and match rules. Each class contains an eponymous class map and a traffic resolution command. Each match rule contains packet content descriptors and a traffic resolution parameter.

- A class map uses ACLs that identify packets that comprise a specified data stream
- Packet content descriptors specify packet field values that are compared to inbound packets.
- A traffic resolution command or parameter specifies data handling methods for filtered traffic.

Each data packet entering an entity to which a policy map is assigned is managed as defined by the traffic resolution command of the highest priority class or rule that matches the packet.

Class maps are user created and can be edited or deleted. They filter traffic with IPv4 ACLs and are listed in `running-config`. Tapagg traffic resolution commands perform one of the following:

- specify a tap aggregation group to direct the packet
- specify a VLAN number for identity tagging the packet.

Tap Aggregation policy maps do not define an implicit deny statement. Packets that do not match a policy map class or rule are replicated and sent out tool ports specified by the default aggregation group assigned to the ingress tap port. If no default group is selected, these packets are dropped.

17.4.2 Configuring Tapagg Traffic Policies

Tapagg traffic policies are implemented by creating class maps and policy maps, then applying the policy maps to Ethernet and port channel interfaces.

Creating Class Maps

A class map is an ordered list of IPv4 access control lists (ACLs). Each ACL is assigned a sequence number that specifies its priority in the class map. Tapagg class maps utilize ACL permit rules to pass packets and deny rules to drop packets.

Class maps are created and modified in class-map configuration mode, which is entered through `class-map type tapagg`. The `match (class-map (tapagg))` command inserts a specified ACL into the class map, assigning it a sequence number that denotes its placement.

Class-map configuration mode is a group-change mode. Changes made in a group-change mode are saved by exiting the mode. The `show active` command displays the saved version of class map. The `exit` command returns the switch to global configuration mode and saves pending class map changes. The `abort` command returns the switch to global configuration mode and discards pending changes.
Examples

- This command creates a tapagg class map named t-class_1 and places the switch in class-map configuration mode.

  ```
  switch(config)#class-map type tapagg match-any t-class_1
  switch(config-cmap-t-class_1)#
  ```

- These commands add two IPv4 ACLs (tacl-1, tacl-2) to the t-class_1 class map. The commands use the default method of assigning sequence numbers to the ACLs.

  ```
  switch(config-cmap-t-class_1)#match ip access-group tacl-1
  switch(config-cmap-t-class_1)#match ip access-group tacl-2
  switch(config-cmap-t-class_1)#
  ```

- These commands exit class-map configuration mode, stores pending changes to running-config, then displays the class map.

  ```
  switch(config-cmap-t-class_1)#exit
  switch(config)#class-map type tapagg match-any t-class_1
  switch(config-cmap-t-class_1)#show active
  class-map type tapagg match-any t-class_1
    10 match ip access-group tacl-1
    20 match ip access-group tacl-2
  switch(config-cmap-t-class_1)#
  ```

Creating Policy Maps

Policy maps are created and modified in policy-map configuration mode. A policy map is an ordered list of classes and match rules. Policy maps are edited by adding or removing map elements. Data packets are managed by commands of the highest priority class or rule that matches the packet.

Classes: Each class contains a class map, a set command, and a sequence number:

- The class map identifies a data stream by using an ordered list of ACLs. Class maps are configured in class-map (tapagg) configuration mode.
- The Set command specifies the replication method for filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- Sequence number specifies the class's priority within the policy map. Lower sequence numbers denote higher priority.

Matching rules: Each rule contains a filter list, an action, and a sequence number:

- The filter list identifies a data stream by using a set of packet field values.
- The action, (SET_VALUE parameter) specifies the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- Sequence number specifies the rule's priority within the policy map. Lower sequence numbers denote higher priority.

Policy-map and policy-map-class configuration modes are group-change modes. Changes are saved with the exit command or discarded with the abort command. The show active and show pending commands display the saved and modified policy map versions, respectively.

The policy-map type tapagg command enters policy-map configuration mode.

Example

- This command creates the tapagg policy map named t-policy_1 and places the switch in policy-map configuration mode.

  ```
  switch(config)#policy-map type tapagg t-policy_1
  switch(config-pmap-t-policy_1)#
  ```
Chapter 17: Tap Aggregation

Tap Aggregation Traffic Steering

The **class (policy-map (tapagg))** command adds a class to the configuration mode policy map and places the switch in policy-map-class configuration mode for adding a traffic resolution command to the class. The **set (policy-map-class (tapagg))** command specifies the data replication method for traffic filtered by the associated class map in the configuration mode policy map. The **set** command specifies one of these replication actions for filtered data packets.

- specifies an aggregation group
- specifies a VLAN identity tag for replicated packets.
- specifies an aggregation group and a VLAN identity tag.

**Example**

- These commands add the **t-class_1** class map to the **t-policy_1** policy map, associate a set statement with class, then saves the policy map by exiting the modes. Packets filtered by the class map are identity tagged with VLAN 444 and replicated as specified by the **t-grp** aggregation group.

```
switch(config-pmap-t-policy_1)#class t-class_1
switch(config-pmap-c-t-policy_1-t-class_1)#set aggregation-group t-grp id-tag 444
switch(config-pmap-c-t-policy_1-t-class_1)#exit
switch(config-pmap-t-policy_1)#exit
```

The **match (policy-map (tapagg))** command adds a match rule to the configuration mode tapagg policy map.

**Example**

- This command enters policy-map configuration mode for **t-policy_1**, then creates a match rule for the policy map that filters OSPF packets and replicates them as specified by **t-grp** tap aggregation group.

```
switch(config-pmap-t-policy_1)#match ip ospf any any set aggregation-group t-grp
```

**Applying Policy Maps to an Interface**

The **service-policy type tapagg (Interface mode)** command applies a specified policy map to the configuration mode interface.

**Example**

- These commands applies the **t-policy_1** policy map to Ethernet interface 17.

```
switch(config)#interface ethernet 17
switch(config-if-Et17)#service-policy type tapagg input t-policy_1
switch(config-if-Et17)#
```
17.5 Tap Aggregation GUI

The switch provides a graphical user interface (GUI) for creating and viewing a tap aggregation configuration and displaying LANZ traffic statistics.

All commands available on the GUI are accessible through the CLI. The tap aggregation configuration created through either the CLI or the GUI can be viewed and modified through either medium.

This section provides a brief description of the tap aggregation GUI.

17.5.1 Accessing the GUI

The URL for the tap-agg GUI is

https://<hostname>/apps/TapAgg/index.html

where <hostname> is the switch's configured hostname. Figure 17-2 displays the initial tap-agg panel for the switch with the hostname ro402.

The tap-agg panel contains two sections:

- The configuration section displays the tap-agg configuration, including the tap interfaces, tool interfaces, and aggregation groups. Links are displayed to indicate interface group membership.
- The component section displays information and control buttons for the active configuration entity. When an entity is not selected, the section displays information for the switch (device).

The configuration section displays tap-agg components only when the switch is in tap aggregation mode. To enter tap aggregation mode, click the Tap Aggregation icon in the component section for the device. The icon is a toggle mechanism; clicking it again disables tag aggregation mode.

Figure 17-2: Tag-Agg GUI Initial Panel
17.5.2 Viewing Tap Aggregation Component Details

Figure 17-3 displays the tap-agg panel when the switch is in tap aggregation mode. The configuration section indicates that the tap aggregation configuration consists of three tool interfaces, one tap interface, and four aggregation groups. Ethernet 10 is the active component; configuration control and traffic information for this interface is available in the component section.

The active component is changed by clicking on the desired component in the configuration section. To display device (switch) information, click on any configuration section outside of any component.

17.5.3 Modifying a Tap Aggregation Configuration

The tap aggregation configuration can be modified only when the switch is in tap-agg mode, (Section 17.5.1). The following is a partial list of configuration tasks that are available from the GUI:

- To add a tap or tool interface: Begin typing the interface name in the desired add interface data entry area to access a drop-down list of available interfaces. Select the desired interface and press the Add button.
- Removing an interface from the configuration: Select the desired interface in the configuration section and click the deconfigure button in that interface’s component section.
- To add an aggregation group: Type the desired name of the new group in the data entry area and press the Add button.
- To add an interface to an aggregation group: Select the desired interface in the configuration section, then press the icon of the group in the group membership area of the interface’s component section.

Group icons are toggle buttons; clicking the icon of a group to which the interface belongs removes that interface from the group.

Figure 17-3: Tag-Agg GUI Panel – Tap aggregation mode enabled
17.6 Keyframe and Timestamp Configuration

17.6.1 Keyframe Generation

Keyframes contain routable IP packets that provide information to relate timestamps with the complete ASIC counter and absolute UTC time. The switch supports a maximum of ten keyframes, which are distinguished by their name label. Each keyframe can egress from every ethernet port.

Keyframe generation is enabled by the `platform fm6000 keyframe` command. Command options specify ports that transmit keyframes along with the destination MAC address and IP address in the keyframe’s header. Other keyframe commands specify the transmission rate and the frame’s source:

- The `platform fm6000 keyframe rate` command configures the keyframe’s transmission rate.
- The `platform fm6000 keyframe source` command configures the source IP address that is placed in each keyframe’s header. The management interface IP address is the default source address.
  
  The source MAC address is the MAC address of the egress interface transmitting the keyframe.
- The `platform fm6000 keyframe device` command configures the 16-bit number that keyframes list as the device ID in their payload.
- The `platform fm6000 keyframe fields skew` command enables the inclusion of clock skew fields in the keyframe.
- The `show platform fm6000 keyframe` command displays keyframe configuration information.

Examples

- This command enables the generation of a keyframe named key-1. This keyframe egresses from Ethernet interfaces 11 through 15, specifies a source IP address of 10.21.1.4 and a MAC address of 10.4E21.9F11.

  
  ```
  switch(config)#platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
  switch(config)#
  ```

- This command configures the generation rate for the keyframe of 10 frames per second on each of the five interfaces that it is configured to egress.

  ```
  switch(config)#platform fm6000 keyframe key-1 rate 10
  switch(config)#
  ```

- These commands enable the generation of a keyframe named key-1, then configures 100 as the value that is placed in the keyframe’s device ID field.

  ```
  switch(config)#platform fm6000 keyframe key-1 device 100
  switch(config)#
  ```

- This command enables the inclusion of clock skew fields in the keyframe named “key-1”.

  ```
  switch(config)#platform fm6000 keyframe key-1 fields skew
  switch(config)#
  ```
17.6.2 Enabling Timestamp Insertion on an Interface

Timestamps are based on a frame’s ingress time and applied to frames sent on egress ports, ensuring that timestamps on monitored traffic reflect ingress timing of the original frames. Time-stamping is configured on the egress port where the timestamp is applied to the frame.

When timestamping is enabled on an egress interface, packets leave the interface with timestamps that were applied in hardware upon arriving at the switch. This is facilitated by applying a hardware timestamp to all frames arriving on all interfaces when timestamping is enabled on any interface, then removing timestamps on packets egressing interfaces where timestamping is not enabled.

The `mac timestamp` command enables time-stamping on the configuration mode interface. The switch supports two timestamp modes, which differ in managing the egress frame’s 32-bit frame check sequence (FCS):

- **before-fcs**: the switch discards the original FCS, appends the ingress timestamp at the end of the frame data, recalculates a new FCS based on the appended timestamp, then appends the new FCS to the end of the frame. This creates a valid Ethernet frame but does not update headers of any nested protocols.
- **replace-fcs**: the switch replaces the original FCS with the timestamp. This mode maintains the size of the original frame without any latency impact, but the FCS is not valid.

**Examples**

- These commands enable timestamping in before-fcs mode on Ethernet interface 44.

  ```
  switch(config)#interface ethernet 44
  switch(config-if-Et44)#mac timestamp before-fcs
  switch(config-if-Et44)#show active
  interface Ethernet44
    mac timestamp before-fcs
  switch(config-if-Et44)#
  ```

- These commands disable timestamping on Ethernet interface 44.

  ```
  switch(config-if-Et44)#no mac timestamp
  switch(config-if-Et44)#show active
  interface Ethernet44
  switch(config-if-Et44)#
  ```
17.7 Tap Aggregation Command Descriptions

Global Configuration Commands
- platform fm6000 keyframe
- platform fm6000 keyframe device
- platform fm6000 keyframe fields skew
- platform fm6000 keyframe rate
- platform fm6000 keyframe source
- tap aggregation

Interface Configuration Commands
- mac timestamp
- switchport tap allowed vlan
- switchport tap default group
- switchport tap identity
- switchport tap native vlan
- switchport tap truncation
- switchport tool allowed vlan
- switchport tool group
- switchport tool identity

Tap Aggregation Configuration Mode
- mode (tap-agg configuration mode)
- mode exclusive no-errdisable (tap-agg configuration mode)

Tap Aggregation Traffic Steering
- class (policy-map (tapagg))
- class-map type tapagg
- match (class-map (tapagg))
- match (policy-map (tapagg))
- policy-map type tapagg
- resequence (class-map (tapagg))
- resequence (policy-map (tapagg))
- service-policy type tapagg (Interface mode)
- set (policy-map-class (tapagg))

Display Commands – EXEC Mode
- show interfaces tap
- show interfaces tool
- show platform fm6000 keyframe
- show tap aggregation groups
**class (policy-map (tapagg))**

The `class` command places the switch in policy-map-class (tapagg) configuration mode, which is a group change mode that defines a tapagg class by associating the class’s eponymous class-map to a set statement. Upon exiting the policy-map-class mode, the class is placed in the policy-map as specified by an assigned sequence number.

A policy map is an ordered list of classes and match rules. Each class contains a class map, a set command, and a sequence number:

- The class map identifies a data stream by using an ordered list of ACLs. Class maps are configured in class-map (tapagg) configuration mode. Data packets are managed by commands of the highest priority class or rule that matches the packet.
- **Set** commands specify the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- **Sequence number** specifies the class’s priority within the policy map. Lower sequence numbers denote higher priority.

The `exit` command returns the switch to policy-map configuration mode. However, saving policy-map-class changes also require an exit from policy-map mode. This saves all pending policy map and policy-map-class changes to `running-config` and returns the switch to global configuration mode. The `abort` command discards pending changes, and returns the switch to global configuration mode.

The `no class` and `default class` commands remove the class assignment from the configuration mode policy map by deleting the corresponding `class` configuration from `running-config`.

**Command Mode**

Policy-Map (tapagg) Configuration
accessed through `policy-map type tapagg`

**Command Syntax**

```
[SEQ_NUM] class class_name
no [SEQ_NUM] class class_name
default [SEQ_NUM] class class_name
```

**Parameters**

- `SEQ_NUM`  Priority of the class within the policy map. Lower numbers denote higher priority.
  - `<no parameter>`  Number is derived by adding 10 to number of the map’s last class or rule.
  - `<1 to 4294967295>`  Number assigned to class.
- `class_name`  name of the class.

**Guidelines**

When a class is not associated with a `set (policy-map-class (tapagg))` command, the filtered traffic is managed as specified by the tap port’s default aggregation group.

**Commands Available in Policy-map-class (tapagg) Configuration Mode**

- `set (policy-map-class (tapagg))` assigns VLAN identity tag or tap aggregation group to class.
- `exit` returns the switch to parent policy map configuration mode.
- `abort` discards pending class map changes, then returns the switch to global configuration mode.

**Related Commands**

- `policy-map type tapagg` places the switch in policy-map (tapagg) configuration mode.
- **match (policy-map (tapagg))** assigns a match rule to a tapagg policy map.

**Example**

- These commands place the switch in policy-map-class and add the **t-class_1** class map to the **t-policy_1** policy map. Packets filtered by the class map are identity tagged with VLAN 444.

```plaintext
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#class t-class_1
switch(config-pmap-c-t-policy_1-t-class_1)#set id-tag 444
switch(config-pmap-c-t-policy_1-t-class_1)#exit
switch(config-pmap-t-policy_1)#exit
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#show active
  policy-map type tapagg t-policy_1
  10 class t-class_1
    set id-tag 444
switch(config-pmap-t-policy_1)#
```
class-map type tapagg

The **class-map type tapagg** command places the switch in class-map (tapagg) configuration mode, which is a group change mode that modifies a tapagg class map. A tapagg class map is a data structure that uses access control lists (ACLs) to define a data stream by specifying characteristics of data packets that comprise the stream. Tapagg policy maps use class maps to specify traffic that is managed by policy map criteria.

The **exit** command saves pending class map changes to **running-config**, then returns the switch to global configuration mode. Class map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes and returns the switch to global configuration mode.

The **no class-map type tapagg** and **default class-map type tapagg** commands delete the specified class map by removing the corresponding **class-map type qos** command and its associated configuration.

**Command Mode**
Global Configuration

**Command Syntax**

```
class-map type tapagg match-any class_name
no class-map type tapagg match-any class_name
default class-map type tapagg match-any class_name
```

**Parameters**
- **class_name** Name of class map.

**Commands Available in Class-Map (tapagg) configuration mode**
- **match** (class-map (tapagg))
- **resequence** (class-map (tapagg))

**Related Commands**
- **policy-map type tapagg**
- **class** (policy-map (tapagg))

**Example**

- This command creates a tapagg class map named **t-class_1** and places the switch in class-map configuration mode.

  ```
switch(config)#class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)#
```
mac timestamp

The `mac timestamp` command enables timestamping on the configuration mode interface.

When timestamping is enabled on an egress interface, packets leave the interface with timestamps that were applied in hardware upon arriving at the switch. This is facilitated by applying a hardware timestamp to all frames arriving on all interfaces when timestamping is enabled on any interface, then removing timestamps on packets egressing interfaces where timestamping is not enabled.

The switch supports two timestamp modes, which differ in managing the egress frame’s 32-bit frame check sequence (FCS):

- `before-fcs`: the switch discards the original FCS, appends the ingress timestamp at the end of the frame data, recalculates a new FCS based on the appended timestamp, then appends the new FCS to the end of the frame. This creates a valid Ethernet frame but does not update headers of any nested protocols.
- `replace-fcs`: the switch replaces the original FCS with the timestamp. This mode maintains the size of the original frame without any latency impact, but the FCS is not valid.

The `no mac timestamp` and `default mac timestamp` commands restore the default behavior of disabling timestamping on the configuration mode interface by removing the corresponding `mac timestamp` command from `running-config`.

Command Mode

Interface-Ethernet Configuration

Command Syntax

```text
mac timestamp TS_PROPERTY
no mac timestamp
default mac timestamp
```

Parameters

- `TS_PROPERTY` Specifies the timestamp insertion mode. Options include:
  - `before-fcs` The ingress timestamp is appended to the frame and the FCS is recalculated.
  - `replace-fcs` The ingress timestamp replaces the original FCS.

Example

- These commands enable timestamping in before-fcs mode on Ethernet interface 44.
  ```text
  switch(config)#interface ethernet 44
  switch(config-if-Et44)#mac timestamp before-fcs
  switch(config-if-Et44)#show active
  interface Ethernet44
    mac timestamp before-fcs
  switch(config-if-Et44)#
  ```

- These commands disable timestamping on Ethernet interface 44.
  ```text
  switch(config-if-Et44)#no mac timestamp
  switch(config-if-Et44)#show active
  interface Ethernet44
  switch(config-if-Et44)#
  ```
**match (class-map (tapagg))**

The `match` command adds an ACL to the configuration mode class map and associates a sequence number to the ACL. A class map is an ordered list of ACLs that define a data stream; the sequence number specifies an ACL's priority within the list. A class map is used by policy maps to filter data packets. Tapagg class maps utilize ACL permit rules to pass packets and deny rules to drop packets.

Class map (tapagg) configuration mode is a group change mode. Match statements are not saved to `running-config` until the edit session is completed by exiting the mode.

The `no match` and `default match` commands remove the specified `match` statement from the configuration mode class map by deleting the corresponding command from `running-config`.

**Command Mode**

Class-map (tagagg) configuration
accessed through `class-map type tapagg` command

**Command Syntax**

```plaintext
[SEQ_NUM] match ip access-group list_name
no [SEQ_NUM] match ip access-group list_name
default [SEQ_NUM] match ip access-group list_name
```

**Parameters**

- `SEQ_NUM` Sequence number assigned to the ACL. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the map's last ACL.
  - `<1 to 4294967295>` Number assigned to ACL.
- `list_name` name of ACL assigned to class map.

**Guidelines**

Match statements accept IPv4 ACLs.

**Related Commands**

- `class-map type tapagg` places the switch in Class-Map configuration mode.
- `exit` saves pending class map changes, then returns the switch to global configuration mode.
- `abort` discards pending class map changes, then returns the switch to global configuration mode.
- `class (policy-map (tapagg))` assigns a class map to a policy map.

**Example**

These commands add two IPv4 ACLs (`tacl-1`, `tacl-2`) to the `t-class_1` class map, saves the command by exiting class-map mode, then re-enters the mode to display the added ACLs.

```plaintext
switch(config)#class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)#match ip access-group tacl-1
switch(config-cmap-t-class_1)#match ip access-group tacl-2
switch(config-cmap-t-class_1)#exit
switch(config)#class-map type tapagg match-any t-class_1
switch(config-cmap-t-class_1)#show active
    class-map type tapagg match-any t-class_1
      10 match ip access-group tacl-1
      20 match ip access-group tacl-2
switch(config-cmap-t-class_1)#
```
match (policy-map (tapagg))

The `match` command adds a rule to the configuration mode tapagg policy map. A policy map is an ordered list of classes and rules. Each rule contains a filter list, an action, and a sequence number:

- The filter list identifies a data stream through a set of packet field values.
- The action, ( `SET_VALUE` parameter) specifies the replication method of filtered data packets, either through an associated aggregation group or identity VLAN tagging.
- `Sequence number` specifies the rule’s priority with the policy map.

The `no match` and `default match` commands remove the `match` rule from the configuration mode policy by deleting the corresponding statement from `running-config`.

**Command Mode**
Policy-Map (tapagg) Configuration
accessed through `policy-map type tapagg`

**Command Syntax**

```
[SEQ_NUM] match [VLAN_TAG] ip SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [PROTOCOL] [FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log] SET_VALUE
```

```
no match [VLAN_TAG] ip SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [PROTOCOL] [FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log] SET_VALUE
```

```
no SEQ_NUM
```

```
default match [VLAN_TAG] ip SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [PROTOCOL] [FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log] SET_VALUE
```

```
default SEQ_NUM
```

Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

**Parameters**

- **SEQ_NUM** Priority of the rule within the policy map. Lower numbers denote higher priority.
  - `<no parameter>` Number derived by adding 10 to number of the map’s last class or rule.
  - `<1 to 4294967295>` Number assigned to class.
- **VLAN_TAG** VLAN field filter. Options include:
  - `<no parameter>` packets are not filtered by VLAN field.
  - `vlan <1 to 4094> <0 to 4095>` VLAN ID and mask.
  - `vlan inner <1 to 4094> <0 to 4095>` VLAN ID and mask.
- **PROTOCOL** protocol field filter. Values include:
  - `<no parameter>` packets are not filtered by host name.
  - `ahp` authentication header protocol (51).
  - `icmp` internet control message protocol (1).
  - `igmp` internet group management protocol (2).
• **ip** internet protocol – IPv4 (4).
• **ospf** open shortest path first (89).
• **pim** protocol independent multicast (103).
• **tcp** transmission control protocol (6).
• **udp** user datagram protocol (17).
• **vrrp** virtual router redundancy protocol (112).
• **protocol_num** integer corresponding to an IP protocol. Values range from 0 to 255.

**SOURCE_ADDR** and **DEST_ADDR** source and destination address filters. Options include:
- **network_addr** subnet address (CIDR or address-mask).
- **any** Packets from all addresses are filtered.
- **host ip_addr** IP address (dotted decimal notation).

Source and destination subnet addresses support discontiguous masks.

**SOURCE_PORT** and **DEST_PORT** source and destination port filters. Options include:
- **any** all ports
- **eq port-1 port-2 ... port-n** A list of ports. Maximum list size is 10 ports.
- **neq port-1 port-2 ... port-n** The set of all ports not listed. Maximum list size is 10 ports.
- **gt port** The set of ports with larger numbers than the listed port.
- **lt port** The set of ports with smaller numbers than the listed port.
- **range port_1 port_2** The set of ports whose numbers are between the range.
- **fragments** filters packets with FO bit set (indicates a non-initial fragment packet).
- **FLAGS** flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
- **MESSAGE** message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
- **tracked** rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **DSCP_FILTER** rule filters packet by its DSCP value. Values include:
  - **<no parameter>** Rule does not use DSCP to filter packets.
  - **dscp dscp_value** Packets match if DSCP field in packet is equal to **dscp_value**.
- **TTL_FILTER** rule filters packet by its TTL (time-to-live) value. Values include:
  - **<no parameter>** Rule does not use TTL field to filter packets.
  - **ttl eq ttl_value** Packets match if **ttl** in packet is equal to **ttl_value**.
  - **ttl gt ttl_value** Packets match if **ttl** in packet is greater than **ttl_value**.
  - **ttl lt ttl_value** Packets match if **ttl** in packet is less than **ttl_value**.
  - **ttl neq ttl_value** Packets match if **ttl** in packet is not equal to **ttl_value**.
  - **log** triggers an informational log message to the console about the matching packet.
    - Valid in ACLs applied to the control plane.
    - Validity in ACLs applied to data plane varies by switch platform.
- **SET_VALUE** specifies the replication method for filtered packets.
  - **set aggregation group agg_group** Replication specified by aggregation group.
- `set id-tag <1 to 4094>` Packet is identity tagged with specified VLAN number.
- `set aggregation group agg_group id-tag <1 to 4094>` Assigns agg group and identity tag.

**Related Commands**
- `policy-map type tapagg` places the switch in policy-map (tapagg) configuration mode.
- `class (policy-map (tapagg))` assigns a class to the configuration mode policy-map.

**Example**
- This command creates a match rule for the `t-policy_1` policy map that filters OSPF packets and replicates them as specified by the `t-group` tap aggregation group.

```
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#match ip ospf any any set aggregation-group t-group
switch(config-pmap-t-policy_1)#exit
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#show active
  policy-map type tapagg t-policy_1
      10 match ip ospf any any set aggregation-group t-group
switch(config-pmap-t-policy_1)#
```
mode (tap-agg configuration mode)

The `mode` command configures the switch's tap aggregation mode. The switch supports these `mode` command options:

- **exclusive**: Tap aggregation mode is enabled. Switching mode is disabled. Tap and tool ports are enabled. Switching ports are errdisabled.

- `<not configured>`: Tap aggregation mode is disabled. Switching mode is enabled. Tap and tool ports are errdisabled. Switching mode ports are enabled.

The default setting enables switching mode and disables tap aggregation mode.

The no `mode` and default `mode` commands disables tap aggregation mode and enables switching mode by removing the mode command from `running-config`.

**Command Mode**

Tap-agg Configuration

**Command Syntax**

```
mode TAP_MODE
no mode TAP_MODE
default mode TAP_MODE
```

**Parameters**

- **TAP_MODE** specifies the switch's switch's tap aggregation mode.
  - **exclusive** tap aggregation is enabled.

**Related Commands**

- **tap aggregation** places the switch in tap-aggregation configuration mode.

**Example**

- These commands place the switch in tap-agg configuration mode and enable tap aggregation mode.

  ```
  switch(config)#tap aggregation
  switch(config-tap-agg)#mode exclusive
  switch(config-tap-agg)#show active
tap aggregation
  mode exclusive
  switch(config-tap-agg)#
  ```

- These commands disable tap aggregation mode by removing the mode command from `running-config`.

  ```
  switch(config-tap-agg)#no mode
  switch(config-tap-agg)#show active
  switch(config-tap-agg)#
  ```
mode exclusive no-errdisable (tap-agg configuration mode)

The **mode exclusive no-errdisable** command configures the specified interface to remain enabled regardless of its switchport mode, when tap aggregation is enabled. This command is used primarily to configure a port to support PTP functions while the switch operates as a tap aggregator.

Each command configures one Ethernet or port channel interface. Subsequent mode exclusive no-errdisable commands add to the list of ports that remain enabled when tap aggregation is enabled.

The **no mode exclusive no-errdisable** and **default mode exclusive no-errdisable** commands configure the specified interface to be errdisabled when programmed in access, trunk, or dot1q-tunnel switching mode when tap aggregation is enabled by removing the corresponding **mode exclusive no-errdisable** command from **running-config**.

**Command Mode**

Tap-agg Configuration

**Command Syntax**

```
mode exclusive no-errdisable INT_NAME
no mode exclusive no-errdisable INT_NAME
default mode exclusive no-errdisable INT_NAME
```

**Parameters**

- **INT_NAME** Interface type and numbers. Options include:
  - **ethernet e_num** Ethernet interface specified by *e_num*.
  - **port-channel p_num** Port-Channel Interface specified by *p_num*.

**Related Commands**

- **tap aggregation** places the switch in tap-aggregation configuration mode.
- **mode (tap-agg configuration mode)** configures the switch’s tap-aggregation mode.

**Example**

- These commands places the switch in tap-agg configuration mode and places Ethernet interface 21/3 in no-errdisable mode.

  ```
  switch(config)#tap aggregation
  switch(config)#mode exclusive
  switch(config-tap-agg)#mode exclusive no-errdisable ethernet 21/4
  switch(config-tap-agg)#
  ```
platform fm6000 keyframe

The platform fm6000 keyframe command enables keyframe generation for data streams transmitted from specified ethernet interfaces. Keyframes are routable IP packets that the switch inserts into a data stream to provide contextual information that correlate timestamps inserted into data packets with absolute UTC time and the switch’s complete ASIC time counter.

The switch supports a maximum of ten keyframes. The keyframe name is the label that distinguishes different keyframes. Each keyframe can egress from every ethernet port. Command options specify the destination MAC address and IP address in the keyframe’s header. Other keyframe commands specify the transmission rate and the frame’s source.

The no platform fm6000 keyframe and default platform fm6000 keyframe commands disable generation of the specified keyframe by deleting the corresponding platform fm6000 keyframe command from running-config. These command also remove all supporting platform fm6000 keyframe commands for the specified keyframe.

Command Mode
Global Configuration

Command Syntax
platform fm6000 keyframe kf_name interface ethernet e_range ipv4_addr mac_addr
no platform fm6000 keyframe kf_name
default platform fm6000 keyframe kf_name

Parameters
- **kf_name** The keyframe’s name.
- **e_range** Ethernet interface range over which the keyframe egresses. Valid formats include number, range, or comma-delimited list of numbers and ranges.
- **ipv4_addr** Destination IPv4 address inserted into keyframes. (Dotted decimal notation)
- **mac_addr** Destination MAC address inserted into keyframes. (48-bit dotted hex notation).

Guidelines
Subsequent issuance of this command for a specified keyframe replaces the existing command in running-config. Ethernet interfaces are inserted into an existing keyframe only by issuing the complete command that identifies all interfaces through which the keyframe is transmitted.

Examples
- This command enables the generation of a keyframe named key-1. This keyframe egresses from Ethernet interfaces 11 through 15, specifies a source IP address of 10.21.1.4 and a MAC address of 10.4E21.9F11.

  switch(config)#platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
  switch(config)#
platform fm6000 keyframe device

The **platform fm6000 keyframe device** command configures the 16-bit number that the specified keyframe lists as the device ID in its payload. By default, the default device value placed in the specified keyframes is 0.

The **no platform fm6000 keyframe device** and **default platform fm6000 keyframe device** commands restore the default device ID insertion value of 0 for the specified keyframe by removing the corresponding **platform fm6000 keyframe device** command from running-config. The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** commands also remove the corresponding **platform fm6000 keyframe device** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

- `platform fm6000 keyframe kf_name device device_id`
- `no platform fm6000 keyframe kf_name device`
- `default platform fm6000 keyframe kf_name device`

**Parameters**

- **kf_name** Keyframe name.
- **device_id** Value inserted in keyframe’s device ID field. Value ranges from 0 to 65535. Default is 0.

**Examples**

- These commands enable the generation of a keyframe named key-1, then configures 100 as the value that is placed in the keyframe’s device ID field.

  ```
  switch(config)#platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
  switch(config)#platform fm6000 keyframe key-1 device 100
  switch(config)#
  ```
platform fm6000 keyframe fields skew

Keyframes may optionally include skew numerator and skew denominator fields. These skew fields form a ratio indicating the ASIC clock skew. If the ratio is greater than 1, the clock is skewed fast; if the ratio is less than 1, the clock is skewed slow. Clock skew fields are omitted by default.

The platform fm6000 keyframe fields skew command enables the inclusion of clock skew fields in the keyframe.

The no platform fm6000 keyframe fields skew and default platform fm6000 keyframe fields skew remove the clock skew fields from the keyframe.

Command Mode
   Global Configuration

Command Syntax
   platform fm6000 keyframe kf_name fields skew
   no platform fm6000 keyframe kf_name fields skew
   default platform fm6000 keyframe kf_name fields skew

Parameters
   • kf_name  Keyframe name.

Examples
   • This command enables the inclusion of clock skew fields in the keyframe named “key-1”.
     switch(config)#platform fm6000 keyframe key-1 fields skew
     switch(config)#
platform fm6000 keyframe rate

The **platform fm6000 keyframe rate** command specifies the transmission rate for the specified keyframe from each interface from which it is configured to egress. By default, one keyframe is sent per second.

The **no platform fm6000 keyframe rate** and **default platform fm6000 keyframe rate** commands restore the default transmission rate for the specified keyframe of one per second by removing the corresponding **platform fm6000 keyframe rate** command from running-config. The **no platform fm6000 keyframe** and **default platform fm6000 keyframe** commands also remove the corresponding **platform fm6000 keyframe rate** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
platform fm6000 keyframe kf_name rate tx_rate
no platform fm6000 keyframe kf_name rate
default platform fm6000 keyframe kf_name rate
```

**Parameters**

- **kf_name** The keyframe's name.
- **tx_rate** Keyframe transmission rate (frames per second). Value ranges from 1 to 100. Default value is 1.

**Examples**

- These commands enable the generation of a keyframe named key-1, then configures the generation rate for the keyframe of 10 frames per second on each of the five interfaces that it is configured to egress.

```
switch(config)#platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
switch(config)#platform fm6000 keyframe key-1 rate 10
switch(config)#
```
platform fm6000 keyframe source

The platform fm6000 keyframe source command configures the source IP address that the specified keyframe lists in its IP header. By default, keyframes use the IP address of the management interface as their source address.

The no platform fm6000 keyframe source and default platform fm6000 keyframe source commands restore the management interface IP address as the specified keyframe’s source IP address by removing the corresponding platform fm6000 keyframe source command from running-config. The no platform fm6000 keyframe and default platform fm6000 keyframe commands also remove the corresponding platform fm6000 keyframe source command from running-config.

Command Mode
Global Configuration

Command Syntax
platform fm6000 keyframe kf_name source ip ipv4_addr
no platform fm6000 keyframe kf_name source ip
default platform fm6000 keyframe kf_name source ip

Parameters
- kf_name    Keyframe’s name.
- ipv4_addr   Keyframe’s source IPv4 address. (Dotted decimal notation – A.B.C.D)

Examples
- These commands enable the generation of a keyframe named key-1, then configures the IP address of keyframes as 10.1.1.101.

  switch(config)#platform fm6000 keyframe key-1 interface ethernet 11-15 10.21.1.4 10.4E21.9F11
  switch(config)#platform fm6000 keyframe key-1 source 10.1.1.101
  switch(config)#
policy-map type tapagg

The **policy-map type tapagg** command places the switch in policy-map (tapagg) configuration mode, which is a group change mode that modifies a tapagg policy map. A tapagg policy map is a data structure that consists of class maps and match statements that filter a specific data stream. Packets in that data stream are either managed as specified by a tap aggregation group or modified to add a VLAN identity tag. Policy maps manage traffic when applied to an Ethernet or port channel interface.

The **exit** command saves pending policy map changes to **running-config** and returns the switch to global configuration mode. Policy map changes are also saved by entering a different configuration mode. The **abort** command discards pending changes, returning the switch to global configuration mode.

The **no policy-map type tapagg** and **default policy-map type tapagg** commands delete the specified policy map by removing the corresponding **policy-map type tapagg** command and the associated policy map statements.

**Command Mode**

Global Configuration

**Command Syntax**

```
policy-map type tapagg map_name
no policy-map type tapagg map_name
default policy-map type tapagg map_name
```

**Parameters**

- `map_name` Name of policy map.

**Commands Available in Policy-Map configuration mode**

- `class (policy-map (tapagg))`
- `match (policy-map (tapagg))`

**Related Commands**

- `class-map type tapaggs`
- `service-policy type tapagg (Interface mode)`

**Example**

- This command creates the tapagg policy map named `t-policy_1` and places the switch in policy-map configuration mode.

```
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#
```
resequence (class-map (tapagg))

The `resequence` command assigns sequence numbers to access control lists (ACLs) in the configuration mode tapagg class map. Sequence numbers denote an ACL’s priority within the class map. Command parameters specify the number of the first ACL and the numeric interval between consecutive ACLs.

Maximum rule sequence number is 4294967295.

Command Mode

Class-map (tagagg) configuration
accessed through `class-map type tapagg` command

Command Syntax

```
resequence [start_num [inc_num]]
```

Parameters

- `start_num` sequence number assigned to the first rule. Default is 10.
- `inc_num` numeric interval between consecutive rules. Default is 10.

Example

- These commands display a policy map whose entities were entered with default sequence numbers, then renumber the contents.

```
switch(config-pmap-t-policy_1)#show active
policy-map type tapagg t-policy_1
  10 match ip ospf any any set aggregation-group t-group
  20 class fred
      set aggregation-group t-group id-tag 444
  30 class t-class_2
      set id-tag 500
  40 class t-class_3
      set id-tag 600
  50 class t-class_4
      set id-tag 700
switch(config-pmap-t-policy_1)#resequence 100 20
switch(config-pmap-t-policy_1)#exit
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#show active
policy-map type tapagg t-policy_1
  100 match ip ospf any any set aggregation-group t-group
  120 class fred
      set aggregation-group t-group id-tag 444
  140 class t-class_2
      set id-tag 500
  160 class t-class_3
      set id-tag 600
  180 class t-class_4
      set id-tag 700
switch(config-pmap-t-policy_1)#
```
resequence (policy-map (tapagg))

The `resequence` command assigns sequence numbers to classes and rules in the configuration mode tapagg policy map. Sequence numbers denote a class or rule’s priority within the policy map. Command parameters specify the number of the first policy map entity and the numeric interval between consecutive entities.

Maximum rule sequence number is 4294967295.

**Command Mode**

Policy-Map (tapagg) Configuration
accessed through `policy-map type tapagg` command

**Command Syntax**

```
resequence [start_num [inc_num]]
```

**Parameters**

- `start_num` sequence number assigned to the first rule. Default is 10.
- `inc_num` numeric interval between consecutive rules. Default is 10.

**Example**

These commands display a policy map whose entities were entered with default sequence numbers, then use the `resequence` command to renumber the contents.

```
switch(config-pmap-t-policy_1)#show active
policy-map type tapagg t-policy_1
  10 match ip ospf any any set aggregation-group t-group
  20 class fred
    set aggregation-group t-group id-tag 444
  30 class t-class_2
    set id-tag 500
  40 class t-class_3
    set id-tag 600
  50 class t-class_4
    set id-tag 700
switch(config-pmap-t-policy_1)#resequence 100 20
switch(config-pmap-t-policy_1)#exit
switch(config)#policy-map type tapagg t-policy_1
switch(config-pmap-t-policy_1)#show active
policy-map type tapagg t-policy_1
  100 match ip ospf any any set aggregation-group t-group
  120 class fred
    set aggregation-group t-group id-tag 444
  140 class t-class_2
    set id-tag 500
  160 class t-class_3
    set id-tag 600
  180 class t-class_4
    set id-tag 700
switch(config-pmap-t-policy_1)#
```
service-policy type tapagg (Interface mode)

The **service-policy type tapagg** command applies a specified tapagg policy map to the configuration mode interface. A policy map is a data structure that identifies data traffic through class maps and match rules, then specifies the method of replicating the traffic. This command is active only when tap aggregation mode is enabled on the switch.

The **no service-policy type tapagg** and **service-policy type tapagg** commands remove the policy map assignment from the configuration mode interface by deleting the corresponding **service-policy tapagg** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
service-policy type tapagg TRAFFIC_DIRECTION policymap_name
no service-policy tapagg TRAFFIC_DIRECTION
default service-policy tapagg TRAFFIC_DIRECTION
```

**Parameters**
- **TRAFFIC_DIRECTION**  IP address or peer group name. Values include:
  - **input**  Policy map applies to inbound packet streams.
  - **map_name**  Name of policy map.

**Guidelines**

A policy map that is attached to a port channel interface takes precedence for member interfaces of the port channel over their individual Ethernet interface configuration. Members that are removed from a port channel revert to the policy map implementation specified by its Ethernet interface configuration.

**Related Commands**
- **policy-map type tapagg** places the switch in policy-map configuration mode to create a policy map.

**Example**
- These commands apply the **t-policy_1** policy map to Ethernet interface 17.

```
switch(config)#interface ethernet 17
switch(config-if-Et17)#service-policy type tapagg input t-policy_1
switch(config-if-Et17)#
```
set (policy-map-class (tapagg))

The `set` command specifies the data replication method for traffic filtered by the associated class map in the configuration mode policy map. The `set` command specifies one of these replication actions for filtered data packets.

- specifies an aggregation group
- specifies a VLAN identity tag for replicated packets.
- specifies an aggregation group and a VLAN identity tag.

The `no set` and `default set` commands remove the specified set command data action from the configuration mode class by deleting the associated `set` command from `running-config`.

Command Mode
Policy-map-class (tapagg) configuration accessed through `class (policy-map (tapagg))` command

Command Syntax
```
set SET_VALUE
no set SET_VALUE
default set SET_VALUE
```

Parameters
- `SET_VALUE` specifies the replication method for filtered packets.
  - aggregation group `agg_group` Replication specified by aggregation group.
  - `id-tag <1 to 4094>` Packet is identity tagged with specified VLAN number.
  - aggregation group `agg_group id-tag <1 to 4094>` Assigns agg group and identity tag.

Related Commands
- `policy-map type tapagg` places the switch in policy-map (tapagg) configuration mode.
- `class (policy-map (tapagg))` assigns a class to the configuration mode policy-map.
- `match (policy-map (tapagg))` assigns a rule to the configuration mode policy-map.

Guidelines
When a class is not associated with a `set` command, the filtered traffic is managed as specified by the tap port’s default aggregation group.

Example
- These commands place the switch in policy-map-class to add the `t-class_1` class map to the `t-policy_1` policy map. Packets filtered by the class map are identity tagged with VLAN 444 and replicated as specified through the `t-group` aggregation group.
  ```
  switch(config)#policy-map type tapagg t-policy_1
  switch(config-pmap-t-policy_1)#class t-class_1
  switch(config-pmap-c-t-policy_1-t-class_1)#set aggregation-group t-group id-tag 444
  switch(config-pmap-c-t-policy_1-t-class_1)#exit
  switch(config-pmap-t-policy_1)#exit
  switch(config)#policy-map type tapagg t-policy_1
  switch(config-pmap-t-policy_1)#show active
  policy-map type tapagg t-policy_1
  10 class t-class_1
  set aggregation-group t-group id-tag 444
  switch(config-pmap-t-policy_1)#
  ```
show interfaces tap

The show interfaces tap command displays tap port configuration information for the specified interfaces.

Command Mode
EXEC

Command Syntax
show interfaces [INTERFACE] tap [INFO_LEVEL]

Parameters
- **INTERFACE** Interface type and numbers. Options include:
  - <no parameter> all interfaces.
  - ethernet *e_range* Ethernet interface range specified by *e_range*.
  - management *m_range* Management interface range specified by *m_range*.
  - port-channel *p_range* Port-Channel Interface range specified by *p_range*.
  Valid *e_range*, *m_range*, and *p_range* formats include number, number range, or comma-delimited list of numbers and ranges.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - <no parameter> command displays table that summarizes tap data.
  - detail command tap data summary table and a list of ACLS applied to tap ports.

Example
- This command displays tap port configuration information for ethernet interfaces 36 through 40.
  ```
  switch> show interface ethernet 31-35 tap
  Port        Configured Mode Status Native Vlan Id Truncation Default Group
  ---------------------------------------------------------------
  Et31        tap          tap 0  301 31  0  tag_1
  Et32        tap          tap 1  132 0  tag_1
  Et33        tap          tap 303 233 0  tag_1
  Et34        tap          tap 1  334 0  tag_3
  Et35        tap          tap 1  345 0  tag_3
  switch>
  ```
- This command displays detailed tap port configuration information for ethernet interface 31.
  ```
  switch> show interface ethernet 31 tap detail
  Port        Configured Mode Status Native Vlan Id Truncation Default Group
  ---------------------------------------------------------------
  Et31        tap          tap 0  301 31  0  tag_1
  Port         ACLs Applied
  ---------------------------------------------------------------
  switch>
  ```
show interfaces tool

The `show interfaces tool` command displays tool port configuration information for the specified interfaces.

**Command Mode**

EXEC

**Command Syntax**

`show interfaces [INTERFACE] tool`

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

Valid `e_range`, `m_range`, and `p_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays tool port configuration information for ethernet interfaces 36 through 40.

```
switch>show interface ethernet 36-40 tool
Port  Configured Status  Allowed  Id  Timestamp
Mode  Vlans   Tag    Mode
-----------------------------------------------
Et36  tool   tool   201-205  Off  None
Et37  tool   tool   201-205  Off  None
Et38  tool   tool   201-205  Off  None
Et39  access errdisabled  All  Off  None
Et40  tool   tool   All    On   None
```

switch>
show platform fm6000 keyframe

The `show platform fm6000 keyframe` command displays configured information for the specified keyframes. Keyframes are routable IP packets that the switch inserts into a data stream to provide contextual information that correlates timestamps inserted into data packets with the absolute UTC time and the switch’s complete ASIC time counter.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show platform fm6000 keyframe [KEYFRAME_ID]
```

**Parameters**
- **KEYFRAME_ID**  Specifies keyframes that the command displays. Options include:
  - <no parameter>  Command displays all configured keyframes.
  - `kf_name`  Name of single keyframe that the command displays.

**Examples**
- This command displays information concerning the three keyframes that the switch sends.
  ```
  switch# show platform fm6000 keyframe
  
  Keyframe key-2
  ------------------------
  Egress Interface(s): Ethernet17, Ethernet18, Ethernet19, Ethernet20, Ethernet21
  Source IP: 10.22.30.144
  Destination IP: 10.21.1.14
  Destination MAC: 00:09:00:09:00:09
  Device ID: 0
  Rate: 5 packet(s) per second
  
  Keyframe key-1
  ------------------------
  Egress Interface(s): Ethernet11, Ethernet12, Ethernet13, Ethernet14, Ethernet15
  Source IP: 10.22.30.146
  Destination IP: 10.21.1.4
  Destination MAC: 00:10:4e:21:9f:11
  Device ID: 0
  Rate: 2 packet(s) per second
  ```
  switch#
**show tap aggregation groups**

The `show tap aggregation groups` command displays the tap and tool port members of the specified tap aggregation groups.

**Command Mode**

EXEC

**Command Syntax**

```
show tap aggregation groups [INFO_LEVEL] [GROUP_NAMES]
```

**Parameters**

- **INFO_LEVEL**  Port information that is displayed.
  - `<no parameter>` command displays active tap and tool ports.
  - `detail` command displays all configured tap and tool ports, including inactive ports.

- **GROUP_NAMES**  Tap aggregation groups. Options include:
  - `<no parameter>` All tap aggregation groups
  - `group_list` Tap aggregation group list.

Valid `group_list` format is a space-delimited list of one or more tap aggregation group names.

**Example**

- This command displays the contents of all configured tap aggregation groups.

```
switch>show tap aggregation groups
Group Name            Tool Members
------------------------------------------
analyze2              Po101, Po102
analyze3              Po101, Po103

Group Name            Tap Members
------------------------------------------
analyze2              Et41, Et42
analyze3              Et43
switch>
```
switchport tap allowed vlan

The switchport tap allowed vlan command creates or modifies the list of VLANs for which the configuration mode interface, in tap mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in running-config without taking effect when the switch is not in tap aggregation mode or the interface is not in tap aggregation mode.

The no switchport tap allowed vlan and default switchport tap allowed vlan commands restore the tap mode default allowed VLAN setting of all by removing the corresponding switchport tap allowed vlan statement from running-config.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

Command Syntax
- switchport tap allowed vlan EDIT_ACTION
- no switchport tap allowed vlan
- default switchport tap allowed vlan

Parameters
- **EDIT_ACTION** modifications to the VLAN list.
  - v_range Creates VLAN list from v_range.
  - add v_range Adds specified VLANs to current list.
  - all VLAN list contains all VLANs.
  - except v_range VLAN list contains all VLANs except those specified.
  - none VLAN list is empty (no VLANs).
  - remove v_range Removes specified VLANs from current list.
  
  Valid v_range formats include number (1 to 4094), range, or comma-delimited list of numbers and ranges.

Example
- These commands create the tap mode allowed VLAN list of 26-30 for Ethernet interface 20.
  
  switch(config)#interface ethernet 20
  switch(config-if-Et20)#switchport tap allowed vlan 26-30
  switch(config-if-Et20)#show active
  interface Ethernet20
      switchport mode tap
  switchport tap allowed vlan 26-30
  switch(config-if-Et20)#

**switchport tap default group**

The `switchport tap default group` command assigns the configuration mode interface as a tap port member to the specified tool group. Tap aggregation groups associate a set of tap ports with a set of tool ports. Both tap ports and tool ports may belong to multiple tap aggregation groups.

The `no switchport tap default group` and `default switchport tap default group` commands remove the configuration mode interface from the tap aggregation group to which it is assigned by deleting the corresponding statement from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```plaintext
switchport tap default group group_name
no switchport tap default group
default switchport tap default group
```

**Parameters**

- `group_name` tool group name.

**Restriction**
This command is only available on FM6000 platform switches.

**Example**

- These commands assign port channel 101 to tap aggregation group `tag-1`.

```plaintext
switch(config)#interface port-channel 101
switch(config-if-Po101)#switchport tap default group tag-1
switch(config-if-Po101)#show interfaces port-channel 101 tap
Port Configured Status Native Id Truncation Default Mode Vlan Vlan Group
-----------------------------------------------------------------------
Po101 access notconnect 1 1 0 tag-1
```

`switch(config)#`
**switchport tap identity**

The `switchport tap identity` command associates a VLAN number to the configuration mode tap interface. Tool ports that are configured to encapsulate packets with an dot1q-style tag enter the number specified by this command as the s-VLAN (tier 1) for packets received from this tap port. The default identity value is 1.

The `no switchport tap identity` and `default switchport tap identity` commands restore VLAN 1 as the configuration mode port's identity vlan by removing the corresponding switchport tap identity command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
```
switchport tap identity port_id
no switchport tap identity
default switchport tap identity
```

**Parameters**
- `port_id` port's identity VLAN. Value ranges from 1 to 4094. Default is 1.

**Related Commands**
- `switchport tool identity` configures a tool port to encapsulate packets received from tap ports.

**Restriction**
This command is available on FM6000 platform switches.

**Example**
- These commands set the identity value for ethernet interface 17.

```
switch(config)#interface ethernet 17
switch(config-if-Et17)#switchport tap identity 17
switch(config-if-Et17)#show active
interface Ethernet17
  switchport tap identity 17

Switch(config-if-Et17)#show interfaces ethernet 17 tap
<table>
<thead>
<tr>
<th>Port</th>
<th>Configured</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et17</td>
<td>access</td>
<td>connected</td>
<td>1</td>
<td>171</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>
```

switch(config-if-Et17)#
**switchport tap native vlan**

The `switchport tap native vlan` command specifies the tap mode native VLAN for the configuration mode interface. Interfaces in tap mode associate untagged frames with the native VLAN. The default native VLAN for all interfaces is VLAN 1. Command settings persist in `running-config` without taking effect when the switch is not in tap aggregation mode or the interface is not in tap mode.

The `no switchport tap native vlan` and `default switchport tap native vlan` commands restore VLAN 1 as the tap mode native VLAN to the configuration mode interface by removing the corresponding switchport tap native vlan command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
switchport tap native vlan v_num
no switchport tap native vlan
default switchport tap native vlan
```

**Parameters**

- `v_num` tap mode native VLAN ID. Value ranges from 1 to 4094. Default is 1.

**Restriction**

This command is available on FM6000 platform switches.

**Example**

- These commands assign VLAN 25 as the tap mode native VLAN for Ethernet interface 7.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#switchport tap native vlan 25
switch(config-if-Et7)#show interface ethernet 7 tap
```

```
Port  Configured Status Native Id  Truncation Default
Mode                          Vlan  Vlan            Group
-----------------------------------------------
Et7   tool    connected  25   1   0          ---
```

switch(config-if-Et7)#
switchport tap truncation

The switchport tap truncation command configures the configuration mode interface, as a tap port, to truncate inbound packets to the specified packet size. This command is in effect when the port is in tap mode and the switch is in tap aggregation mode. Command settings persist in running-config without taking effect when the switch is not in tap aggregation mode or the interface is not in tap mode. By default, tap ports do not truncate inbound packets.

The no switchport tap truncation and default switchport tap truncation commands restore the default behavior of not truncating packets received by the configuration mode interface by removing the corresponding switchport tap truncation command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Port Channel Configuration

Command Syntax
switchport tap truncation packet_size
no switchport tap truncation
default switchport tap truncation

Parameters
• packet_size Size of truncated packets (bytes). Value ranges from 100 to 9236. Default value of 0 corresponds to not truncating packets.

Restriction
This command is available on FM6000 platform switches.

Examples
• These commands configure ethernet interface 38 to truncate packets to 150 bytes.

switch(config)#interface ethernet 38
switch(config-if-Et38)#switchport tap truncation 150
switch(config-if-Et38)#show interface ethernet 38 tap

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured Mode</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et38</td>
<td>access</td>
<td>notconnect</td>
<td>1</td>
<td>1</td>
<td>150</td>
<td>---</td>
</tr>
</tbody>
</table>

• These commands configure ethernet interface 38 to send complete packets to tool ports in its tap aggregation group.

switch(config-if-Et38)#no switchport tap truncation
switch(config-if-Et38)#show interface ethernet 38 tap

<table>
<thead>
<tr>
<th>Port</th>
<th>Configured Mode</th>
<th>Status</th>
<th>Native Vlan</th>
<th>Id</th>
<th>Truncation</th>
<th>Default Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et38</td>
<td>access</td>
<td>notconnect</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>---</td>
</tr>
</tbody>
</table>

switch(config-if-Et38)#
switchport tool allowed vlan

The `switchport tool allowed vlan` command creates or modifies the list of VLANs for which the configuration mode interface, in tool mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in `running-config` without taking effect when the switch is not in tap aggregation mode or the interface is not in tap aggregation mode.

The `no switchport tool allowed vlan` and `default switchport tool allowed vlan` commands restore the tool mode default allowed VLAN setting of `all` by removing the corresponding `switchport tool allowed vlan` statement from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
```
switchport tool allowed vlan EDIT_ACTION
no switchport tool allowed vlan
default switchport tool allowed vlan
```

**Parameters**
- `EDIT_ACTION` modifications to the VLAN list.
  - `v_range` Creates VLAN list from `v_range`.
  - `add v_range` Adds specified VLANs to current list.
  - `all` VLAN list contains all VLANs.
  - `except v_range` VLAN list contains all VLANs except those specified.
  - `none` VLAN list is empty (no VLANs).
  - `remove v_range` Removes specified VLANs from current list.

Valid `v_range` formats include number, range, or comma-delimited list of numbers and ranges.

**Example**
- These commands create the tool mode allowed VLAN list of 16-20 for Ethernet interface 38.
  ```
  switch(config)#interface ethernet 38
  switch(config-if-Et38)#switchport tool allowed vlan 16-20
  switch(config-if-Et38)#show interfaces ethernet 38 tool
  Port  Configured  Status  Allowed       Id    Timestamp
       Mode      Vlans        Tag  Mode
  -----------------------------------------------------------------------
  Et38  access     notconnect 16-20     Off   None
  switch(config-if-Et38)#
  ```
switchport tool group

The `switchport tool group` command modifies the configuration mode interface’s tool port membership in the specified tap aggregation groups. Tool ports may belong to multiple tap aggregation groups. Command options for configuring a port’s tap aggregation group membership include:

- specify the groups to which the port belongs (supersedes the port’s previous group memberships).
- add to the list of groups to which the port is a member.
- delete from the list of groups to which the port is a member.

Tap aggregation groups associate a set of tap ports with a set of tool ports. A tap port can belong to a maximum of one default tap aggregation group.

The `no switchport tool default group` and `default switchport tool default group` commands remove the configuration mode interface from all tap aggregation groups to which it is assigned as a tool port by modifying the corresponding statements in `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
```
switchport tool group EDIT_ACTION
no switchport tool group
default switchport tool group
```

**Parameters**
- `EDIT_ACTION` specifies changes to the list of groups to which interface is a member.
  - `add group_list` Specifies additional groups to which port belongs.
  - `remove group_list` Removes interface as a tool port member from specified groups.
  - `set group_list` Specifies groups to which interface belongs as a tool port.

Valid `group_list` format is a space-delimited list of one or more tap aggregation group names.

**Restriction**
This command is available on FM6000 platform switches.

**Example**
- These commands associate interface ethernet 40 with three tap aggregation groups.
  ```
  switch(config)#interface ethernet 40
  switch(config-if-Et40)#switchport tool group set tag-1 tag-2 tag-3
  switch(config-if-Et40)#show active
  interface Ethernet40
      switchport tool group set tag-3 tag-2 tag-1
  switch(config-if-Et40)#
  ```
- These commands add tag-7 to the tap aggregation groups of which ethernet interface 40 belongs.
  ```
  switch(config-if-Et40)#switchport tool group add tag-7
  switch(config-if-Et40)#show active
  interface Ethernet40
      switchport tool group set tag-3 tag-7 tag-2 tag-1
  switch(config-if-Et40)#
  ```
• These commands specify tag-9 as the only group of which ethernet interface 40 is a member.

```
switch(config-if-Et40)#switchport tool group set tag-9
switch(config-if-Et40)#show active
interface Ethernet40
    switchport tool group set tag-9
switch(config-if-Et40)#
```
switchport tool identity

The `switchport tool identity` command configures the configuration mode interface to include a tier 1 VLAN tag (dot1q) to packets it receives from tap ports. The VLAN number on the dot1q tag is specified by the `switchport tap identity` command configured for the tap port that supplies the packets. By default, tool ports do not encapsulate packets with the tier 1 VLAN tag.

The `no switchport tool identity` and `default switchport tool identity` commands restore the default VLAN handling method for the configuration mode interface by removing the corresponding `switchport tool identity` statement from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**

```
switchport tool identity dot1q
no switchport tool identity
default switchport tool identity
```

**Restriction**
This command is available on FM6000 platform switches.

**Example**
- These commands configure ethernet interface 40 to include a dot1q tag on egress packets.

```
switch(config)#interface ethernet 40
switch(config-if-Et40)#switchport tool identity dot1q
switch(config-if-Et40)#show active
interface Ethernet40
  switchport mode tool
  switchport tool identity dot1q
  switchport tool group set tag-9
switch(config-if-Et40)#
```
switchport tool truncation

The `switchport tool truncation` command configures the configuration mode interface, as a tool port, to truncate outbound packets to 160 bytes. This command is in effect when the port is in tool mode and the switch is in tap aggregation mode. Command settings persist in `running-config` without taking effect when the switch is not in tap aggregation mode or the interface is not in tool mode. By default, tool ports do not truncate outbound packets.

The `no switchport tool truncation` and `default switchport tool truncation` commands restore the default behavior (not truncating packets that exit the configuration mode interface) by removing the corresponding `switchport tool truncation` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
- `switchport tool truncation packet_size`
- `no switchport tool truncation`
- `default switchport tool truncation`

**Parameters**
- `packet_size` Size of truncated packets in bytes. The only permitted value is 160.

**Examples**
- These commands configure ethernet interface 38, as a tool port, to truncate packets on egress to 160 bytes.
  ```
  switch(config)#interface ethernet 38
  switch(config-if-Et38)#switchport mode tool
  switch(config-if-Et38)#switchport tool truncation 160
  switch(config-if-Et38)#
  ```
- These commands configure ethernet interface 38 to send complete packets.
  ```
  switch(config-if-Et38)#no switchport tool truncation
  switch(config-if-Et38)#
  ```
tap aggregation

The tap aggregation command places the switch in tap-agg configuration mode. The switch’s tap aggregation mode is enabled or disabled by the mode command in tap-agg configuration mode.

When tap aggregation mode is enabled, normal switching and routing operations are disabled. A port’s switchport status depends on the switch’s tap aggregation mode and the port’s switchport mode:

- tap aggregation mode enabled: tap and tool ports are enabled. Switching ports are errdisabled.
- tap aggregation mode disabled: tap and tool ports are errdisabled. Switching ports are enabled.

The no tap aggregation and default tap aggregation commands disable tap aggregation mode on the switch by removing all tap-agg configuration mode commands from running-config.

Tap-agg configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting tap-agg configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
- tap aggregation
- no tap aggregation
- default tap aggregation

Commands Available in Tap Aggregation Configuration Mode
- mode (tap-agg configuration mode)
- switchport mode

Related Commands
- switchport mode

Example
- These commands place the switch in tap-agg configuration mode and enables tap aggregation mode.
  switch(config)#tap aggregation
  switch(config-tap-agg)#mode exclusive
  switch(config-tap-agg)#show active
  tap aggregation
  mode exclusive
  switch(config-tap-agg)#

- These commands disables tap aggregation mode by removing all tap-agg configuration mode commands from running-config.
  switch(config)#no tap aggregation
  switch(config)#
This chapter describes Arista’s VLAN implementation and MAC address tables.

Sections in this chapter include:

- Section 18.1: VLAN Introduction
- Section 18.2: VLAN Conceptual Overview
- Section 18.3: VLAN Configuration Procedures
- Section 18.4: VLAN Configuration Commands

18.1 VLAN Introduction

Arista switches support industry standard 802.1q VLANs. Arista EOS provides tools to manage and extend VLANs throughout the data center network.

18.2 VLAN Conceptual Overview

18.2.1 VLAN Definition

A virtual local area network (VLAN) allows a group of devices to communicate as if they were in the same network regardless of their physical location. VLANs are layer 2 structures based on the 802.1Q standard.

These parameters are associated with a VLAN:

- VLAN number (1-4094): VLAN numbers uniquely identify the VLAN within a network. VLAN 1 exists by default; all other VLANs only exist after they are configured.
- VLAN name (optional): The VLAN name is a text string that describes the VLAN.
- VLAN state (active or suspended): The state specifies the VLAN transmission status within the switch. In the suspended state, VLAN traffic is blocked on all switch ports. The default state is active.

VLANs define layer 2 broadcast domains in a layer 2 network, in which each device can receive broadcast frames sent by any other within the domain. Switches accommodating multiple broadcast domains serve as multi-port bridges where each broadcast domain is a distinct virtual bridge. Traffic does not pass directly between different VLANs within a switch or between two switches.

18.2.2 VLAN Switching

Ethernet and port channel interfaces are configured as switched ports by default. Switched ports are configurable as members of one or more VLANs. Switched ports ignore all IP-level configuration commands, including IP address assignments.
18.2.2.1 VLAN Trunking and Trunk Groups

Trunking extends multiple VLANs beyond the switch through a common interface or port channel. A trunk group is the set of physical interfaces that comprise the trunk and the collection of VLANs whose traffic is carried on the trunk. The traffic of a VLAN that belongs to one or more trunk groups is carried only on ports that are members of trunk groups to which the VLAN belongs, i.e., VLANs configured in a trunk group are 'pruned' off all ports that are not associated with the trunk group. See the Trunk Ports example section for further details.

**Important!** Be cautious when using allowed VLAN lists or trunk groups to ensure that the VLAN topology is consistent with any Layer-2 control protocol topology, or unpredictable results can occur.

VLAN traffic is carried through Ethernet or LAG ports. A port's switchport mode defines the number of VLANs for which the port can carry traffic.

- Access ports carry traffic for one VLAN – the access VLAN. Access ports associate untagged frames with the access VLAN. Access ports drop tagged frames that are not tagged with the access VLAN.
- Trunk ports carry traffic for multiple VLANs. Tag frames specify the VLAN for which trunk ports process packets.

18.2.2.2 Q-in-Q Trunking

A Q-in-Q network is a multi-tier layer 2 VLAN network. A typical Q-in-Q network is composed of a service provider network (tier 1) where each node connects to a customer network (tier 2). 802.1ad is a networking standard that supports Q-in-Q networks by allowing multiple 802.1Q tags in an Ethernet frame.

Each interface in a customer network is assigned to a customer-VLAN (c-VLAN). Packets in c-VLANs contain 802.1q tags that switch traffic within the network. c-VLANs access the service provider VLAN (s-VLAN) through a provider switch. Customer switch ports connect to an s-VLAN through provider switch edge ports, which are configured as dot1q ports and operate as follows:

- Inbound traffic (from customer switches): adds an s-VLAN tag, then forwards packets to the provider network.
- Outbound traffic (to customer switches): removes the s-VLAN tag, then forwards packets to the customer network.

18.2.2.3 TPID (Configurable Ethertypes)

By default, VLAN-tagged packets carry a tag protocol identifier (TPID) of 0x8100. On some Arista platforms, however, the TPID of a switchport can be modified in accordance with IEEE 802.1ad to allow for the use of 802.1q TPIDs other than 0x8100. Well known and standard tags include:

- **0x8100** customer VLAN
- **0x88a8** service VLAN tag used in provider bridging
- **0x9100** service VLAN tag used in provider bridging (common, but not standardized)

Other non-standard TPID values may also be configured for interoperability with legacy equipment or non-standard systems. Values range from 0x600 (1536) through 0xFFFF (65535).

Non-default TPID values are most commonly used for provider bridging on a network-to-network interface.
18.2.3 VLAN Routing

Each VLAN can be associated with a switch virtual interface (SVI), also called a VLAN interface. The VLAN interface functions in a routed network (layer 3) with an assigned IP subnet address. Connecting different VLANs requires layer 3 networking.

18.2.3.1 VLAN Interfaces

A switched virtual interface (SVI) connects to the VLAN segment on the switch to provide layer 3 processing for packets from the VLAN. An SVI can be activated only after it is connected to a VLAN. SVIs are typically configured for a VLAN to a default gateway for a subnet to facilitate traffic routing with other subnets.

In a layer 3 network, each VLAN SVI is associated with an IP subnet, with all stations in the subnet members of the VLAN. Traffic between different VLANs is routed when IP routing is enabled.

18.2.3.2 Internal VLANs

A routed port is an Ethernet or port channel interface that functions as a layer 3 interface. Routed ports do not bridge frames nor switch VLAN traffic. Routed ports have IP addresses assigned to them and packets are routed directly to and from the port.

The switch allocates an internal VLAN for an interface when it is configured as a routed port. The internal VLAN is assigned a previously unused VLAN ID. The switch prohibits the subsequent configuration of VLANs and VLAN interfaces with IDs corresponding to allocated internal VLANs.

18.2.3.3 VLAN Translation

VLAN translation allows you to map packets from one VLAN to another.
18.3 VLAN Configuration Procedures

These sections describe basic VLAN configuration tasks.

- Section 18.3.1: Creating and Configuring VLANs
- Section 18.3.2: Configuring VLAN Switching
- Section 18.3.3: Creating and Configuring VLAN Interfaces
- Section 18.3.4: Allocating Internal VLANs
- Section 18.3.5: VLAN Translation

18.3.1 Creating and Configuring VLANs

The CLI provides two methods of creating VLANs.

- Explicitly through the `vlan` command.
- Implicitly through the `switchport access vlan` command.

The `switchport access vlan` command generates a warning message when it creates a VLAN.

To create a VLAN, use the `vlan` command in global configuration mode. Valid VLAN numbers range between 1 and 4094. To create multiple VLANs, specify a range of VLAN numbers.

To edit an existing VLAN, enter the `vlan` command with the number of the existing VLAN.

**Example**

- This command creates VLAN 45 and enters VLAN configuration mode for the new VLAN.

```
switch(config)#vlan 45
switch(config-vlan-45)#
```

Use the `name (VLAN configuration mode)` command to assign a name to a VLAN.

**Example**

- These commands assign the name Marketing to VLAN 45.

```
switch(config)#vlan 45
switch(config-vlan-45)#name Marketing
switch(config-vlan-45)#show vlan 45
```

```
VLAN Name                             Status    Ports
---- -------------------------------- --------- ------------------------
45   Marketing                        active    Et1
```

```
switch(config-vlan-45)#
```

To change a VLAN’s state, use the `state` command in VLAN configuration mode.

**Examples**

- These commands suspend VLAN 45. VLAN traffic is blocked on all switch ports.

```
switch(config)#vlan 45
switch(config-vlan-45)#state suspend
switch(config-vlan-45)#show vlan 45
```

```
VLAN Name                             Status    Ports
---- -------------------------------- --------- ------------------------
45   Marketing                        suspended
```

```
switch(config-vlan-45)#
```
These commands activate VLAN 45.

```
switch(config)#vlan 45
switch(config-vlan-45)#state active
switch(config-vlan-45)#show vlan 45
```

<table>
<thead>
<tr>
<th>VLAN Name</th>
<th>Status</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>active</td>
<td>E1</td>
</tr>
</tbody>
</table>

```
switch(config-vlan-45)#
```

### 18.3.2 Configuring VLAN Switching

The following describe the configuration of VLAN ports.

#### 18.3.2.1 Access Ports

Access ports carry traffic for one VLAN, as designated by a `switchport access vlan` command. Access ports associate untagged frames with the access VLAN. Tagged frames received by the interface are dropped unless they are tagged with the access VLAN.

To configure an interface group as an access port, use the `switchport mode` command.

**Example**

- These commands configure Ethernet interface 1 as an access port.

```
switch(config)#interface ethernet 1
switch(config-if-Et1)#switchport mode access
switch(config-if-Et1)#
```

To specify the port's access VLAN, use the `switchport access vlan` command.

**Examples**

- These commands configure VLAN 15 as the access VLAN for Ethernet interface 5.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport access vlan 15
switch(config-if-Et5)#
```

- These commands configure Ethernet interface 1 through 3 as access ports that process untagged frames as VLAN 5 traffic.

```
switch(config)#interface Ethernet 1-3
switch(config-if-Et1-3)#switchport mode access
switch(config-if-Et1-3)#switchport access vlan 5
```

```
switch(config-if-Et1-3)#show interfaces ethernet 1-3 vlans

<table>
<thead>
<tr>
<th>Port</th>
<th>Untagged Tagged</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1</td>
<td>None 23,25</td>
</tr>
<tr>
<td>Et2</td>
<td>18     -</td>
</tr>
<tr>
<td>Et3</td>
<td>None 14</td>
</tr>
</tbody>
</table>
```

```
switch(config-if-Et1-3)#
```

#### 18.3.2.2 Trunk Ports

Trunk ports carry traffic for multiple VLANs. Messages use tagged frames to specify the VLAN for which trunk ports process traffic.

- The `vlan trunk list` specifies the VLANs for which the port handles tagged frames. The port drops any packets tagged for VLANs not in the VLAN list.
- The `native vlan` is the VLAN where the port switches untagged frames.
To configure an interface group as a trunk port, use the `switchport mode` command.

**Example**

- These commands configure Ethernet interface 8 as a trunk port.

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#switchport mode trunk
switch(config-if-Et8)#
```

By default all VLANs are permitted on a port configured with ‘switchport mode trunk’. To limit the port's VLAN trunk list, use the `switchport trunk allowed vlan` command. Only VLANs in the allowed list will be permitted.

**Examples**

- These commands configure VLAN 15, 20, 21, 22, 40, and 75 as the explicitly permitted VLAN trunk list for Ethernet interface 12-16.

```
switch(config)#interface ethernet 12-16
switch(config-if-Et12-16)#switchport trunk allowed vlan 15,20-22,40,75
switch(config-if-Et12-16)#
```

- These commands explicitly permit VLAN 100 through 120 to the VLAN trunk list for Ethernet interface 14.

```
switch(config)#interface ethernet 14
switch(config-if-Et14)#switchport trunk allowed vlan add 100-120
switch(config-if-Et14)#
```

To specify the port’s native VLAN, use the `switchport trunk native vlan` command.

**Example**

- These commands configure VLAN 12 as the native VLAN trunk for Ethernet interface 10.

```
switch(config)#interface ethernet 10
switch(config-if-Et10)#switchport trunk native vlan 12
switch(config-if-Et10)#
```

By default, ports send native VLAN traffic with untagged frames. The `switchport trunk native vlan` command can also configure the port to send native VLAN traffic with tag frames.

**Examples**

- These commands configure Ethernet interface 10 to send native VLAN traffic as tagged.

```
switch(config)#interface ethernet 10
switch(config-if-Et10)#switchport trunk native vlan tag
switch(config-if-Et10)#
```

- These commands configure Ethernet interface 12 as a trunk with VLAN 15 as the native VLAN. The port’s trunk list includes all VLANs except 201-300.

```
switch(config)#interface ethernet 12
switch(config-if-Et12)#switchport trunk mode trunk
switch(config-if-Et12)#switchport trunk native vlan 15
switch(config-if-Et12)#switchport trunk allowed vlan except 201-300
switch(config-if-Et12)#
```
Example

- Assume that all ports on the switch are configured with switchport mode trunk similar to ethernet 1 and 2 shown below:

```
! interface ethernet 1
  switchport mode trunk
!
interface ethernet 2
  switchport mode trunk
!
```

Further assume that VLAN 30 is not configured as part of a trunk group

```
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- -------------------------------
 1     default                          active    Et1, Et2
30    vlan30                           active    Et1, Et2
```

Now configure VLAN 30 as part of trunk group 30:

```
switch(config)#vlan 30
switch(config-vlan-30)#trunk group 30
```

This updates the VLAN membership for VLAN 30.

```
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- -------------------------------
 1     default                          active    Et1, Et2
30    vlan30                           active    Et1, Et2
```

**Note:** Vlan 30 is no longer on Et1, Et2 i.e. it has been 'pruned' due to the trunk group command in the vlan configuration.

To permit VLAN 30 on Et1 you need to associate the interface with the trunk group as follows:

```
switch(config-if-Et1)#switchport trunk group 30
```

Now we see Et1 included in the vlan 30 list

```
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- -------------------------------
 1     default                          active    Et1, Et2
30    vlan30                           active    Et1
```

The trunk group command is not additive to the allowed vlan command

```
interface ethernet 1
  switchport mode trunk
  switchport trunk allowed vlan 10
  switchport trunk group trunk30
```

Vlan 30 will not be permitted on the interface as it is not listed in the allowed vlan list.
**18.3.2.3 Dot1q Tunnel Ports**

Dot1q (802.1Q) is a tunneling protocol that encapsulates traffic from multiple customer (c-tag) VLANs in an additional single outer service provider (s-tag) VLAN for transit across a larger network structure that includes traffic from all customers. Tunneling eliminates the service provider requirement that every VLAN be configured from multiple customers, avoiding overlapping address space issues.

Tunneling preserves the inner VLANs through the tunneled network; these inner VLANs are ignored by intermediate devices that make forwarding decisions based only on the outermost VLAN tag (S-Tag).

A dot1q-tunnel port sits at the edge of the tunneled network. Unlike regular access ports, a dot1q-tunnel port does not drop traffic that arrives with 802.1Q tags in place; it ignores existing 802.1Q information and associates arriving traffic (with or without 802.1Q headers) with a new tunnel VLAN ID.

Packets arriving at a tunnel port are encapsulated with an additional 802.1Q tag that can be trunked between multiple devices like any traditional VLAN. When exiting a dot1-tunnel port, the S-Tag is removed to revert the customer traffic to its original tagged or untagged state.

To configure an interface group as a dot1q tunnel port, use the `switchport mode` command.

**Example**

```
 These commands configure Ethernet interface 12 as a dot1q tunnel port.

 switch(config)#interface ethernet 12
 switch(config-if-Et12)#switchport mode dot1q-tunnel
 switch(config-if-Et12)#
```

To specify the dot1q-tunnel port’s access VLAN, use the `switchport access vlan` command. The port then handles all inbound traffic as untagged VLAN traffic.

**Example**

```
 These commands configure VLAN 60 as the access VLAN for Ethernet interface 12.

 switch(config)#interface ethernet 12
 switch(config-if-Et12)#switchport access vlan 60
 switch(config-if-Et12)#
```

**18.3.2.4 TPID Configuration**

The default tag protocol identifier (TPID, also called dot1q ethertype) on all switch ports is 0x8100. To configure a different TPID on a port, use the `switchport dot1q ethertype` command. This feature is available only on 7280E and 7500E platforms.

**Important!** If dot1q tunneling is enabled on the interface, a TPID configured on the interface becomes irrelevant.

**Example**

```
 These commands configure VLAN 60 as the access VLAN for Ethernet interface 12.

 switch(config)#interface ethernet 12
 switch(config-if-Et12)#switchport mode dot1q-tunnel
 switch(config-if-Et12)#interface ethernet 2
 switch(config-if-Et2)#switchport mode trunk
 switch(config-if-Et2)#switchport dot1q ethertype 0x9100
 switch(config-if-Et2)#
```
In the above configuration, packets from Et1 to Et2 will undergo dot1q-tunneling (stacking of an additional dot1q tag), with an outer TPID of 0x9100 at egress, while packets with outer TPID 0x9100 going from Et2 to Et1 will have the outer tag removed at egress.

18.3.2.5 Layer 2 802.1Q Encapsulation

Layer 2 traffic encapsulation is enabled on the configuration mode interface for a specified VLAN through `l2-protocol encapsulation dot1q vlan`.

**Example**
- These commands enable traffic encapsulation for VLAN 200 traffic passing through Ethernet interface 2/5.

```
switch(config)#interface ethernet 5/2
switch(config-if-Et5/2)#l2-protocol encapsulation dot1q vlan 200
```

18.3.3 Creating and Configuring VLAN Interfaces

The `interface vlan` command places the switch in VLAN-interface configuration mode for modifying an SVI. An SVI provides a management address point and Layer 3 processing for packets from all VLAN ports.

**Example**
- This command enters VLAN-interface configuration mode for VLAN 12. The command also creates VLAN 12 interface if it was not previously created.

```
switch(config)#config t
switch(config)#interface vlan 12
switch(config-if-Vl12)#
```

18.3.4 Allocating Internal VLANs

The `vlan internal allocation policy` command specifies the VLANs that the switch allocates as internal VLANs when configuring routed ports and the order of their allocation. By default, the switch allocates VLANs in ascending order. The default allocation range is between VLAN 1006 and VLAN 4094.

The `no switchport` command converts an Ethernet or port channel interface into a routed port, disabling layer 2 switching for the interface.

**Examples**
- This command configures the switch to allocate internal VLANs in ascending order starting with 1006.

```
switch(config)#vlan internal allocation policy ascending
switch(config)#
```

- This command configures the switch to allocate internal VLANs in descending order starting with 4094.

```
switch(config)#vlan internal allocation policy descending
switch(config)#
```

- This command configures the switch to allocate internal VLANs in descending order from 4094 through 4000.

```
switch(config)#vlan internal allocation policy descending range 4000 4094
switch(config)#
```
18.3.5 VLAN Translation

VLAN translation allows you to map packets from one VLAN to another. This can be carried out only on packets having a dot1q header (tagged frames). The translation rewrites the VID field (VLAN ID) in dot1q headers on packets passing through a switched port without changing any other fields.

VLAN translation also supports the ability to translate packets with a dot1q header to the internal VLAN for a routed port. The VLAN in the incoming packets is mapped to the internal VLAN of the routed port and packets egressing the routed port are encapsulated with a dot1q header for the specified VLAN. For egress packets, no priority information is added to the dot1q header and the priority from the incoming encapsulation will be retained.

When configuring the VLAN translation mode, consider the following:

- VLAN translation is only supported for tagged packets.
- BPDUs from STP, LLDP and other protocols are not affected by this mapping.
- VLAN translation is not applicable for access ports.
- Untagged packets entering the switch on the trunk native VLAN are not mapped.
- TPID and VLAN priority does not get re-written during the translation.

Per-port VLAN Translation on Switched Ports

The `switchport vlan mapping` command allows translation of the VLAN tag of traffic entering or exiting a switched port.

To use VLAN translation on a switched port, the port must be configured as a trunk port using the `switchport mode` command.

Example

- This command configures Ethernet interface 5 as a trunk port.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport mode trunk
  ```

By default, the translation is bidirectional: packets ingressing an interface through VLAN A are internally mapped to VLAN B; VLAN B packets egressing the same interface are mapped to VLAN A.

Examples

- These commands map Ethernet interface 5 traffic with dot1q tag 50 to bridging VLAN 60.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)# switchport vlan mapping 50 60
  ```

- These commands provides multiple 1:1 VLAN mappings under an interface.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)# switchport vlan mapping 50 60
  switch(config-if-Et5)# switchport vlan mapping 61 71
  switch(config-if-Et5)# switchport vlan mapping 62 72
  ```

- These commands translate only incoming packets.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)# switchport vlan mapping in 50 60
  ```
• These commands translate only egress packets.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport vlan mapping out 60 50
switch(config-if-Et5)#
```

**Per-port VLAN Translation on Routed Ports**

On routed ports, the `encapsulation dot1q vlan` command (permitted only on routed ports) configures the VLAN on the interface to act as the native VLAN. This command will map packets ingressing with the specified VLAN ID to the internal VLAN ID of the routed port. All traffic egressing out of the routed port will be tagged with the VLAN ID specified in the command.

**Examples**

• These commands translate between VLAN 50 and the internal VLAN for Ethernet interface 5 (a routed port).

```
switch(config)#interface ethernet 5
switch(config-if-Et5)# no switchport
switch(config-if-Et5)# encapsulation dot1q vlan 50
switch(config-if-Et5)#
```
18.4 VLAN Configuration Commands

Global VLAN Configuration Commands
- interface vlan
- vlan
- vlan internal allocation policy

VLAN Configuration Mode Commands
- name (VLAN configuration mode)
- state
- trunk group

Layer 2 Interface (Ethernet and Port Channel) Configuration Commands
- switchport access vlan
- switchport mode
- switchport trunk allowed vlan
- switchport trunk group
- switchport trunk native vlan
- switchport vlan mapping

VLAN Interface Configuration Mode Commands
- autostate
- encapsulation dot1q vlan
- l2-protocol encapsulation dot1q vlan

Show Commands
- show dot1q-tunnel
- show interfaces switchport
- show interfaces switchport backup
- show interfaces trunk
- show interfaces vlans
- show vlan
- show vlan dynamic
- show vlan internal allocation policy
- show vlan internal usage
- show vlan summary
- show vlan trunk group
autostate

When autostate is *enabled*, the VLAN interface will be up when:

- the corresponding VLAN exists and is in the active state.
- one or more layer 2 ports in the VLAN are up and in spanning-tree forwarding state.
- the VLAN interface exists and is not in a shutdown state.

Autostate is *enabled* by default. When autostate is *disabled*, the VLAN interface is forced to be active.

- The **no autostate** command disables autostate on the configuration mode interface. The **no autostate** command is stored to *running-config*.
- The **autostate** command enables the autostate function on the configuration mode VLAN SVI by removing the corresponding **no autostate** statement from *running-config*.
- The **default autostate** command restores the autostate default state of *enabled* by removing the corresponding **no autostate** statement from *running-config*.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

```
autostate
no autostate
default autostate
```

**Guidelines**

Autostate should be disabled on SVIs configured as an MLAG local interface.

**Examples**

- These commands disable autostate on VLAN 100.
  
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#no autostate
  switch(config-if-Vl100)#
  ```

- These commands enable autostate on VLAN 100.
  
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#autostate
  switch(config-if-Vl100)#
  ```
encapsulation dot1q vlan

Routed Port VLAN Translation

In the configuration mode for an Ethernet or port channel interface, the **encapsulation dot1q vlan** translates packets with a dot1q header to the internal VLAN for a routed port. The VLAN in the incoming packets is mapped to the internal VLAN of the routed port, and packets egressing the routed port are encapsulated with a dot1q header for the specified VLAN. For egress packets, no priority information is added to the dot1q header and the priority from the incoming encapsulation will be retained.

Subinterface VLAN Assignment

When used in the configuration mode for an Ethernet or port channel subinterface, however, the **encapsulation dot1q vlan** command assigns a dot1q tag to the subinterface. Traffic ingressing on the parent interface with that dot1q tag will then be sent to the configured subinterface. See [Subinterfaces](#) and [Subinterface Configuration](#) for details.

The **no encapsulation dot1q vlan** and **default encapsulation dot1q vlan** commands restore the default VLAN to the configuration mode interface by removing the corresponding **encapsulation dot1q vlan** command from **running-config**.

Command Mode

- Interface-Ethernet Configuration
- Interface-port-channel Configuration
- Subinterface-Ethernet Configuration
- Subinterface-port-channel Configuration

Command Syntax

```
encapsulation dot1q vlan vlan_id
no encapsulation dot1q vlan
default encapsulation dot1q vlan
```

Parameters

- **vlan_id**  For VLAN translation, the ID of the external VLAN to be translated; for subinterface configuration, the VLAN of the subinterface. Values range from 1 to 4094.

Example

- These commands translate between VLAN 50 and the internal VLAN for Ethernet interface 5 (a routed port).
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)# no switchport
  switch(config-if-Et5)# encapsulation dot1q vlan 50
  switch(config-if-Et5)#
  ```

- These commands assign packets ingressing on Ethernet interface 1/1 with VLAN ID 100 to Ethernet subinterface 1/1.1.
  ```
  switch(config)#interface ethernet1/1.1
  switch(config-if-Et1/1.1)# no switchport
  switch(config-if-Et1/1.1)# encapsulation dot1q vlan 100
  switch(config-if-Et1/1.1)#
  ```
interface vlan

The `interface vlan` command places the switch in VLAN-interface configuration mode for modifying parameters of the switch virtual interface (SVI). An SVI provides Layer 3 processing for packets from all ports associated with the VLAN. There is no physical interface for the VLAN.

When entering configuration mode to modify existing SVIs, the command can specify multiple interfaces. The command creates an SVI if the specified interface does not exist prior to issuing the command. When creating an SVI, the command can only specify a single interface.

The `no interface vlan` command deletes the specified SVI interfaces from `running-config`. The `default interface vlan` commands remove all configuration statements for the specified SVI interfaces from `running-config` without deleting the interfaces.

**Command Mode**
- Global Configuration

**Command Syntax**

```
interface vlan v_range
no interface vlan v_range
default interface vlan v_range
```

**Parameter**
- `v_range` : VLAN interfaces (number, range, or comma-delimited list of numbers and ranges).
  
  VLAN number ranges from 1 to 4094.

**Restrictions**

Internal VLANs: A VLAN interface cannot be created or configured for internal VLAN IDs. The switch rejects any `interface vlan` command that specifies an internal VLAN ID.

**Example**
- This example creates an SVI for VLAN 12:
  ```
  switch#config
  switch(config)#interface vlan 12
  switch(config-if-V12)#
  ```
**l2-protocol encapsulation dot1q vlan**

The **l2-protocol encapsulation dot1q vlan** command enables Layer 2 802.1Q traffic encapsulation on the configuration mode interface for a specified VLAN. The default VLAN for all interfaces is VLAN 1.

The **no l2-protocol encapsulation dot1q vlan** and **default l2-protocol encapsulation dot1q vlan** commands disable the specified encapsulation on the configuration mode interface by removing the corresponding **l2-protocol encapsulation dot1q vlan** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

```
l2-protocol encapsulation dot1q vlan vlan_id
no l2-protocol encapsulation dot1q vlan
default l2-protocol encapsulation dot1q vlan
```

**Parameters**

- **vlan_id**  the ID of the native VLAN. Values range from 1 to 4094.

**Example**

- These commands enable 802.1Q encapsulation of traffic on VLAN 200.

```
switch(config)#interface ethernet 5/2
switch(config-if-Et5/2)#l2-protocol encapsulation dot1q vlan 200
switch(s1)(config-if-Et5/2)#show active
interface Ethernet5/2
  12-protocol encapsulation dot1q vlan 200
switch(config-if-Et5/2)#
```
name (VLAN configuration mode)

The `name` command configures the VLAN name. The name can have up to 32 characters. The default name for VLAN 1 is `default`. The default name for all other VLANs is VLANxxxx, where xxxx is the VLAN number. The default name for VLAN 55 is VLAN0055. The `show vlan` command displays the VLAN name.

The `name` command accepts all characters except the space.

The `no name` and `default name` commands restore the default name by removing the `name` command from `running-config`.

**Command Mode**

VLAN Configuration

**Command Syntax**

```
name label_text
no name
default name
```

**Parameters**

- `label_text` character string assigned to name attribute. Maximum length is 32 characters. The space character is not permitted in the name string.

**Examples**

- These commands assign corporate_100 as the name for VLAN 25, then displays the VLAN name.

```
switch(config)#vlan 25
switch(config-vlan-25)#name corporate_100
switch(config-vlan-25)#show vlan 25

VLAN  Name                  Status    Ports
------ ------------------------ -------- --------------------
 25    corporate_100          active

switch(config-vlan-25)#
```
The `show dot1q-tunnel` command displays the ports that are configured in dot1q-tunnel switching mode. The `switchport mode` command configures the switching mode for the configuration mode interface.

**Command Mode**

EXEC

**Command Syntax**

```
show dot1q-tunnel [INTERFACE]
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.
  - `vxlan vx_range` VXLAN interface range specified by `vx_range`.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays the ports that are configured in dot1q-tunnel switching mode.

  ```
  switch>show dot1q-tunnel
  dot1q-tunnel mode LAN Port (s)
  ------------------------------
  Po4
  Po21
  Po22
  switch>
  ```
show interfaces switchport

The `show interfaces switchport` command displays the switching configuration and operational status of the specified ports.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] switchport
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display the switching status for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.

Valid `e_range`, `l_range`, `m_range`, `p_range`, and `v_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays the switching status for all interfaces.

```bash
switch(config)#show interface switchport
Default switchport mode: access

Name: Et5/1
Switchport: Enabled
Administrative Mode: static access
Operational Mode: static access
MAC Address Learning: enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Static Trunk Groups:
Dynamic Trunk Groups:

Name: Et5/2
Switchport: Enabled
Administrative Mode: static access
Operational Mode: static access
MAC Address Learning: enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Static Trunk Groups:
Dynamic Trunk Groups:

[...]
```

```bash
switch(config)#
```
This command displays the switching status of port channel interfaces 21 and 22.

```
switch>show interface port-channel 21-22 switchport
Name: Po21
Switchport: Enabled
Administrative Mode: tunnel
Operational Mode: tunnel
Access Mode VLAN: 1 (inactive)
Trunking Native Mode VLAN: 100 (VLAN0100)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Trunk Groups: foo

Name: Po22
Switchport: Enabled
Administrative Mode: tunnel
Operational Mode: tunnel
Access Mode VLAN: 1 (inactive)
Trunking Native Mode VLAN: 1 (inactive)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Trunk Groups:
```

switch>
show interfaces switchport backup

The `show interfaces switchport backup` command displays interfaces that are configured as switchport backup pairs and the operational status of each interface. For each pair, the command displays the names, roles, status, and VLAN traffic of each interface.

Command Mode

EXEC

Command Syntax

```
show interfaces [INTERFACE] switchport backup
```

Parameters

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.

Valid `e_range`, `l_range`, `m_range`, `p_range`, and `v_range` formats include number, number range, or comma-delimited list of numbers and ranges.

Display Values

- **State** Operational status of the interface. Values include:
  - `Up` Spanning tree mode is `backup`, interface status is `up`.
  - `Down` Spanning tree mode is `backup`, interface status is `down`.
  - **Inactive Configuration** The spanning tree mode is not `backup`.
- **Forwarding vlans** VLANs forwarded by the interface. Depends on interface operation status and prefer option specified by the `switchport backup` command.

Example

```
This command displays the configured switchport primary-backup pairs.

switch>show interfaces switchport backup
Switch backup interface pair: Ethernet17, Ethernet18
Primary Interface: Ethernet17  State: Up
Backup Interface:  Ethernet18  State: Up
Ethernet17 forwarding vlans:  1-20
Ethernet18 forwarding vlans:
```
show interfaces trunk

The `show interfaces trunk` command displays configuration and status information for interfaces configured in switchport trunk mode.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] trunk
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - `<no parameter>` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.

Valid `e_range`, `m_range`, and `p_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

- This command displays the trunk status for all interfaces configured in switchport trunk mode.

```
switch> show interfaces trunk
Port     Mode  Status       Native vlan
Po1      trunk trunking  1
Po2      trunk trunking  1

Port     Vlans allowed
Po1      1-15
Po2      16-30

Port     Vlans allowed and active in management domain
Po1      1-10
Po2      21-30

Port     Vlans in spanning tree forwarding state
Po1      1-10
Po2      21-30

switch>
```
show interfaces vlans

The `show interfaces vlans` command displays a table that lists the VLANs that are carried by the specified interfaces. Interfaces that do not carry VLANs are not listed in the table. The table lists the untagged (native or access) and tagged VLANs for each interface.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INT_NAME] vlans
```

**Parameters**

- `INT_NAME` Interface type and number. Values include
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-Channel Interface specified by `p_num`.

**Example**

- This command displays the VLANs carried by all L2 ports.

```
switch>show interfaces vlans
Port       Untagged Tagged
Et9        3910     -
Et11       3912     -
Et16       500      -
Et17       3908     -
Et18       3908     -

```
show vlan

The `show vlan` command displays the VLAN ID, name, status, and member ports of all configured VLANs. The command only displays active ports by default; by specifying `configured-ports`, the command displays all ports that are members of a configured VLAN regardless of their activity status, including Ethernet ports that are members of a port channel.

Command Mode

EXEC

Command Syntax

```
show vlan [VLAN_LIST] [PORT_ACTIVITY]
```

Parameters

- **VLAN_LIST** List of VLANs displayed by command. Options include:
  - `<no parameter>` all VLANs.
  - `v_range` VLANs specified by `v_range`.
  - `id v_range` VLANs specified by `v_range`.
  - `name v_name` VLANs specified by the VLAN name `v_name`.

  *v_range* formats include number, number range, or comma-delimited list of numbers and ranges.

- **PORT_ACTIVITY** Ports listed in table. Options include:
  - `<no parameter>` table displays only active ports (same as `active-configuration` option).
  - `active-configuration` table displays only active ports.
  - `configured-ports` table displays all configured ports.

Display Values

- **VLAN** The VLAN ID.
- **Name** The name of the VLAN.
- **Status** The status of the VLAN.
- **Ports** The ports that are members of the VLAN.

Example

- This command displays status and ports of VLANs 1-1000.

```
switch> show vlan 1-1000
VLAN | Name    | Status | Ports
-----|---------|--------|-----------------------------
 1   | default | active | Po1
184  | fet.arra| active | Cpu, Po1, Po2
262  | mgq.net | active | Pfo2, Po1
512  | sant.test| active | Cpu, Et16, Po1
821  | ipv6.net| active | Cpu, Po1, Po7

switch>
```
**show vlan dynamic**

The `show vlan dynamic` command displays the source and quantity of dynamic VLANs on the switch. Dynamic VLANs support VM Tracer monitoring sessions.

**Command Mode**

EXEC

**Command Syntax**

```
show vlan dynamic
```

**Example**

- This command displays the source and quantity of dynamic VLANs on the switch.

```
switch>show vlan dynamic
Dynamic VLAN source   VLANS
vmtracer-poc           88
switch>
```
show vlan internal allocation policy

The `show vlan internal allocation policy` command displays the method the switch uses to allocate VLANs to routed ports. The `vlan internal allocation policy` command configures the allocation method.

The allocation method consists of two configurable components:

- range: the list of VLANs that are allocated to routed ports.
- direction: the direction by which VLANs are allocated (ascending or descending).

**Command Mode**

EXEC

**Command Syntax**

`show vlan internal allocation policy`

**Example**

- This command displays the internal allocation policy.

  `switch>show vlan internal allocation policy`
  Internal VLAN Allocation Policy: ascending
  Internal VLAN Allocation Range: 1006-4094
  `switch>`
**show vlan internal usage**

The **show vlan internal usage** command shows the VLANs that are allocated as internal VLANs for routed ports.

A routed port is an Ethernet or port channel interface that is configured as a layer 3 interface. Routed ports do not bridge frames and are not members of any VLANs. Routed ports can have IP addresses assigned to them and packets are routed directly to and from the port.

When an interface is configured as a routed port, the switch allocates an SVI with a previously unused VLAN ID. The switch prohibits the configuration of VLANs with numbers corresponding to internal VLAN interfaces allocated to a routed port. VLAN interfaces corresponding to SVIs allocated to a routed port cannot be configured by VLAN interface configuration mode commands.

**Command Mode**

EXEC

**Command Syntax**

```
show vlan internal usage
```

**Example**

- This command displays the VLANs that are allocated to routed ports.

```
switch>show vlan internal usage
1006  Ethernet3
1007  Ethernet4
switch>
```
show vlan summary

The show vlan summary command displays the number of VLANs that are configured on the switch.

Command Mode

EXEC

Command Syntax

show vlan summary

Example

- This command displays the number of VLANs on the switch.

  switch>show vlan summary
  Number of existing VLANs : 18

  switch>
show vlan trunk group

The **show vlan trunk group** command displays the trunk group membership of the specified VLANs.

**Command Mode**
EXEC

**Command Syntax**
```
show vlan [VLAN_LIST] trunk group
```

**Parameters**
- **VLAN_LIST** VLAN list. Options include:
  - <no parameter> all VLANs.
  - `v_range` VLANs specified by `v_range`.
  - `id v_range` VLANs specified by `v_range`.
  - `name v_name` VLANs specified by the VLAN name `v_name`.

**Display Values**
- **VLAN** VLAN ID.
- **Trunk Groups** Trunk groups associated with the listed VLANs.

**Example**
- This command displays the trunk group membership of all configured VLANs.
  switch>**show vlan trunk group**
  VLAN     Trunk Groups
  ----     ----------------------------------------------------------------------
  5         first_group
  12        second_group
  40        third_group
  100       middle_group
  101       middle_group
  102       middle_group
  200

  switch>
**state**

The **state** command configures the VLAN transmission state of the configuration mode VLAN.

- **Active** state: Ports forward VLAN traffic.
- **Suspend** state: Ports block VLAN traffic.

The default transmission status is **active**.

The **no state** command restores the default VLAN transmission state to the configuration mode VLAN by removing the corresponding **state** command from **running-config**.

**Command Mode**

VLAN Configuration

**Command Syntax**

```
state OPERATION_STATE
do state
default state
```

**Parameters**

- **OPERATION_STATE** VLAN transmission state. Options include:
  - **active** VLAN traffic is forwarded
  - **suspend** LAN traffic is blocked.

**Example**

- These commands suspend VLAN traffic on VLANs 100-102.

```
switch(config)#vlan 100-102
switch(config-vlan-100-102)#state suspend
switch(config-vlan-100-102)#
```
**switchport dot1q ethertype**

The `switchport dot1q ethertype` command configures the tag protocol identifier (TPID, also known as a dot1q ethertype), of the configuration mode interface. By default, all switch ports use the standard TPID of 0x8100.

The `no switchport dot1q ethertype` and `default switchport dot1q ethertype` commands restore the TPID to 0x8100 by removing the corresponding `switchport dot1q ethertype` statement from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
switchport dot1q ethertype ethertype
no switchport dot1q ethertype
default switchport dot1q ethertype
```

**Parameters**

- `ethertype` ethertype number (TPID). Value ranges from 0x600 (1536) through 0xFFFF (65535), and can be entered in decimal or hexadecimal notation. Value is stored and displayed in hexadecimal form; the default value is 0x8100.

**Example**

- These commands configure 0x9100 as the TPID of Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport dot1q ethertype 0x9100
  switch(config-if-Et5)#
  ```
**switchport access vlan**

The `switchport access vlan` command specifies the access VLAN of the configuration mode interface. Ethernet or port channel interfaces that are in access mode are members of only the access VLAN. Untagged frames that the interface receives are associated with the access VLAN. Frames tagged with the access VLAN are also associated with the access VLAN. The interface drops all other tagged frames that it receives. By default, VLAN 1 is the access VLAN of all Ethernet and port channel interfaces.

An interface's access mode is effective only when the interface is in access mode or dot1q-tunnel mode, as specified by the switchport mode command. Interfaces in dot1q-tunnel mode handle inbound traffic as untagged traffic and associate all traffic with the access VLAN. Interfaces configured to switchport trunk mode maintain and ignore existing switchport access commands.

The `no switchport access vlan` and `default switchport access vlan` commands restore VLAN 1 as the access VLAN of the configuration mode interface by removing the corresponding `switchport access vlan` statement from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**
- `switchport access vlan v_num`
- `no switchport access vlan`
- `default switchport access vlan`

**Parameters**
- `v_num` number of access VLAN. Value ranges from 1 to 4094. Default is 1.

**Example**
- These commands assign VLAN 100 as the access VLAN to Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport access vlan 100
  switch(config-if-Et5)#
  ```
**switchport mode**

The **switchport mode** command specifies the switching mode of the configuration mode interface. The switch supports five switching modes: access, trunk, dot1q-tunnel, tap, and tool.

- **Access switching mode**: The interface is a member of one VLAN, called the access VLAN, as specified by the `switchport access vlan` command. Tagged frames received on the interface are dropped unless they are tagged with the access VLAN. Frames transmitted from the interface are always untagged.

- **Trunk switching mode**: The interface may be a member of multiple VLANs, as configured by the `switchport trunk allowed vlan` command. Untagged traffic is associated with the interface’s native VLAN, as configured with the `switchport trunk native vlan` command.

- **Dot1q-tunnel switching mode**: The interface treats all inbound packets as untagged traffic and handles them as traffic of its access VLAN, as specified by the `switchport access vlan` command.

- **Tap mode**: The interface operates as a tap port. Tap ports receive traffic for replication on one or more tool ports. The interface may be a member of multiple VLANs, as configured by the `switchport tap allowed vlan` command. Untagged traffic is associated with the interface’s native VLAN, as configured with the `switchport tap native vlan` command.

  Tap ports are in STP forwarding state and prohibit egress traffic. MAC learning, control plane interaction and traps for inbound traffic are disabled.

- **Tool mode**: The interface operates as a tool port. Tool ports replicate traffic received by tap ports. The interface may be a member of multiple VLANs, as configured by the `switchport tool allowed vlan` command. MAC learning, control plane interaction and traps for inbound traffic are disabled.

  Tool ports are in STP forwarding state and prohibit ingress traffic that uses port settings.

The status of switchport configured ports depends on the switch’s tap aggregation mode (which can be viewed by using the `mode (tap-agg configuration mode)` command):

- tap aggregation mode enabled: tap and tool ports are enabled. Switching ports are errdisabled.
- tap aggregation mode disabled: tap and tool ports are errdisabled. Switching ports are enabled.

The **no switchport mode** and **default switchport mode** commands return the configuration mode interface to its default setting as an access port by deleting the corresponding **switchport mode** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

```
switchport mode MODE_TYPE
no switchport mode
default switchport mode
```

**Parameters**

- **MODE_TYPE** switching mode of the configuration mode interfaces. Options include:
  - access access switching mode.
  - dot1q-tunnel dot1q-tunnel switching mode.
  - tap tap switching mode.
  - tool tool switching mode.
  - trunk trunk switching mode.
Restrictions
Dot1q-tunnel switching mode is not available on Petra platform switches.
Tap aggregation (tap and tool modes) is available on FM6000 and Arad platform switches.

Example
• These commands configure Ethernet 4 interface as a trunk port.

switch(config)#interface ethernet 4
switch(config-if-Et4)#switchport mode trunk
switch(config-if-Et4)#
switchport trunk allowed vlan

The `switchport trunk allowed vlan` command creates or modifies the list of VLANs for which the configuration mode interface, in trunk mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in `running-config` without taking effect when the switch is in tap aggregation mode or the interface is not in trunk mode.

The `no switchport trunk allowed vlan` and `default switchport trunk allowed vlan` commands restore the trunk mode default allowed VLAN setting of all by removing the corresponding `switchport trunk allowed vlan` statement from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

```plaintext
switchport trunk allowed vlan  EDIT_ACTION
no switchport trunk allowed vlan
default switchport trunk allowed vlan
```

**Parameters**

- **EDIT_ACTION**  modifications to the VLAN list.
  - `v_range`  Creates VLAN list from `v_range`.
  - `add v_range`  Adds specified VLANs to current list.
  - `all`  VLAN list contains all VLANs.
  - `except v_range`  VLAN list contains all VLANs except those specified.
  - `none`  VLAN list is empty (no VLANs).
  - `remove v_range`  Removes specified VLANs from current list.

Valid `v_range` formats include number, range, or comma-delimited list of numbers and ranges.

**Example**

- These commands create the trunk mode allowed VLAN list of 6-10 for Ethernet interface 14, then verifies the VLAN list.

```plaintext
switch(config)#interface ethernet 14
switch(config-if-Et14)#switchport trunk allowed vlan 6-10
switch(config-if-Et14)#show interfaces ethernet 14 switchport
Name: Et14
  Switchport: Enabled
  Administrative Mode: trunk
  Operational Mode: trunk
  Access Mode VLAN: 1 (inactive)
  Trunking Native Mode VLAN: 1 (inactive)
  Administrative Native VLAN tagging: disabled
  Trunking VLANs Enabled: 6-10
  Trunk Groups:

switch(config-if-Et14)#
```
**switchport trunk group**

The `switchport trunk group` command assigns the configuration mode interface to the specified trunk group. Trunk group ports handle traffic of the VLANs assigned to the group.

The `no switchport trunk group` and `default switchport trunk group` commands remove the configuration mode interface from the specified trunk group by deleting the corresponding statement from `running-config`. If the command does not specify a trunk group, the interface is removed from all trunk groups to which it is assigned.

**Note**

On platforms which support the use of port channels as mirror destinations, a port channel which is being used as a mirror destination *must not* be assigned to an MLAG.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

```
switchport trunk group  group_name
no switchport trunk group [group_name]
default switchport trunk group [group_name]
```

**Parameters**

- `group_name` trunk group name.

**Example**

- These commands assign port channel 4 to trunk group `fe-1`.

```
switch(config)#interface port-channel 4
switch(config-if-Po4)#switchport trunk group fe-1
switch(config-if-Po4)#
```
**switchport trunk native vlan**

The **switchport trunk native vlan** command specifies the trunk mode native VLAN for the configuration mode interface. Interfaces in trunk mode associate untagged frames with the native VLAN. Trunk mode interfaces can also be configured to drop untagged frames. The default native VLAN for all interfaces is VLAN 1.

The **no switchport trunk native vlan** and **default switchport trunk native vlan** commands restore VLAN 1 as the trunk mode native VLAN to the configuration mode interface by removing the corresponding **switchport trunk native vlan** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

```plaintext
switchport trunk native vlan VLAN_ID
no switchport trunk native vlan
default switchport trunk native vlan
```

**Parameters**
- **VLAN_ID** the ID of the native VLAN. Options include
  - `v_num` VLAN number. Value ranges from 1 to 4094
  - `tag` interface drops all untagged frames.

**Example**
- These commands configure VLAN 100 as the native VLAN for port channel 21.

```
switch(config)#interface port-channel 21
switch(config-if-Po21)#switchport trunk native vlan 100
switch(config-if-Po21)#
```
switchport vlan mapping

The `switchport vlan mapping` command allows you to map packets from one VLAN to another using VLAN translation. This can be carried out only on packets having a dot1q header (tagged frames). The translation rewrites the VID field (VLAND ID) in dot1q headers on packets passing through a switched port without changing any other fields.

By default, the translation is bidirectional: packets ingressing an interface through VLAN A are internally mapped to VLAN B; VLAN B packets egressing the same interface are mapped to VLAN A.

To use VLAN translation on a switched port, the port must be configured as a trunk port using the `switchport mode` command.

VLAN translation on routed ports is accomplished through the `encapsulation dot1q vlan` command.

The `no switchport vlan mapping` and `default switchport vlan mapping` commands remove VLAN mapping by removing the switchport vlan mapping command from `running-config`.

Command Mode

- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

Command Syntax

```
switchport vlan mapping [DIRECTION] incoming_vlanid new_vlanid
no switchport vlan mapping incoming_vlanid new_vlanid
no switchport vlan mapping DIRECTION incoming_vlanid
default switchport vlan mapping incoming_vlanid new_vlanid
default switchport vlan mapping DIRECTION incoming_vlanid
```

Parameters

- `DIRECTION` transmission direction of traffic to be translated.
  - `<no parameter>` translates the specified VLAN IDs for transmitted and received traffic.
  - `in` translates the specified VLAN IDs for received traffic only.
  - `out` translates the specified VLAN IDs for transmitted traffic only.
- `incoming_vlanid` The VLAN ID to be translated. Value ranges from 1 to 4094.
- `new_vlanid` The new VLAN ID or bridging VLAN ID which will be used internally. Value ranges from 1 to 4094.

Example

- These commands translate only incoming packets, changing the VID to 2008 in the dot1q header of packets ingressing on VLAN 201.

  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# switchport vlan mapping in 201 2008
  switch(config-if-Et5)#
  ```

- These commands translate multiple VLAN mappings under an interface.

  ```
  switch(config)# interface ethernet 5
  switch(config-if-Et5)# switchport vlan mapping 50 60
  switch(config-if-Et5)# switchport vlan mapping 61 71
  switch(config-if-Et5)# switchport vlan mapping 62 72
  switch(config-if-Et5)#
  ```
trunk group

The **trunk group** command assigns the configuration mode VLAN to a specified trunk group.

A trunk group is the set of physical interfaces that comprise the trunk and the collection of VLANs whose traffic is carried on the trunk. The traffic of a VLAN that belongs to one or more trunk groups is carried only on ports that are members of trunk groups to which the VLAN belongs. Switchport commands specify the physical interfaces that carry trunk group traffic.

The **no trunk group** and **default trunk group** commands remove the configuration mode VLAN from the specified trunk group by removing the corresponding **trunk group** statement from **running-config**. If a trunk group is not specified, the commands remove the configuration mode VLAN from all trunk groups.

**Command Mode**

VLAN Configuration

**Command Syntax**

```
trunk group name
no trunk group [name]
default trunk group [name]
```

**Parameters**

- `name` a name representing the trunk group.

**Example**

- These commands assigns VLAN 49 to the trunk group **mlagpeer**.

  ```
  switch(config)#vlan 49
  switch(config-vlan-49)#trunk group mlagpeer
  switch(config-vlan-49)#
  ```
vlan

The `vlan` command places the switch in VLAN configuration mode to configure a set of virtual LANs. The command creates the specified VLANs if they do not exist prior to issuing the command. A VLAN that is in use as an internal VLAN may not be created or configured. The switch rejects any `vlan` command that specifies an internal VLAN ID.

The `default vlan` and `no vlan` commands removes the VLAN statements from `running-config` for the specified VLANs.

The `exit` command returns the switch to global configuration mode.

**Command Mode**
- Global Configuration

**Command Syntax**
```
vlan vlan_range
no vlan vlan_range
default vlan vlan_range
```

**Parameters**
- `vlan_range` VLAN list.
  Formats include a name, number, number range, or comma-delimited list of numbers and ranges.

**Commands Available in VLAN configuration mode**
- `name (VLAN configuration mode)`
- `state`
- `trunk group`

**Guidelines**
In MLAG configurations, VLANs operate as follows:
- The VLAN must be configured identically on both MLAG peer switches.
- The port-specific bridging configuration originates on the switch where the port is physically located. This configuration includes the switchport access VLAN, switchport mode (trunk or access), trunk-allowed VLANs, the trunk native VLAN, and the switchport trunk groups.

**Example**
- This command creates VLAN 49 and enters VLAN configuration mode for the new VLAN:
  ```
  switch(config)#vlan 49
  switch(config-vlan-49)#
  ```
**vlan internal allocation policy**

The `vlan internal allocation policy` command specifies the range that the switch can allocate as internal VLANs when configuring routed ports and the order of their allocation. By default, the switch allocates VLANs in ascending order from VLAN 1006 to VLAN 4094.

The `no vlan internal allocation policy` and `default vlan internal allocation policy` commands revert the policy to its default.

**Command Mode**

- Global Configuration

**Command Syntax**

- `vlan internal allocation policy DIRECTION [RANGE_VLAN]`
- `no vlan internal allocation policy`
- `default vlan internal allocation policy`

**Parameters**

- **DIRECTION** VLAN allocation number direction. Options include:
  - `ascending` allocates internal VLANs from lower VLAN bound to upper VLAN bound.
  - `descending` allocates internal VLAN from upper VLAN bound to lower VLAN bound.
- **RANGE_VLAN** allocation range. Options include:
  - `<no parameter>` 1006 (lower bound) to 4094 (upper bound).
  - `range lower upper` specifies lower bound (lower) and upper bound (upper).

**Examples**

- This command configures the switch to allocate internal VLANS from 3000 through 3999.
  ```
  switch(config)#vlan internal allocation policy ascending range 3000 3999
  switch(config)#
  ```
- This command configures the switch to allocate internal VLANS from 4094 through 1006.
  ```
  switch(config)#vlan internal allocation policy descending
  switch(config)#
  ```
- This command configures the switch to allocate internal VLANS from 4094 down through 4000.
  ```
  switch(config)#vlan internal allocation policy descending range 4000 4094
  switch(config)#
  ```
- This command reverts the allocation policy to its default (`ascending`, between 1006 and 4094).
  ```
  switch(config)#no vlan internal allocation policy
  switch(config)#
  ```
This chapter describes Arista’s VXLAN implementation. Sections in this chapter include:

- Section 19.1: VXLAN Introduction
- Section 19.2: VXLAN Description
- Section 19.3: VXLAN Configuration
- Section 19.4: VXLAN Command Descriptions

19.1 VXLAN Introduction

Virtual Extensible LAN (VXLAN) is a networking technology that encapsulates MAC-based Layer 2 Ethernet frames within Layer 3 UDP packets to aggregate and tunnel multiple layer 2 networks across a Layer 3 infrastructure. VXLAN scales up to 16 million logical networks and supports layer 2 adjacency across IP networks. Multicast transmission architecture is used for broadcast, multicast, and unknown unicast traffic.

For a list of VXLAN feature support in a specific EOS release, consult the appropriate release notes here: https://www.arista.com/en/support/software-download.

For a list of VXLAN feature support by platform in the latest EOS release, see http://www.arista.com/support/supported-features.

Note

VxLAN and NAT cannot co-exist.
19.2 VXLAN Description

These sections describe VXLAN architecture, the data objects that comprise a VXLAN network, and process of bridging packets through a VXLAN network.

- Section 19.2.1: VXLAN Architecture
- Section 19.2.2: VXLAN Processes
- Section 19.2.3: Multicast and Broadcast over VXLAN
- Section 19.2.4: VXLAN Gateway
- Section 19.2.5: VXLAN and MLAG
- Section 19.2.6: Data Structures

19.2.1 VXLAN Architecture

The VXLAN architecture extends an L2 network by connecting VLANs from multiple hosts through UDP tunnels called VXLAN segments. VXLAN segments are identified by a 24-bit virtual network identifier (VNI). Within a host, each VLAN whose network is extended to other hosts is associated with a VNI. An extended L2 network comprises the devices attached to VLANs from all hosts that are on VLANs that are associated with the same VNI.

Figure 19-1 displays the data objects that comprise a VXLAN implementation on a local host.

**VTEP**
- **VXLAN Tunnel End Point (VTEP):** a host with at least one VXLAN Tunnel Interface (VTI).
- **VXLAN Tunnel Interface (VTI):** a switchport linked to a UDP socket that is shared with VLANs on various hosts. Packets bridged from a VLAN to the VTI are sent out the UDP socket with a VXLAN header. Packets arriving on the VTI through the UDP socket are demuxed to VLANs for bridging.
- **Virtual Network Identifier (VNI):** a 24-bit number that distinguishes between the VLANs carried on a VTI. It facilitates the multiplexing of several VLANs over a single VTI.

VNIs can be expressed in digital or dotted decimal formats. VNI values range from 1 to 16777215 or from 0.0.1 to 255.255.255.
The network in Figure 19-1 has the following assignments:

- VTEP IP address of 10.10.1.1
- UDP port of 4789
- One VTI that supports three VXLAN segments (UDP tunnels): VNI 200, VNI 2000, and VNI 20000
- Five VLANs, of which three VLANs can communicate with remote devices over Layer 2.

19.2.2 VXLAN Processes

When a packet enters a VLAN from a member (ingress) port, the VLAN learns the source address by adding an entry to the MAC address table that associates the source to the ingress-port. The VLAN then searches the table for destination address. If the MAC address table lists the address, the packet is sent out the corresponding port. If the MAC address table does not lists the address, the packet is flooded to all ports except the ingress port.

VXLANs extend VLANs through the addition of a VXLAN address table that correlates remote MAC addresses to their port and resident host IP address. Packets that are destined to a remote device are sent to the VXLAN tunnel interface (VTI), which is the switchport that is linked to the UDP socket. The packet is encapsulated with a VXLAN header which includes the VNI associated with the VLAN and the IP mapping of the destination host. The packet is sent through a UDP socket to the destination VTEP IP. The VTI on the remote host extracts the original packet and bridges it to the VLAN associated with the VNI on the remote host.

UDP port 4789 is recognized as the VXLAN socket and listed as the destination port on the UDP packets. The UDP source port field is filled with a hash of the inner header to facilitate load balancing.

Figure 19-2 displays a configuration that includes three VTEPs. The VXLAN defines three inter-host L2 networks. The VLANs that comprise the networks include:

- VNI 200: VTEP 10.20.2.2: VLAN 1200 and VTEP 10.30.3.3: VLAN 200
- VNI 2000: VTEP 10.10.1.1: VLAN 300, VTEP 10.20.2.2: VLAN 1400, and VTEP 10.30.3.3: VLAN 300
- VNI 20000: VTEP 10.10.1.1: VLAN 200, and VTEP 10.20.2.2: VLAN 1600
**VXLAN Routing**

VXLAN routing is enabled by creating a VLAN interface on the VXLAN-enabled VLAN and assigning an IP address to the VLAN interface. The IP address serves as VXLAN gateway for devices that are accessible from the VXLAN-enabled VLAN.

**19.2.3 Multicast and Broadcast over VXLAN**

These sections describe multicast and broadcast over VXLANs. Multicast packet flooding describes broadcast and multicast transmission by associating a multicast group to a VTI through a configuration command. Head-end Replication (HER) optimizes flooding of inter VTEP broadcast, unknown unicast and broadcast (BUM) traffic by using hardware and flood lists to perform replication on the supported platform.

**19.2.3.1 Multicast Packet Flooding**

Multicast packet flooding is supported with VXLAN bridging without MLAG. A VTI is associated with a multicast group through a configuration command.

**VXLAN and Broadcast**

When a VLAN receives or sends a broadcast packet the VTI is treated as a bridging domain L2 interface. The packet is sent from this interface on the multicast group associated with the VTI. The VTIs on remote VTEPs that receive this packet extract the original packet, which is then handled by the VLAN associated with the packet’s VNI. The VLAN floods the packet, excluding the VTI. When the broadcast results in a response, the resulting packet can be unicast back to the originating VTEP because the VXLAN address table obtained the host MAC to VTEP association from the broadcast packet.

**VXLAN and Multicast**

A VTI is treated as an L2 interface in the VLAN for handling multicast traffic, which is mapped from the VLAN to the multicast group associated with the VTI. All VTEPs join the configured multicast group for inter-VTEP communication within a VXLAN segment; this multicast group is independent of any other multicast groups that the hosts in the VLAN join.

The IP address space for the inter-host VXLAN communication may be sourced from a different VRF than the address space of the hosts in the VLAN. The multicast group for inter-VTEP transmissions must not be used for other purposes by any device in the VXLAN segment space.

**19.2.3.2 Head-end Replication**

Head-end replication uses a flood list to support broadcast, unknown unicast, and multicast (BUM) traffic over VXLAN. The flood list specifies a list of remote VTEPs. The switch replicates BUM data locally for bridging across the remote VTEPs specified by the flood list. This data flooding facilitates remote MAC address learning by forwarding data with unknown MAC addresses.

Head-end replication is required for VXLAN routing and to support VXLANs over MLAG.

**19.2.4 VXLAN Gateway**

A VXLAN gateway is a service that exchanges VXLAN data and packets with devices connected to different network segments. VXLAN traffic must pass through a VXLAN gateway to access services on physical devices in a distant network.

A VXLAN gateway requires the following information:

- An IP address that is designated as the VXLAN interface source.
• VLAN to VNI mapping.
• VTEP list for each VNI.
• A method for handling broadcast, unknown unicast, and multicast (BUM) packets.

Arista switches manually perform VXLAN gateway services. The switch connects to VXLAN gateways that serve other network segments. MAC address learning is performed in hardware from inbound VXLAN packets. BUM packets are supported though one of the methods specified in Section 19.2.3.

19.2.5 VXLAN and MLAG

The switch platforms which use this feature are:
• DCS-7050X

VXLAN over MLAG provides redundancy in hardware VTEPs. VTI configuration must be identical on each MLAG peer for them to act as a single VTEP. This also prevents the remote MAC from flapping between the remote VTEPs by ensuring that the rest of the network sees a host that is connected to the MLAG interface as residing behind a single VTEP.

Differences between VXLAN bridging and routing implementations over MLAG are applicable for the DCS-7050X series platform.

• VXLAN routing recirculates a packet twice, with the first iteration performing the routing action involving an L2 header rewrite, and the second recirculation performing VXLAN encap and decap operations. Recirculation is achieved by MAC loopback on dedicated loopback interfaces.
• The configuration for VXLAN routing on an MLAG VTEP includes separate Recirc-Channel configuration on both peers. The virtual IP, virtual MAC, and virtual VARP VTEP IP addresses are identical on both peers.

The following VTI elements must be configured identically on both MLAG peers:
• VLAN-VNI mappings
• VTEP IP address of the source loopback interface
• Flood VTEP list used for head-end replication

If OSPF is also in use, configure the OSPF router ID manually to prevent the switch from using the common VTEP IP address as the router ID.

The following rules are observed by MLAG switches so that they behave as a single VXLAN VTEP:
• Only the MLAG peer that receives a packet performs VXLAN encapsulation on it.
• Packets are not VXLAN encapsulated if they are received from the peer link.
• If a packet is decapsulated and sent over the peer link, it should not be flooded to active MLAG interfaces.
• If a packet is sent over the peer link to the CPU, it is not head-end replicated to other remote VTEPs.
• If a packet’s destination is the VTEP IP address, it is terminated by the MLAG peer that receives it.
The following example is applicable to the DCS-7050X series platform.

**Example**

- These commands complete the configuration required for a VXLAN routing deployment.

```sh
switch(config)#interface Vxlan1
switch(config-if-Vx1)#vxlan source-interface Loopback0
switch(config-if-Vx1)#vxlan udp-port 4789
switch(config-if-Vx1)#vxlan vlan 2417 vni 8358534
switch(config-if-Vx1)#vxlan flood vtep 1.0.1.1 1.0.2.1
switch(config-if-Vx1)#interface Vlan2417
switch(config-if-Vl2417)#ip address 1.0.4.1/24
switch(config-if-Vl2417)#interface Loopback0
switch(config-if-Lo0)#ip address 1.0.1.1/32
switch(config-if-Lo0)#ip routing
switch(config)#interface Recirc-Channel627
switch(config-if-Re627)#switchport recirculation features vxlan
switch(config-if-Re627)#interface Ethernet 1
switch(config-if-Et1)#traffic-loopback source system device mac
switch(config-if-Et1)#channel-group recirculation 627
switch(config-if-Et1)#exit
switch(config)#interface Ethernet 2
switch(config-if-Et2)#traffic-loopback source system device mac
switch(config-if-Et2)#channel-group recirculation 627
```

### Configuring UnconnectedEthernet interfaces for recirculation

On systems where bandwidth is not fully used by the front panel ports, unused bandwidth is used for recirculation.

The following example is applicable to the DCS-7050X series platform.

**Example**

- These commands expose UnconnectedEthernet interfaces which are used for recirculation, in order to use them to replace or use along with front panel Ethernet interfaces.

```sh
switch(config)#service interface unconnected expose
switch(config)#interface UnconnectedEthernet 2
switch(config-if-Ue2)#traffic-loopback source system device mac
switch(config-if-Ue2)#channel-group recirculation 627
```

#### 19.2.6 Data Structures

VXLAN implementation requires two VXLAN tables and a MAC address table accommodation.

##### 19.2.6.1 MAC Address Table VXLAN Support

MAC address table entries correlate MAC addresses with the port upon which packets arrive. In addition to Ethernet and port channels, the port column may specify a VTI for packets that arrive on a VLAN from a remote port through the VXLAN segment.

##### 19.2.6.2 VTEP-MAC Address Table

VTEP-MAC address table entries correlate MAC address with the IP address of the VTEP from where packets bearing the MAC address arrive. The VTI uses this table to determine the destination address for packets that are sent to remote hosts.
19.2.6.3 VNI-VLAN Map

The VNI-VLAN map displays the one-to-one correspondence between the VNIs assigned on the switch and the VLANs to which they are assigned. Each VNI can be assigned to only one VLAN; each VLAN can be assigned a maximum of one VNI. Each VNI-VLAN assignment constitutes a VXLAN segment.
19.3 VXLAN Configuration

These sections describe VXLAN configuration tasks:

- Section 19.3.1: Configuring the VTI
- Section 19.3.2: Head End Replication Configuration
- Section 19.3.3: VXLAN Routing Configuration
- Section 19.3.4: Configuring VXLAN Routing with Overlay VRFs
- Section 19.3.5: Configuring VXLAN over MLAG
- Section 19.3.6: Configuring VXLAN Control Service
- Section 19.3.7: Configuring VXLAN Multicast Decapsulation
- Section 19.3.8: VXLAN Rules Support for Mirror ACLs Configuration
- Section 19.3.9: Displaying VXLAN Configuration

19.3.1 Configuring the VTI

Configuring the VTI enables VXLAN bridging and is a requirement for VXLAN Routing. The following sections describe the steps required to enabling VXLAN bridging by bringing up the VXLAN line protocol. Section 19.3.3 describes the additional steps required to enable VXLAN routing.

Instantiating the VTI and VXLAN Configuration Mode

The `interface vxlan` command places the switch in VXLAN-interface configuration mode for modifying the specified VXLAN tunnel interface (VTI). The command also instantiates the interface if it was not previously created.

VXLAN interface configuration mode is not a group change mode; `running-config` is changed immediately after commands are executed. The `exit` command does not affect the configuration.

Example

- These commands create VXLAN tunnel interface 1, place the switch in VXLAN-interface configuration mode, and display parameters of the new VTI.

```
switch(config)#interface vxlan 1
switch(config-if-Vx1)#show active
interface Vxlan1
    vxlan udp-port 4789
switch(config-if-Vx1)#
```

Assigning an IP address to the VTEP

The `vxlan source-interface` command specifies the loopback interface from which the VTEP derives the source address (IP) that it uses when exchanging VXLAN frames. This address is used by UDP headers to specify source and destination addresses of hosts that send or receive VXLAN encapsulated packets.

There is no default source interface assignment. A valid VXLAN configuration requires the assignment of a loopback interface to the VTEP and the assignment of a valid IP address to the specified interface.
Example

- These commands configure VTI 1 to use IP address 10.25.25.3 (loopback interface 15) as the source interface in the encapsulation fields of outbound VXLAN frames.

```
switch(config)#interface loopback 15
switch(config-if-Lo15)#ip address 10.25.25.3/24
switch(config-if-Lo15)#exit
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan source-interface loopback 15
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan source-interface Loopback15
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

**Assigning a UDP Port to the VTEP**

Packets bridged to the VTI from a VLAN are encapsulated with a VXLAN header, then sent through a pre-configured UDP port. Packets that arrive through this port are assumed to be VXLAN encapsulated and sent to the bridging domain of the recipient VLAN as determined by the VNI in the VXLAN header and the VNI-VLAN map.

The `vxlan udp-port` command associates a UDP port with the configuration mode VXLAN interface (VTI). By default, UDP port 4789 is associated with the VTI.

**Important!** UDP port 4789 is reserved by convention for VXLAN usage. Under most typical applications, this parameter should be set to the default value.

Example

- This command associates UDP port 5500 with VXLAN interface 1.

```
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan udp-port 5500
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 5500
switch(config-if-Vx1)#
```

- This command resets the VXLAN interface 1 UDP port association of 4789.

```
switch(config-if-Vx1)#no vxlan udp-port
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

**Assigning a VNI to a VLAN**

When a VLAN bridges a packet to the VTI, the packet is encapsulated with a VXLAN header that includes the VNI associated with the VLAN. Packets that arrive on the VTI’s UDP socket are bridged to the VLAN that is associated with the VNI specified by the VXLAN header that encapsulates the packet.

The VTI requires a one-to-one correspondence between specified VLANs and VNI values. Commands that assign a new VNI to a previously configured VLAN replace existing VLAN assignment statements in `running-config`. Commands that attempt to assign a VNI value to a second VLAN generate a CLI error.

The `vxlan vlan vni` command associates a VLAN ID with a virtual network identifier (VNI).

Example

- These commands associate VLAN 100 to VNI 100 and VLAN 200 to VNI 10.10.200.

```bash
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan vlan 100 vni 100
switch(config-if-Vx1)#vxlan vlan 200 vni 10.10.200
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 200 vni 658120
  vxlan vlan 100 vni 100
switch(config-if-Vx1)#vxlan vni notation dotted
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 100 vni 0.0.100
  vxlan vlan 200 vni 10.10.200
switch(config-if-Vx1)#
```

Assigning a Multicast Group to the VTI

The VTI maps multicast traffic from its associated VLANS to a specified multicast group. Inter-VTEP multicast communications include all VTEPs that are associated with the specified multicast group, which is independent of any other multicast groups that VLAN hosts may join.

The `vxlan multicast-group` command associates a specified multicast group with the configuration mode VXLAN interface (VTI), which handles multicast and broadcast traffic as a layer 2 interface in a bridging domain.

Example

- This command associates the multicast address of 227.10.1.1 with VTI 1.

```bash
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan multicast-group 227.10.1.1
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan multicast-group 227.10.1.1
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

Verifying the VXLAN Configuration

The `show interface vxlan 1` displays the configuration and connection status of the VXLAN

Example

- This command indicates that the VXLAN line protocol status is `up`.

```bash
switch(config-if-Vx1)#show interface vxlan 1
Vxlan1 is up, line protocol is up (connected)
  Hardware is Vxlan
  Source interface is Loopback15 and is active with 10.25.25.3
  Static vlan to vni mapping is
    [100, 0.0.100] [200, 10.10.200]
  Multicast group address is 227.1.1.1
switch(config-if-Vx1)#
```
19.3.2 Head End Replication Configuration

Head-end replication is a data distribution method that supports broadcast, unknown unicast, and multicast (BUM) traffic over VXLANs by replicating BUM data locally for transmission to the set of remote VTEPs specified by a flood list. This data flooding facilitates remote MAC address learning through the forwarding of data with unknown MACs.

Each `vxlan flood vtep` statement in `running-config` associates a set of VTEP addresses to an access VNI. A default flood list is also configurable that applies to all VNIs for which a flood list is not configured.

The VTEP flood list is created and modified through the `vxlan flood vtep` command. When configuring VXLAN bridging, the flood list can replace `vxlan multicast-group`.

Example

- These commands create a default VXLAN head-end replication flood list.

  ```
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan flood vtep 10.1.1.1 10.1.1.2
  switch(config-if-Vx1)#show active
  interface Vxlan1
  vxlan flood vtep 10.1.1.1 10.1.1.2
  vxlan udp-port 4789
  switch(config-if-Vx1)#
  ```

- These commands create VXLAN head-end replication flood lists for the VNIs accessed through VLANs 101 and 102.

  ```
  switch(config-if-Vx1)#vxlan vlan 101-102 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
  switch(config-if-Vx1)#show active
  interface Vxlan1
  vxlan flood vtep 10.1.1.1 10.1.1.2
  vxlan vlan 101 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
  vxlan vlan 102 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
  vxlan udp-port 4789
  switch(config-if-Vx1)#
  ```

19.3.3 VXLAN Routing Configuration

19.3.3.1 Implementing VXLAN Routing

VXLAN routing is enabled by creating a VLAN interface (SVI) on a VLAN that is associated to a VNI. In Figure 19-3, VXLAN routing is enabled on Switch A by configuring a VLAN interface with an IP address of 10.10.10.1. Packets from Devices A-1 and B-2 that have destinations other than 10.10.10.0/28 are VXLAN-bridged to the default gateway (10.10.10.1), then routed from Switch A.
These commands configure Switch A to perform VXLAN routing. The example includes OSPF routing that is used for underlay routing.

```
switch-A(config)#route-map vxlanvlan permit 10
switch-A(config-route-map-vxlanvlan)#match interface loopb5
switch-A(config-route-map-vxlanvlan)#exit
switch-A(config)#route-map vxlanvlan permit 20
switch-A(config-route-map-vxlanvlan)#match interface vlan 100
switch-A(config-route-map-vxlanvlan)#exit
switch-A(config)#router ospf 1
switch-A(config-router-ospf)#redistribute connected route-map vxlanvlan
switch-A(config-router-ospf)#exit
switch-A(config)#interface loopback 5
switch-A(config-if-Lo5)#ip address 10.25.25.3/24
switch-A(config-if-Lo5)#exit
switch-A(config)#interface vxlan 1
switch-A(config-if-Vxl)#vxlan source-interface loopback 5
switch-A(config-if-Vxl)#vxlan vlan 100 vni 10000
switch-A(config)#interface vlan 100
switch-A(config-if-Vl100)#ip address 10.10.10.1/28
switch-A(config-if-Vl100)#exit
```
19.3.3.2 Configuring Direct VXLAN Routing

In Figure 19-3, VXLAN routing is enabled on Switch A only; Switch B supports VXLAN bridging. Traffic from Switch B devices to the external routes must go through the core route twice: once as they are bridged to its VXLAN gateway and once when routed to its next hop device.

Direct VXLAN routing with VXLAN enabled addresses this issue by configuring each VTEP with all VLANs. This allows packets to be VXLAN-bridged to a local VTEP and routed to remote VTEPs. Indirect routing scales well but is complex to engineer efficiently, and naked routing provides the same scalability to indirect routing. Direct routing leads to the most efficient traffic flows, with the number of virtual subnets or virtual machines increasing at scale, and is thereby optimal from a data plane viewpoint.

The following sections describe conventions required to implement Direct VXLAN Routing, then presents a direct VXLAN routing implementation.

Configuring VARP addresses

For direct routing, an anycast IP address is used as the gateway address on the SVI for a VLAN on all hardware VTEPs associated with that VLAN.

Examples

- These commands configure an IP virtual-router and virtual MAC address.
  
  switch(config)#interface Vlan2417
  switch(config-if-Vl2417)#ip address 1.0.4.50/24
  switch(config-if-Vl2417)#ip virtual-router address 1.0.4.1
  switch(config-if-Vl2417)#ip virtual-router mac-address 00:00:11:11:22:22
  switch(config)#

- These commands configure an IP virtual address (instead of IP virtual-router address) for the VLAN SVI, and a secondary address on the loopback interface for the virtual VTEP IP. The virtual VTEP IP is the logical VTEP hosting the virtual MAC address.

  switch(config)#interface Vlan2417
  switch(config-if-Vl2417)#ip address virtual 1.0.4.1/24
  switch(config-if-Vl2417)#exit
  switch(config)#interface Loopback0
  switch(config-if-Lo0)#ip address 1.0.1.1/32
  switch(config-if-Lo0)#ip address 1.0.1.2/32 secondary
  switch(config-if-Lo0)#ip virtual-router mac-address 00:00:11:11:22:22
  switch(config)#

Virtual IP and MAC Addresses

Virtual-router IP addresses can be configured on VLAN interfaces in addition to a primary address. All VTEPs in a direct VXLAN network can be configured with the same virtual router address. This allows devices to use a common IP address as their VXLAN gateway.

The `ip address virtual` command configures a specified address as the primary IPv4 address and as a virtual IP address for the configuration mode VLAN interface. This results in the virtual MAC address (`ip virtual-router mac-address`) assignment to the VLAN interface. In large VXLAN networks, using distinct primary IP addresses for each VTEP limits the number addresses on its subnet for connected hosts. Defining a common virtual IP address for all VTEPs and using that their primary addresses conserves subnet addresses.
Example

- These commands specify a virtual router address of 00:00:00:00:00:48 for the switch and, for VLAN 100, a primary address of 10.10.10.10/28 and a virtual IP address of 10.10.10.10.

```
switch(config)#ip virtual-router mac-address 00:00:00:00:00:48
switch(config)#interface vlan 100
switch(config-if-Vl100)#ip address virtual 10.10.10.10/28
switch(config-if-Vl100)#show active
  interface Vlan100
    ip address virtual 10.10.10.10/28
switch(config-if-Vl100)#
```

Virtual VTEP Configuration

A virtual VTEP address is specified by configuring a secondary address on the loopback interface designated as the VXLAN's source interface. All VTEPs in the direct routing topology share the same virtual VTEP address.

You must also configure the secondary VTEP IP on the flood-list of the downstream VXLAN VTEPS as shown below.

Example

- These commands specify a primary (10.1.1.1) and virtual VTEP address (10.2.2.2).

```
Switch1
  switch(config)#interface loopback 5
  switch(config-if-Lo5)#ip address 10.1.1.1/24
  switch(config-if-Lo5)#ip address 10.2.2.2/24 secondary
  switch(config-if-Lo5)#show active
    interface Loopback5
      ip address 10.1.1.1/24
      ip address 10.2.2.2/24 secondary
  switch(config-if-Lo5)#exit
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan source-interface loopback 5
  switch(config-if-Vx1)#show active
    interface Vxlan1
      vxlan source-interface Loopback5
      vxlan udp-port 4789
      vxlan vlan 100 vni 10000
  switch(config-if-Vx1)#

Switch2
  switch(config)#interface vxlan1
  switch(config-if-Vx1)#vxlan flood vtep 10.1.1.1
  switch(config-if-Vx1)#vxlan flood vtep 10.2.2.2
```

Direct VXLAN Topology

Figure 19-4 displays a direct VXLAN topology, where each VTEP is configured with the same set of VNIs, VLAN interfaces, and virtual VTEP address.
Example

- These commands configure VXLAN parameters for Switch-A in Figure 19-4.

```
switch-A(config)#route-map vxlanvlan permit 10
switch-A(config-route-map-vxlanvlan)#match interface loopb5
switch-A(config-route-map-vxlanvlan)#exit
switch-A(config)#route-map vxlanvlan permit 20
switch-A(config-route-map-vxlanvlan)#match interface vlan 100
switch-A(config-route-map-vxlanvlan)#exit
switch-A(config)#router ospf 1
switch-A(config-router-ospf)#redistribute connected route-map vxlanvlan
switch-A(config-router-ospf)#exit
switch-A(config)#ip virtual-router mac-address 00:00:00:00:00:48
switch-A(config)#interface loopback 5
switch-A(config-if-Lo5)#ip address 10.1.1.3/24
switch-A(config-if-Lo5)#ip address 10.1.1.10/24 secondary
switch-A(config-if-Lo5)#exit
switch-A(config)#interface vxlan 1
switch-A(config-if-Vx1)#vxlan source-interface loopback 5
switch-A(config-if-Vx1)#vxlan vlan 100 vni 10000
switch-A(config)#interface vlan 100
switch-A(config-if-Vl100)#ip address virtual 10.10.10.28
switch-A(config-if-Vl100)#exit
```

19.3.3.3 Configuring VXLAN VTEP counters

The switch platforms which use this feature are:

- DCS-7050X
- DCS-7250X
- DCS-7300X

The VXLAN VTEP counters feature enables a device to count VXLAN packets received and sent by the device on a per VTEP basis. Specifically, it enables the device to count bytes and packets that are getting encapsulated and decapsulated as they are passing through.
The counters are logically split up in the two VXLAN directions. Encapsulated on the device and directed to the core, “encap” counters count packets coming from the edge. Decapsulated on the device and heading towards the edge, “decap” counters count packets coming from the core.

To be able to count VXLAN packets the device has to support VXLAN and have a VXLAN interface correctly configured.

**Examples**

- This command configures the enabling of VXLAN VTEP counters for encap.
  ```
  switch(config)#hardware counter feature vtep encap
  switch(config)#
  ```
- This command configures the disabling of VXLAN VTEP counters for encap.
  ```
  switch(config)#no hardware counter feature vtep encap
  switch(config)#
  ```
- This command configures the enabling of VXLAN VTEP counters for decap.
  ```
  switch(config)#hardware counter feature vtep decap
  switch(config)#
  ```
- This command configures the disabling of VXLAN VTEP counters for decap.
  ```
  switch(config)#no hardware counter feature vtep decap
  switch(config)#
  ```

### 19.3.4 Configuring VXLAN Routing with Overlay VRFs

The switch platforms which use this feature are:

- DCS-7050X
- DCS-7250X
- DCS-7300X

VXLAN SVIs configured in non-default VRFs are supported with VXLAN routing using overlay VRFs. Overlay SVIs are configured in non-default VRFs but underlay SVIs, which provide IP connectivity between VTEPs, must remain in the default VRF. VXLAN routing is deployable by allowing users to configure separate overlay routing domains using VRFs per tenant, thereby allowing support for overlapping IP addresses in the overlay. This provides separation between overlay and underlay traffic, including simpler and cleaner protocol configuration, without using complicated route-maps to control distribution of prefixes to peers in the overlay VRFs and underlay SVIs. IPv4 based VXLAN routing is currently supported.

### 19.3.5 Configuring VXLAN over MLAG

VTI configuration must be identical on each MLAG peer for them to act as a single VTEP.

The following VTI elements must be configured identically on both MLAG peers:

**VLAN-VNI Mappings**

Configure identical VLAN to VNI mappings on both MLAG peers using the `vxlan vlan vni` command.

**Example**

- These commands associate VLAN 100 to VNI 100 and VLAN 200 to VNI 10.10.200.
  ```
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan vlan 100 vni 100
  switch(config-if-Vx1)#vxlan vlan 200 vni 10.10.200
  switch(config-if-Vx1)#
  ```
VTEP IP Address of the Source Loopback Interface

Configure the same VTEP IP address for the source loopback interface on both MLAG peers using the `vxlan source-interface` command.

**Example**

- These commands configure a primary VTEP address.

  ```
  switch(config)#interface loopback 5
  switch(config-if-Lo5)#ip address 10.1.1.1/24
  switch(config-if-Lo5)#exit
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan source-interface loopback 5
  ```

Flood VTEP List

Configure the same VTEP flood list on both MLAG peers using the `vxlan flood vtep` command.

**Example**

- These commands create a default VXLAN head-end replication flood list.

  ```
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan flood vtep 10.1.1.1 10.1.1.2
  ```

OSPF Configuration

If OSPF is in use, configure the OSPF router ID using the `router-id (OSPFv2)` command to prevent the switch from using the common VTEP IP address as the router ID.

**Example**

- These commands assign 10.0.0.1 as the OSPFv2 router ID.

  ```
  switch(config)#router ospf 100
  switch(config-router-ospf)#router-id 10.0.0.1
  ```

19.3.6 Configuring VXLAN Control Service

The VXLAN Control Service (VCS) provides a mechanism by which hardware VTEPs share states between each other in order to establish VXLAN tunnels, without the need for a multicast control plane. This feature enables the use of a VCS client.

**Examples**

- These commands connect a switch to the VCS running on CVX. The server host IP address is the management IP address of the CVX controller or the IP address that CVX is listening on for client connections.

  ```
  switch(config)#management cvx
  switch(config-mgmt-cvx)#server host 172.27.6.248
  switch(config-mgmt-cvx)#no shutdown
  ```

- These commands configure the VXLAN interface, except for the multicast group configuration, in order to learn from the controller.

  ```
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan controller-client
  ```
19.3.7 Configuring VXLAN Multicast Decapsulation

The switch platforms which use this feature are:

- DCS-7050X
- DCS-7250X
- DCS-7300X

VXLAN multicast decapsulation enables VTEPs that support Head End Replication (HER). Multicast encapsulated Broadcast/Unknown/Multicast (BUM) packets terminate VTEPs from remote VTEPs that do not support HER.

**Examples**

- These commands enable VXLAN multicast decapsulation.
  
  ```
  switch(config)#interface vxlan 1
  switch(config-config-if-Vx1)#vxlan multicast-group decap 230.1.1.1
  switch(config-config-if-Vx1)#
  ```

- These commands disable VXLAN multicast decapsulation.
  
  ```
  switch(config)#interface vxlan 1
  switch(config-config-if-Vx1)#no vxlan multicast-group decap 230.1.1.1
  switch(config-config-if-Vx1)#
  ```

19.3.8 VXLAN Rules Support for Mirror ACLs Configuration

The switch platforms which use this feature are:

- DCS-7150S

VXLAN rules support for mirror ACLs configuration permit VXLAN deep inspection rules to be specified in the mirroring ACLs when the switch is operating in normal mode.

**Examples**

The following are examples of VXLAN rules specified in mirroring ACLs.

- These commands permit all VXLAN traffic (udp protocol and destination port 4789).
  
  ```
  switch(config)#ip access-list miracl
  switch(config-acl-miracl)#permit vxlan any any
  switch(config-acl-miracl)#
  ```

- These commands permit VXLAN traffic with vni 1001 only.
  
  ```
  switch(config)#ip access-list miracl
  switch(config-acl-miracl)#permit vxlan any any vni 1001 0x000000
  switch(config-acl-miracl)#
  ```

- These commands deny VXLAN traffic with vni 0x1000 through 0x100f.
  
  ```
  switch(config)#ip access-list miracl
  switch(config-acl-miracl)#permit vxlan any any vni 0x1000 0x100f
  switch(config-acl-miracl)#
  ```
19.3.9 Displaying VXLAN Configuration

The following section describes the commands that control the display format of VNIs and the commands that list VXLAN configuration and transmission information.

Configuring VNI Display Format

The **vxlan vni notation dotted** command configures the switch to display VNIs in dotted decimal notation. VNI values range from 1 to 16777215 in decimal notation and from 0.0.1 to 255.255.255 in dotted decimal notation.

The command affects the VNI number display in all **show** commands, including **show running-config**. Commands that include VNI as a parameter may use decimal or dotted decimal notion regardless of the setting of this command. By default, show commands display VNI number in decimal notation.

Examples

- These commands configure the switch to display vni numbers in dotted decimal notation, then displays a configuration that includes a VNI setting.

```plaintext
switch(config)#vxlan vni notation dotted
switch(config)#interface vxlan 1
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 333 vni 3.4.5
switch(config-if-Vx1)#
```

- These commands configure the switch to display vni numbers in decimal notation, then displays a configuration that includes a VNI setting.

```plaintext
switch(config)#no vxlan vni notation dotted
switch(config)#interface vxlan 1
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 333 vni 197637
switch(config-if-Vx1)#
```

MAC Address Table

The MAC address table indicates a MAC address from a device on a remote host by indicating Vx interface as the port that corresponds to the address.
Example

- This command displays a MAC address table that includes entries of devices from remote hosts by specifying Vx1 as the corresponding port.

  switch> show mac address-table

  Mac Address Table

  +----+-----------------+-----+-------------+-----+----------------+
  | Vlan | Mac Address     | Type | Ports      | Moves | Last Move       |
  +----+-----------------+-----+-------------+-----+----------------+
  | 1   | 0050.5682.6725  | DYNAMIC | Et16 | 1 | 0:02:01 ago   |
  | 1   | 0050.568e.58e9 | DYNAMIC | Et23 | 2 | 0:08:53 ago   |
  | 1   | 0050.56a0.474a | DYNAMIC | Et16 | 1 | 0:18:04 ago   |
  | 51  | 0000.0051.0004 | DYNAMIC | Et5  | 1 | 12 days, 1:02:44 ago |
  | 51  | 0000.0051.0005 | DYNAMIC | Et5  | 1 | 12 days, 1:02:44 ago |
  | 51  | 0000.0051.0101 | DYNAMIC | Vx1  | 1 | 12 days, 0:17:30 ago |
  | 51  | 0000.0051.0102 | DYNAMIC | Vx1  | 1 | 12 days, 0:17:30 ago |
  | 61  | 0000.0061.0005 | DYNAMIC | Et5  | 1 | 12 days, 1:02:44 ago |
  +----+-----------------+-----+-------------+-----+----------------+

  Total Mac Addresses for this criterion: 8

Multicast Mac Address Table

  +----+-----------------+-----+-------------+-----+----------------+
  | Vlan | Mac Address     | Type | Ports      | Moves | Last Move       |
  +----+-----------------+-----+-------------+-----+----------------+
  +----+-----------------+-----+-------------+-----+----------------+

  Total Mac Addresses for this criterion: 0

switch>

VXLAN MAC Address Table

VXLAN MAC address table entries correlate MAC addresses accessible through remote VTEPs with the local VLAN and the IP address of the VTEP through which the addressed device is accessed. The VTI uses this table when constructing the VXLAN encapsulation to specify the destination IP address of the recipient VTEP and the VNI segment through which the device’s remote VLAN is accessed.

The `show vxlan address-table` command displays the VXLAN MAC address table.

Example

- This command displays the VXLAN address table.

  switch> show vxlan address-table

  VXLAN Mac Address Table

  +----+-----------------+-----+-------------+-----+----------------+
  | Vlan | Mac Address     | Type | Prt | Vtep | Moves | Last Move       |
  +----+-----------------+-----+-----+-----+-----+----------------+
  | 51  | 0000.0051.0101 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 51  | 0000.0051.0102 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 51  | 0000.0051.0103 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 51  | 0000.0051.0104 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 51  | 0000.0051.0105 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 61  | 0000.0061.0103 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 61  | 0000.0061.0104 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  | 61  | 0000.0061.0105 | DYNAMIC | Vx1 | 10.25.2.12 | 1 | 4 days, 0:37:14 ago |
  +----+-----------------+-----+-----+-----+-----+----------------+

  Total Mac Addresses for this criterion: 8

switch>
VXLAN MAC Address Table

The `show vxlan vtep` command displays information about remote VTEPs that the configured VTI has discovered and with whom it has exchanged packets.

Example

- These commands display the VTEPs that have exchanged data with the configured VTI.

```
switch>show vxlan vtep
Remote vteps for Vxlan1:
  10.52.2.12
Total number of remote vteps: 1
```

VXLAN Counters

The `clear vxlan counters` command resets the VXLAN counters. The `show vxlan counters` command displays the VXLAN counters.

Example

- This command displays the VXLAN counters

```
switch>show vxlan counters software
encap_bytes:3452284
encap_pkts:27841
encap_read_err:1
encap_discard_runt:0
encap_discard_vlan_range:0
encap_discard_vlan_map:0
encap_send_err:0
encap_timeout:1427
decap_bytes_total:382412426
decap_pkts_total:2259858
decap_bytes:0
decap_pkts:0
decap_runt:0
decap_pkt_filter:45128
decap_bytes_filter:5908326
decap_discard_vxhdr:0
decap_discard_vlan_map:2214730
decap_timeout:0
decap_sock_err:1
```

switch>
19.4 VXLAN Command Descriptions

**VXLAN Global Configuration Commands**
- interface vxlan
- ip address virtual
- vxlan vni notation dotted

**VXLAN Interface Configuration Commands**
- vxlan flood vtep
- vxlan multicast-group
- vxlan multicast-group decap
- vxlan source-interface
- vxlan udp-port
- vxlan vlan vni

**VXLAN Display and Clear Commands**
- clear vxlan counters
- show service vxlan
- show vxlan address-table
- show vxlan counters
- show vxlan flood vtep
- show vxlan vtep
clear vxlan counters

The `clear vxlan counters` command resets the VXLAN counters.

**Command Mode**
- Privileged EXEC

**Command Syntax**

```
clear vxlan counters ROUTE_TYPE
```

**Parameters**
- **ROUTE_TYPE** Specifies the type of VXLAN counter reset by the command.
  - `software` Command resets software counters.
  - `varp` Command resets virtual-ARP counters.

**Related Commands**
- `show vxlan counters` displays the VXLAN counters.

**Example**
- This command resets the VXLAN counters

```
switch#clear vxlan counters software
switch#show vxlan counters software
encap_bytes:0
encap_pkts:0
encap_read_err:0
encap_discard_runt:0
encap_discard_vlan_range:0
encap_discard_vlan_map:0
encap_send_err:0
encap_timeout:0
decap_bytes_total:0
decap_pkts_total:0
decap_bytes:0
decap_pkts:0
decap_runt:0
decap_pkt_filter:0
decap_bytes_filter:0
decap_discard_vxhdr:0
decap_discard_vlan_map:0
decap_timeout:0
decap_sock_err:0
switch#
```
interface vxlan

The **interface vxlan** command places the switch in VXLAN-interface configuration mode for modifying the specified VXLAN tunnel interface (VTI). The command also instantiates the interface if it was not previously created.

VXLAN interface configuration mode is not a group change mode; **running-config** is changed immediately after commands are executed. The **exit** command does not affect the configuration.

The **no interface vxlan** deletes the specified VTI interface, including its configuration statements, from **running-config**. The **default interface vxlan** command removes all configuration statements for the specified VTI from **running-config** without deleting the interfaces.

**Command Mode**
- Global Configuration

**Command Syntax**

```
interface vxlan vx_range
no interface vxlan vx_range
default interface vxlan vx_range
```

**Parameter**
- **vx_range** VXLAN interface number. The only permitted value is 1.

**Commands Available in link-flap Configuration Mode**
- **vxlan multicast-group**
- **vxlan source-interface**
- **vxlan udp-port**
- **vxlan vlan vni**

**Example**
- These commands create VXLAN tunnel interface 1, place the switch in VXLAN-interface configuration mode, then display parameters of the new VTI.

```
switch(config)#interface vxlan 1
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

- This command exits VXLAN-interface configuration mode, placing the switch in global configuration mode.

```
switch(config-if-Vx1)#exit
switch(config)#
```
**ip address virtual**

The **ip address virtual** command configures a specified address as the primary IPv4 address and as a virtual IP address for the configuration mode VLAN interface. The address resolves to the virtual MAC address configured through the **ip virtual-router mac-address** command. The command includes a subnet designation that is required in primary IP address assignments.

This command is typically used in VXLAN routing configurations as an alternative to assigning a unique IP address to each VTEP. All existing IPv4 addresses must be removed from the interface before executing this command.

The **no ip address virtual** and **default ip address virtual** commands remove the IPv4 address and virtual IP assignment from the configuration mode interface by deleting the **ip address virtual** command from **running-config**.

Removing the IPv4 address assignments from an interface disables IPv4 processing on that port.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

```plaintext
ip address virtual ipv4_subnet
no ip address virtual
default ip address virtual
```

**Parameters**

- **ipv4_subnet** IPv4 and subnet address (CIDR or address-mask notation).

**Related Commands**

- **ip address**
- **ip address virtual**
- **ip virtual-router mac-address**

**Example**

- This command configures 10.10.10.1 as the IPv4 address and virtual address for VLAN 100.

```plaintext
switch(config-if-Vl100)#show active
interface Vlan100
    ip address virtual 10.10.10.1/28
switch(config-if-Vl100)#
```
show service vxlan

The `show service vxlan` command displays the status of the Vxlan Control Service (VCS) and the received (from all connected VTEPs) and advertised (to all connected VTEPs) MAC address reachability information.

**Command Mode**

EXEC

**Command Syntax**

```
show service vxlan [status | switch [SWITCH_TYPE] | vni [VNI_INFO]]
```

**Parameters**

- `SWITCH_TYPE` displayed by switch type. Options include:
  - `word` hostname, IP address, or ID of the switch.
  - `all` all switches.
- `VNI_INFO` displayed with VNI information. Options include:
  - `advertised` advertised MAC addresses.
  - `received` received MAC addresses.

**Example**

- This command displays the status of the VCS.

  ```
  switch(config)#show service vxlan status
  Vxlan Controller Service is   : stopped
  Mac learning                  : Control plane
  Resync period                 : 300 seconds
  Resync in progress            : No
  Capability                    : VXLAN v4 overlay routing
                                 VXLAN v4 overlay indirect routing
  fm319(config-if-Vx1)#show service vxlan status
  Vxlan Controller Service is   : stopped
  Mac learning                  : Control plane
  Resync period                 : 300 seconds
  Resync in progress            : No
  Capability                    : VXLAN v4 overlay routing
                                 VXLAN v4 overlay indirect routing
  ```

  switch(config)#
show vxlan address-table

The `show vxlan address-table` command displays the VXLAN address table. Entries are created by extracting information from packets received from remote VTEPs.

The VXLAN address table correlates MAC addresses that are accessible through remote VTEPs with the local VLAN and the IP address of the VTP through which the addressed device is accessible. The VTI uses this table when constructing the VXLAN encapsulation fields to specify the destination IP address of the recipient VTEP and the VNI segment through which the device’s remote VLAN is accessed.

**Command Mode**

EXEC

**Command Syntax**

```
show vxlan address-table [ENTRY_TYPE] [MAC_ADDR] [VLANS] [REMOTE_VTEP]
```

**Parameters**

- **ENTRY_TYPE** command filters display by entry type. Options include:
  - `<no parameter>` all table entries.
  - `configured` static entries; includes unconfigured VLAN entries.
  - `dynamic` entries learned through packet receipts.
  - `static` entries entered by CLI commands.
  - `unicast` entries with unicast MAC address.
- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - `<no parameter>` all MAC addresses table entries.
  - `address mac_address` displays entries with specified address (dotted hex notation – H.H.H).
- **VLANS** command filters display by VLAN.
  - `<no parameter>` all VLANs.
  - `vlan v_num` VLAN specified by `v_num`.
- **REMOTE_VTEP** Filters entries by IP address of the remote VTEPs. Options include:
  - `<no parameter>` all items.
  - `vtep ipaddr_1 [ipaddr_2...ipaddr_n]` Identifies VTEPs by their IP address.
Example

- This command displays the VXLAN address table.

  switch> **show vxlan address-table**

  switch>
show vxlan counters

The show vxlan counters command displays the VXLAN counters.

Command Mode
EXEC

Command Syntax
show vxlan counters ROUTE_TYPE

Parameters
- **ROUTE_TYPE**  Specifies the type of VXLAN counter displayed by the command.
  - **software**  Command displays software routers.
  - **varp**  Command displays virtual-ARP counters.
  - **vtep**  Command displays counters for VTEPs which are identified by their IP address. An optional keyword allows the user to view a single direction of the counters:
    - **encap**  “encap” counters count packets coming from the edge, encapsulated on the device and directed to the core.
    - **decap**  “decap” counters count packets coming from the core, decapsulated on the device and heading towards the edge.

Related Commands
- **clear vxlan counters** resets the VXLAN counters.

Example
- This command displays the VXLAN counters for software routers.

```
switch>show vxlan counters software

switch>
```
show vxlan flood vtep

The `show vxlan flood vtep` command displays the flood list that the switch is using to perform head-end replication. Head-end replication is a data distribution method that supports broadcast, unknown unicast, and multicast (BUM) traffic over VXLANs by replicating BUM data locally for transmission to the set of remote VTEPs that a flood list specifies. The command displays the VLAN ID that references the configured VNIs (`vxlan vlan vni`).

The flood list is determined by the `vxlan flood vtep` command.

Command Mode

EXEC

Command Syntax

```
show vxlan flood vtep [VLANS]
```

Parameters

- `VLANS` command filters display by the reference VLAN.
  - `<no parameter>` all VLANs.
  - `vlan v_range` VLANs specified by `v_range`.

Valid `v_range` formats include number, range, or comma-delimited list of numbers and ranges.

Guidelines

The command displays flood list contents only when the VLAN line protocol status is `up`.

Related Commands

- `vxlan flood vtep` configures the flood list.

Example

```
These commands display the VTEPs that have exchanged data with the configured VTI.

switch>show vxlan flood vtep vlan 100-102

Vxlan Flood Vtep Table

+----+---------------------+
| Vlan | Ip Address          |
+----+---------------------+
| 100 | 3.3.3.3              |
| 101 | 11.1.1.1 11.1.1.2 11.1.1.3 |
| 102 | 11.1.1.1 11.1.1.2 11.1.1.3 |
| 12  | 12.1.1.1            |

switch>
```
**show vxlan vtep**

The `show vxlan vtep` command displays information about remote VTEPs that the configured VTI has discovered and with whom it has exchanged packets.

**Command Mode**

EXEC

**Command Syntax**

```
show vxlan vtep
```

**Example**

- These commands display the VTEPs that have exchanged data with the configured VTI.

```
switch>show vxlan vtep
Remote vteps for Vxlan1: 10.52.2.12
Total number of remote vteps: 1
switch>
```
vxlan flood vtep

The `vxlan flood vtep` command supports VXLAN head-end replication by creating or modifying a list that specifies remote VTEPs to which the switch bridges replicated traffic. Head-end replication is a data distribution method that supports broadcast, unknown unicast, and multicast (BUM) traffic over VXLANs by replicating BUM data locally for transmission to the set of remote VTEPs that a flood list specifies. This data flooding facilitates remote MAC address learning through the forwarding of data with unknown MACs.

Each `vxlan flood vtep` statement in `running-config` associates a set of VTEP addresses to an access VNI. A default flood list is also configurable that applies to all VNIs for which a flood list is not configured. The `vxlan flood vtep` command is available in the following formats to create or modify corresponding `running-config` statements:

- `vxlan flood vtep` creates a statement for a specified VNI and replaces existing statements for that VNI.
- `vxlan flood vtep add` modifies an existing flood statement by adding the specified VTEPs. This statement creates a list if it references a VNI that has no flood statement.
- `vxlan flood vtep remove` modifies an existing flood statement by deleting the specified VTEPs. This statement has no effect if it references a VNI that has no flood statement.

The `vxlan flood vtep` command specifies a VNI by referencing its associated VLAN ID (`vxlan vlan vni`). The command provides these options for specifying the reference VLANs:

- a single VLAN: creates or modifies a single statement referenced by the command.
- a range of VLANs: creates or modifies all statements referenced by the VLAN range.
- no VLAN: creates or modifies the default list

The `no vxlan flood vtep` and `default vxlan flood vtep` commands remove the specified flood list by deleting the corresponding `vxlan flood vtep` statements from `running-config`. Commands that specify a VLAN range remove all corresponding statements.

**Command Mode**

Interface-VXLAN Configuration

**Command Syntax**

```
vxlan [ACCESS_VNI] flood vtep [MODIFY] VTEP_1 [VTEP_2] ... [VTEP_N]
no vxlan [ACCESS_VNI] flood vtep
default vxlan [ACCESS_VNI] flood vtep
```

**Parameters**

- **ACCESS_VNI**: VLAN ID associated to the flood list’s target VNI. Value ranges from 1 to 4094.
  - <no parameter> default list.
  - `vlan vlan_range` List of VLANs. (Number, range, comma-delimited list of numbers and ranges). Numbers range from 1 to 4094.
- **MODIFY**: Statement modification method. Options include:
  - <no parameter> creates new list for specified VLANs. Current list is overwritten.
  - add specified VTEPs are added to existing list.
  - remove specified VTEPs are deleted from existing list.
- **VTEP_X**: IPv4 address of VTEPs that are added or removed from the list.
Example

- These commands create a default VXLAN head-end replication flood list.

```plaintext
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan flood vtep 10.1.1.1 10.1.1.2
switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan flood vtep 10.1.1.1 10.1.1.2
switch(config-if-Vx1)#
```

- These commands create VXLAN head-end replication flood lists for the VNIs accessed through VLANs 101 and 102.

```plaintext
switch(config-if-Vx1)#vxlan vlan 101-102 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan flood vtep 10.1.1.1 10.1.1.2
    vxlan vlan 101 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
    vxlan vlan 102 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
    vxlan udp-port 4789
switch(config-if-Vx1)#
```

- These commands add two VTEPs for the VNI access through VLAN 102.

```plaintext
switch(config-if-Vx1)#vxlan vlan 102 flood vtep add 12.1.1.1
switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan flood vtep 10.1.1.1 10.1.1.2
    vxlan vlan 101 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3
    vxlan vlan 102 flood vtep 11.1.1.1 11.1.1.2 11.1.1.3 12.1.1.1
    vxlan udp-port 4789
switch(config-if-Vx1)#
```
vxlan multicast-group

The `vxlan multicast-group` command associates a specified multicast group with the configuration mode VXLAN interface (VTI), which handles multicast and broadcast traffic as a layer 2 interface in a bridging domain.

The VTI maps multicast traffic from its associated VLANs to the specified multicast group. Inter-VTEP multicast communications include all VTEPs that are associated with the specified multicast group, which is independent of any other multicast groups that VLAN hosts may join.

A VTI can be associated with one multicast group. By default, a VTI is not associated with any multicast group.

The `no vxlan multicast-group` and `default vxlan multicast-group` commands removes the multicast group – VTI association by removing the `vxlan multicast-group` command from `running-config`.

**Command Mode**

Interface-VXLAN Configuration

**Command Syntax**

```
xvlan multicast-group  group_addr
no vxlan multicast-group
default vxlan multicast-group
```

**Parameters**

- `group_addr` IPv4 address of multicast group. Dotted decimal notation of a valid multicast address.

**Related Commands**

- `interface vxlan` places the switch in VXLAN interface configuration mode.

**Examples**

- This command associates the multicast address of 227.10.1.1 with VTI 1.

```
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan multicast-group 227.10.1.1
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan multicast-group 227.10.1.1
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

- This command changes VTI 1’s multicast group association.

```
switch(config-if-Vx1)#vxlan multicast-group 227.10.5.5
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan multicast-group 227.10.5.5
  vxlan udp-port 4789
switch(config-if-Vx1)#
```

- This command removes the multicast group association from VTI 1.

```
switch(config-if-Vx1)#no vxlan multicast-group
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
switch(config-if-Vx1)#
```
**vxlan multicast-group decap**

The `vxlan multicast-group decap` command enables VXLAN multicast decapsulation.

VTEPs are enabled by VXLAN multicast decapsulation, supporting Head End Replication (HER). Multicast encapsulated Broadcast/Unknown/Multicast (BUM) packets terminate VTEPs from remote VTEPs that do not support HER.

The `no vxlan multicast-group decap` and `default vxlan multicast-group decap` commands disable VXLAN multicast decapsulation.

**Command Mode**
- Interface-VXLAN Configuration

**Command Syntax**

```
vxlan multicast-group decap group_addr
no vxlan multicast-group decap
default vxlan multicast-group decap
```

**Parameters**
- `group_addr` IPv4 address of multicast group. Dotted decimal notation of a valid multicast address.

**Examples**
- This command enables VXLAN multicast decapsulation.

```
switch(config)#interface vxlan 1
switch(config-config-if-Vx1)#vxlan multicast-group decap 230.1.1.1
switch(config-config-if-Vx1)#
```
- This command disables VXLAN multicast decapsulation.

```
switch(config)#interface vxlan 1
switch(config-config-if-Vx1)#no vxlan multicast-group decap 230.1.1.1
switch(config-config-if-Vx1)#
```
vxlan source-interface

The `vxlan source-interface` command specifies the interface from which the configuration mode VXLAN interface (VTI) derives the source address (IP) that it uses when exchanging VXLAN frames. There is no default source interface assignment.

The `no vxlan source-interface` and `default vxlan source-interface` commands remove the source interface assignment from the configuration mode VXLAN interface by deleting the corresponding `ip vxlan source-interface` command from `running-config`.

**Command Mode**

Interface-VXLAN Configuration

**Command Syntax**

```
  vxlan source-interface INT_NAME
  no vxlan source-interface
  default vxlan source-interface
```

**Parameters**

- `INT_NAME` Interface type and number. Options include:
  - `loopback l_num` Loopback interface specified by `l_num`.

**Guidelines**

A VXLAN interface is inoperable without the source-interface assignment.

**Related Commands**

- `interface vxlan` places the switch in VXLAN interface configuration mode.

**Example**

- These commands configure VTI 1 to use the IP address 10.25.25.3 as the source address of outbound VXLAN frames.

  ```
  switch(config)#interface loopback 15
  switch(config-if-Lo15)#ip address 10.25.25.3/24
  switch(config-if-Lo15)#exit
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan source-interface loopback 15
  switch(config-if-Vx1)#show active
  interface Vxlan1
  vxlan source-interface Loopback15
  vxlan udp-port 4789
  switch(config-if-Vx1)#
  ```
**vxlan udp-port**

The `vxlan udp-port` command associates a UDP port with the configuration mode VXLAN interface (VTI). By default, UDP port 4789 is associated with the VTI.

Packets bridged to the VTI from a VLAN are encapsulated with a VXLAN header that includes the VNI associated with the VLAN and the IP address of the VTEP that connects to the recipient, then sent through the UDP port. Packets that arrive through the UDP port are sent to the bridging domain of the recipient VLAN as determined by the VNI number in the VXLAN header and the interface’s VNI-VLAN map.

The `no vxlan udp-port` and `default vxlan udp-port` command restores the default UDP port association (4789) on the configuration mode interface by deleting the corresponding `vxlan udp-port` command from `running-config`.

**Command Mode**

- Interface-VXLAN Configuration

**Command Syntax**

```
vxlan udp-port port_id
no vxlan udp-port
default vxlan udp-port
```

**Parameters**

- **port_id** UDP port number. Value ranges from 1024 to 65535.

**Guidelines**

UDP port 4789 is reserved by convention for VXLAN usage. Under most typical applications, this parameter should be set to the default value.

**Related Commands**

- `interface vxlan` places the switch in VXLAN interface configuration mode.

**Example**

- This command associates UDP port 5500 with VXLAN interface 1.

  ```
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#vxlan udp-port 5500
  switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan udp-port 5500
  switch(config-if-Vx1)#
  ```

- This command resets the VXLAN interface 1 UDP port association of 4789.

  ```
  switch(config-if-Vx1)#no vxlan udp-port
  switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan udp-port 4789
  switch(config-if-Vx1)#
  ```
vxlans/vlan/vni

The **vxlans/vlan/vni** command associates a VLAN ID with a virtual network identifier (VNI). A VNI is a 24-bit number that is assigned to a VLAN to distinguish it from other VLANs that are on a VXLAN tunnel interface (VTI). VNI values range from 1 to 16777215 in decimal notation and from 0.0.1 to 255.255.255 in dotted decimal notation.

When a VLAN bridges a packet to the VTI, the packet is encapsulated with a VXLAN header that includes the VNI that is associated with the VLAN. Packets that arrive on the VTI’s UDP socket are bridged to the VLAN that is associated with the VNI specified by the VXLAN header that encapsulates the packet.

The VTI requires a one-to-one correspondence between specified VLANs and VNI values. Commands that assign a new VNI to a previously configured VLAN replace the existing VLAN assignment statement in **running-config**. Commands that attempt to assign a VNI value to a second VLAN generate a CLI error.

The **no vxlans/vlan/vni** and **default vxlans/vlan/vni** commands remove the specified VLAN-VNI association from the configuration mode interface by deleting the corresponding **vxlans/vlan** command from **running-config**.

**Command Mode:** Interface-VXLAN Configuration

**Command Syntax**

- `vxlans/vlan vlan_id vni vni_id`
- `no vxlans/vlan vlan_id vni [vni_id]`
- `default vxlans/vlan vlan_id vni [vni_id]`

**Parameters**

- **vlan_id**  
  number of access VLAN. Value ranges from 1 to 4094.
- **vni_id**  
  VNI number. Valid formats: decimal <1 to 16777215> or dotted decimal <0.0.1 to 255.255.255>.

**Example**

- These commands associate VLAN 100 to VNI 100 and VLAN 200 to VNI 10.10.200.

```plaintext
switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlans/vlan 100 vni 100
switch(config-if-Vx1)#vxlans/vlan 200 vni 10.10.200
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 200 vni 658120
  vxlan vlan 100 vni 100
switch(config-if-Vx1)#vxlans/vlan vni notation dotted
switch(config-if-Vx1)#show active
interface Vxlan1
  vxlan udp-port 4789
  vxlan vlan 200 vni 10.10.200
  vxlan vlan 100 vni 0.0.100
switch(config-if-Vx1)#
```
vxlan vni notation dotted

The `vxlan vni notation dotted` command configures the switch to display VNIs in dotted decimal notation. A virtual network identifier (VNI) is a 24-bit number that is assigned to a VLAN to distinguish it from other VLANs that are on a VXLAN tunnel interface. VNI values range from 1 to 16777215 in decimal notation and from 0.0.1 to 255.255.255 in dotted decimal notation.

The command affects the VNI number display in all `show` commands, including `show running-config`. Commands that include VNI as a parameter may use decimal or dotted decimal notation regardless of the setting of this command. By default, show commands display VNI number in decimal notation.

The `no vxlan vni notation dotted` and `default vxlan vni notation dotted` commands restore the default setting of displaying vni numbers in decimal notation by deleting the `vxlan vni notation dotted` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
  vxlan vni notation dotted
  no vxlan vni notation dotted
  default vxlan vni notation dotted
```

**Examples**

- These commands configure the switch to display vni numbers in dotted decimal notation, then displays a configuration that includes a vni setting.

  ```
  switch(config)#vxlan vni notation dotted
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan udp-port 4789
    vxlan vlan 333 vni 3.4.5
  switch(config-if-Vx1)#
  ```

- These commands configure the switch to display vni numbers in decimal notation, then displays a configuration that includes a vni setting.

  ```
  switch(config)#no vxlan vni notation dotted
  switch(config)#interface vxlan 1
  switch(config-if-Vx1)#show active
  interface Vxlan1
    vxlan udp-port 4789
    vxlan vlan 333 vni 197637
  switch(config-if-Vx1)#
  ```
Chapter 20

ACLs and Route Maps

The switch uses rule based lists to control packet access to ports and to select routes for redistribution to routing domains defined by dynamic routing protocols. This chapter describes the construction of access control lists (ACLs), prefix lists, and route maps.

This chapter includes the following sections:

- Section 20.1: ACL, Route Map, and Prefix List Introduction
- Section 20.2: Access Control Lists
- Section 20.3: Route Maps
- Section 20.4: Prefix Lists
- Section 20.5: ACL, Route Map, and Prefix List Commands

20.1 ACL, Route Map, and Prefix List Introduction

Access control lists, route maps, and prefix lists are all processed in order, beginning with the first rule and proceeding until a match is encountered.

An access control list (ACL) is a list of rules that control the inbound flow of packets into Ethernet interfaces, port channel interfaces or the switch control plane. The switch supports the implementation of a wide variety of filtering criteria including IP and MAC addresses, TCP/UDP ports with include/exclude options without compromising its performance or feature set. Filtering syntax is industry standard.

A route map is a list of rules that control the redistribution of IP routes into a protocol domain on the basis of such criteria as route metrics, access control lists, next hop addresses, and route tags. Route maps can also alter parameters of routes as they are redistributed.

A prefix list is a list of rules that defines route redistribution access for a specified IP address space. Route maps often use prefix lists to filter routes.
20.2 Access Control Lists

These sections describe Access Control Lists:

- Section 20.2.1: ACL Description
- Section 20.2.2: ACL Configuration
- Section 20.2.3: Applying ACLs

20.2.1 ACL Description

This section describes ACL composition and function. The switch supports the following ACL types:

- IPv4
- IPv6
- Standard IPv4
- Standard IPv6
- MAC

20.2.1.1 ACL Structure

An ACL is an ordered list of rules that defines access restrictions for the entities (the control plane, or an interface) to which it is applied. ACLs are also used by route maps to select routes for redistribution into specified routing domains.

ACL rules specify the data to which packet contents are compared when filtering data.

- The interface forwards packets that match all conditions in a permit rule.
- The interface drops packets that match all conditions in a deny rule.
- The interface drops packets that do not match at least one rule.

Upon its arrival at an interface, a packet's fields are compared to the first rule of the ACL applied to the interface. Packets that match the rule are forwarded (permit rule) or dropped (deny rule). Packets that do not match the rule are compared to the next rule in the list. This process continues until the packet either matches a rule or the rule list is exhausted. The interface drops packets not matching a rule.

The sequence number designates the rule's placement in the ACL.

20.2.1.2 ACL Rules

ACL rules consist of a condition list that is compared to inbound packet fields. When all of a rule's criteria match a packet's contents, the interface performs the action specified by the rule.

The set of available conditions depend on the ACL type and the specified protocol within rule. The following is a list of conditions available for supported ACL types.

**IPv4 ACL Rule Parameters**

All rules in IPv4 ACLs include the following criteria:

- **Protocol**: The packet's IP protocol. Valid rule inputs include:
  - Protocol name for a limited set of common protocols.
  - Assigned protocol number for all IP protocols.
- **Source Address**: The packet's source IPv4 address. Valid rule inputs include:
  - a subnet address (CIDR or address-mask). Discontiguous masks are supported.
Chapter 20: ACLs and Route Maps

Access Control Lists

- a host IP address (dotted decimal notation).
- any to denote that the rule matches all source addresses.

**Destination Address:** The packet’s destination IP address. Valid rule inputs include:
- a subnet address (CIDR or address-mask). Discontiguous masks are supported.
- a host IP address (dotted decimal notation).
- any to denote that the rule matches all destination addresses.

All rules in IPv4 ACLs may include the following criteria:

- **Fragment:** Rules filter on the fragment bit.
- **Time-to-live:** Compares the TTL (time-to-live) value in the packet to a specified value. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform. Comparison options include:
  - Equal: Packets match if packet value equals statement value.
  - Greater than: Packets match if packet value is greater than statement value.
  - Less than: Packets match if packet value is less than statement value.
  - Not equal: Packets match if packet value does not equal statement value.

The availability of the following optional criteria depends on the specified protocol:

- **Source Ports / Destination Ports:** A rule filters on ports when the specified protocol supports IP address-port combinations. Rules provide one of these port filtering values:
  - any denotes that the rule matches all ports.
  - A list of ports that matches the packet port. Maximum list size is 10 ports.
  - Negative port list. The rule matches any port not in the list. Maximum list size is 10 ports.
  - Integer (lower bound): The rule matches any port with a number larger than the integer.
  - Integer (upper bound): The rule matches any port with a number smaller than the integer.
  - Range integers: The rule matches any port whose number is between the integers.
- **Flag bits:** Rules filter TCP packets on flag bits.
- **Message type:** Rules filter ICMP type or code.
- **Tracked:** Matches packets in existing ICMP, UDP, or TCP connections. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform.

**IPv6 ACL Rule Parameters**

**Note** When calculating the size of ACLs, be aware that Arista switches install four rules in every IPv6 ACL so that ICMPv6 neighbor discovery packets bypass the default drop rule.

All rules in IPv6 ACLs include the following criteria:

- **Protocol:** All rules filter on the packet’s IP protocol field. Rule input options include:
  - Protocol name for a limited set of common protocols.
  - Assigned protocol number for all IP protocols.
- **Source Address:** The packet’s source IPv6 address. Valid rule inputs include:
  - an IPv6 prefix (CIDR). Discontiguous masks are supported.
  - a host IP address (dotted decimal notation).
  - any to denote that the rule matches all addresses.
• **Destination Address**: The packet’s destination IP address. Valid rule inputs include:
  - a subnet address (CIDR or address-mask). Discontiguous masks are supported.
  - a host IP address (dotted decimal notation).
  - *any* to denote that the rule matches all addresses.

All rules in IPv6 ACLs **may** include the following criteria:

- **Fragment**: Rules filter on the fragment bit.
- **Hop**: Compares the packet’s hop-limit value to a specified value. Comparison options include:
  - **Equal**: Packets match if packet value equals statement value.

The availability of the following optional criteria depends on the specified protocol:

- **Source Ports / Destination Ports**: A rule filters on ports when the specified protocol supports IP address-port combinations. Rules provide one of these port filtering values:
  - *any* denotes that the rule matches all ports.
  - A list of ports that matches the packet port. Maximum list size is 10 ports.
  - Negative port list. The rule matches any port not in the list. Maximum list size is 10 ports.
  - Integer (lower bound): The rule matches any port with a number larger than the integer.
  - Integer (upper bound): The rule matches any port with a number smaller than the integer.
  - Range integers: The rule matches any port whose number is between the integers.

- **Flag bits**: Rules filter TCP packets on flag bits.
- **Message type**: Rules filter ICMP type or code.
- **Tracked**: Matches packets in existing ICMP, UDP, or TCP connections. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform.

### Standard IPv4 and IPv6 ACL Rule Parameters

**Note**

When calculating the size of ACLs, be aware that Arista switches install four rules in every IPv6 ACL so that ICMPv6 neighbor discovery packets bypass the default drop rule.

Standard ACLs filter only on the source address.

### MAC ACL Rule Parameters

MAC ACLs filter traffic on a packet’s layer 2 header. Criteria that MAC ACLs use to filter packets include:

- **Source Address and Mask**: The packet’s source MAC address. Valid rule inputs include:
  - MAC address range (address-mask in 3x4 dotted hexadecimal notation).
  - *any* to denote that the rule matches all source addresses.

- **Destination Address and Mask**: The packet’s destination MAC address. Valid rule inputs include:
  - MAC address range (address-mask in 3x4 dotted hexadecimal notation).
  - *any* to denote that the rule matches all destination addresses.

- **Protocol**: The packet’s protocol as specified by its EtherType field contents. Valid inputs include:
  - Protocol name for a limited set of common protocols.
  - Assigned protocol number for all protocols.
20.2.1.3 Creating and Modifying Lists

The switch provides configuration modes for creating and modifying ACLs. The command that enters an ACL configuration mode specifies the name of the list that the mode modifies. The switch saves the list to the running configuration when the configuration mode is exited.

- ACLs are created and modified in ACL configuration mode.
- Standard ACLs are created and modified in Standard-ACL-configuration mode.
- MAC ACLs are created and modified in MAC-ACL-configuration mode.

Lists that are created in one mode cannot be modified in any other mode.

A sequence number designates the rule’s placement in a list. New rules are inserted into a list according to their sequence numbers. A rule’s sequence number can be referenced when deleting it from a list.

Section 20.2.2 describes procedures for configuring ACLs.

20.2.1.4 Implementing Access Control Lists

An access control list is implemented by assigning the list to an Ethernet or Port Channel interface, or to the Control Plane. The switch assigns a default ACL to the Control Plane unless the configuration contains a valid Control-Plane ACL assignment statement. Ethernet and Port Channel interfaces are not assigned an ACL by default. Standard ACLs are applied to interfaces in the same manner as other ACLs.

IPv4 and MAC ACLs are separately applied for inbound and outbound packets. An interface can be assigned multiple ACLs, with a limit of one ACL per packet direction per ACL type. Egress ACLs are supported on a subset of all available switches. The control-plane does not support egress ACLs.

Section 20.2.3 describes procedures for applying ACLs to interfaces or the control plane.

20.2.1.5 ACL Rule Tracking

ACL rule tracking determines the impact of ACL rules on the traffic accessing interfaces upon which they are applied. ACLs provide two tracking mechanisms:

- ACL logging: A syslog entry is logged when a packet matches specified ACL rules.
- ACL counters: ACL counters increment when a packet matches a rule in specified ACLs.

ACL Logging

ACL rules provide a log option that produces a log message when a packet matches the rule. ACL logging creates a syslog entry when a packet matches an ACL rule where logging is enabled. Packets that match a logging-enabled ACL rule are copied to the CPU by the hardware. These packets trigger the creation of a syslog entry. The information provided in the entry depends on the ACL type or the protocol specified by the ACL. Hardware rate limiting is applied to packets written to the CPU, avoiding potential DoS attacks. The rate of logging is also software limited to avoid the creation of syslog lists that are too large for practical use by human operators.

Section 20.2.2.3 describes procedures for configuring and enabling ACL logging.
ACL Counters

An ACL counter is assigned to each ACL rule. The activity of the ACL counters for rules within a list depend on the list's counter state. When the list is in counting state, the ACL counter of a rule increments when the rule matches a packet. When the list is in non-counting state, the counter does not increment. A list’s counter state applies to all rules in the ACL. The initial state for new ACLs is non-counting.

When an ACL changes from counting state to non-counting state, or when the ACL is no longer applied to any interfaces that increment counters, counters for all rules in the list maintain their values and do not reset. When the ACL returns to counting mode or is applied to an interface that increments counters, the counter operation resumes from its most recent value.

Counters never decrement and are reset only through CLI commands.

Section 20.2.2.3 describes procedures for configuring and enabling ACL counters.

20.2.2 ACL Configuration

Access Control Lists are created and modified in an ACL-configuration mode. A list can be edited only in the mode where it was created. The switch provides five configuration modes for creating and modifying Access Control Lists:

- **ACL configuration mode** for IPv4 Access Control Lists.
- **IPv6-ACL configuration mode** for IPv6 Access Control Lists.
- **Std-ACL configuration mode** for Standard IPv4 Access Control Lists.
- **Std-IPv6-ACL configuration mode** for Standard IPv6 Access Control Lists.
- **MAC-ACL configuration mode** for MAC Access Control Lists.

These sections describe the creation and modification of ACLs:

- Section 20.2.2.1: Managing ACLs
- Section 20.2.2.2: Modifying an ACL
- Section 20.2.2.3: ACL Rule Tracking Configuration
- Section 20.2.2.4: Displaying ACLs

20.2.2.1 Managing ACLs

Creating and Opening a List

To create an ACL, enter one of the following commands, followed by the name of the list:

- **ip access-list** for IPv4 ACLs.
- **ipv6 access-list** for IPv6 ACLs.
- **ip access-list standard** for standard IPv4 ACLs.
- **ipv6 access-list standard** for standard IPv6 ACLs.
- **mac access-list** for MAC ACLs.

The switch enters the appropriate ACL configuration mode for the list. If the command is followed by the name of an existing ACL, subsequent commands edit that list (see Modifying an ACL for additional information).
Examples

- This command places the switch in ACL configuration mode to create an ACL named test1.
  
  ```
  switch(config)#ip access-list test1
  switch(config-acl-test1)#
  ```

- This command places the switch in Standard-ACL-configuration mode to create a Standard ACL named stest1.
  
  ```
  switch(config)#ip access-list standard stest1
  switch(config-std-acl-stest1)#
  ```

- This command places the switch in MAC-ACL configuration mode to create an MAC ACL named mtest1.
  
  ```
  switch(config)#mac access-list mtest1
  switch(config-mac-acl-mtest1)#
  ```

Saving List Modifications

ACL configuration modes are group-change modes. Changes made in a group-change mode are saved by exiting the mode.

**Important!** After exiting ACL mode, the running-config file must be saved to the startup configuration file to preserve an ACL after a system restart.

Example

- The second example in Adding a Rule (page 978) results in this edited ACL:
  
  ```
  switch(config-acl-test1)#show
  IP Access List test1
    10 permit ip 10.10.10.0/24 any
    20 permit ip 10.30.10.0/24 host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
    40 permit ip any any
  ```

  Because the changes were not yet saved, the ACL remains empty, as shown by `show ip access-lists`.

  ```
  switch(config-acl-test1)#show ip access-lists test1
  switch(config-acl-test1)#
  ```

  To save all current changes to the ACL and exit ACL configuration mode, type `exit`.

  ```
  switch(config-acl-test1)#exit
  switch(config)#show ip access-lists test1
  IP Access List test1
    10 permit ip 10.10.10.0/24 any
    20 permit ip 10.30.10.0/24 host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
    40 permit ip any any
  ```

Discarding List Changes

The `abort` command exits ACL configuration mode without saving pending changes.
Example

- Example 2 in Adding a Rule (page 978) results in this edited ACL:

```
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

To discard the changes, enter `abort`. If the ACL existed before entering ACL-configuration mode, `abort` restores the version that existed before entering ACL-configuration mode. Otherwise, `show ip access-lists` shows the ACL was not created.

```
switch(config-acl-test1)#abort
switch(config)#
```

20.2.2.2 Modifying an ACL

An existing ACL, including those currently applied to interfaces, can be modified by entering the appropriate configuration mode for the ACL as described in Creating and Opening a List. By default, while an ACL is being modified all traffic is blocked on any interface to which the ACL has been applied.

Permit All Traffic During ACL Update

Because blocking ports during ACL modifications can result in packet loss and can interfere with features such as routing and dynamic NAT, 7150 series switches can be configured instead to permit all traffic on Ethernet and VLAN interfaces while ACLs applied to those interfaces are being modified. This is done with the `hardware access-list update default-result permit` command.

These commands add deny rules to the appropriate ACL:

- `deny (IPv4 ACL)` adds a deny rule to an IPv4 ACL.
- `deny (IPv6 ACL)` adds a deny rule to an IPv6 ACL.
- `deny (Standard IPv4 ACL)` adds a deny rule to an IPv4 standard ACL.
- `deny (Standard IPv6 ACL)` adds a deny rule to an IPv6 standard ACL.
- `deny (MAC ACL)` adds a deny rule to a MAC ACL.

These commands add permit rules to the appropriate ACL:

- `permit (IPv4 ACL)` adds a permit rule to an IPv4 ACL.
- `permit (IPv6 ACL)` adds a permit rule to an IPv6 ACL.
- `permit (Standard IPv4 ACL)` adds a permit rule to an IPv4 standard ACL.
- `permit (Standard IPv6 ACL)` adds a permit rule to an IPv6 standard ACL.
- `permit (MAC ACL)` adds a permit rule to a MAC ACL.

Adding a Rule

To append a rule to the end of a list, enter the rule without a sequence number while in ACL configuration mode for the list. The new rule’s sequence number is derived by adding 10 to the last rule’s sequence number.
Examples

- This command configures the switch to permit all traffic during ACL modifications on interfaces to which the ACL has been applied. The rules in modified ACLs are applied after exiting ACL configuration mode, and after the ACL rules have been populated in hardware.

  `switch(config)#hardware access-list update default-result permit`

- These commands enter the first three rules into a new ACL.

  `switch(config-acl-test1)#permit ip 10.10.10.0/24 any
  switch(config-acl-test1)#permit ip any host 10.20.10.1
  switch(config-acl-test1)#deny ip host 10.10.10.1 host 10.20.10.1`

To view the edited list, type `show`.

  `switch(config-acl-test1)#show
  IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1`

- This command appends a rule to the ACL. The new rule’s sequence number is 40.

  `switch(config-acl-test1)#permit ip any any
  switch(config-acl-test1)#show
  IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any`

Inserting a Rule

To insert a rule into a ACL, enter the rule with a sequence number between the existing rules’ numbers.

Example

- This command inserts a rule between the first two rules by assigning it the sequence number 15.

  `Switch(config-acl-test1)#15 permit ip 10.30.10.0/24 host 10.20.10.1
  Switch(config-acl-test1)#show
  IP Access List test1
  10 permit ip 10.10.10.0/24 any
  15 permit ip 10.30.10.0/24 host 10.20.10.1
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any`

Deleting a Rule

To remove a rule from the current ACL, perform one of these commands:

- Enter `no`, followed by the sequence number of the rule to be deleted.
- Enter `no`, followed by the rule to be deleted.
- Enter `default`, followed by the rule to be deleted.
Example

- These equivalent commands remove rule 20 from the list.

```
switch(config-acl-test1)#no 20
switch(config-acl-test1)#no permit ip any host 10.20.10.1
switch(config-acl-test1)#default permit ip any host 10.20.10.1
```

This ACL results from entering one of the preceding commands.

```
switch(config-acl-test1)#show
ip access list test1
  10 permit ip 10.10.10.0/24 any
  15 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

Resequencing Rule Numbers

Sequence numbers determine the order of the rules in an Access Control List. After a list editing session where existing rules are deleted and new rules are inserted between existing rules, the sequence number distribution may not be uniform. Resequencing rule numbers changes adjusts the sequence number of rules to provide a constant difference between adjacent rules. The `resequence (ACLs)` command adjusts the sequence numbers of ACL rules.

Example

- The `resequence` command renumbers rules in the test1 ACL. The sequence number of the first rule is 100; subsequent rules numbers are incremented by 20.

```
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  25 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  50 permit ip any any
  90 remark end of list
```

```
switch(config-acl-test1)#resequence 100 20
switch(config-acl-test1)#show
IP Access List test1
  100 permit ip 10.10.10.0/24 any
  120 permit ip any host 10.20.10.1
  140 deny ip host 10.10.10.1 host 10.20.10.1
  160 permit ip any any
  180 remark end of list
```

20.2.2.3 ACL Rule Tracking Configuration

ACL rules provide a `log` option that produces a syslog message about the packets matching packet. ACL logging creates a syslog entry when a packet matches an ACL rule with logging enabled.

This feature is currently available on Arad switches and on 7100 series switches. On 7100 series switches, matches are logged only on ingress, not on egress.

Example

- This command creates an ACL rule with logging enabled.

```
switch(config-acl-test1)#15 permit ip 10.30.10.0/24 host 10.20.10.1 log
switch(config-acl-test1)#
```
The format of the generated syslog message depends on the ACL type and the specified protocol:

- Messages generated by a TCP or UDP packet matching an IP ACL use this format:
  
  **IPACCESS:** list acl intf filter protocol src-ip(src_port) -> dst-ip(dst_port)

- Messages generated by ICMP packets matching an IP ACL use this format:
  
  **IPACCESS:** list acl intf filter icmp src-ip(src_port) -> dst-ip(dst-port) type=n code=m

- Messages generated by all other IP packets matching an IP ACL use this format:
  
  **IPACCESS:** list acl intf filter protocol src-ip -> dst-ip

- Messages generated by packets matching a MAC ACL use this format:
  
  **MACACCESS:** list acl intf filter vlan ether src_mac -> dst_mac

- Messages generated by a TCP or UDP packet matching a MAC ACL use this format:
  
  **MACACCESS:** list acl intf filter vlan ether ip-prt src-mac src-ip: src-prt -> dst-mac dst-ip: dst-prt

- Messages generated by any other IP packet matching a MAC ACL use this format:
  
  **MACACCESS:** list acl intf filter vlan ether src_mac src_ip -> dst_mac dst_ip

Variables in the syslog messages display the following values:

- acl Name of ACL.
- intf Name of interface that received the packet.
- filter Action triggered by ACL (denied or permitted).
- protocol IP protocol specified by packet.
- vlan Number of VLAN receiving packet.
- ether EtherType protocol specified by packet.
- src-ip and dst-ip source and destination IP addresses.
- src-prt and dst-prt source and destination ports.
- src-mac and dst-mac source and destination MAC addresses.

ACLs provide a command that configures its counter state (counting or non-counting). The counter state applies to all rules in the ACL. The initial state for new ACLs is non-counting.

The **statistics per-entry (ACL configuration modes)** command places the ACL in counting mode.

- This command places the configuration mode ACL in counting mode.

  switch(config-acl-test1)#statistics per-entry
  switch(config-acl-test1)#exit
  switch(config-acl-test1)#show ip access-list test1
  IP Access List test1
    statistics per-entry
    10 permit ip 10.10.10.0/24 any
    20 permit ip any host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
    40 permit ip any any
    50 remark end of list

The **clear ip access-lists counters** and **clear ipv6 access-lists counters** commands set the IP access list counters to zero for the specified IP access list.
This command clears the ACL counter for the test1 ACL.

```
switch(config)#clear ip access-lists counters test1
```

20.2.2.4 Displaying ACLs

ACLs can be displayed by a `show running-config` command. The `show ip access-lists` also displays ACL rosters and contents, as specified by command parameters.

When editing an ACL, the `show (ACL configuration modes)` command displays the current or pending list, as specified by command parameters.

**Displaying a List of ACLs**

To display the roster of ACLs on the switch, enter `show ip access-lists` with the `summary` option.

**Example**

- This command lists the available Access Control Lists.

```
switch(config)#show ip access-list summary
IPV4 ACL default-control-plane-acl
  Total rules configured: 12
  Configured on: control-plane
  Active on    : control-plane

IPV4 ACL list2
  Total rules configured: 3

IPV4 ACL test1
  Total rules configured: 6

IPv4 ACL test_1
  Total rules configured: 1

IPV4 ACL test_3
  Total rules configured: 0
```

**Displaying Contents of an ACL**

These commands display ACL contents.

- `show ip access-lists`
- `show ipv6 access-lists`
- `show mac access-lists`

Each command can display the contents of one ACL or of all ACLs of the type specified by the command:

- To display the contents of one ACL, enter `show ip access-lists` followed by the name of the ACL.
- To display the contents of all ACLs on the switch, enter the command without any options.

ACLs that are in counting mode display the number of inbound packets each rule in the list matched and the elapsed time since the last match.
Chapter 20: ACLs and Route Maps

Example

- This command displays the rules in the default-control-plane-acl ACL.

  ```
  switch#show ip access-lists default-control-plane-acl
  IP Access List default-control-plane-acl [readonly]
  statistics per-entry
  10 permit icmp any any
  20 permit ip any any tracked [match 1725, 0:00:00 ago]
  30 permit ospf any any
  40 permit tcp any any eq ssh telnet www snmp bgp https
  50 permit udp any any eq bootpc snmp [match 993, 0:00:29 ago]
  60 permit tcp any any eq mlag ttl eq 255
  70 permit udp any any eq mlag ttl eq 255
  80 permit vrrp any any
  90 permit ahp any any
  100 permit pim any any
  110 permit igmp any any [match 1316, 0:00:23 ago]
  120 permit tcp any any range 5900 5910
  ```

- This command displays the rules in all ACLs on the switch.

  ```
  switch#show ip access-lists
  IP Access List default-control-plane-acl [readonly]
  statistics per-entry
  10 permit icmp any any
  20 permit ip any any tracked [match 1371, 0:00:00 ago]
  30 permit ospf any any
  40 permit tcp any any eq ssh telnet www snmp bgp https
  50 permit udp any any eq bootpc snmp
  60 permit tcp any any eq mlag ttl eq 255
  70 permit udp any any eq mlag ttl eq 255
  80 permit vrrp any any
  90 permit ahp any any
  100 permit pim any any
  110 permit igmp any any [match 1316, 0:00:23 ago]
  120 permit tcp any any range 5900 5910
  ```

  IP Access List list2
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 permit ip any host 10.20.10.1
  40 deny ip host 10.10.10.1 host 10.20.10.1
  50 permit ip any any

  IP Access List test1

  Switch(config)#

Displaying ACL Modifying

While editing an ACL in ACL-configuration mode, the show (ACL configuration modes) command provides options for displaying ACL contents.

- To display the list, as modified in ACL configuration mode, enter show or show pending.
- To display the list, as stored in running-config, enter show active.
- To display differences between the pending list and the stored list, enter show diff.
Examples

The examples in this section assume these ACL commands were previously entered.

These commands are stored in the configuration:

10 permit ip 10.10.10.0/24 any
20 permit ip any host 10.21.10.1
30 deny ip host 10.10.10.1 host 10.20.10.1
40 permit ip any any
50 remark end of list

The current edit session removed this command. This change is not yet stored to running-config:

20 permit ip any host 10.21.10.1

The current edit session added these commands ACL. They are not yet stored to running-config:

20 permit ip 10.10.0.0/16 any
25 permit tcp 10.10.20.0/24 any
45 deny pim 239.24.124.0/24 10.5.8.4/30

This command displays the pending ACL, as modified in ACL configuration mode.

switch(config-acl-test_1)#show pending
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.10.0.0/16 any
  25 permit tcp 10.10.20.0/24 any
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  45 deny pim 239.24.124.0/24 10.5.8.4/30
  50 remark end of list

This command displays the ACL, as stored in the configuration.

switch(config-acl-test_1)#show active
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.21.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list

This command displays the difference between the saved and modified ACLs.

• Rules added to the pending list are denoted with a plus sign (+).
• Rules removed from the saved list are denoted with a minus sign (-).

switch(config-acl-test_1)#show diff
---
+++ @@ -1,7 +1,9 @@

20.2.3 Applying ACLs

Access Control Lists become active when they are assigned to an interface or the Control Plane. This section describes the process of adding and removing ACL interface assignments.

Applying an ACL to an Interface

The switch must be in interface configuration mode to assign an ACL to an interface.

- The `ip access-group` command applies the specified IP or standard IP ACL to the configuration mode interface.
- The `mac access-group` command applies the specified MAC ACL to the configuration mode interface.

IPv4, IPv6, and MAC ACLs are separately applied for inbound and outbound packets. An interface can be assigned multiple ACLs, with a limit of one ACL per packet direction per ACL type. Egress ACLs are supported on a subset of all available switches. IPv6 egress ACLs have limited availability, and IPv6 egress ACLs applied to routed interfaces across the same chip on the DCS-7500E and the DCS-7280E series can be shared. In addition to that, the DSCP value can match on IPv6 egress ACLs. This result in a more efficient utilization of system resources, and is particularly useful for environments with few, potentially large, IPv6 egress ACLs applied across multiple routed interfaces.

Example

- These commands assign `test1` ACL to Ethernet interface 3, then verify the assignment.

```
switch(config)#interface ethernet 3
switch(config-if-Et3)#ip access-group test1 in
switch(config-if-Et3)#show running-config interfaces ethernet 3
interface Ethernet3
   ip access-group test1 in
switch(config-if-Et3)#
```

- This command enables shared ACLs.

```
switch(config)#hardware access-list resource sharing vlan ipv6 out
switch(config)#
```

- This command disables shared ACLs.

```
switch(config)#no hardware access-list resource sharing vlan ipv6 out
switch(config)#
```

Removing an ACL from an Interface

The `no ip access-group` command removes an IP ACL assignment statement from `running-config` for the configuration mode interface. After an ACL is removed, the interface is not associated with an IP ACL.

The `no mac ip access-group` command removes a MAC ACL assignment statement from `running-config` for the configuration mode interface. After a MAC ACL is removed, the interface is not associated with an MAC ACL.

To remove an ACL from the control plane, enter the `no ip access-group` command in control plane configuration mode. Removing the control plane ACL command from `running-config` reinstates `default-control-plane-acl` as the control plane ACL.
Examples

- These commands remove the assigned IPv4 ACL from Ethernet interface 3.
  
  ```
  switch(config)#interface ethernet 3
  switch(config-if-Et3)#no ip access-group test in
  switch(config-if-Et3)#
  ```

- These commands place the switch in control plane configuration mode and remove the ACL assignment from `running-config`, restoring `default-control-plane-acl` as the Control Place ACL.
  
  ```
  switch(config)#control-plane
  switch(config-cp)#no ip access-group test_cp in
  switch(config-cp)#
  ```
20.3 Route Maps

A route map is an ordered set of rules that control the redistribution of IP routes into a protocol domain on the basis of such criteria as route metrics, access control lists, next hop addresses, and route tags. Route maps can also alter parameters of routes as they are redistributed.

These sections describe the route map implementation:

- Section 20.3.1 describes route maps.
- Section 20.3.2 describes the route map configuration process.
- Section 20.3.3 describes the usage of route maps.

20.3.1 Route Map Description

Route maps are composed of route map clauses, each of which consists of a list of match and set statements.

Route Map Clauses

Route map clauses are categorized by the resolution of routes that the clause filters.

- Permit clauses facilitate the redistribution of matched routes.
- Deny clauses prevent the redistribution of matched routes.

Route map clause elements include name, sequence number, filter type, match statements, set statements, and continue statements.

- **name** identifies the route map to which the clause belongs.
- **sequence number** designates the clause’s placement within the route map.
- **filter type** specifies the route resolution. Valid types are *permit* and *deny*.
- **match statements** specify criteria that select routes that the clause is evaluating for redistribution.
- **set statements** modify route parameters for redistributed routes.
- **continue statements** prolong the route map evaluation of routes that match a clause.

Clauses filter routes for redistribution. Routes that clauses pass are redistributed (permit clauses) or rejected (deny clauses). Routes that clauses fail are filtered by the next clause in the route map.

- When a clause does not contain a **match** statement, the clause passes all routes.
- When a clause contains a single **match** statement that lists a single object, the clause passes routes whose parameters match the object.
- When a clause contains a single **match** statement that lists multiple objects, the clauses passes routes whose parameters match at least one object.
- When a clause contains multiple **match** statements, the clause passes routes whose parameters match all match statements.

Set statements modify parameters for redistributed routes. Set statements are valid in permit clauses.

Example

- The following route map clause is named MAP_1 with sequence number 10. The clause matches all routes from BGP Autonomous system 10 and redistributes them with a local preference set to 100. Routes that do not match the clause are evaluated against the next clause in the route map.

  ```
  route-map MAP_1 permit 10
  match as 10
  set local-preference 100
  ```
Route Maps with Multiple Clauses

A route map consists of clauses with the same name and different sequence numbers. Clauses filter routes in ascending order of their sequence numbers. When a clause passes a route, the redistribution action is performed as specified by the filter type and all subsequent clauses are ignored. When the clause fails the route, the clause with the next lowest sequence number filters the route.

All route maps have an implied final clause that contains a single deny clause with no match statement. This denies redistribution to routes that are not passed by any clause.

Example

- The following route map is named MAP_1 with two permit clauses. Routes that do not match either clause are denied redistribution into the target protocol domain.

```
route-map MAP_1 permit 10
  match as 10
  set local-preference 100
!
route-map MAP_1 permit 20
  match metric-type type-1
  match as 100
```

Section 20.3.2 describes route map configuration procedures.

Route Maps with Multiple Clauses and Continue Statements

Route map clauses that contain a `continue (route-map)` command support additional route map evaluation of routes whose parameters meet the clauses’s matching statements. Routes that match a clause containing a `continue` statement are evaluated against the clause specified by the `continue` statement.

When a route matches multiple route-map clauses, the filter action (deny or permit) is determined by the last clause that the route matches. The `set` statements in all clauses matching the route are applied to the route after the route map evaluation is complete. Multiple set statements are applied in the same order by which the route was evaluated against the clauses containing them.

Example

- The following route map is named MAP_1 with a permit clause and a deny clause. The permit clause contains a continue statement. Routes that map clause 10 are evaluated against clause 20.

```
route-map MAP_2 permit 10
  match as 10
  continue 20
  set local-preference 100
!
route-map MAP_2 deny 20
  match metric-type type-1
  match as 100
```

The route is redistributed if it passes clause 10 and is rejected by clause 20. The route is denied redistribution in all other instances. The `continue` statement guarantees the evaluation of all routes against both clauses.

20.3.2 Route Map Configuration

Route maps are created and modified in route map configuration mode. These sections describe the configuration mode and its commands.

- Section 20.3.2.1: Route Map Creation and Editing
Section 20.3.2.2: Modifying Route Map Components

20.3.2.1 Route Map Creation and Editing

Creating a Route Map Clause

To create a route map, enter `route-map` followed by the map name and filter type (`deny` or `permit`). The default sequence number is assigned to the clause if the command does not include a number.

Example

- This command places the switch in route map configuration mode to create a route map clause named `map1` with a sequence number of 50.

  ```
  switch(config)#route-map map1 permit 50
  switch(config-route-map-map1)#
  ```

Editing a Route Map Clause

To edit an existing route map clause, enter `route-map` with the map’s name and clause’s number. The switch enters route-map configuration mode for the clause. Subsequent `match (route-map)` and `set (route-map)` commands add the corresponding statements to the clause.

The `show` command displays contents of the existing route map.

Example

- This command places the switch in route map configuration mode to edit an existing route map clause. The `show` command displays contents of all clauses in the route map.

  ```
  switch(config)#route-map MAP2
  switch(config-route-map-MAP2)#show
  route-map MAP2 deny 10
  Match clauses:
  match as 10
  match tag 333
  Set clauses:
  set local-preference 100
  switch(config-route-map-MAP2)#
  ```

Saving Route Map Modifications

Route map configuration mode is a group-change mode. Changes are saved by exiting the mode.

Example

- The first command creates the `map1` clause with sequence number of 10. The second command is not yet saved to the route map, as displayed by the `show` command.

  ```
  switch(config)#route-map map1 permit
  switch(config-route-map-map1)#match as 100
  switch(config-route-map-map1)#show
  ```

  ```
  switch(config-route-map-map1)#
  ```
The `exit` command saves the `match` command.

```
switch(config-route-map-map1)#exit
switch(config)#show route-map map1
route-map map1 permit 10
  Match clauses:
    match as 100
  Set clauses:
switch(config)#
```

### Discarding Route Map Modifications

The `abort` command discards all pending changes and exits route map configuration mode.

**Example**

- The `abort` command discards the pending `match` command and restores the original route map.

```
switch(config)#route-map map1 permit
switch(config-route-map-map1)#match as 100
switch(config-route-map-map1)#abort
switch(config)#show route-map map1
switch(config)#
```

#### 20.3.2.2 Modifying Route Map Components

These commands add rules to the configuration mode route-map:

- `match (route-map)` adds a match rule to a route map.
- `set (route-map)` adds a set rule to a route map.

**Editing a Clause**

To append a rule to a list, enter the rule without a sequence number in route map configuration mode for the list. The new rule's sequence number is derived by adding 10 to the last rule's sequence number.

**Example**

- These commands enter route map configuration mode for an existing route map clause, then adds a set and match statement to the clause.

```
switch(config)#route-map Map1 permit 20
switch(config-route-map-Map1)#set ip next-hop 10.2.4.5
switch(config-route-map-Map1)#match tag 500
switch(config-route-map-Map1)#
```

This command displays the contents of the clause before saving the statements.

```
switch(config-route-map-Map1)#show
route-map Map1 deny 10
  Match clauses:
    match as 10
    match tag 333
  Set clauses:
    set local-preference 100
route-map Map1 permit 20
  Match clauses:
    match metric-type type-1
    match as-path List1
  Set clauses:
```
This command exits route map configuration mode, saves the new statements, and displays the contents of the clause after the statements are saved.

```
switch(config-route-map-Map1)#exit
switch(config)#show route-map Map1
route-map Map1 deny 10
  Match clauses:
    match as 10
    match tag 333
  Set clauses:
    set local-preference 100
route-map Map1 permit 20
  Match clauses:
    match metric-type type-1
    match as-path List1
    match tag 500
  Set clauses:
    set ip next-hop 10.2.4.5
switch(config)#
```

### Inserting a Clause

To insert a new clause into an existing route map, create a new clause with a sequence number that differs from any existing clause in the map.

#### Example

- This command adds clause 50 to the *Map1* route map, then displays the new route map.

```
switch(config)#route-map Map1 permit 50
switch(config-route-map-Map1)#match as 150
switch(config-route-map-Map1)#exit
switch(config)#show route-map Map1
route-map Map1 deny 10
  Match clauses:
    match as 10
    match tag 333
  Set clauses:
    set local-preference 100
route-map Map1 permit 50
  Match clauses:
    match as 150
  Set clauses:
switch(config)#
```

### Deleting Route Map Components

To remove a component from a route map, perform one of the following:

- To remove a statement from a clause, enter `no`, followed by the statement to be removed.
- To remove a clause, enter `no` followed by the sequence number of the clause to be removed.
- To remove a route map, enter `no` followed by the route map without a sequence number.

#### 20.3.3 Using Route Maps

Protocol redistribution commands include a route map parameter that determines the routes to be redistributed into the specified protocol domain.
Example

- This command uses `Map1` route map to select OSPFv2 routes for redistribution into BGP AS1.

  
  ```
  switch(config)#router bgp 1
  switch(config-router-bgp)#redistribute ospf route-map Map1
  switch(config-router-bgp)#exit
  switch(config)#
  ```

20.4 Prefix Lists

A prefix list is an ordered set of rules that defines route redistribution access for a specified IP address space. A prefix list rule consists of a filter action (deny or permit), an address space identifier (IPv4 subnet address or IPv6 prefix), and a sequence number.

Prefix lists are referenced by route-map match commands when filtering routes for redistribution.

- Section 20.4.1 describes the prefix list configuration process.
- Section 20.4.2 describes the use of prefix lists.

20.4.1 Prefix List Configuration

A prefix list is an ordered set of rules that defines route redistribution access for a specified IP address space. A prefix list rule consists of a filter action (deny or permit), a network address (IPv4 subnet or IPv6 prefix), and a sequence number. A rule may also include a alternate mask size.

The switch supports IPv4 and IPv6 prefix lists. IPv4 lists are constructed in global configuration mode, whereas the switch is placed in a Prefix-list configuration mode to create and edit IPv6 prefix lists.

20.4.1.1 IPv4 Prefix Lists

IPv4 prefix lists are created or modified by adding an IPv4 prefix list rule in global configuration mode. Each rule includes the name of a prefix list, in addition to the sequence number, network address, and filter action. A list consists of all rules that have the same prefix list name.

The `ip prefix-list` command creates a prefix list or adds a rule to an existing list. Route map match statements use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains.
Example

- These commands create two IPv4 prefix lists: a two-rule list named route-one and a three-rule list named route-two.

```
switch(config)#ip prefix-list route-one seq 10 deny 10.1.1.1/24
switch(config)#ip prefix-list route-one seq 20 deny 10.1.0.0/16
switch(config)#ip prefix-list route-one seq 30 permit 12.15.4.9/32
```

```
switch(config)#ip prefix-list route-two seq 10 deny 10.1.1.0/24 ge 26 le 30
switch(config)#ip prefix-list route-two seq 20 deny 10.1.0.0/16
switch(config)#ip prefix-list route-two seq 30 permit 12.15.4.9/32
switch(config)#ip prefix-list route-two seq 40 deny 1.1.1.0/24
```

```
<--------OUTPUT OMITTED FROM EXAMPLE-------->
```

IPv4 prefix lists are referenced in route-map `match (route-map)` commands.

20.4.1.2 IPv6 Prefix Lists

Creating an IPv6 Prefix List

The switch provides IPv6 prefix-list configuration mode for creating and modifying IPv6 prefix lists. A list can be edited only in the mode where it was created.

To create an IP ACL, enter the `ipv6 prefix-list` command, followed by the name of the list. The switch enters IPv6 prefix-list configuration mode for the list. If the command is followed by the name of an existing ACL, subsequent commands edit that list.

Example

- This command places the switch in IPv6 prefix list configuration mode to create an IPv6 prefix list named `map1`.

```
switch(config)#ipv6 prefix-list map1
```

Adding a Rule

To append a rule to the end of a list, enter the rule without a sequence number while in Prefix-List configuration mode for the list. The new rule’s sequence number is derived by adding 10 to the last rule’s sequence number.

Example

- These commands enter the first two rules into a new prefix list.

```
switch(config-ipv6-pfx)#permit 3:4e96:8c01:33cf::/64
switch(config-ipv6-pfx)#permit 3:1b1:8fe4:1a0c::/64
```
To view the list, save the rules by exiting the prefix-list command mode, then re-enter the configuration mode and type `show active`.

```
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#show active
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
switch(config-ipv6-pfx)#
```

This command appends a rule to the end of the prefix list. The new rule’s sequence number is 30.

```
switch(config-ipv6-pfx)#permit 3:1bca:1141:ab34::/64
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#show active
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:1141:ab34::/64
switch(config-ipv6-pfx)#
```

### Inserting a Rule

To insert a rule into a prefix list, use the `seq (IPv6 Prefix Lists)` command to enter a rule with a sequence number that is between numbers of two existing rules.

**Example**

- This command inserts a rule between the first two rules by assigning it the sequence number 15.

```
switch(config-ipv6-pfx)#seq 15 deny 3:4400::/64
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:1141:ab34::/64
switch(config)#
```

### Deleting a Rule

To remove a rule from the configuration mode prefix list, enter `no seq` (see `seq (IPv6 Prefix Lists)`), followed by the sequence number of the rule to be removed.

**Example**

- These commands remove rule 20 from the prefix list, then displays the resultant prefix list.

```
switch(config-ipv6-pfx)#no seq 20
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
switch(config)#
```
20.4.2 Using Prefix Lists

Route map match statements include an option that matches on a specified prefix list.

**Example**

- The MAP_1 route map uses a match statement that references the PL_1 prefix list.

```plaintext
switch(config)#route-map MAP_1 permit
switch(config-route-map-MAP_1)#match ip address prefix-list PL_1
switch(config-route-map-MAP_1)#set community 500
switch(config-route-map-MAP_1)#exit
```
20.5 ACL, Route Map, and Prefix List Commands

This section describes CLI commands that this chapter references.

**ACL Creation and Access Commands**
- `ip access-list`
- `ip access-list standard`
- `ipv6 access-list`
- `ipv6 access-list standard`
- `mac access-list`

**ACL Implementation Commands**
- `ip access-group`
- `ipv6 access-group`
- `mac access-group`

**ACL Edit Commands**
- `hardware access-list update default-result permit`
- `no <sequence number> (ACLs)`
- `resequence (ACLs)`
- `show (ACL configuration modes)`
- `statistics per-entry (ACL configuration modes)`

**ACL Rule Commands**
- `deny (IPv4 ACL)`
- `deny (IPv6 ACL)`
- `deny (MAC ACL)`
- `deny (Standard IPv4 ACL)`
- `deny (Standard IPv6 ACL)`
- `permit (IPv4 ACL)`
- `permit (IPv6 ACL)`
- `permit (MAC ACL)`
- `permit (Standard IPv4 ACL)`
- `permit (Standard IPv6 ACL)`
- `remark`

**ACL List Counter Commands**
- `clear ip access-lists counters`
- `clear ipv6 access-lists counters`

**ACL Display Commands**
- `show ip access-lists`
- `show ipv6 access-lists`
- `show mac access-lists`

**Prefix List Creation and Access Commands**
- `ip prefix-list`
- `ipv6 prefix-list`

**Prefix List Edit Commands**
- `deny (IPv6 Prefix List)`
- `permit (IPv6 Prefix List)`
Chapter 20: ACLs and Route Maps

ACL, Route Map, and Prefix List Commands

- seq (IPv6 Prefix Lists)

Prefix List Display Commands
- show ip prefix-list
- show ipv6 prefix-list

Route Map Creation and Access Command
- route-map

Route Map Edit Commands
- continue (route-map)
- description (route-map)
- match (route-map)
- set (route-map)
- set community (route-map)
- set extcommunity (route-map)

Route Map Display Commands
- show route-map
clear ip access-lists counters

The `clear ip access-lists counters` command sets ACL counters to zero for the specified IPv4 access control list (ACL). The `session` parameter limits ACL counter clearing to the current CLI session.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
clear ip access-lists counters [ACL_NAME] [SCOPE]
```

**Parameters**

- `ACL_NAME` Name of ACL. Options include:
  - `<no parameter>` all ACLs.
  - `access_list` name of ACL.
- `SCOPE` Session affected by command. Options include:
  - `<no parameter>` command affects counters on all CLI sessions.
  - `session` affects only current CLI session.

**Example**

- This command resets all IPv4 ACL counters.

```bash
switch(config)#clear ip access-lists counters
switch(config)#
```
clear ipv6 access-lists counters

The `clear ipv6 access-lists counters` command sets ACL counters to zero for the specified IPv6 access control list (ACL). The `session` parameter limits ACL counter clearing to the current CLI session.

**Command Mode**
- Privileged EXEC

**Command Syntax**
```
clear ipv6 access-lists counters [ACL_NAME] [SCOPE]
```

**Parameters**
- **ACL_NAME** name of ACL. Options include:
  - `<no parameter>` all IPv6 ACLs.
  - `access_list` name of IPv6 ACL.
- **SCOPE** Session affected by command. Options include:
  - `<no parameter>` command affects counters on all CLI sessions.
  - `session` affects only current CLI session.

**Example**
- This command resets all IPv6 ACL counters.
```
switch(config)#clear ipv6 access-lists counters
switch(config)#
```
**continue (route-map)**

The `continue` command creates a route map clause entry that enables additional route map evaluation of routes whose parameters meet the clause’s matching criteria.

A clause typically contains a `match (route-map)` and a `set (route-map)` statement. The evaluation of routes whose settings are the same as `match` statement parameters normally end and the clause’s `set` statement are applied to the route. Routes that match a clause containing a `continue` statement are evaluated against the clause specified by the `continue` statement.

When a route matches multiple route-map clauses, the filter action (deny or permit) is determined by the last clause that the route matches. The `set` statements in all clauses matching the route are applied to the route after the route map evaluation is complete. Multiple set statements are applied in the same order by which the route was evaluated against the clauses containing them.

The `no continue` and `default continue` commands remove the corresponding `continue` statement from the configuration mode route map clause by deleting the corresponding command from `running-config`.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
continue NEXT_SEQ
no continue NEXT_SEQ
default continue NEXT_SEQ
```

**Parameters**

- `NEXT_SEQ` specifies next clause for evaluating matching routes. Options include:
  - `<no parameter>` Next clause in the route map, as determined by sequence number.
  - `seq_number` Specifies the number of the next clause. Values range from 1 to 16777215.

**Restrictions**

A continue statement cannot specify a sequence number smaller than the sequence number of its route-map clause.

**Related Commands**

- `route-map` enters route-map configuration mode.

**Example**

- This command creates route map map1, clause 40 with a match statement, a set statement, and a continue statement. Routes that match the clause are subsequently evaluated against clause 100. The `set local-preference` statement is applied to matching routes regardless of subsequent matching operations.

```
switch(config)#route-map map1 deny 40
switch(config-route-map-map1)#match as 15
switch(config-route-map-map1)#continue 100
switch(config-route-map-map1)#set local-preference 50
switch(config-route-map-map1)#
```
deny (IPv4 ACL)

The **deny** command adds a deny rule to the configuration mode IPv4 access control list (ACL). Packets filtered by a **deny** rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The **no deny** and **default deny** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**

ACL Configuration

**Command Syntax**

```markdown
[SEQ_NUM] deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

```markdown
no deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

```markdown
default deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a deny rule.

**Parameters**

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - <no parameter> Number is derived by adding 10 to the number of the ACL’s last rule.
  - 1 – 4294967295 Number assigned to entry.
- **PROTOCOL**  protocol field filter. Values include:
  - ahp Authentication Header Protocol (51).
  - icmp Internet Control Message Protocol (1).
  - igmp Internet Group Management Protocol (2).
  - ip Internet Protocol v4 (4).
  - ospf Open Shortest Path First (89).
  - pim Protocol Independent Multicast (103).
  - tcp Transmission Control Protocol (6).
  - udp user datagram protocol (17).
  - vrrp Virtual Router Redundancy Protocol (112).
  - protocol_num integer corresponding to an IP protocol. Values range from 0 to 255.
- **SOURCE_ADDR** and **DEST_ADDR**  source and destination address filters. Options include:
  - network_addr subnet address (CIDR or address-mask).
  - any Packets from all addresses are filtered.
  - host ip_addr IP address (dotted decimal notation).
    Subnet addresses support discontiguous masks.
- **SOURCE_PORT** and **DEST_PORT**  source and destination port filters. Options include:
• any all ports
• eq port-1 port-2 ... port-n A list of ports. Maximum list size is 10 ports.
• neq port-1 port-2 ... port-n The set of all ports not listed. Maximum list size is 10 ports.
• gt port The set of ports with larger numbers than the listed port.
• lt port The set of ports with smaller numbers than the listed port.
• range port_1 port_2 The set of ports whose numbers are between the range.
• fragments filters packets with FO bit set (indicates a non-initial fragment packet).
• FLAGS flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
• MESSAGE message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
• tracked rule filters packets in existing ICMP, UDP, or TCP connections.
  • Valid in ACLs applied to the control plane.
  • Validity in ACLs applied to data plane varies by switch platform.
• DSCP_FILTER rule filters packet by its DSCP value. Values include:
  • <no parameter> Rule does not use DSCP to filter packets.
  • dscp dscp_value Packets match if DSCP field in packet is equal to dscp_value.
• TTL_FILTER rule filters packet by its TTL (time-to-live) value. Values include:
  • ttl eq ttl_value Packets match if ttl in packet is equal to ttl_value.
  • ttl gt ttl_value Packets match if ttl in packet is greater than ttl_value.
  • ttl lt ttl_value Packets match if ttl in packet is less than ttl_value.
  • ttl neq ttl_value Packets match if ttl in packet is not equal to ttl_value.
  • Valid in ACLs applied to the control plane.
  • Validity in ACLs applied to data plane varies by switch platform.
• log triggers an informational log message to the console about the matching packet.
  • Valid in ACLs applied to the control plane.
  • Validity in ACLs applied to data plane varies by switch platform.

Examples
• This command appends a deny statement at the end of the ACL. The deny statement drops OSPF packets from 10.10.1.1/24 to any host.
  
  switch(config)#ip access-list text1
  switch(config-acl-text1)#deny ospf 10.1.1.0/24 any
  switch(config-acl-text1)#

• This command inserts a deny statement with the sequence number 65. The deny statement drops all PIM packets.
  
  switch(config-acl-text1)#65 deny pim any any
  switch(config-acl-text1)#
**deny (IPv6 ACL)**

The `deny` command adds a deny rule to the configuration mode IPv6 access control list (ACL). Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**
IPv6-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP]
[tracked] [DSCP_FILTER] [log]
```

```
no deny PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP] [tracked]
[DSCP_FILTER] [log]
```

```
default deny PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP] [tracked]
[DSCP_FILTER] [log]
```

Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a deny rule.

**Parameters**

- `SEQ_NUM`  
  Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>` Number assigned to entry.
- `PROT`  
  Protocol field filter. Values include:
  - `icmpv6` Internet Control Message Protocol for version 6 (58).
  - `ipv6` Internet Protocol – IPv6 (41).
  - `ospf` Open Shortest Path First (89).
  - `tcp` Transmission Control Protocol (6).
  - `udp` User Datagram Protocol (17).
  - `protocol_num` Integer corresponding to an IP protocol. Values range from 0 to 255.
- `SRC_ADDR` and `DEST_ADDR`  
  Source and destination address filters. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.
- `SRC_PT` and `DEST_PT`  
  Source and destination port filters. Options include:
  - `any` All ports.
  - `eq port-1 port-2 ... port-n` A list of ports. Maximum list size is 10 ports.
  - `neq port-1 port-2 ... port-n` The set of all ports not listed. Maximum list size is 10 ports.
  - `gt port` The set of ports with larger numbers than the listed port.
  - `lt port` The set of ports with smaller numbers than the listed port.
  - `range port_1 port_2` The set of ports whose numbers are between the range.
**HOP** filters by packet’s hop-limit value. Options include:
- `<no parameter>` Rule does not use hop limit to filter packets.
- **hop-limit eq hop_value** Packets match if *hop-limit* value in packet equals *hop_value*.
- **hop-limit gt hop_value** Packets match if *hop-limit* in packet is greater than *hop_value*.
- **hop-limit lt hop_value** Packets match if *hop-limit* in packet is less than *hop_value*.
- **hop-limit neq hop_value** Packets match if *hop-limit* in packet is not equal to *hop_value*.

**FLAG** flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.

**MSG** message type filters (ICMPv6 packets). Use CLI syntax assistance (?) to display options.

**tracked** rule filters packets in existing ICMP, UDP, or TCP connections.
- Valid in ACLs applied to the control plane.
- Validity in ACLs applied to data plane varies by switch platform.

**DSCP_FILTER** rule filters packet by its DSCP value. Values include:
- `<no parameter>` Rule does not use DSCP to filter packets.
- **dscp dscp_value** Packets match if DSCP field in packet is equal to *dscp_value*.
- **log** triggers an informational log message to the console about the matching packet.
- Valid in ACLs applied to the control plane.
- Validity in ACLs applied to data plane varies by switch platform.

**Example**
- This command appends a **deny** statement at the end of the ACL. The **deny** statement drops IPv6 packets from 3710:249a:c643:ef11::/64 to any host.

```
switch(config)#ipv6 access-list text1
switch(config-acl-text1)#deny ipv6 3710:249a:c643:ef11::/64 any
switch(config-acl-text1)#
```
deny (IPv6 Prefix List)

The `deny` command adds a rule to the configuration mode IPv6 prefix list. Route map match statements use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains. Routes are denied access when they match the prefix that a `deny` statement specifies.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode prefix list. The `no seq (IPv6 Prefix Lists)` command also removes the specified rule from the prefix list.

**Command Mode**
IPv6-pfx Configuration

**Command Syntax**

```
[SEQUENCE] deny ipv6_prefix [MASK]
```

**Parameters**

- `SEQUENCE` Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the list's last rule.
  - `seq seq_num` Number is specified by `seq_num`. Value ranges from 0 to 65535.
- `ipv6_prefix` IPv6 prefix upon which command filters routes (CIDR notation).
- `MASK` range of the prefix to be matched.
  - `<no parameter>` exact match with the subnet mask is required.
  - `eq mask_e` prefix length is equal to `mask_e`.
  - `ge mask_g` range is from `mask_g` to 128.
  - `le mask_l` range is from subnet mask length to `mask_l`.
  - `ge mask_l le mask_g` range is from `mask_g` to `mask_l`.
    `mask_e, mask_l` and `mask_g` range from 1 to 128.

  when `le` and `ge` are specified, subnet mask > `mask_g` < `mask_l`

**Example**

- This command appends a `deny` statement at the end of the text1 prefix list. The `deny` statement denies redistribution of routes with the specified prefix.

```
switch(config)#ipv6 prefix-list route-five
switch(config-ipv6-pfx)#deny 3100::/64
switch(config-ipv6-pfx)#
```
deny (MAC ACL)

The **deny** command adds a deny rule to the configuration mode MAC access control list (ACL). Packets filtered by a deny rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The **no deny** and **default deny** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**

MAC-ACL Configuration

**Command Syntax**

```powershell
[SEQ_NUM] deny SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
no deny SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
default deny SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
```

**Parameters**

- **SEQ_NUM**  
  Sequence number assigned to the rule. Options include:
  - <no parameter>  
    Number is derived by adding 10 to the number of the ACL’s last rule.
  - <1 – 4294967295>  
    Number assigned to entry.

- **SOURCE_ADDR** and **DEST_ADDR**  
  Source and destination address filters. Options include:
  - `mac_address mac_mask`  
    MAC address and mask
  - `any`  
    Packets from all addresses are filtered.

  ```plaintext
  mac_address specifies a MAC address in 3x4 dotted hexadecimal notation
  (hhhh.hhhh.hhhh)
  mac_mask specifies a MAC address mask in 3x4 dotted hexadecimal notation
  (hhhh.hhhh.hhhh)
  ```

  - 0 bits require an exact match to filter
  - 1 bits filter on any value

- **PROTOCOL**  
  Protocol field filter. Values include:
  - `aarp`  
    Appletalk Address Resolution Protocol (0x80f3)
  - `appletalk`  
    Appletalk (0x809b)
  - `arp`  
    Address Resolution Protocol (0x806)
  - `ip`  
    Internet Protocol Version 4 (0x800)
  - `ipx`  
    Internet Packet Exchange (0x8137)
  - `lldp`  
    LLDP (0x88cc)
  - `novell`  
    Novell (0x8138)
  - `rarp`  
    Reverse Address Resolution Protocol (0x8035)
  - `protocol_num`  
    Integer corresponding to a MAC protocol. Values range from 0 to 65535
  - `log`  
    Triggers an informational log message to the console about the matching packet.
Examples

- This command appends a permit statement at the end of the ACL. The deny statement drops all aarp packets from 10.1000.0000 through 10.1000.FFFF to any host.
  
  switch(config)#mac access-list text1
  switch(config-mac-acl-text1)#deny 10.1000.0000 0.0.FFFF any aarp

- This command inserts a permit statement with the sequence number 25. The deny statement drops all packets through the interface.
  
  switch(config-mac-acl-text1)#25 deny any any
deny (Standard IPv4 ACL)

The `deny` command adds a deny rule to the configuration mode standard IPv4 access control list (ACL). Standard ACL rules filter on the source field.

Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

Std-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny SOURCE_ADDR [log]
no deny SOURCE_ADDR [log]
default deny SOURCE_ADDR [log]
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>` Number assigned to entry.
- **SOURCE_ADDR** source address filter. Options include:
  - `network_addr` subnet address (CIDR or address-mask).
  - `any` packets from all addresses are filtered.
  - `host ip_addr` IP address (dotted decimal notation).
  - Subnet addresses support discontiguous masks.
- `log` triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Example**

- This command appends a `deny` statement at the end of the ACL. The `deny` statement drops packets from 10.10.1.1/24.

  ```
  switch(config)#ip access-list standard text1
  switch(config-std-acl-text1)#deny 10.1.1.1/24
  switch(config-std-acl-text1)#
  ```
deny (Standard IPv6 ACL)

The `deny` command adds a deny rule to the configuration mode standard IPv6 access control list (ACL). Standard ACL rules filter on the source field.

Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

Std-IPv6-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny SOURCE_ADDR
no deny SOURCE_ADDR
default deny SOURCE_ADDR
```

**Parameters**

- `SEQ_NUM`  Sequence number assigned to the rule. Options include:
  - `<no parameter>`   Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>`   Number assigned to entry.
- `SOURCE_ADDR`  source address filter. Options include:
  - `ipv6_prefix`   IPv6 address with prefix length (CIDR notation).
  - `any`   Packets from all addresses are filtered.
  - `host ipv6_addr`   IPv6 host address.

**Example**

- This command appends a `deny` statement at the end of the ACL. The `deny` statement drops packets from 2103::/64.

```
switch(config)#ipv6 access-list standard text1
switch(config-std-acl-ipv6-text1)#deny 2103::/64
switch(config-std-acl-ipv6-text1)#
```
**description (route-map)**

The `description` command adds a text string to the configuration mode route map. The string has no functional impact on the route map.

The `no description` and `default description` commands remove the text string from the configuration mode route map by deleting the corresponding `description` command from `running-config`.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
description label_text
no description
default description
```

**Parameters**

- `label_text` character string assigned to the route map configuration.

**Related Commands**

- `route-map` enters route-map configuration mode.

**Examples**

- These commands add description text to the XYZ-1 route map.

  switch(config)#route-map XYZ-1
  switch(config-route-map-XYZ-1)#description This is the first map.
  switch(config-route-map-XYZ-1)#exit
  switch(config)#show route-map XYZ-1
  route-map XYZ-1 permit 10
  Description:
  description This is the first map.
  Match clauses:
  Set clauses:
  switch(config)#
hardware access-list update default-result permit

The `hardware access-list update default-result permit` command configures the switch to permit all traffic on Ethernet and VLAN interfaces with ACLs applied to them while those ACLs are being modified. Traffic is permitted beginning when the ACL is opened for modification using one of the `ip access-list` commands, and ending when the ACL configuration mode is exited and rules are populated in hardware. This feature is disabled by default.

The `no hardware access-list update default-result permit` and `default hardware access-list update default-result permit` commands restore the switch to its default state (blocking traffic during ACL modifications) by removing the corresponding `hardware access-list update default-result permit` command from `running-config`.

Command Mode
- Global Configuration

Command Syntax
- `hardware access-list update default-result permit`
- `no hardware access-list update default-result permit`
- `default hardware access-list update default-result permit`

Restrictions
This feature available only on 7150 series switches.

This feature does not work well with egress ACLs.

While this feature is enabled, modification of an ACL may cause packet loss even on interfaces where an unrelated ACL is applied.

While this feature is enabled, static NAT and ACL-based mirroring will also be affected during ACL updates.

Example
- This command configures a 7150 series switch to permit all traffic on Ethernet and VLAN interfaces with ACLs applied to them while those ACLs are being modified.

  switch(config)#hardware access-list update default-result permit
  switch(config)#
ip access-group

The ip access-group command applies an IPv4 or standard IPv4 access control list (ACL) to the configuration mode interface.

The no ip access-group and default ip access-group commands remove the corresponding ip access-group command from running-config.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

Command Syntax

```
ip access-group list_name DIRECTION
no ip access-group list_name DIRECTION
default ip access-group list_name DIRECTION
```

Parameters
- list_name name of ACL assigned to interface.
- DIRECTION transmission direction of packets, relative to interface. Valid options include:
  - in inbound packets.
  - out outbound packets.

Restrictions
Filtering of outbound packets by ACLs is not supported on Petra platform switches.
Filtering of outbound packets by ACLs on FM6000 switches is supported only on physical interfaces (Ethernet and port channels).

Example
- These commands apply the IPv4 ACL named test2 to Ethernet interface 3.

```
switch(config)#interface ethernet 3
switch(config-if-Et3)#ip access-group test2 in
switch(config-if-Et3)#
```
**ip access-list**

The *ip access-list* command places the switch in ACL configuration mode, which is a group change mode that modifies an IPv4 access control list. The command specifies the name of the IPv4 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The *exit* command saves pending ACL changes to *running-config*, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The *abort* command discards pending ACL changes, returning the switch to global configuration mode.

The *no ip access-list* and *default ip access-list* commands delete the specified IPv4 ACL.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip access-list list_name
no ip access-list list_name
default ip access-list list_name
```

**Parameters**

- *list_name* Name of ACL. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in ACL configuration mode:**

- *deny* (IPv4 ACL)
- *no <sequence number> (ACLs)*
- *permit* (IPv4 ACL)
- *remark*
- *resequence (ACLs)*
- *show (ACL configuration modes)*

**Related Commands**

- *ip access-list standard* enters std-acl configuration mode for editing standard IP ACLs.
- *show ip access-lists* displays IP and standard ACLs.

**Examples**

- This command places the switch in ACL configuration mode to modify the *filter1* IPv4 ACL.
  
  ```
switch(config)#ip access-list filter1
switch(config-acl-filter1)#
  ```

- This command saves changes to *filter1* ACL, then returns the switch to global configuration mode.
  
  ```
switch(config-acl-filter1)#exit
switch(config)#
  ```

- This command discards changes to *filter1*, then returns the switch to global configuration mode.
  
  ```
switch(config-acl-filter1)#abort
switch(config)#
  ```
ip access-list standard

The ip access-list standard command places the switch in std-ACL configuration mode, which is a group change mode that modifies a standard IPv4 access control list. The command specifies the name of the standard IPv4 ACL that subsequent commands modify, and creates an ACL if it references a nonexistent list. All group change mode edit session changes are pending until the session ends.

The exit command saves pending ACL changes to running-config, then returns the switch to global configuration mode. Pending changes are also saved by entering a different configuration mode.

The abort command discards pending ACL changes, returning the switch to global configuration mode.

The no ip access-list standard and default ip access-list standard commands delete the specified ACL.

Command Mode

Global Configuration

Command Syntax

```
ip access-list standard list_name
no ip access-list standard list_name
default ip access-list standard list_name
```

Parameters

- **list_name**  Name of standard ACL.
  Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

Commands Available in std-ACL configuration mode:

- deny (Standard IPv4 ACL)
- no <sequence number> (ACLs)
- permit (Standard IPv4 ACL)
- remark
- resequence (ACLs)
- show (ACL configuration modes)

Related Commands

- ip access-list  enters ACL configuration mode for editing IPv4 ACLs.
- show ip access-lists  displays IPv4 and standard IPv4 ACLs.

Examples

- This command places the switch in std-ACL configuration mode to modify the filter2 IPv4 ACL.
  ```
  switch(config)#ip access-list standard filter2
  switch(config-std-acl-filter2)#
  ```
- This command saves changes to filter2 ACL, then returns the switch to global configuration mode.
  ```
  switch(config-std-acl-filter2)#exit
  switch(config)#
  ```
- This command discards changes to filter2, then returns the switch to global configuration mode.
  ```
  switch(config-std-acl-filter2)#abort
  switch(config)#
  ```
ip prefix-list

The `ip prefix-list` command creates a prefix list or adds an entry to an existing list. Route map match statements use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains.

A prefix list comprises all prefix list entries with the same label. The sequence numbers of the rules in a prefix list specify the order that the rules are applied to a route that the match statement is evaluating.

The `no ip prefix-list` and `default ip prefix-list` commands delete the specified prefix list entry by removing the corresponding `ip prefix-list` statement from `running-config`. If the `no` or `default ip prefix-list` command does not list a sequence number, the command deletes all entries of the prefix list.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip prefix-list list_name [SEQUENCE] FILTER_TYPE network_addr [MASK]
no ip prefix-list list_name [SEQUENCE]
default ip prefix-list list_name [SEQUENCE]
```

**Parameters**

- `list_name` The label that identifies the prefix list.
- `SEQUENCE` Sequence number of the prefix list entry. Options include:
  - `<no parameter>` entry’s number is ten plus highest sequence number in current list.
  - `seq seq_num` number assigned to entry. Value ranges from 0 to 65535.
- `FILTER_TYPE` specifies route access when it matches IP prefix list. Options include:
  - `permit` routes are permitted access when they match the specified subnet.
  - `deny` routes are denied access when they match the specified subnet.
- `network_addr` Subnet upon which command filters routes. Format is CIDR or address-mask.
- `MASK` range of the prefix to be matched.
  - `<no parameter>` exact match with the subnet mask is required.
  - `eq mask_e` prefix length is equal to `mask_e`.
  - `ge mask_g` range is from `mask_g` to 32.
  - `le mask_l` range is from `subnet` mask length to `mask_l`.
  - `ge mask_l` and `ge mask_g` range is from `mask_g` to `mask_l`.

```
mask_e, mask_l and mask_g range from 1 to 32.
when le and ge are specified, subnet mask > mask_g > mask_l
```

**Example**

- These commands create a two-entry prefix list named route-one.

```
switch(config)#ip prefix-list route-one seq 10 deny 10.1.1.1/24 ge 26 le 30
switch(config)#ip prefix-list route-one seq 20 deny 10.1.2.1/16
switch(config)#
```
**ipv6 access-group**

The `ipv6 access-group` command applies an IPv6 or standard IPv6 access control list (ACL) to the configuration mode interface.

The `no ipv6 access-group` and `default ipv6 access-group` commands remove the corresponding `ipv6 access-group` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ipv6 access-group list_name DIRECTION
no ipv6 access-group list_name DIRECTION
default ipv6 access-group list_name DIRECTION
```

**Parameters**

- `list_name` name of ACL assigned to interface.
- `DIRECTION` transmission direction of packets, relative to interface. Valid options include:
  - `in` inbound packets.
  - `out` outbound packets.

**Examples**

- These commands assign the IPv6 ACL named `test2` to the Ethernet 3 interface.

  ```
  switch(config)#interface ethernet 3
  switch(config-if-Et3)#ipv6 access-group test2 in
  switch(config-if-Et3)#
  ```
ipv6 access-list

The ipv6 access-list command places the switch in IPv6-ACL configuration mode, which is a group change mode that modifies an IPv6 access control list. The command specifies the name of the IPv6 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The exit command saves pending ACL changes to running-config, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The abort command discards pending ACL changes, returning the switch to global configuration mode.

The no ipv6 access-list and default ipv6 access-list commands delete the specified IPv6 ACL.

Command Mode
Global Configuration

Command Syntax
ipv6 access-list list_name
no ipv6 access-list list_name
default ipv6 access-list list_name

Parameters
- list_name Name of ACL.
  Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

Commands Available in IPv6-ACL configuration mode:
- deny (IPv6 ACL)
- no <sequence number> (ACLs)
- permit (IPv6 ACL)
- remark
- resequence (ACLs)
- show (ACL configuration modes)

Related Commands
- ipv6 access-list standard enters std-ipv6-acl configuration mode for editing standard IPv6 ACLs.
- show ipv6 access-lists displays IPv6 and standard IPv6 ACLs.

Examples
- This command places the switch in IPv6-ACL configuration mode to modify the filter1 IPv6 ACL.
  switch(config)#ipv6 access-list filter1
  switch(config-ipv6-acl-filter1)#
- This command saves changes to filter1 ACL, then returns the switch to global configuration mode.
  switch(config-ipv6-acl-filter1)#exit
  switch(config)#
- This command discards changes to filter1, then returns the switch to global configuration mode.
  switch(config-ipv6-acl-filter1)#abort
  switch(config)#
ipv6 access-list standard

The **ipv6 access-list standard** command places the switch in std-IPv6-ACL-configuration mode, which is a group change mode that modifies a standard IPv6 access control list. The command specifies the name of the standard IPv6 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All group change mode edit session changes are pending until the session ends.

The **exit** command saves pending ACL changes to **running-config**, then returns the switch to global configuration mode. Pending changes are also saved by entering a different configuration mode.

The **abort** command discards pending ACL changes, returning the switch to global configuration mode.

The **no ipv6 access-list standard** and **default ipv6 access-list standard** commands delete the specified ACL.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
ipv6 access-list standard list_name
no ipv6 access-list standard list_name
default ipv6 access-list standard list_name
```

**Parameters**
- `list_name` Name of ACL.
  Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in std-IPv6-ACL configuration mode:**
- **deny (Standard IPv6 ACL)**
- **no <sequence number> (ACLs)**
- **permit (Standard IPv6 ACL)**
- **remark**
- **resequence (ACLs)**
- **show (ACL configuration modes)**

**Related Commands**
- **ipv6 access-list** enters IPv6-ACL configuration mode for editing IPv6 ACLs.
- **show ipv6 access-lists** displays IPv6 and standard IPv6 ACLs.

**Examples**
- This command places the switch in Std-IPv6 ACL configuration mode to modify the **filter2** ACL.
  ```shell
  switch(config)#ipv6 access-list standard filter2
  switch(config-std-ipv6-acl-filter2)#
  ```
- This command saves changes to **filter2** ACL, then returns the switch to global configuration mode.
  ```shell
  switch(config-std-ipv6-acl-filter2)#exit
  switch(config)#
  ```
- This command discards changes to **filter2**, then returns the switch to global configuration mode.
  ```shell
  switch(config-std-ipv6-acl-filter2)#abort
  switch(config)#
  ```
ipv6 prefix-list

The `ip prefix-list` command places the switch in IPv6 prefix-list configuration mode, which is a group change mode that modifies an IPv6 prefix list. The command specifies the name of the IPv6 prefix list that subsequent commands modify and creates a prefix list if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The `exit` command saves pending prefix list changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending changes, returning the switch to global configuration mode.

The `no ipv6 prefix-list` and `default ipv6 prefix-list` commands delete the specified IPv6 prefix list.

**Command Mode**

Global Configuration

**Command Syntax**

```
ipv6 prefix-list list_name
no ipv6 prefix-list list_name
default ipv6 prefix-list list_name
```

**Parameters**

- `list_name` Name of prefix list. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in IPv6-pfx configuration mode:**

- `deny (IPv6 Prefix List)`
- `permit (IPv6 Prefix List)`
- `seq (IPv6 Prefix Lists)`

**Examples**

- This command places the switch in IPv6 prefix-list configuration mode to modify the `route-five` prefix list.
  
  ```
  switch(config)#ipv6 prefix-list route-five
  switch(config-ipv6-pfx)#
  ```

- This command saves changes to the prefix list, then returns the switch to global configuration mode.
  
  ```
  switch(config-ipv6-pfx)#exit
  switch(config)#
  ```

- This command saves changes to the prefix list, then places the switch in interface-Ethernet mode.
  
  ```
  switch(config-ipv6-pfx)#interface ethernet 3
  switch(config-if-Et3)#
  ```

- This command discards changes to the prefix list, then returns the switch to global configuration mode.
  
  ```
  switch(config-ipv6-pfx)#abort
  switch(config)#
  ```
**mac access-group**

The `mac access-group` command applies a MAC-ACL (access control list) to the configuration mode interface.

The `no mac access-group` and `default mac access-group` commands remove the specified `mac access-group` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**
```plaintext
mac access-group list_name DIRECTION
no mac access-group list_name DIRECTION
default mac access-group list_name DIRECTION
```

**Parameters**
- `list_name` name of MAC ACL.
- `DIRECTION` transmission direction of packets, relative to interface. Valid options include:
  - `in` inbound packets.
  - `out` outbound packets.

**Restrictions**
Filtering of outbound packets by MAC ACLs is supported only on Helix, Trident, and Trident-II platform switches.

**Example**
- These commands assign the MAC ACL named `mtest2` to the Ethernet 3 interface to filter inbound packets.
  ```plaintext
  switch(config)#interface ethernet 3
  switch(config-if-Et3)#mac access-group mtest2 in
  switch(config-if-Et3)#
  ```
mac access-list

The **mac access-list** command places the switch in MAC-ACL configuration mode, which is a group change mode that modifies a MAC access control list. The command specifies the name of the MAC ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The **exit** command saves pending ACL changes to **running-config**, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The **abort** command discards pending ACL changes, returning the switch to global configuration mode.

The **no mac access-list** and **default mac access-list** commands delete the specified list.

**Command Mode**

    Global Configuration

**Command Syntax**

    mac access-list list_name
    no mac access-list list_name
    default mac access-list list_name

**Parameters**

- **list_name** Name of MAC ACL. Names must begin with an alphabetic character and cannot contain a space or quotation mark.

**Commands Available in MAC-ACL configuration mode:**

- **deny (MAC ACL)**
- **no <sequence number> (ACLs)**
- **permit (MAC ACL)**
- **remark**
- **resequence (ACLs)**
- **show (ACL configuration modes)**

**Examples**

- This command places the switch in MAC-ACL configuration mode to modify the **mfilter1** MAC ACL.
  
  switch(config)#mac access-list mfilter1
  switch(config-mac-acl-mfilter1)#

- This command saves changes to **mfilter1** ACL, then returns the switch to global configuration mode.
  
  switch(config-mac-acl-mfilter1)#exit
  switch(config)#

- This command saves changes to **mfilter1** ACL, then places the switch in interface-Ethernet mode.
  
  switch(config-mac-acl-mfilter1)#interface ethernet 3
  switch(config-if-Et3)#

- This command discards changes to **mfilter1**, then returns the switch to global configuration mode.
  
  switch(config-mac-acl-mfilter1)#abort
  switch(config)#
match (route-map)

The **match** command creates a route map clause entry that specifies one route filtering condition. When a clause contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each **match** statement. When a route’s properties do not equal the statement parameters, the route is evaluated against the next clause in the route map, as determined by sequence number. If all clauses fail to permit or deny the route, the route is denied.

The **no match** and **default match** commands remove the **match** statement from the configuration mode route map clause by deleting the corresponding command from **running-config**.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
match CONDITION
no match CONDITION
default match CONDITION
```

**Parameters**

- **CONDITION** specifies criteria for evaluating a route. Options include:
  - **as** `<1 to 4294967295>` BGP autonomous system number.
  - **as-path** `path_name` BGP autonomous system path access list.
  - **community** `NAME` BGP community. Options for `NAME` include:
    - `listname` BGP community.
    - `listname exact-match` BGP community; list must match set that is present.
  - **extcommunity** `listname` BGP extended community. Options for `NAME` include:
    - `listname` BGP community.
    - `listname exact-match` BGP community; list must match set that is present.
  - **interface** `INTF_NAME` Specifies an interface. Options for `INTF_NAME` include:
    - `ethernet` `e_num` Ethernet interface.
    - `loopback` `l_num` Loopback interface.
    - `port-channel` `p_num` Port channel interface.
    - `vlan` `v_num` VLAN interface.
  - **ip address** `LIST` IPv4 address filtered by an ACL or prefix list. `LIST` options include:
    - `access-list` `acl_name` IPv4 address filtered by Access Control List (ACL).
    - `prefix-list` `plv4_name` IPv4 address filtered by IP prefix list.
  - **ip next-hop prefix-list** `plv4_name` IPv4 next-hop filtered by IP prefix list.
  - **ip resolved-next-hop prefix-list** `plv4_name` IPv4 resolved nexthop filtered by IP prefix list.
  - **ipv6 address** `plv6_name` IPv6 address filtered by IPv6 prefix list.
  - **ipv6 next-hop prefix-list** `plv6_name` IPv6 next-hop filtered by IPv6 prefix list.
  - **ipv6 resolved-next-hop prefix-list** `plv6_name` IPv6 resolved nexthop filtered by IPv6 prefix list.
  - **local-preference** `<1 to 4294967295>` BGP local preference metric.
  - **metric** `<1 to 4294967295>` route metric.
• **metric-type** *OSPF_TYPE*  OSPF metric type. Options include:
  • **type-1**  OSPF type 1 metric.
  • **type-2**  OSPF type 2 metric.
• **source-protocol** *protocol_type*  Routing protocol of route's source. Options include:
  • bgp
  • connected
  • ospf
  • rip
  • static
• **tag <1 to 4294967295>**  route tag.

**Related Commands**
• **route-map** enters route-map configuration mode.

**Example**
• This command creates a route-map match rule that filters routes from BGP AS 15.
  ```
  switch(config)#route-map map1
  switch(config-route-map-map1)#match as 15
  switch(config-route-map-map1)#
  ```
no <sequence number> (ACLs)

The `no <sequence number>` command removes the rule with the specified sequence number from the ACL. The `default <sequence number>` command also removes the specified rule.

**Command Mode**
- ACL Configuration
- IPv6-ACL Configuration
- Std-ACL Configuration
- Std-IPv6-ACL Configuration
- MAC-ACL Configuration

**Command Syntax**

```
no line_num
default line_num
```

**Parameters**
- `line_num` sequence number of rule to be deleted. Values range from 1 to 4,294,967,295.

**Example**
- This command removes statement 30 from the list

```
switch(config-acl-test1)#show
IP Access List test1

```
Chapter 20: ACLs and Route Maps

ACL, Route Map, and Prefix List Commands

permit (IPv4 ACL)

The `permit` command adds a permit rule to the configuration mode IPv4 access control list (ACL). Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no permit` and `default permit` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes a specified rule from the ACL.

Command Mode

ACL Configuration

Command Syntax

```
[SEQ_NUM] permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

```
no permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

```
default permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT]
[FLAGS] [MESSAGE] [fragments] [tracked] [DSCP_FILTER] [TTL_FILTER] [log]
```

Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

Parameters

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>` Number assigned to entry.
- **PROTOCOL** protocol field filter. Values include:
  - `ahp` Authentication Header Protocol (51).
  - `icmp` Internet Control Message Protocol (1).
  - `igmp` Internet Group Management Protocol (2).
  - `ip` Internet Protocol v4 (4).
  - `ospf` Open Shortest Path First (89).
  - `pim` Protocol Independent Multicast (103).
  - `tcp` Transmission Control Protocol (6).
  - `udp` user datagram protocol (17).
  - `vrrp` Virtual Router Redundancy Protocol (112).
  - `protocol_num` integer corresponding to an IP protocol. Values range from 0 to 255.
- **SOURCE_ADDR** and **DEST_ADDR** source and destination address filters. Options include:
  - `network_addr` subnet address (CIDR or address-mask).
  - `any` Packets from all addresses are filtered.
  - `host ip_addr` IP address (dotted decimal notation).
  Source and destination subnet addresses support discontiguous masks.
- **SOURCE_PORT** and **DEST_PORT** source and destination port filters. Options include:
- **any** all ports
- **eq** \( \text{port-1 port-2} \ldots \text{port-n} \) A list of ports. Maximum list size is 10 ports.
- **neq** \( \text{port-1 port-2} \ldots \text{port-n} \) The set of all ports not listed. Maximum list size is 10 ports.
- **gt** \( \text{port} \) The set of ports with larger numbers than the listed port.
- **lt** \( \text{port} \) The set of ports with smaller numbers than the listed port.
- **range** \( \text{port-1 port-2} \) The set of ports whose numbers are between the range.
- **fragments** filters packets with FO bit set (indicates a non-initial fragment packet).
- **FLAGS** flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
- **MESSAGE** message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
- **tracked** rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **DSCP_FILTER** rule filters packet by its DSCP value. Values include:
  - `<no parameter>` Rule does not use DSCP to filter packets.
  - **dscp** \( \text{dscp_value} \) Packets match if DSCP field in packet is equal to \( \text{dscp_value} \).
- **TTL_FILTER** rule filters packet by its TTL (time-to-live) value. Values include:
  - **ttl eq** \( \text{ttl_value} \) Packets match if \( \text{ttl} \) in packet is equal to \( \text{ttl_value} \).
  - **ttl gt** \( \text{ttl_value} \) Packets match if \( \text{ttl} \) in packet is greater than \( \text{ttl_value} \).
  - **ttl lt** \( \text{ttl_value} \) Packets match if \( \text{ttl} \) in packet is less than \( \text{ttl_value} \).
  - **ttl neq** \( \text{ttl_value} \) Packets match if \( \text{ttl} \) in packet is not equal to \( \text{ttl_value} \).
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **log** triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Examples**

- This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all OSPF packets from 10.10.1.1/24 to any host.

  ```
  switch(config)#ip access-list text1
  switch(config-acl-text1)#permit ospf 10.1.1.0/24 any
  switch(config-acl-text1)#
  ```

- This command inserts a **permit** statement with the sequence number 25. The **permit** statement passes all PIM packets through the interface.

  ```
  switch(config-acl-text1)#25 permit pim any any
  switch(config-acl-text1)#
  ```
permit (IPv6 ACL)

The *permit* command adds a permit rule to the configuration mode IPv6 access control list (ACL). Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The *no permit* and *default permit* commands remove the specified rule from the configuration mode ACL. The *no <sequence number> (ACLs)* command also removes a specified rule from the ACL.

**Command Mode**
IPv6-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP] [tracked] [DSCP_FILTER] [log]
```

```
no permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP] [tracked] [DSCP_FILTER] [log]
```

```
default permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT] [FLAG] [MSG] [HOP] [tracked] [DSCP_FILTER] [log]
```

Command syntax uses a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

**Parameters**

- **SEQ_NUM**  
  Sequence number assigned to the rule. Options include:
  - `<no parameter>`  
    Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>`  
    Number assigned to entry.

- **PROT**  
  Protocol field filter. Values include:
  - `icmpv6`  
    Internet Control Message Protocol for v6 (58).
  - `ipv6`  
    Internet Protocol – IPv6 (41).
  - `ospf`  
    Open Shortest Path First (89).
  - `tcp`  
    Transmission Control Protocol (6).
  - `udp`  
    User Datagram Protocol (17).
  - `protocol_num`  
    Integer corresponding to an IP protocol. Values range from 0 to 255.

- **SRC_ADDR** and **DEST_ADDR**  
  Source and destination address filters. Options include:
  - `ipv6_prefix`  
    IPv6 address with prefix length (CIDR notation).
  - `any`  
    Packets from all addresses are filtered.
  - `host ipv6_addr`  
    IPv6 host address.

- **SRC_PT** and **DEST_PT**  
  Source and destination port filters. Options include:
  - `any`  
    All ports.
  - `eq port-1 port-2 ... port-n`  
    A list of ports. Maximum list size is 10 ports.
  - `neq port-1 port-2 ... port-n`  
    The set of all ports not listed. Maximum list size is 10 ports.
  - `gt port`  
    The set of ports with larger numbers than the listed port.
  - `lt port`  
    The set of ports with smaller numbers than the listed port.
  - `range port_1 port_2`  
    The set of ports whose numbers are between the range.
- **HOP** filters by packet’s hop-limit value. Options include:
  - `<no parameter>` Rule does not use hop limit to filter packets.
  - **hop-limit eq hop_value** Packets match if `hop-limit` value in packet equals `hop_value`.
  - **hop-limit gt hop_value** Packets match if `hop-limit` in packet is greater than `hop_value`.
  - **hop-limit lt hop_value** Packets match if `hop-limit` in packet is less than `hop_value`.
  - **hop-limit neq hop_value** Packets match if `hop-limit` in packet is not equal to `hop_value`.

- **FLAG** flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.

- **MSG** message type filters (ICMPv6 packets). Use CLI syntax assistance (?) to display options.

- **tracked** rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

- **DSCP_FILTER** rule filters packet by its DSCP value. Values include:
  - `<no parameter>` Rule does not use DSCP to filter packets.
  - **dscp dscp_value** Packets match if DSCP field in packet is equal to `dscp_value`.
  - **log** triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Example**
- This command appends a `permit` statement at the end of the ACL. The `permit` statement passes all IPv6 packets with the source address 3710:249a:c643:ef11::/64 and with any destination address.

```
switch(config)#ipv6 access-list text1
switch(config-acl-text1)#permit ipv6 3710:249a:c643:ef11::/64 any
switch(config-acl-text1)#
```
permit (IPv6 Prefix List)

The permit command adds a rule to the configuration mode IPv6 prefix list. Route map match statements use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains. Routes are redistributed into the specified domain when they match the prefix that a permit statement specifies.

The no permit and default permit commands remove the specified rule from the configuration mode prefix list. The no seq (IPv6 Prefix Lists) command also removes the specified rule from the prefix list.

Command Mode
IPv6-pfx Configuration

Command Syntax

```plaintext
[SEQUENCE] deny ipv6_prefix [MASK]
```

Parameters

- **SEQUENCE** Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the list's last rule.
  - `seq seq_num` Number is specified by `seq_num`. Value ranges from 0 to 65535.
- **ipv6_prefix** IPv6 prefix upon which command filters routes (CIDR notation).
- **MASK** Range of the prefix to be matched.
  - `<no parameter>` exact match with the subnet mask is required.
  - `eq mask_e` prefix length is equal to `mask_e`.
  - `ge mask_g` range is from `mask_g` to 128.
  - `le mask_l` range is from subnet mask length to `mask_l`.
  - `ge mask_l le mask_g` range is from `mask_g` to `mask_l`.
    - When `le` and `ge` are specified, the prefix list size > `mask_g`> `mask_l`

Example

- This command appends a permit statement at the end of the text1 prefix list. The permit statement allows redistribution of routes with the specified prefix.

```
switch(config)#ipv6 prefix-list route-five
switch(config-ipv6-pfx)#permit 3100::/64
switch(config-ipv6-pfx)#
```
**permit (MAC ACL)**

The **permit** command adds a permit rule to the configuration mode MAC access control list packets through the interface to which the list is applied. Rule filters include protocol, source, and destination.

The **no permit** and **default permit** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**

MAC-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
no permit SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
default permit SOURCE_ADDR DEST_ADDR [PROTOCOL] [log]
```

**Parameters**

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - <no parameter>  Number is derived by adding 10 to the number of the ACL’s last rule.
  - <1 – 4294967295>  Number assigned to entry.
- **SOURCE_ADDR** and **DEST_ADDR**  source and destination address filters. Options include:
  - `mac_address mac_mask`  MAC address and mask
  - `any`  Packets from all addresses are filtered.
  - `mac_address` specifies a MAC address in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh)
  - `mac_mask` specifies a MAC address mask in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh)
  - 0 bits require an exact match to filter
  - 1 bits filter on any value
- **PROTOCOL**  protocol field filter. Values include:
  - `aarp`  Appletalk Address Resolution Protocol (0x80f3)
  - `appletalk`  Appletalk (0x809b)
  - `arp`  Address Resolution Protocol (0x806)
  - `ip`  Internet Protocol Version 4 (0x800)
  - `ipx`  Internet Packet Exchange (0x8137)
  - `lldp`  LLDP (0x88cc)
  - `novell`  Novell (0x8138)
  - `rarp`  Reverse Address Resolution Protocol (0x8035)
  - `protocol_num`  integer corresponding to a MAC protocol. Values range from 0 to 65535
- **log**  triggers an informational log message to the console about the matching packet.

**Examples**

- This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all aarp packets from 10.1000.0000 through 10.1000.FFFF to any host.

```bash
switch(config)#mac access-list text1
switch(config-mac-acl-text1)#permit 10.1000.0000 0.0.FFFF any aarp
switch(config-mac-acl-text1)#
```
• This command inserts a `permit` statement with the sequence number 25. The `permit` statement passes all packets through the interface.

```
switch(config-mac-acl-text1)#25 permit any any
switch(config-mac-acl-text1)#
```
permit (Standard IPv4 ACL)

The **permit** command adds a permit rule to the configuration mode standard IPv4 access control list (ACL). Standard ACL rules filter on the source field.

Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The **no permit** and **default permit** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**

Std-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR [log]
no permit SOURCE_ADDR [log]
default permit SOURCE_ADDR [log]
```

**Parameters**

- **SEQ_NUM**  Sequence number assigned to the rule. Options include:
  - <no parameter>  Number is derived by adding 10 to the number of the ACL’s last rule.
  - <1 – 4294967295>  Number assigned to entry.
- **SOURCE_ADDR**  source address filter. Options include:
  - network_addr  subnet address (CIDR or address-mask).
  - any  Packets from all addresses are filtered.
  - host ip_addr  IP address (dotted decimal notation). Subnet addresses support discontiguous masks.

- **log**  triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Example**

- This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all packets with a source address of 10.10.1.1/24.

  ```
  switch(config)#ip access-list standard text1
  switch(config-std-acl-text1)#permit 10.1.1.1/24
  switch(config-std-acl-text1)#
  ```
permit (Standard IPv6 ACL)

The `permit` command adds a permit rule to the configuration mode standard IPv6 access control list. Standard ACL rules filter on the source field.

Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no permit` and `default permit` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

Std-IPv6-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR
no permit SOURCE_ADDR
default permit SOURCE_ADDR
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `<no parameter>` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `<1 – 4294967295>` Number assigned to entry.
- **SOURCE_ADDR** source address filter. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.

**Example**

- This command appends a `permit` statement at the end of the ACL. The `permit` statement drops packets with a source address of 2103::/64.

  ```
  switch(config)#ipv6 access-list standard text1
  switch(config-std-acl-ipv6-text1)#permit 2103::/64
  switch(config-std-acl-ipv6-text1)#
  ```
**remark**

The `remark` command adds a non-executable comment statement into the pending ACL. Remarks entered without a sequence number are appended to the end of the list. Remarks entered with a sequence number are inserted into the list as specified by the sequence number.

The `default remark` command removes the comment statement from the ACL.

The `no remark` command removes the comment statement from the ACL. The command can specify the remark by content or by sequence number.

**Command Mode**
- ACL Configuration
- IPv6-ACL Configuration
- Std-ACL Configuration
- Std-IPv6-ACL Configuration
- MAC-ACL Configuration

**Command Syntax**

```
remark text
line_num remark [text]
no remark text
default remark text
```

**Parameters**
- `text` the comment text.
- `line_num` sequence number assigned to the remark statement. Value ranges from 1 to 4294967295

**Example**
- This command appends a comment to the list.

```
switch(config-acl-test1)#remark end of list
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```
**resequence (ACLs)**

The `resequence` command assigns sequence numbers to rules in the configuration mode ACL. Command parameters specify the number of the first rule and the numeric interval between consecutive rules.

Maximum rule sequence number is 4294967295.

**Command Mode**
- ACL Configuration
- IPv6-ACL Configuration
- Std-ACL Configuration
- Std-IPv6-ACL Configuration
- MAC-ACL Configuration

**Command Syntax**
```
resequence [start_num [inc_num]]
```

**Parameters**
- `start_num` sequence number assigned to the first rule. Default is 10.
- `inc_num` numeric interval between consecutive rules. Default is 10.

**Example**
- The `resequence` command renumbers the list, starting the first command at number 100 and incrementing subsequent lines by 20.

```
switch(config-acl-test1)#show
IP Access List test1
   10 permit ip 10.10.10.0/24 any
   20 permit ip any host 10.20.10.1
   30 deny ip host 10.10.10.1 host 10.20.10.1
   40 permit ip any any
   50 remark end of list
switch(config-acl-test1)#resequence 100 20
switch(config-acl-test1)#show
IP Access List test1
   100 permit ip 10.10.10.0/24 any
   120 permit ip any host 10.20.10.1
   140 deny ip host 10.10.10.1 host 10.20.10.1
   160 permit ip any any
   180 remark end of list
```
route-map

The `route-map` command places the switch in route-map configuration mode, which is a group change mode that modifies a route map clause. The command specifies the name and number of the route map clause that subsequent commands modify and creates a route map clause if it references a nonexistent clause. All changes in a group change mode edit session are pending until the end of the session.

Route maps define conditions for redistributing routes between routing protocols. A route map clause is identified by a name, filter type (permit or deny) and sequence number. Clauses with the same name are components of a single route map; the sequence number determines the order in which the clauses are compared to a route.

The `exit` command saves pending route map clause changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending changes, returning the switch to global configuration mode.

The `no route-map` and `default route-map` commands delete the specified route map clause from `running-config`.

### Command Mode
Global Configuration

### Command Syntax
```
route-map  map_name [FILTER_TYPE] [sequence_number]
no route-map map_name [FILTER_TYPE] [sequence_number]
default route-map map_name [FILTER_TYPE] [sequence_number]
```

### Parameters
- `map_name` label assigned to route map. Protocols reference this label to access the route map.
- `FILTER_TYPE` disposition of routes matching conditions specified by route map clause.
  - `permit` routes are redistributed when they match route map clause.
  - `deny` routes are not redistributed when they match route map clause.
  - `<No parameter>` assigns `permit` as the `FILTER_TYPE`.

When a route does not match the route map criteria, the next clause within the route map is evaluated to determine the redistribution action for the route.

- `sequence_number` the route map position relative to other clauses with the same name.
  - `<no parameter>` sequence number of 10 (default) is assigned to the route map.
  - `<1-16777215>` specifies sequence number assigned to route map.

### Commands Available in route-map configuration mode:
- `continue (route-map)`
- `match (route-map)`
- `set (route-map)`

### Examples
- This command creates the route map named `map1` and places the switch in route-map configuration mode. The route map is configured as a permit map.

  ```
  switch(config)#route-map map1 permit 20
  switch(config-route-map-map1)#
  ```
• This command saves changes to `map1` route map, then returns the switch to global configuration mode.
  ```
  switch(config-route-map-map1)#exit
  switch(config)#
  ```

• This command saves changes to `map1` route map, then places the switch in interface-Ethernet mode.
  ```
  switch(config-route-map-map1)#interface ethernet 3
  switch(config-if-Et3)#
  ```

• This command discards changes to `map1` route map, then returns the switch to global configuration mode.
  ```
  switch(config-route-map-map1)#abort
  switch(config)#
  ```
seq (IPv6 Prefix Lists)

The `no seq` command removes the rule with the specified sequence number from the ACL. The `default seq` command also removes the specified rule.

The `seq` keyword is a command option used at the beginning of `deny (IPv6 Prefix List)` and `permit (IPv6 Prefix List)` commands that places a new rule between two existing rules.

**Command Mode**
IPv6-pfx Configuration

**Command Syntax**

```
no seq  line_num
default seq  line_num
```

**Parameters**
- `line_num` sequence number of rule to be deleted. Valid rule numbers range from 0 to 65535.

**Example**
- These commands remove rule 20 from the `map1` prefix list, then displays the resultant list.

```
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#no seq 20
switch(config-ipv6-pfx)#exit
switch(config)#show ipv6 prefix-list map1
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
  seq 40 permit 3:1bca:1141:ab34::/64
switch(config)#
```
set (route-map)

The set command specifies modifications to routes that are selected for redistribution by the configuration mode route map.

The no set and default set commands remove the specified set statement from the configuration mode route map clause by deleting the corresponding set statement from running-config.

Command Mode
Route-Map Configuration

Command Syntax

```
set CONDITION
no set CONDITION
default set CONDITION
```

Parameters

- `CONDITION` specifies the route modification parameter and value. Options include:
  - as-path prepend <1 to 4294967295> BGP AS number that is prepended to as-path.
  - distance <1 to 255> Protocol independent administrative distance.
  - ip next-hop ipv4_address next hop IPv4 address.
  - ip next-hop peer-address Use BGP peering address as next hop IPv4 address.
  - ipv6 next-hop ipv6_address next hop IPv6 address.
  - ipv6 next-hop peer-address Use BGP peering address as next hop IPv6 address.
  - local-preference <1 to 4294967295> BGP local preference metric.
  - metric <1 to 4294967295> route metric.
  - metric +<1 to 4294967295> add specified value to current route metric.
  - metric – <1 to 4294967295> subtract specified value to current route metric.
  - metric-type OSPF_TYPE OSPF metric type. Options include:
    - type-1 OSPF type 1 metric.
    - type-2 OSPF type 2 metric.
  - origin O_TYPE BGP origin attribute. Options for O_TYPE include
    - egp exterior BGP route.
    - igp interior BGP route.
    - incomplete BGP route of unknown origin.
  - tag <1 to 4294967295> route tag.
  - weight <1 to 65535> BGP weight parameter.

Related Commands

- `route-map` enters route-map configuration mode.
- `set (route-map)` specifies community modifications for the redistributed routes.
- `set community (route-map)` specifies ext community modifications for the redistributed routes.
Example

- This command creates a route-map entry that sets the local preference metric to 100 on redistributed routes.

```
switch(config)#route-map map1
switch(config-route-map-map1)#set local-preference 100
switch(config-route-map-map1)#
```
set community (route-map)

The `set community` command specifies community attribute modifications to routes that are selected for redistribution by the configuration mode route map. The `set community none` command removes community attributes from the route.

The `no set community` and `default set community` commands remove the specified `set community` statement from the configuration mode route map clause by deleting the corresponding statement from `running-config`.

**Command Mode**
- Route-Map Configuration

**Command Syntax**

```
set community Cond_1 Cond_2 Cond_N Mod_Type
set community community-list clist_name Mod_Type
set community none
no set community Cond_1 Cond_2 Cond_N Mod_Type
no set community community-list clist_name Mod_Type
no set community none
default set community Cond_1 Cond_2 Cond_N Mod_Type
default set community community-list clist_name Mod_Type
default set community none
```

**Parameters**
- `Cond_X` Specifies community modification. Command may contain multiple attributes. Options include:
  - `<0 to 65535>`: `<0 to 65535>` community number, expressed as AS:NN.
  - `<1 to 4294967040>`: community number. `Running-config` stores in AS:NN format.
  - `internet`: Advertise to Internet community (community 0:0).
  - `local-as`: Do not send outside local AS.
  - `no-advertise`: Do not advertise to any peer.
  - `no-export`: Do not export to next AS.
- `clist_name`: Name of community list.
- `Mod_Type` Specifies community modification method. Options include:
  - `<no parameter>`: command replaces existing community with specified parameters.
  - `additive`: command adds specified parameters to existing community.
  - `delete`: command removes specified parameters to existing community.

**Related Commands**
- `route-map` enters route-map configuration mode.
- `set (route-map)` specifies attribute modifications for the redistributed routes.
- `set community (route-map)` specifies extended community attributes modifications for redistributed routes.

**Example**
- This command creates a route-map entry that sets the community attribute to 0:0.

```
switch(config)#route-map map1
switch(config-route-map-map1)#set community internet
```

set extcommunity (route-map)

The `set extcommunity` command specifies extended community attribute modifications to routes that are selected for redistribution by the configuration mode route map. The `set extcommunity none` command removes extended community attributes from the route.

The `no set extcommunity` and `default set extcommunity` commands remove the specified `set extcommunity` statement from the configuration mode route map clause by deleting the corresponding statement from `running-config`.

Command Mode
Route-Map Configuration

Command Syntax
```
set extcommunity COND_1 [COND_2] [COND_N] [MOD_TYPE]
set extcommunity none
no set extcommunity COND_1 [COND_2] [COND_N] [MOD_TYPE]
no set extcommunity none
default set extcommunity COND_1 [COND_2] [COND_N] [MOD_TYPE]
default set extcommunity none
```

Parameters
- `COND_X` Specifies extended community route map modification. Command may contain multiple attributes. Options include:
  - `rt ASN:nn` Route target attribute (AS:network number).
  - `rt IP-address:nn` Route target attribute (IP address: network number).
  - `soo ASN:nn` Site of origin attribute (AS:network number).
  - `soo IP-address:nn` Site of origin attribute (IP address: network number).
- `MOD_TYPE` Specifies route map modification method. Options include:
  - `<no parameter>` command replaces existing route map with specified parameters.
  - `additive` command adds specified parameters to existing route map.
  - `delete` command removes specified parameters from existing route map.

Related Commands
- `route-map` enters route-map configuration mode.
- `set (route-map)` specifies attribute modifications for the redistributed routes
- `set (route-map)` specifies community modifications for the redistributed routes.

Example
- This command creates a route-map entry in map1 that sets the route target extended community attribute.
```
switch(config)#route-map map1
switch(config-route-map-map1)#set extcommunity rt 10.13.2.4:100
switch(config-route-map-map1)#
```
show (ACL configuration modes)

The **show** command displays the ACL (Access Control List) contents:

- **show** or **show pending** – displays the list as modified in ACL configuration mode.
- **show active** – displays the list as stored in **running-config**.
- **show comment** – displays the comment stored with the list.
- **show diff** – displays the modified and stored lists, with flags denoting the modified rules.

Exiting the ACL configuration mode stores all pending ACL changes to **running-config**.

**Command Mode**

- ACL Configuration
- IPv6-ACL Configuration
- Std-ACL Configuration
- Std-IPv6-ACL Configuration
- MAC-ACL Configuration

**Command Syntax**

- `show`
- `show active`
- `show comment`
- `show diff`
- `show pending`

**Examples**

The examples in this section assume these ACL commands are entered as specified.

These commands are stored in running-config:

```
10 permit ip 10.10.10.0/24 any
20 permit ip any host 10.21.10.1
30 deny ip host 10.10.10.1 host 10.20.10.1
40 permit ip any any
50 remark end of list
```

The current edit session removed this command. This change is not yet stored to running-config:

```
20 permit ip any host 10.21.10.1
```

The current edit session added these commands ACL. They are not yet stored to running-config:

```
20 permit ip 10.10.0.0/16 any
25 permit tcp 10.10.20.0/24 any
45 deny pim 239.24.124.0/24 10.5.8.4/30
```

- This command displays the ACL, as stored in the configuration.

```
switch(config-acl-test_1)#show active
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.21.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```
- This command displays the pending ACL, as modified in ACL configuration mode.

```
switch(config-acl-test_1)##show pending
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.10.0.0/16 any
  25 permit tcp 10.10.20.0/24 any
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  45 deny pim 239.24.124.0/24 10.5.8.4/30
  50 remark end of list
```

- This command displays the difference between the saved and modified ACLs.
  - Rules added to the pending list are denoted with a plus sign (+).
  - Rules removed from the saved list are denoted with a minus sign (-)

```
switch(config-acl-test_1)##show diff

show ip access-lists

The `show ip access-list` command displays the contents of IPv4 and standard IPv4 access control lists (ACLs) on the switch. Use the `summary` option to display only the name of the lists and the number of lines in each list.

Command Mode

Privileged EXEC

Command Syntax

```
show ip access-list [LIST] [SCOPE]
```

Parameters

- **LIST** name of lists to be displayed. Selection options include:
  - `<no parameter>` all IPv4 ACLs are displayed.
  - `list_name` specified IPv4 ACL is displayed.
- **SCOPE** information displayed. Selection options include:
  - `<no parameter>` all rules in the specified lists are displayed.
  - `summary` the number of rules in the specified lists are displayed.

Examples

- This command displays all rules in `test1` IPv4 ACL.
  ```
  switch#show ip access-list list2
  IP Access List list2
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  switch#
  ```

- This command displays the name of, and number of rules in, each list on the switch.
  ```
  switch#show ip access-list summary
  IPV4 ACL default-control-plane-acl
  Total rules configured: 12
  Configured on: control-plane
  Active on    : control-plane
  
  IPV4 ACL list2
  Total rules configured: 3
  
  IPV4 ACL test1
  Total rules configured: 6
  
  Standard IPV4 ACL test_1
  Total rules configured: 1
  
  IPV4 ACL test_3
  Total rules configured: 0
  ```

switch#
show ip prefix-list

The `show ip prefix-list` command displays all rules for the specified IPv4 prefix list. The command displays all IPv4 prefix list rules if a prefix list name is not specified.

**Command Mode**
EXEC

**Command Syntax**
```
show ip prefix-list [DISPLAY_ITEMS]
```

**Parameters**
- `DISPLAY_ITEMS` specifies the name of prefix lists for which rules are displayed. Options include:
  - `<no parameter>` all IPv4 prefix list rules are displayed.
  - `list_name` specifies the IPv4 prefix list for which rules are displayed.

**Examples**
- This command displays all rules in the route-one IPv4 prefix list:
  ```
  switch> show ip prefix-list route-one
  ip prefix-list route-one seq 10 deny 10.1.1.0/24
  ip prefix-list route-one seq 20 deny 10.1.0.0/16
  switch>
  ```
- This command displays all prefix list rules:
  ```
  switch> show ip prefix-list
  ip prefix-list route-one seq 10 deny 10.1.1.0/24
  ip prefix-list route-one seq 20 deny 10.1.0.0/16
  ip prefix-list route-two seq 10 deny 10.1.1.0/24 ge 26 le 30
  ip prefix-list route-two seq 20 deny 10.1.0.0/16
  ip prefix-list route-two seq 30 deny 3.3.3.3/32
  ip prefix-list route-two seq 500 deny 1.1.1.0/24 ge 28 le 30
  switch>
  ```
show ipv6 access-lists

The show ipv6 access-list command displays the contents of all IPv6 access control lists (ACLs) on the switch. Use the summary option to display only the name of the lists and the number of lines in each list.

Command Mode
Privileged EXEC

Command Syntax
show ipv6 access-list [LIST] [SCOPE]

Parameters
- LIST name of lists to be displayed. Selection options include:
  - <no parameter> all IPv6 ACLs are displayed.
  - list_name specified IPv6 ACL is displayed.
- SCOPE information displayed. Selection options include:
  - <no parameter> all rules in the specified lists are displayed.
  - summary the number of rules in the specified lists are displayed.

Examples
- This command displays all rules in test1 IPv6 ACL.
  switch#show ipv6 access-list list2
  IP Access List list2
  10 permit ipv6 3891:3c58:6300::/64 any
  20 permit ipv6 any host 2fe1:b468:024a::
  30 deny ipv6 host 3411:91c1:: host 4210:cc23:d2de::
  switch#

- This command displays the name of, and number of rules in, each list on the switch.
  switch#show ipv6 access-list summary
  IPV6 ACL list2
  Total rules configured: 3

  IPV6 ACL test1
  Total rules configured: 6

  IPV6 ACL test_1
  Total rules configured: 1

  Standard IPV6 ACL test_3
  Total rules configured: 0

  switch#
The `show ipv6 prefix-list` command displays all rules for the specified IPv6 prefix list. The command displays all IPv6 prefix lists if a prefix list name is not specified.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 prefix-list [DISPLAY_ITEMS]
```

**Parameters**

- `DISPLAY_ITEMS` specifies the name of prefix lists for which rules are displayed. Options include:
  - `<no parameter>` all IPv6 prefix lists are displayed.
  - `list_name` specifies the IPv6 prefix list for which rules are displayed.

**Examples**

- This command displays all rules in the map1 IPv6 prefix list:
  
  ```
  switch>show ipv6 prefix-list map1
  ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
  seq 40 permit 3:1bca:1141:ab34::/64
  switch>
  ```

- This command displays all prefix lists:
  
  ```
  switch>show ipv6 prefix-list
  ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
  seq 40 permit 3:1bca:1141:ab34::/64
  ipv6 prefix-list FREDD
  ipv6 prefix-list route-five
  ipv6 prefix-list map2
  seq 10 deny 10:1:1:1::/64 ge 72 le 80
  seq 20 deny 10:1::/32
  switch>
  ```
show mac access-lists

The `show mac access-list` command displays the contents of all MAC access control lists (ACLs) on the switch. Use the summary to display only the name of the lists and the number of lines in each list.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show mac access-lists [LIST] [SCOPE]
```

**Parameters**

- **LIST** name of lists to be displayed. Selection options include:
  - `<no parameter>` command displays all ACLs.
  - `list_name` command displays ACL specified by parameter.
- **SCOPE** information displayed. Selection options include:
  - `<no parameter>` command displays all rules in specified lists.
  - `summary` command displays the number of rules in specified lists.

**Examples**

- This command displays all rules in `mtest2` MAC ACL.
  ```
switch#show mac access-list mlist2
  IP Access List mlist2
      10 permit 1024.4510.F125 0.0.0 any aarp
      20 permit any 4100.4500.0000 0.FF.FFFF novell
      30 deny any any
  switch#
  ```

- This command displays the number of rules in each MAC ACL on the switch.
  ```
switch#show mac access-list summary
  MAC ACL mlist1
      Total rules configured: 6

  MAC ACL mlist2
      Total rules configured: 3

  MAC ACL mlist3
      Total rules configured: 1

  MAC ACL mlist4
      Total rules configured: 0
  switch#
  ```
**show route-map**

The `show route-map` command displays the contents of the specified route maps. The command displays all route maps if an individual map is not specified.

**Command Mode**

 EXEC

**Command Syntax**

 `show route-map [MAP]`

**Parameters**

- **MAP** name of maps to be displayed. Selection options include:
  - `<no parameter>` command displays all ACLs.
  - `map_name` route map that the command displays.

**Example**

- This command displays the `map1` route map.

```
switch>show route-map map1
route-map map1 permit 5
  Match clauses:
    match as 456
  Set clauses:
route-map map1 permit 10
  Match clauses:
    match ip next-hop 2.3.4.5
    match as-path path_2
  Set clauses:
    set local-preference 100
```
statistics per-entry (ACL configuration modes)

The statistics per-entry command places the ACL in counting mode. An ACL in counting mode displays the number of instances each rule in the list matches an inbound packet and the elapsed time since the last match. The show access list commands display the statistics next to each rule in the ACL.

On the FM6000 platform, this command has no effect when used in an ACL that is part of a PBR class map.

The no statistics per-entry and default statistics per-entry command places the ACL in non-counting mode.

Command Mode

ACL Configuration
IPv6-ACL Configuration
Std-ACL Configuration
Std-IPv6-ACL Configuration
MAC-ACL Configuration

Command Syntax

statistics per-entry
no statistics per-entry
default statistics per-entry

Examples

- This command places the test1 ACL in counting mode.
  
  switch(config)#ip access-list test1
  switch(config-acl-test1)#statistics per-entry
  switch(config-acl-test1)#

- This command displays the ACL, with counter information, for an ACL in counting mode.
  
  switch#show ip access-lists
  IP Access List default-control-plane-acl [readonly]
    statistics per-entry
    10 permit icmp any any
    20 permit ip any any tracked [match 12041, 0:00:00 ago]
    30 permit ospf any any

    50 permit udp any any eq bootps bootpc snmp rip [match 78, 0:00:27 ago]
    60 permit tcp any any eq mlag ttl eq 255
    70 permit udp any any eq mlag ttl eq 255
    80 permit vrrp any any
    90 permit ahp any any
    100 permit pim any any
    110 permit igmp any any [match 14, 0:23:27 ago]
    120 permit tcp any any range 5900 5910
    130 permit tcp any any range 50000 50100
    140 permit udp any any range 51000 51100
A virtual IP (VIP) address is an IP address that does not directly connect to a specific interface. Inbound packets sent to a Virtual IP address are redirected to a physical network interface. VIPs support connection redundancy by assigning the address to multiple switches. If one device becomes unavailable, packets sent to the address are still serviced by the functioning device.

Arista switches support virtual IP addresses through Virtual Router Redundancy Protocol, version 2 (VRRPv2), Virtual Router Redundancy Protocol, version 3 (VRRPv3), and Virtual-ARP (VARP). This chapter describes the Arista switch support of virtual IP addresses and contains these sections:

- Section 21.1: VRRP and VARP Conceptual Overview
- Section 21.2: VRRP and VARP Implementation Procedures
- Section 21.3: VRRP and VARP Implementation Examples
- Section 21.4: VRRP and VARP Configuration Commands

21.1 VRRP and VARP Conceptual Overview

21.1.1 VRRPv2

A virtual router, also known as a virtual router group, is defined by a virtual router identifier (VRID) and a virtual IP address. A virtual router’s mapping of VRID and IP address must be consistent among all switches implementing the virtual router group. A virtual router’s scope is restricted to a single LAN.

A LAN may contain multiple virtual routers for distributing traffic. Each virtual router on a LAN is assigned a unique VRID. A switch may be configured with virtual routers among multiple LANs.

VRRP uses priority ratings to assign Master or Backup roles for each VRRP router configured for a virtual router group. The Master router sends periodic VRRP Advertisement messages along the LAN and forwards packets received by the virtual router to their destination. Backup routers are inactive but are available to assume Master router duties when the current Master fails.

A VRRP can be configured to allow VRRP routers with higher priority to take over Master router duties. Alternatively, the group can be configured to prevent a router from preemptively assuming the Master role. A VRRP router is always assigned the Master of any virtual router configured with the address owned by the VRRP router, regardless of the preemption prevention setting.

21.1.2 VRRPv3

RFC 5798 defines version 3 of the Virtual Router Redundancy Protocol (VRRP) for both IPv4 and IPv6. It is based on version 2 of VRRP, as defined in RFC 3768.
21.1.3 VARP

Virtual-ARP (VARP) allows multiple switches to simultaneously route packets from a common IP address in an active-active router configuration. Each switch is configured with the same set of virtual IP addresses on corresponding VLAN interfaces and a common virtual MAC address. In MLAG configurations, VARP is preferred over VRRP because VARP does not require traffic to traverse the peer-link to the master router as VRRP would.

A maximum of 500 virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address.

VARP functions by having each switch respond to ARP and GARP requests for the configured router IP address with the virtual MAC address. The virtual MAC address is only for inbound packets and never used in the source field of outbound packets.

When *ip routing* is enabled, packets to the virtual MAC address are routed to the next hop destination.

Figure 21-1: VARP Configuration
21.2 VRRP and VARP Implementation Procedures

This section contains the following configuration instructions:

- Section 21.2.1: VRRP Configuration for IPv4
- Section 21.2.2: VRRP Configuration for IPv6
- Section 21.2.3: VARP Configuration

21.2.1 VRRP Configuration for IPv4

To implement a virtual router, it must be configured and enabled. A virtual router is typically configured before it is enabled; this ensures that the VRRP router operates as required before its priority settings immediately make it the master virtual router. Because assigning a primary address to a virtual router enables it, address assignment is normally performed after all other configuration tasks.

The **no vrrp** command removes all vrrp commands for the specified virtual router from **running-config**.

21.2.1.1 Virtual Router Configuration

Most configuration tasks are optional because all mandatory parameters have a default value. The following virtual router parameters are configurable:

- VRRP version (default = version 2)
- Router priority (default = 100)
- Preemption option (default is enabled)
- Advertisement timer (default = one second)
- Description (optional parameter)
- Authentication (optional parameter)
- Secondary IP addresses (optional parameter)

**VRRP version**

The **vrrp ip version** command sets the version of VRRP used on an interface. The version selected in a VRRP group must be the same for all group members. By default, Arista switches use VRRP version 2, which supports only IPv4 environments. VRRP version 3 supports both IPv4 and IPv6 environments.

**Example**

- This command causes VLAN 20 to use VRRP version 3.
  
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 1 ip version 3
  switch(config-if-vl20)#
  ```

**Master and Backup Router**

The VRRP routers within a virtual router group determine the Master router through priority settings. Priority values range from 254 (highest priority) to 1 (lowest priority). Priority is either set by a CLI command or is assigned the default value of 100. A switch specifies priority settings for each of its virtual routers. Once set, VRRP priority can also be changed by a tracked object. The **vrrp track** command configures the VRRP client process to track an object created by the **vrrp track** command and react if its status changes to **down**.
Preemption mode determines when a VRRP router with a higher priority rating becomes the Master router. If preemption is enabled, the VRRP router with the highest priority immediately becomes the Master router. If preemption is disabled, a VRRP router with a higher priority value does not become the Master router unless the current Master becomes unavailable; this is applicable when a new VRRP router becomes available on the LAN or VRRP router’s priority value changes for the virtual router.

The `vrrp priority` command configures the switch’s priority setting for the specified virtual router.

**Example**

- This command sets the priority value of 250 for the virtual router with VRID 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 priority 250
switch(config-if-vl20)#
```

The `vrrp preempt` command controls the preempt mode setting of the specified virtual router. By default, preempt mode is enabled.

**Examples**

- This command disables preempt mode for the virtual router 15 on VLAN 20.

```
switch(config-if-vl20)#no vrrp 15 preempt
switch(config-if-vl20)#
```

- This command enables preempt mode for the virtual router 30 on VLAN 20.

```
switch(config-if-vl20)#vrrp 30 preempt
switch(config-if-vl20)#
```

The `vrrp preempt delay` command configures a period between an event that elevates a switch to master vrrp router status and the switch’s assumption of master vrrp router role. Command options configure delays during normal operation and after a switch reboot.

**Advertisement Timer**

The Master router sends periodic VRRP Advertisement messages to other VRRP routers. The `vrrp timers advertise` command specifies the interval between successive advertisement message transmissions.

The advertisement interval also defines the timeout that determines when the switch assumes the Master router role. This timeout interval is three times the advertisement interval.

**Example**

- This command sets the advertisement interval of 10 seconds for virtual router 35 on VLAN 100.

```
switch(config-if-vl100)#vrrp 35 timers advertise 10
switch(config-if-vl100)#
```

**Description**

The `vrrp description` command associates a text string to the specified virtual router. The maximum string length is 80 characters. The string has no functional impact on the virtual router.

**Example**

- This command associates the text string `Laboratory Router` to virtual router 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 description Laboratory Router
switch(config-if-vl20)#
```
Authentication

VRRP authentication validates VRRP advertisement packets that the switch receives from other VRRP routers in a specified virtual router group. When a virtual router uses authentication, all VRRP routers in the group must use the same authentication parameters.

The `vrrp authentication` command configures virtual router authentication parameters for the specified virtual router.

Example

- This command implements plain-text authentication, using 12345 as the key, for virtual router 40 on VLAN 100.

  switch(config-if-vl100)#vrrp 40 authentication text 12345

Secondary Addresses

The `vrrp ip secondary` command assigns a secondary IP address to a virtual router. Secondary addresses are optional; a virtual router’s configuration may include more than one secondary address command. The primary and secondary address list must be identical for all switches in a virtual router group.

A primary IP address is assigned to a virtual router with the `vrrp ip` command (Section 21.2.1.2).

Example

- This command assigns the IP address of 10.2.4.5 as the secondary IP address for the virtual router 15 on VLAN 20

  switch(config-if-vl20)#vrrp 15 ip 10.2.4.5 secondary

21.2.1.2 Virtual Router Enabling and the Primary IP address

The `vrrp ip` command configures the primary IP address of the specified virtual router and enables the virtual router if the primary address is contained within the configuration mode interface’s IP address subnet. A virtual router’s configuration may contain only one primary IP address assignment command; subsequent `vrrp ip` commands reassign the virtual router’s primary IP address.

Example

- This command enables virtual router group 15 (VRID) on VLAN 20 and assigns 10.1.1.5 as the virtual router’s primary address.

  switch(config-if-vl20)#vrrp 15 ip 10.1.1.5

21.2.1.3 VRRP Disabling and Shutdown

The `vrrp shutdown` command places the switch in stopped state for the specified virtual router. While in stopped state, the switch cannot act as a Master or backup router for the virtual router group. The `no vrrp shutdown` command changes the switch’s virtual router state to backup or master if the virtual router is properly configured.

VRRP can also be shut down when the status of a tracked object configured by the `vrrp track` command changes to down.
21.2.2 VRRP Configuration for IPv6

To implement a virtual router, it must be configured and enabled. A virtual router is typically configured before it is enabled; this ensures that the VRRP router operates as required before its priority settings immediately make it the master virtual router. Because assigning a primary address to a virtual router enables it, address assignment is normally performed after all other configuration tasks.

The no vrrp command removes all VRRP commands for the specified virtual router from running-config.

21.2.2.1 Configuring VRRP for IPv6

Specify the VRRP version

The vrrp ip version command sets the version of VRRP used on an interface. The version selected in a VRRP group must be the same for all group members. By default, Arista switches use VRRP version 2, which is not compatible with IPv6.

Example

- This command causes VLAN 20 to use VRRP version 3.
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 1 ip version 3
  switch(config-if-vl20)#

Create a VRRP Group and Configure a Virtual IPv6 Address

The vrrp ipv6 command assigns an IPv6 address to the interface being configured and creates a VRRP group.
Chapter 21: VRRP and VARP

VRRP and VARP Implementation Procedures

Example
- These commands create VRRP group 3 and configure a virtual IPv6 address for the VRRP group on the VLAN 20 interface.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 3 ipv6 2001:db8:0:1::1
  switch(config-if-vl20)#
  ```

ConfigureTracking
The `vrrp track` command configures the VRRP client process to track an object created by the `vrrp track` command and react if its status changes to `down`.

The `vrrp track` command configures VRRP to track a specified track entry.

Example
- This command causes interface VLAN 20 to disable VRRP when tracked object ETH8 changes state.
  ```
  switch(config-if-vl20)#vrrp 1 track ETH8 shutdown
  switch(config-if-vl20)#
  ```

Configure the Priority
The `vrrp priority` command configures the switch’s priority setting for the specified virtual router.

Example
- This command sets the priority value of 250 for the virtual router with VRID 15 on VLAN 20.
  ```
  switch(config-if-vl20)#vrrp 15 priority 250
  switch(config-if-vl20)#
  ```

Configure the Preemption Mode
Preemption mode determines when a VRRP router with a higher priority rating becomes the Master router. If preemption is enabled, the VRRP router with the highest priority immediately becomes the Master router. If preemption is disabled, a VRRP router with a higher priority value does not become the Master router unless the current Master becomes unavailable; this is applicable when a new VRRP router becomes available on the LAN or VRRP router’s priority value changes for the virtual router.

The `vrrp preempt` command controls the preempt mode setting of the specified virtual router. By default, preempt mode is enabled.

Example
- This command enables preempt mode for the virtual router 30 on VLAN 20.
  ```
  switch(config-if-vl20)#vrrp 30 preempt
  ```

Configure the VRRP Advertisement Interval
The `ip virtual-router mac-address advertisement-interval` command specifies the interval between advertisement packets sent by the master router to the VRRP group members.
Examples

- This command configures a MAC address advertisement interval of one minute (60 seconds).
  
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#ip virtual-router mac-address advertisement-interval 60
  switch(config-if-vl20)#
  ```

21.2.2.2 Verify VRRP IPv6 Configurations

Use the following commands to display the VRRP configurations and status.

**Show VRRP Group**

The `show vrrp` command displays information about the Virtual Router Redundancy Protocol (VRRP) groups configured on a specified interface.

**Examples**

- This command displays a table of information for VRRP groups on the switch.
  
  ```
  switch>show vrrp interface vlan 3060 brief
  Interface Id  Ver Pri Time  State   VrIps
  Vlan3060  1   3   100 3609  Master  2001::2
  2001::3
  Vlan3060  2   3   100 3609  Master  2002::2
  2002::3
  switch>
  ```

**Show VRRP Internal**

The `show vrrp internal` command displays the internal Pluggable Authentication Modules (PAM) packet counters on the switch.

**Examples**

- This command displays the internal PAM packet counters on the switch.
  
  ```
  switch>show vrrp internal
  VRRP PAM Counters
  ----------------
  ARP Responder:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  ND Responder:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  IPv4 VRRP Packet Manager:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  IPv6 VRRP Packet Manager:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  switch>
  ```
21.2.3 VARP Configuration

Implementing VARP consists of assigning virtual IP addresses to VLAN interfaces and configuring a virtual MAC address.

**Virtual IP Addresses**

The `ip virtual-router address` command assigns a virtual IP address to the VLAN interface being configured. Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A virtual IPv4 address may optionally be configured with a subnet, but doing so will modify the behavior of ARP requests sent from the router. When the router sends an ARP request for an IPv4 address in a virtual subnet, the ARP request will use the virtual IPv4 address as the source IP address and the virtual MAC address as the source MAC address inside the ARP header. For virtual IP addresses configured without the subnet option, no modifications are made to outgoing ARP requests.

**Examples**

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address for VLAN 10.

```
switch(config)#interface vlan 10
switch(config-if-Vl10)#ip address 10.0.0.2/24
switch(config-if-Vl10)#ip virtual-router address 10.0.0.6
switch(config-if-Vl10)#ip address 2001::1/64
switch(config-if-Vl10)#ip6 virtual-router address 2001::2
switch(config-if-Vl10)#exit
switch(config)#
```

- These commands configure a Switch Virtual Interface (SVI) and a virtual IPv4 address with a subnet for VLAN 10. A static route is added to indicate that the virtual subnet is reachable through VLAN 10.

```
switch(config)#ip route 192.0.0.0/24 vlan 10
switch(config)#interface vlan 10
switch(config-if-Vl10)#ip address 10.0.0.2/24
switch(config-if-Vl10)#ip virtual-router address 192.0.0.6/24
switch(config-if-Vl10)#exit
switch(config)#
```

**Virtual MAC Address**

The `ip virtual-router mac-address` command assigns a virtual MAC address to the switch. The switch maps all virtual router IP addresses to this MAC address. The address is receive-only; the switch never sends packets with this address as the source.

When the destination MAC of a packet destined to a remote network matches the virtual MAC address, the MLAG peer forwards the traffic to the next hop destination. Each MLAG peer must have the same routes available, either through static configuration or learned through a dynamic routing protocol.

**Example**

- This command configures a virtual MAC address.

```
switch(config)#ip virtual-router mac-address 001c.7300.0099
switch(config)#
```

**Show Virtual MAC Address**

To display the virtual router MAC and IP addresses, enter the `show ip virtual-router` command.
Example

This command displays the virtual router addresses assigned on the switch.

```
switch> show ip virtual-router
IP virtual router is configured with MAC address: 24cd.5a29.cc31
Interface   IP Address        Virtual IP Address   Status            Protocol
Vlan15      10.1.1.3/24       10.1.1.15            up                up
Vlan15      10.1.1.3/24       10.1.1.16            up                up
Vlan15      10.1.1.3/24       10.1.1.17            up                up
Vlan20      10.12.1.6/24      10.1.1.51            up                up
Vlan20      10.12.1.6/24      10.1.1.53            up                up
Vlan20      10.12.1.6/24      10.1.1.55            up                up
switch>
```

Show IPv6 Virtual-Router

The `show ipv6 virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IPv6 addresses assigned to each VLAN interface.

Examples

This command displays a table of information for IPv6 VRRP groups on the switch.

```
switch> show ipv6 virtual-router
IP virtual router is configured with MAC address: 001c.7300.0099
MAC address advertisement interval: 30 seconds
Interface Vlan4094
State is up
Protocol is up
IPv6 address
  2001:b8:2001::1011/64
Virtual IPv6 address
  2001:db8:ac10:fe01::
switch>
```
21.3 VRRP and VARP Implementation Examples

This section contains the following example set:

- Section 21.3.1: VRRP Examples
- Section 21.3.2: VARP Example

21.3.1 VRRP Examples

This section provides code that implements three VRRP configurations:

- Example 1 configures two switches in a single virtual router group. This implementation protects the LAN against the failure of one router.
- Example 2 configures two switches into two virtual routers within a single LAN. This implementation protects the LAN against the failure of one router and balances traffic between the routers.
- Example 3 configures three switches to implement virtual routers on two LANs. Each LAN contains two virtual routers. One switch is configured into four virtual routers – two on each LAN.

21.3.1.1 VRRP Example 1: One Virtual Router on One LAN

Figure 21-2 displays the Example 1 network. Two switches are configured as VRRP routers to form one virtual router.

**Figure 21-2: VRRP Example 1 Network Diagram**

The following code configures the first switch (Router A) as the master router and the second switch (Router B) as a backup router for virtual router 10 on VLAN 50. Router A becomes the Master virtual router by setting its priority at 200; Router B maintains the default priority of 100. The advertisement interval is three seconds on both switches. Priority preemption is enabled by default.

**Switch code that implements Router A on the first switch**

```
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#no vrrp 10
switch-A(config-if-vl50)#vrrp 10 priority 200
switch-A(config-if-vl50)#vrrp 10 timers advertise 3
switch-A(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl50)#exit
```
Switch code that implements Router B on the second switch

```bash
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#no vrrp 10
switch-B(config-if-vl50)#vrrp 10 timers advertise 3
switch-B(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl50)#exit
```

21.3.1.2 VRRP Example 2: Two Virtual Routers on One LAN

**Figure 21-3** displays Example 2. Two switches are configured as VRRP routers to form two virtual routers on one LAN. Using two virtual routers distributes the LAN traffic between the switches.

Figure 21-3: VRRP Example 2 Network Diagram

The following code configures two switches as a master and a backup router for two virtual routers on VLAN 50.

- Router A is the master for virtual router 10 and backup for virtual router 20.
- Router B is the master for virtual router 20 and backup for virtual router 10.
- VRRP advertisement interval is 3 seconds on virtual router 10 and 5 seconds on virtual router 20.
- Priority preemption is enabled by default for both virtual routers.

Switch code that implements Router A on the first switch

```bash
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#no vrrp 10
switch-A(config-if-vl50)#vrrp 10 priority 200
switch-A(config-if-vl50)#vrrp 10 timers advertise 3
switch-A(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl50)#no vrrp 20
switch-A(config-if-vl50)#vrrp 20 timers advertise 5
switch-A(config-if-vl50)#vrrp 20 ip 10.10.4.20
switch-A(config-if-vl50)#exit
```
Chapter 21: VRRP and VARP

VRRP and VARP Implementation Examples

Switch code that implements Router B on the second switch

```
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#no vrrp 10
switch-B(config-if-vl50)#vrrp 10 timers advertise 3
switch-B(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl50)#no vrrp 20
switch-B(config-if-vl50)#vrrp 20 priority 200
switch-B(config-if-vl50)#vrrp 20 timers advertise 5
switch-B(config-if-vl50)#vrrp 20 ip 10.10.4.20
switch-B(config-if-vl50)#exit
```

21.3.1.3 VRRP Example 3: Two Virtual Routers on Two LANs

Figure 21-4 displays Example 3. Three switches are configured as VRRP routers to form four virtual router groups – two groups on each of two LANs.

**Figure 21-4: VRRP Example 3 Network Diagram**

The following code configures the three switches as follows:

- Router A is the master for virtual router 10 and backup for virtual router 20 on VLAN 100.
- Router A is the master for virtual router 30 and backup for virtual router 40 on VLAN 150.
- Router B is the master for virtual router 20 and backup for virtual router 10 on VLAN 100.
- Router C is the master for virtual router 40 and backup for virtual router 30 on VLAN 150.
- VRRP advertisement interval is set to one second on all virtual routers.
- Priority preemption is disabled on all virtual routers.
Switch code that implements Router A on the first switch

```bash
switch-A(config)#interface vlan 100
switch-A(config-if-vl100)#ip address 10.10.4.1/24
switch-A(config-if-vl100)#no vrrp 10
switch-A(config-if-vl100)#vrrp 10 priority 200
switch-A(config-if-vl100)#no vrrp 10 preempt
switch-A(config-if-vl100)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl100)#no vrrp 20
switch-A(config-if-vl100)#no vrrp 20 preempt
switch-A(config-if-vl100)#vrrp 20 ip 10.10.4.20
switch-A(config-if-vl100)#interface vlan 150
switch-A(config-if-vl150)#ip address 40.10.5.7/24
switch-A(config-if-vl150)#no vrrp 30
switch-A(config-if-vl150)#vrrp 30 priority 200
switch-A(config-if-vl150)#no vrrp 30 preempt
switch-A(config-if-vl150)#vrrp 30 ip 40.10.5.31
switch-A(config-if-vl150)#no vrrp 40
switch-A(config-if-vl150)#no vrrp 40 preempt
switch-A(config-if-vl150)#vrrp 40 ip 40.10.5.32
switch-A(config-if-vl150)#exit
```

Switch code that implements Router B on the second switch

```bash
switch-B(config)#interface vlan 100
switch-B(config-if-vl100)#ip address 10.10.4.2/24
switch-B(config-if-vl100)#no vrrp 10
switch-B(config-if-vl100)#no vrrp 10 preempt
switch-B(config-if-vl100)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl100)#no vrrp 20
switch-B(config-if-vl100)#vrrp 20 priority 200
switch-B(config-if-vl100)#no vrrp 20 preempt
switch-B(config-if-vl100)#vrrp 20 ip 10.10.4.20
switch-B(config-if-vl100)#exit
```

Switch code that implements Router C on the third switch

```bash
switch-C(config)#interface vlan 150
switch-C(config-if-vl150)#ip address 40.10.5.8/24
switch-C(config-if-vl150)#no vrrp 30
switch-C(config-if-vl150)#no vrrp 30 preempt
switch-C(config-if-vl150)#vrrp 30 ip 40.10.5.31
switch-C(config-if-vl150)#no vrrp 40
switch-C(config-if-vl150)#vrrp 40 priority 200
switch-C(config-if-vl150)#no vrrp 40 preempt
switch-C(config-if-vl150)#vrrp 40 ip 40.10.5.32
switch-C(config-if-vl150)#exit
```

21.3.2 VARP Example

This section provides code that implements a VARP configuration. Figure 21-5 displays the Example 1 network. Two switches in an MLAG domain are configured as VARP routers.

The following code configures 10.10.4.10 as the virtual IP address for VLAN 50, 10.24.4.1 as the virtual IP address for VLAN 70, and 001c.7300.0999 as the virtual MAC address on both switches.
Switch code that implements VARP on the first switch

```
switch-A(config)#ip virtual-router mac-address 001c.7300.0999
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#ip virtual-router address 10.10.4.10
switch-A(config-if-vl50)#interface vlan 70
switch-A(config-if-vl70)#ip address 10.24.4.18/24
switch-A(config-if-vl70)#ip virtual-router address 10.24.4.1
switch-A(config-if-vl70)#exit
```

Switch code that implements VARP on the second switch

```
switch-B(config)#ip virtual-router mac-address 001c.7300.0999
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#ip virtual-router address 10.10.4.10
switch-B(config-if-vl50)#interface vlan 70
switch-B(config-if-vl70)#ip address 10.24.4.17/24
switch-B(config-if-vl70)#ip virtual-router address 10.24.4.1
switch-B(config-if-vl70)#exit
```
21.4 VRRP and VARP Configuration Commands

This section contains descriptions of CLI commands that support VRRP and VARP.

**Global Configuration Commands**
- `ip fhrp accept-mode`
- `ip virtual-router mac-address`
- `ip virtual-router mac-address advertisement-interval`

**Interface Configuration Commands – Ethernet, Port Channel, and VLAN Interfaces**
- `ip virtual-router address`
- `ipv6 virtual-router address`
- `no vrrp`
- `vrrp authentication`
- `vrrp delay reload`
- `vrrp description`
- `vrrp ip`
- `vrrp ip secondary`
- `vrrp ip version`
- `vrrp ipv6`
- `vrrp mac-address advertisement-interval`
- `vrrp preempt`
- `vrrp preempt delay`
- `vrrp priority`
- `vrrp shutdown`
- `vrrp timers advertise`
- `vrrp track`

**Privileged EXEC Commands**
- `show ip virtual-router`
- `show ipv6 virtual-router`
- `show vrrp`
- `show vrrp internal`
**ip fhrp accept-mode**

The **ip fhrp accept-mode** command configures the switch to permit SSH access to the VRRP Master and VARP Master router. All routers within a VRRP or VARP group should be configured consistently. By default, SSH access to the VRRP and VARP Master routers is not permitted.

The **no ip fhrp accept-mode** and **default ip fhrp accept-mode** commands restores the default SSH access availability by removing the **ip fhrp accept-mode** command from **running-config**.

**Command Mode**
- Global Configuration

**Command Syntax**
- `ip fhrp accept-mode`
- `no ip fhrp accept-mode`
- `default ip fhrp accept-mode`

**Example**
- This command configures the switch to permit SSH access to the VRRP and VARP Master routers.

```
switch(config)#ip fhrp accept-mode
switch(config)#show running-config

! ip fhrp accept-mode
! switch(config)#
```

The `ip virtual-router address` command assigns a virtual IPv4 address to the VLAN interface being configured. (To assign a virtual IPv6 address to a VLAN interface, use the `ipv6 virtual-router address` command.) Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A virtual IP address may optionally be configured with a subnet, but doing so will modify the behavior of ARP requests sent from the router. When the router sends an ARP request for an IP address in a virtual subnet, the ARP request will use the virtual IP address as the source IP address and the virtual MAC address as the source MAC address inside the ARP header. For virtual IP addresses configured without the subnet option, no modifications are made to outgoing ARP requests.

A maximum of 500 virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address configured through the `ip virtual-router mac-address` command.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG.

The `no ip virtual-router address` and `default ip virtual-router address` commands remove the specified virtual IP address from the configuration mode interface by deleting the corresponding `ip virtual-router address` command from `running-config`. If the command does not specify an address, all virtual IPv4 addresses are removed from the interface.

### Command Mode

Interface-VLAN Configuration

### Command Syntax

```
ip virtual-router address ipv4_addr
no ip virtual-router address [ipv4_addr]
default ip virtual-router address [ipv4_addr]
```

### Parameters

- `ipv4_addr` IP address of router. Dotted decimal notation.

### Examples

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address for VLAN 10.

  ```
  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 10.0.0.6
  switch(config-if-Vl10)#exit
  switch(config)#
  ```

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address with a subnet for VLAN 10. A static route is added to indicate that the virtual subnet is reachable through VLAN 10.

  ```
  switch(config)#ip route 192.0.0.0/24 vlan 10
  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 192.0.0.6/24
  switch(config-if-Vl10)#exit
  switch(config)#
  ```
ip virtual-router mac-address

The `ip virtual-router mac-address` command assigns a virtual MAC address to the switch. The switch maps all virtual router IP addresses to this MAC address. The address is receive-only; the switch never sends packets with this address as the source. The virtual router is not configured on the switch until this virtual mac-address is assigned.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG. When the destination MAC of a packet destined to a remote network matches the virtual MAC address, the MLAG peer forwards the traffic to the next hop destination. Each MLAG peer must have the same routes available, either through static configuration or learned through a dynamic routing protocol.

The `no ip virtual-router mac-address` command removes a virtual MAC address from the interface by deleting the corresponding `ip virtual-router mac-address` command from `running-config`.

Command Mode
- Global Configuration

Command Syntax
```
ip virtual-router mac-address mac_addr
no ip virtual-router mac address [mac_addr]
```

Parameters
- `mac_addr` MAC IP address (dotted hex notation). Select an address that will not otherwise appear on the switch.

Examples
- This command configures a virtual MAC address.
```
switch(config)#ip virtual-router mac-address 001c.7300.0099
switch(config)#
```
ip virtual-router mac-address advertisement-interval

The `ip virtual-router mac-address advertisement-interval` command specifies the period between the transmission of consecutive gratuitous ARP requests that contain the virtual router mac address for each virtual-router IP address configured on the switch. The default period is 30 seconds.

The `no ip virtual-router mac-address advertisement-interval` command restores the default period of 30 seconds by removing the `ip virtual-router mac-address advertisement-interval` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
ip virtual-router mac-address advertisement-interval period
no ip virtual-router mac-address advertisement-interval
default ip virtual-router mac-address advertisement-interval
```

Parameters
- `period` advertisement interval (seconds). Values range from 0 to 86400. Default is 30.

Examples
- This command configures a MAC address advertisement interval of one minute (60 seconds).

  ```
switch(config)#ip virtual-router mac-address advertisement-interval 60
switch(config)#
```
**ipv6 virtual-router address**

The `ipv6 virtual-router address` command assigns a virtual IPv6 address to the VLAN interface being configured. (To assign a virtual IPv4 address to a VLAN interface, use the `ip virtual-router address` command.) Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A maximum of 500 virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address configured through the `ip virtual-router mac-address` command.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG.

The `no ipv6 virtual-router address` and `default ipv6 virtual-router address` commands remove the specified virtual IPv6 address from the configuration mode interface by deleting the corresponding `ipv6 virtual-router address` command from `running-config`. If the command does not specify an address, all virtual IPv6 addresses are removed from the interface.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

- `ipv6 virtual-router address net_addr`
- `no ipv6 virtual-router address [net_addr]`
- `default ipv6 virtual-router address [net_addr]`

**Parameters**

- `net_addr` network IPv6 address.

**Examples**

- These commands configure a Switch Virtual Interface (SVI) and a virtual IPv6 address for VLAN 10.

```
switch(config)#interface vlan 10
switch(config-if-Vl10)#ipv6 address 2001:0DB8:0:1::1/64
switch(config-if-Vl10)#ipv6 virtual-router address 2001:0DB8:0:1::2
switch(config-if-Vl10)#exit
switch(config)#
```
no vrrp

The **no vrrp** command removes all vrrp configuration commands for the specified virtual router on the configuration mode interface. The default vrrp command also reverts vrrp configuration parameters to default settings by removing the corresponding **vrrp** commands.

Commands removed by the **no vrrp** command include:

- **vrrp authentication**
- **vrrp description**
- **vrrp ip**
- **vrrp ip secondary**
- **vrrp preempt**
- **vrrp preempt delay**
- **vrrp priority**
- **vrrp shutdown**
- **vrrp timers advertise**

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```plaintext
no vrrp group
default vrrp group
```

**Parameters**

- **group** virtual router identifier (VRID). Values range from 1 to 255.

**Examples**

- This command removes all vrrp configuration commands for virtual router group 10 on VLAN 15.

```
switch(config)#interface vlan 15
switch(config-if-vl15)#no vrrp 10
switch(config-if-vl15)#
```
show ip virtual-router

The `show ip virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IP addresses assigned to each VLAN interface.

**Command Mode**

EXEC

**Command Syntax**

`show ip virtual-router`

**Messages**

- **IP virtual router is not configured** a virtual MAC address is not assigned to the switch.
- **No interface with virtual IP address** no virtual IP addresses are assigned to any VLAN interfaces.

**Examples**

- This command displays a table of information for VRRP groups on the switch.

  ```
  switch>show ip virtual-router
  IP virtual router is configured with MAC address: 24cd.5a29.cc31
  Interface  IP Address        Virtual IP Address   Status            Protocol
  Vlan15     10.1.1.3/24       10.1.1.15            up                up
  Vlan15     10.1.1.3/24       10.1.1.16            up                up
  Vlan15     10.1.1.3/24       10.1.1.17            up                up
  Vlan20     10.12.1.6/24      10.1.1.51            up                up
  Vlan20     10.12.1.6/24      10.1.1.53            up                up
  Vlan20     10.12.1.6/24      10.1.1.55            up                up
  switch>
  ```

- This command generates a response that indicates a virtual MAC address is not assigned to the switch.

  ```
  switch>show ip virtual-router
  IP virtual router is not configured
  switch>
  ```
**show ipv6 virtual-router**

The `show ipv6 virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IPv6 addresses assigned to each VLAN interface.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 virtual-router
```

**Messages**

- **IPv6 virtual router is not configured** a virtual MAC address is not assigned to the switch.
- **No interface with virtual IPv6 address** no virtual IPv6 addresses are assigned to any VLAN interfaces.

**Examples**

- This command displays a table of information for IPv6 VRRP groups on the switch.

```
switch>show ipv6 virtual-router
IP virtual router is configured with MAC address: 001c.7300.0099
MAC address advertisement interval: 30 seconds
Interface Vlan4094
  State is up
  Protocol is up
  IPv6 address
    2001:b8:2001::1011/64
  Virtual IPv6 address
    2001:db8:ac10:fe01::
switch>
```
show vrrp

The **show vrrp** command displays information about the Virtual Router Redundancy Protocol (VRRP) groups configured on a specified interface. Parameter options control the amount and formatting of the displayed information.

**Command Mode**
Privileged EXEC

**Command Syntax**

```plaintext
show vrrp [INFO_LEVEL] [STATES]
show vrrp INTF [GROUP_NUM] [INFO_LEVEL] [STATES]
show vrrp GROUP_NUM INTF_GROUP [INFO_LEVEL] [STATES]
```

**Parameters**

- **INTF** specifies the VRRP groups for which the command displays status. When the parameter is omitted or specifies only an interface, the group list is filtered by the **STATES** parameter.
  - <no parameter> specified groups on all interfaces.
  - `interface ethernet e_num` specified groups on Ethernet interface.
  - `interface loopback l_num` specified groups on loopback interface.
  - `interface management m_num` specified groups on management interface.
  - `interface port-channel p_num` specified groups on port channel interface.
  - `interface vlan v_num` specified groups on VLAN interface.
  - `interface vxlan vx_num` specified groups on VXLAN interface.

- **GROUP_NUM** the VRRP ID number of the group for which the command displays status.
  - <no parameter> all groups on specified interface.
  - `vrid_num` virtual router identifier (VRID). Value ranges from 1 to 255.

- **INFO_LEVEL** Specifies format and amount of displayed information. Options include:
  - <no parameter> displays a block of data for each VRRP group.
  - `brief` displays a single table that lists information for all VRRP groups.

- **STATES** Specifies the groups, by VRRP router state, that are displayed. Options include:
  - <no parameter> displays data for groups in the **master** or **backup** states.
  - all displays all groups, including groups in the **stopped** and **interface down** states.

**Examples**

- This command displays a table of information for VRRP groups on the switch.

  ```plaintext
  switch>show vrrp brief
  Interface Id  Ver Pri Time  State   VrIps
  Vlan1006  3   2   100 3609 Master  127.38.10.2
  Vlan1006  4   3   100 3609 Master  127.38.10.10
  Vlan1010  1   2   100 3609 Master  128.44.5.3
  Vlan1014  2   2   100 3609 Master  127.16.14.2
  switch>
  ```
- This command displays data blocks for all VRRP groups on VLAN 46, regardless of the VRRP state.

```
switch> show vrrp interface vlan 1006 all
Vlan1010 - Group 1
  VRRP Version 2
  State is Stopped
  Virtual IPv4 address is 128.44.5.3
  Virtual MAC address is 0000.5e00.0101
  Mac Address Advertisement interval is 30s
  VRRP Advertisement interval is 1s
  Preemption is enabled
  Preemption delay is 0s
  Preemption reload delay is 0s
  Priority is 100
  Master Router is 0.0.0.0
  Master Advertisement interval is 1s
  Skew time is 0.609s
  Master Down interval is 3.609s
```

- This command displays data for all VRRP group 2 on VLAN 1014.

```
switch> show vrrp interface vlan 1014 group 2
Vlan1006 - Group 2
  VRRP Version 2
  State is Master
  Virtual IPv4 address is 127.38.10.2
  Virtual MAC address is 0000.5e00.0103
  Mac Address Advertisement interval is 30s
  VRRP Advertisement interval is 1s
  Preemption is enabled
  Preemption delay is 0s
  Preemption reload delay is 0s
  Priority is 100
  Master Router is 127.38.10.1 (local), priority is 100
  Master Advertisement interval is 1s
  Skew time is 0.609s
  Master Down interval is 3.609s
```

```
show vrrp internal

The `show vrrp internal` command displays the internal PAM packet counters on the switch.

**Command Mode**

EXEC

**Command Syntax**

`show vrrp internal`

**Examples**

- This command displays the internal Packet Access Method (PAM) packet counters on the switch.
  
  ```
  switch>show vrrp internal
  VRRP PAM Counters
  ---------------
  ARP Responder:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  ND Responder:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  IPv4 VRRP Packet Manager:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  IPv6 VRRP Packet Manager:
  numSent : 0
  numRcvd : 0
  numBadRcvd : 0
  ```
  
  switch>
  ```
vrrp authentication

The **vrrp authentication** command configures parameters the switch uses to authenticate virtual router packets it receives from other VRRP routers in the group. This feature is only supported for VRRP IPv4.

The **no vrrp authentication** and **default vrrp authentication** commands disable VRRP authentication of packets from the specified virtual router by removing the corresponding **vrrp authentication** command from **running-config**. The **no vrrp** command also removes the **vrrp authentication** command for the specified virtual router.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `vrrp group authentication AUTH_PARAMETER`
- `no vrrp group authentication`
- `default vrrp group authentication`

**Parameters**

- **group** virtual router identifier (VRID). Values range from 1 to 255.
- **AUTH_PARAMETER** encryption level and authentication key used by router. Options include:
  - `text text_key` plain-text authentication, `text_key` is text.
  - `text_key` plain-text authentication, `text_key` is text.
  - `ietf-md5 key-string 0 text_key` IP authentication of MD5 key hash, `text_key` is text.
  - `ietf-md5 key-string text_key` IP authentication of MD5 key hash, `text_key` is text.
  - `ietf-md5 key-string 7 coded_key` IP authentication of MD5 key hash, `coded_key` is MD5 hash.

**Examples**

- This command implements plain-text authentication, using 12345 as the key, for virtual router 40 on VLAN 100.
  
  ```
  switch(config)#interface vlan 100
  switch(config-if-vl100)#vrrp 40 authentication text 12345
  switch(config-if-vl100)#
  ```

- This command implements ietf-md5 authentication, using 12345 as the key.
  
  ```
  switch(config-if-vl100)#vrrp 40 authentication ietf-md5 key-string 0 12345
  switch(config-if-vl100)#
  ```

- This command implements ietf-md5 authentication, using 12345 as the key. The key is entered as the MD5 hash equivalent of the text string.
  
  ```
  switch(config-if-vl100)#vrrp 40 authentication ietf-md5 key-string 7 EA3TUPxddFCLYT8mb+kxw==
  switch(config-if-vl100)#
  ```
vrrp delay reload

The `vrrp delay reload` command delays the time for VRRP initialization after a system reboot.

The `no vrrp delay reload` and `default vrrp delay reload` commands restore the default value of 0 by deleting the `vrrp delay reload` statement from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group delay reload [INTERVAL]
no vrrp group delay reload
default vrrp group delay reload
```

**Parameters**

- `INTERVAL` The number of seconds for the delay (seconds). Options include:
  - `<no parameter>` Default value of 0 seconds.
  - `<0 to 3600>` Ranges between 0 and 60 minutes.

**Example**

- These commands configure the VRRP reload delay interval to 15 minutes.
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#vrrp 2 delay reload 900
  switch(config-if-Vl100)#
  ```
- These commands removes the VRRP reload delay interval.
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#no vrrp 2 delay reload
  switch(config-if-Vl100)#
  ```
vrrp description

The `vrrp description` command associates a text string to a VRRP virtual router on the configuration mode interface. The string has no functional impact on the virtual router. The maximum length of the string is 80 characters.

The `no vrrp description` and `default vrrp description` commands remove the text string association from the VRRP virtual router by deleting the corresponding `vrrp description` command from `running-config`. The `no vrrp` command also removes the `vrrp description` command for the specified virtual router.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

```
vrrp group description label_text
no vrrp group description
default vrrp group description
```

Parameters

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `label_text` text that describes the virtual router. Maximum string length is 80 characters.

Example

- This command associates the text string `Laboratory Router` to virtual router 15 on VLAN 20.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 15 description Laboratory Router
switch(config-if-vl20)#
```
vrrp ip

The `vrrp ip` command configures the primary IP address for the specified VRRP virtual router. The command also activates the virtual router if the primary address is contained in the interface’s subnet. A VRRP virtual router’s configuration may contain only one primary IP address assignment command; subsequent `vrrp ip` commands replace the existing primary address assignment.

The `vrrp ip secondary` command assigns a secondary IP address to the VRRP virtual router.

The `no vrrp ip` and `default vrrp ip` commands disable the VRRP virtual router and deletes the primary IP address by removing the corresponding `vrrp ip` statement from `running-config`. The `no vrrp` command also removes the `vrrp ip` command for the specified virtual router.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group ip ipv4_address
no vrrp group ip ipv4_address
default vrrp group ip ipv4_address
```

**Parameters**
- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `ipv4_address` IPv4 address of the virtual router.

**Related Commands**
- `vrrp ip secondary`

**Example**
- This command enables virtual router 15 on VLAN 20 and designates 10.1.1.5 as the virtual router’s primary address.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 15 ip 10.1.1.5
switch(config-if-vl20)#
```
vrrp ip secondary

The vrrp ip secondary command assigns a secondary IP address to the specified virtual router. Secondary IP addresses are an optional virtual router parameter. A virtual router may contain multiple secondary address commands. The IP address list must be identical for all VRRP routers in a virtual router group.

The virtual router is assigned a primary IP address with the vrrp ip command.

The no vrrp ip secondary and default vrrp ip secondary commands remove the secondary IP address for the specified VRRP virtual router by deleting the corresponding vrrp ip secondary statement from running-config. The no vrrp command also removes all vrrp secondary commands for the specified virtual router.

Command Mode
  Interface-Ethernet Configuration
  Interface-Port-Channel Configuration
  Interface-VLAN Configuration

Command Syntax
  vrrp group ip ipv4_addr secondary
  no vrrp group ip ipv4_addr secondary
  default vrrp group ip ipv4_addr secondary

Parameters
  • group  virtual router identifier (VRID). Values range from 1 to 255.
  • ipv4_addr  secondary IPv4 address of the virtual router.

Related Commands
  • vrrp ip

Example
  • This command assigns the IP address of 10.2.4.5 as the secondary IP address for the virtual router with VRID of 15 on VLAN 20
    switch(config)#interface vlan 20
    switch(config-if-vl20)#vrrp 15 ip 10.2.4.5 secondary
    switch(config-if-vl20)#
**vrrp ip version**

The **vrrp ip version** command enables VRRP on the configuration mode interface and configures the VRRP version for the specified VRRP virtual router.

The **no vrrp ip version** and **default vrrp ip version** commands restore the default VRRP version to VRRPv2 by removing the corresponding **vrrp ip version** statement from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group ip version VERSION_NUMBER
no vrrp group ip version
default vrrp group ip version
```

**Parameters**
- **group** virtual router identifier (VRID). Values range from 1 to 255.
- **VERSION_NUMBER** Specifies VRRP version that the switch uses. Default value is 2 (VRRPv2)
  Options include:
  - 2 VRRP v2 supports IPv4 environment.
  - 3 VRRP v3 supports IPv4 and IPv6 environment.

**Example**
- This command enables VRRPv3 for IPv6 on interface Ethernet 3.
  ```
  switch#(config)#interface ethernet 3
  switch#(config-if-Et3)# vrrp 1 ip version 3
  switch#
  ```
- This command removes VRRPv3 from interface Ethernet 3 and reverts to the default VRRPv2.
  ```
  switch#(config)#interface ethernet 3
  switch#(config-if-Et3)# no vrrp 1 ip version
  switch#(config-if-Et3)#
  ```
vrrp ipv6

The `vrrp ipv6` command configures the IPv6 address for the specified VRRP virtual router. The command also activates the virtual router if the primary address is contained in the interface’s subnet.

The `no vrrp ipv6` and `default vrrp ipv6` commands disable the VRRP virtual router and deletes the IPv6 address by removing the corresponding `vrrp ipv6` statement from `running-config`. The `no vrrp` command also removes the `vrrp ipv6` command for the specified virtual router.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group ip ipv6_address
no vrrp group ip ipv6_address
default vrrp group ip ipv6_address
```

**Parameters**
- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `ipv6_address` IPv6 address of the virtual router.

**Example**
- This command enables addresss 2001:db8:0:1::1 for IPv6 VRRP on Vlan 20.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 3 ipv6 2001:db8:0:1::1
  switch(config-if-vl20)#
  ```
- This command disables VRRPv3 on Vlan 20 from virtual router 3.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#no vrrp 3 ipv6 2001:db8:0:1::1
  switch(config-if-vl20)#
  ```
vrrp mac-address advertisement-interval

The `vrrp mac-address advertisement-interval` command specifies the interval between advertisement packets sent by the master router to the VRRP group members.

The `vrrp mac-address advertisement-interval 0, no vrrp mac-address advertisement-interval` and `default vrrp mac-address advertisement-interval` commands disable the feature by removing the `vrrp mac-address advertisement-interval` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
  vrrp group mac-address advertisement-interval period
  no vrrp group mac-address
  default vrrp group mac-address
```

**Parameters**

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `period` interval in which the master router sends advertisement packets (seconds). Value ranges from 0 to 3600. Selecting 0 as the interval disables this feature.

**Example**

- This command specifies the interval between advertisement packets sent to the members of VRRP group 3 on VLAN 20.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 3 mac-address advertisement-interval 60
  switch(config-if-vl20)#
  ```

- This command disables the feature on VLAN 20.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#no vrrp 3 mac-address advertisement-interval
  switch(config-if-vl20)#
  ```
vrrp preempt

The `vrrp preempt` command controls a virtual router’s preempt mode setting. When preempt mode is enabled, if the switch has a higher priority it will preempt the current master virtual router. When preempt mode is disabled, the switch can become the master virtual router only when a master virtual router is not present on the subnet, regardless of VRRP priority settings. By default, preempt mode is enabled.

The `no vrrp preempt` and `default vrrp preempt` commands disable preempt mode for the specified virtual router; the `default vrrp preempt` command stores a corresponding `no vrrp preempt` statement in `running-config`. The `vrrp preempt` command enables preempt mode by removing the corresponding `no vrrp preempt` statement from `running-config`.

The `no vrrp` command also enables preempt mode by removing the `no vrrp preempt` command for the specified virtual router.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
```
vrrp group preempt
no vrrp group preempt
default vrrp group preempt
```

**Parameters**
- `group` virtual router identifier (VRID). Values range from 1 to 255.

**Related Commands**
- `vrrp preempt delay`

**Examples**
- This command disables preempt mode for virtual router 20 on VLAN 40.
  ```
  switch(config)#interface vlan 40
  switch(config-if-vl40)#no vrrp 20 preempt
  switch(config-if-vl40)#
  ```
- This command enables preempt mode for virtual router 20 on VLAN 40.
  ```
  switch(config-if-vl40)#vrrp 20 preempt
  switch(config-if-vl40)#
  ```
vrrp preempt delay

The `vrrp preempt delay` command specifies the interval between a VRRP preemption event and the point when the switch becomes the master vrrp router. A preemption event is any event that results in the switch having the highest virtual router priority setting while preemption is enabled. The `vrrp preempt` command enables preemption for a specified virtual router.

The command configures two delay periods:

- **minimum** time delays master vrrp takeover when VRRP is fully implemented.
- **reload** time delays master vrrp takeover after VRRP is initialized following a switch reload (boot). The switch bypasses the reload time to become the VRRP master immediately if it senses there are no other active switches in the virtual router group.

*Running-config* maintains separate delay statements for **minimum** and **reload** parameters. Commands may list both parameters. Commands that list one parameter do not affect the omitted parameter. Values range from 0 to 3600 seconds (one hour). The default delay is zero seconds for both parameters.

The `no vrrp preempt delay` and `default vrrp preempt delay` commands reset the specified delay to the default of zero seconds. Commands that do not list either parameter resets both periods to zero. The `no vrrp` command also removes all `vrrp preempt delay` commands for the specified virtual router.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
 vrrp group preempt delay [MINIMUM_INTERVAL] [RELOAD_INTERVAL]
 no vrrp group preempt delay [DELAY_TYPE]
 default vrrp group preempt delay [DELAY_TYPE]
```

**Parameters**

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- **MINIMUM_INTERVAL** period between preempt event and takeover of master vrrp router role.
  - <no parameter> minimum delay is not altered by command.
  - **minimum** min_time delay during normal operation (seconds). Values range from 0 to 3600.
- **RELOAD_INTERVAL** period after reboot-VRRP initialization and takeover of master vrrp router role.
  - <no parameter> reload delay is not altered by command.
  - **reload** reload_time delay after reboot (seconds). Values range from 0 to 3600.
- **DELAY_TYPE** delay type that is reset to default value.
  - <no parameter> reload and minimum delays are reset to default.
  - **minimum** minimum delay is reset to default.
  - **reload** reload delay is reset to default.

*DELAY_TYPE* parameter is only used in `no vrrp preempt delay` and `default vrrp preempt delay` commands.

**Related Commands**

- `vrrp preempt`
Examples

- This command sets the minimum preempt time of 90 seconds for virtual router 20 on VLAN 40.
  
  ```
  switch(config)#interface vlan 40
  switch(config-if-vl40)#vrrp 20 preempt delay minimum 90
  switch(config-if-vl40)#
  ```

- This command sets the minimum and reload preempt time to zero for virtual router 20 on VLAN 40.
  
  ```
  switch(config-if-vl40)#no vrrp 20 preempt delay
  switch(config-if-vl40)#
  ```
vrrp priority

The `vrrp priority` command configures the switch’s priority setting for a VRRP virtual router. Priority values range from 1 to 254. The default value is 100.

The router with the highest vrrp priority setting for a group becomes the master virtual router for that group. The master virtual router controls the IP address and is responsible for forwarding traffic sent. The `vrrp preempt` command controls the time when a switch can become the master virtual router.

The `no vrrp priority` and `default vrrp priority` commands restore the default priority of 100 to the virtual router on the configuration mode interface by removing the corresponding `vrrp priority` command from `running-config`. The `no vrrp` command also removes the `vrrp priority` command for the specified virtual router.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group priority level
no vrrp group priority
default vrrp group priority
```

**Parameters**

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `level` priority setting for the specified virtual router. Values range from 1 to 254.

**Examples**

- This command sets the virtual router priority value of 250 for virtual router group 45 on VLAN 20.
  
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 45 priority 250
  switch(config-if-vl20)#
vrrp shutdown

The `vrrp shutdown` command places the switch in stopped state for the specified virtual router. While in stopped state, the switch cannot act as a Master or backup router for the virtual router group.

The `no vrrp shutdown` and `default vrrp shutdown` commands remove the corresponding `vrrp shutdown` command from `running-config`. This changes the switch’s virtual router state to `backup` or `master` if the virtual router is properly configured.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

Command Syntax
```
 vrrp group shutdown
 no vrrp group shutdown
 default vrrp group shutdown
```

Parameters
- `group` virtual router identifier (VRID). Values range from 1 to 255.

Example
- These commands place the switch in stopped mode for virtual router 24 on VLAN 20.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 24 shutdown
  switch(config-if-vl20)#
  ```
- This command moves the switch out of stopped mode for virtual router 24 on VLAN 20.
  ```
  switch(config-if-vl20)#no vrrp 24 shutdown
  switch(config-if-vl20)#
  ```
vrrp timers advertise

The `vrrp timers advertise` command configures the interval between successive advertisement messages that the switch sends to VRRP routers in the specified virtual router group. The switch must be the group’s Master virtual router to send advertisement messages. The advertisement interval must be configured identically on all physical routers in the virtual router group.

The advertisement interval also influences the timeout interval that defines when the virtual router becomes the master virtual router. When preemption is enabled, the virtual router becomes the master when three times the advertisement interval elapses after the switch detects master router priority conditions.

The `no vrrp timers advertise` and `default vrrp timers advertise` commands restore the default advertisement interval of one second for the specified virtual router by removing the corresponding `vrrp timers advertise` command from `running-config`. The `no vrrp` command also removes the `vrrp timers advertise` command for the specified virtual router.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
  vrrp group timers advertise adv_time
  no vrrp group timers advertise
  default vrrp group timers advertise
```

**Parameters**

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `adv_time` advertisement interval (seconds). Values range from 1 to 255. Default value is 1.

**Example**

- This command sets the advertisement interval of five seconds for the virtual router 35 on VLAN 100.

  ```
  switch(config)#interface vlan 100
  switch(config-if-vl100)#vrrp 35 timers advertise 5
  switch(config-if-vl100)#
  ```
vrrp track

The `vrrp track` command configures the VRRP client process on the configuration mode interface to track the specified tracked object and react when its status changes to `down`. The tracked object is created by the `vrrp track` command.

The `no vrrp track` and `default vrrp track` commands cause the VRRP client process to stop tracking the specified tracked object by removing the corresponding `vrrp track` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group track object_name ACTION amount
no vrrp group track object_name ACTION
default vrrp group track object_name ACTION
```

**Parameters**

- `group` virtual router identifier (VRID). Values range from 1 to 255.
- `object_name` name of tracked object.
- `amount` amount to decrement VRRP priority. Values range from 1 to 254.
- `ACTION` The action that VRRP is to take when the tracked object’s status changes to `down`. Options include:
  - `decrement` decrease VRRP priority by `amount`.
  - `shutdown` shut down VRRP on the configuration mode interface.

If both `decrement` and `shutdown` are configured on the same interface for the same VRRP group, then VRRP will be shut down on the interface if the tracked object is down.

**Related Commands**

- `track`

**Example**

- This command causes Ethernet interface 5 to disable VRRP when tracked object ETH8 changes state.

  ```
  switch(config-if-Et5)#vrrp 1 track ETH8 shutdown
  switch(config-if-Et5)#
  ```
Spanning Tree Protocol

Spanning Tree Protocols prevent bridging loops in Layer 2 Ethernet networks. Arista switches support Rapid Spanning Tree, Multiple Spanning Tree, and Rapid-Per VLAN Spanning Tree protocols. These sections describe the Arista Spanning Tree Protocol implementation.

- **Section 22.1: Introduction to Spanning Tree Protocols**
- **Section 22.2: Spanning Tree Overview**
- **Section 22.3: Configuring a Spanning Tree**
- **Section 22.4: STP Commands**

### 22.1 Introduction to Spanning Tree Protocols

Arista Switches support the leading spanning tree protocols: RSTP, MST and Rapid-PVST. This variety of options simplifies integration into existing networks without compromising network reliability, scalability or performance.

### 22.2 Spanning Tree Overview

An Ethernet network functions properly when only one active path exists between any two stations. A spanning tree is a loop-free subset of a network topology. STP is a L2 network protocol that ensures a loop-free topology for any bridged Ethernet LAN. STP allows a network to include spare links as automatic backup paths that are available when an active link fails without creating loops or requiring manual intervention. The original STP is standardized as IEEE 802.1D.

Several variations to the original STP improve performance and add capacity. Arista switches support these STP versions:

- Rapid Spanning Tree (RSTP)
- Multiple Spanning Tree (MSTP)
- Rapid Per-VLAN Spanning Tree (Rapid-PVST)

The Overview contains the following sections:

- **Section 22.2.1: Spanning Tree Protocol Versions**
- **Section 22.2.2: Structure of a Spanning Tree Instance**
- **Section 22.2.3: BPDUs**

### 22.2.1 Spanning Tree Protocol Versions

STP versions supported by Arista switches address two limitations of the original Spanning Tree protocol that was standardized as IEEE 802.1D:
- Slow convergence to the new spanning tree topology after a network change
- The entire network is covered by one spanning tree instance.

The following sections describe the supported STP versions, compatibility issues in networks containing switches running different STP versions, and supported alternatives to spanning tree.

22.2.1.1 Rapid Spanning Tree Protocol (RSTP)
RSTP is specified in 802.1w and supersedes STP. RSTP provides rapid convergence after network topology changes. RSTP provides a single spanning tree instance for the entire network, similar to STP. Standard 802.1D-2004 incorporates RSTP and obsoletes STP.

The RSTP instance is the base unit of MST and Rapid-PVST spanning trees.

22.2.1.2 Rapid Per-VLAN Spanning Tree Protocol (Rapid-PVST)
Rapid Per-VLAN Spanning Tree (PVST) extends the original STP to support a spanning tree instance on each VLAN in the network. The quantity of PVST instances in a network equals the number of configured VLANs, up to a maximum of 4094 instances. PVST can load balance layer-2 traffic without creating a loop because it handles each VLAN as a separate network. However, PVST does not address slow network convergence after a network topology change.

Arista switches support Rapid-PVST, which is a variation of PVST based on RSTP instances. Rapid-PVST provides rapid connectivity recovery after the failure of a bridge, port, or LAN. Rapid-PVST can be enabled or disabled on individual VLANs.

22.2.1.3 Multiple Spanning Tree Protocol (MSTP)
MST extends rapid spanning tree protocol (RSTP) to support multiple spanning tree instances on a network, but is still compatible with RSTP. By default, Arista switches use MSTP.
MST supports multiple spanning tree instances, similar to Rapid PVST. However, MST associates an instance with multiple VLANs. This architecture supports load balancing by providing multiple forwarding paths for data traffic. Network fault tolerance is improved because failures in one instance do not affect other instances.

MST Regions
An MST region is a group of connected switches with identical MST configuration. Each region can support a maximum of 65 spanning-tree instances. MST regions are identified by a version number, name, and VLAN-to-instance map; these parameters must be configured identically on all switches in the region. Only MST region members participate with the MST instances defined in the region. A VLAN can only be assigned to one spanning-tree instance at a time. MST does not specify the maximum number of regions that a network can contain.

MST Instances
Each MST instance is identified by an instance number that ranges from 0 to 4094 and is associated with a set of VLANs. An MST region contains two types of spanning tree instances: an internal spanning tree instance (IST) and multiple spanning tree instances (MSTI).
- The Internal Spanning Tree Instance (IST) is the default spanning tree instance in an MST region and is always instance 0. It gives the root switch for the region and contains all VLANs configured on the switch that are not assigned to a MST instance.
Multiple Spanning Tree instances (MSTIs) consist of VLANs that are assigned through MST configuration statements. VLANs assigned to an MSTI are removed from the IST instance. VLANs in an MSTI operate as a part of a single Spanning Tree topology. Because each VLAN can belong to only one instance, MST instances (and the IST) are topologically independent.

22.2.1.4 Version Interoperability

A network can contain switches running different spanning tree versions. The common spanning tree (CST) is a single forwarding path the switch calculates for STP, RSTP, MSTP, and Rapid-PVST topologies in networks containing multiple spanning tree variations.

In multi-instance topologies, the following instances correspond to the CST:

- **Rapid-PVST**: VLAN 1
- **MST**: IST (instance 0)

RSTP and MSTP are compatible with other spanning tree versions:

- An RSTP bridge sends 802.1D (original STP) BPDUs on ports connected to an STP bridge.
- RSTP bridges operating in 802.1D mode remain in 802.1D mode even after all STP bridges are removed from their links.
- An MST bridge detects a port is at a region boundary when it receives an STP BPDU or an MST BPDU from a different region.
- MST ports assume they are boundary ports when the bridges to which they connect join the same region.

The `clear spanning-tree detected-protocols` command forces MST ports to renegotiate with their neighbors.

22.2.1.5 Switchport Interface Pairs

Switchport interface pairs associate two interfaces in a primary-backup configuration. When the primary interface is functioning, the backup interface remains dormant in standby mode. When the primary interface stops functioning, the backup interface handles the traffic.

An alternative implementation balances traffic between the primary and backup interfaces. If either interface shuts down, the other handles traffic addressed to the pair.

The following guidelines apply to switchport interface pairs.

- Ethernet and Port Channels can be primary interfaces.
- Ethernet, Port Channel, Management, Loopback, and VLAN interfaces can be backup interfaces.
- The primary and backup interfaces can be different interface types.
- Interface pairs should be similarly configured to ensure consistent behavior.
- An interface can be associated with a maximum of one backup interface.
- An interface can back up a maximum of one interface.
- Any Ethernet interface configured in an interface pair cannot be a port channel member.
- STP is disabled on ports configured as primary or backup interfaces.
- Static MAC addresses should be configured after primary-backup pairs are established.
22.2.1.6 Disabling Spanning Tree

When spanning tree is disabled and switchport interface pairs are not configured, all interfaces forward packets as specified by their configuration. STP packets are not generated and inbound STP packets are forwarded on the VLAN where they are received as normal multicast data packets.

Important! Disabling all Spanning Tree Protocols on the switch is strongly discouraged.

22.2.2 Structure of a Spanning Tree Instance

A layer 2 network consists of bridges and network segments. A loop exists when multiple active paths connect two components. Spanning tree protocols allow only one active path between any two network components. Loops are removed by blocking selected ports that connect bridges to network segments.

Ports are assigned cost values that reflect their transmission speed and any other criteria selected by the administrator. Ports with faster transmission speeds and other desirable characteristics are assigned lower costs. High cost ports are blocked in deference to lower cost ports.

A network topology defines multiple possible spanning trees. Network bridges collectively compute and implement one spanning tree to maintain connectivity between all network components while blocking ports that could result in loops. Administrators improve network performance by adjusting parameter settings to select the most efficient spanning tree.

Spanning tree bridges continuously transmit topology information to notify all other bridges on the network when topology changes are required, such as when a link fails. Bridge Protocol Data Units (BPDUs) are STP information packets that bridges exchange.

The following sections describe spanning tree configuration parameters.

22.2.2.1 Root and Designated Bridges

The root bridge is the center of the STP topology. A spanning tree instance has one root bridge. Spanning tree bases path calculations on each network component's distance from the root bridge.

All other network bridges calculate paths to the root bridge when selecting spanning tree links. STP calculates the distance to the root bridge to build a loop-free topology that features the shortest distance between devices among all possible paths.

Each switch is assigned a unique bridge ID number for each instance. All network switches collectively elect the root bridge by comparing bridge IDs. The root bridge is the switch with the lowest bridge ID.

The bridge ID contains the following eight bytes, in order of decreasing significance:

- Port priority (four bits)
- Instance number (12 bits): VLAN number (Rapid-PVST); instance number (MST); 0 (RST)
- MAC address of switch (six bytes)

A designated bridge is defined for each network segment as the switch that provides the segment's shortest path to the root bridge. A designated bridge is selected for each segment after a root bridge is selected; a switch can be a designated bridge for multiple segments.

The following network calculations in Figure 22-1 assume that each path has the same cost:

- Switch B is the root bridge – its bridge ID is lowest because it has the smallest port priority.
- Switch A is the designated bridge for VLAN 11.
- Switch B is the designated bridge for VLAN 10, VLAN 13, VLAN 16, VLAN 18, VLAN 19.
- Switch C is the designated bridge for VLAN 25.
Switch D is the designated bridge for VLAN 21, VLAN 23.

Figure 22-1: Spanning Tree Network Example

22.2.2.2 Port Roles

Messages from connected devices to the root bridge traverse a least-cost path, which has the smallest cost among all possible paths to the root bridge. The cost of a path is the sum of the costs of all path segments, as defined through port cost settings.

Active ports in a least cost-path fulfill one of two possible roles: root port and designated port. STP blocks all other network ports. STP also defines alternate and backup ports to handle traffic when an active port is inaccessible.

- **Root port (RP)** accesses the bridge’s least-cost path to the root bridge. Each bridge selects its root port after calculating the cost of each possible path to the root bridge.

The following ports in Figure 22-1 are root ports:

- **Switch A**: port 2
- **Switch C**: port 1
- **Switch D**: port 3

- **Designated port (DP)** accesses a network segment’s designated bridge. Each segment defines one DP. Switches can provide DPs for multiple segments. All ports on the root bridge are DPs.

The following ports in Figure 22-1 are designated ports:

- **Switch A**: port 4 (VLAN 11)
- **Switch B**: port 2 (VLAN 13), port 4 (VLAN 18), port 5 (VLAN 10), port 6 (VLAN 19), port 8 (VLAN 16)
- **Switch C**: port 2 (VLAN 25)
- **Switch D**: port 2 (VLAN 23), port 6 (VLAN 21)
• **Alternate ports** provide backup paths from their bridges to the root bridge. An alternate port is blocked until a network change transforms it into a root port.

• **Backup ports** provide alternative paths from VLANs to their designated bridges. A backup port is blocked until a network change transforms it into a designated port.

### 22.2.2.3 Port Activity States

A port’s activity state defines its current STP activity level. STP monitors BPDUs for network changes that require an activity state transition.

STP defines three port activity states:

• **Forwarding**: The port receives and sends data. Root ports and designated ports are either in, or transitioning to, this state.

• **Discarding**: The port does not receive or send data. Blocked ports receive BPDU packets. All ports except RPs and DPs are blocked, including alternate and backup ports.

• **Learning**: The transitional post-discarding state where the port prepares to forward frames by adding source addresses from inbound data packets to the switching database.

### 22.2.2.4 Port Types

Port type is a configurable parameter that reflects the type of network segment that is connected to the port. Proper port type configuration results in rapid convergence after network topology changes. RSTP port types include normal, network, and edge ports. **Normal** is the default port type.

- **Normal** ports have an unspecified topology.
- **Network** ports connect only to switches or bridges.
  
  RSTP immediately transitions network ports to the discarding state.

- **Edge** ports connect directly to end stations.
  
  Edge ports transition directly to forwarding state because they do not create loops. An edge port becomes a normal port when it receives a BPDU.

### 22.2.2.5 Link Types

Link type is a configurable parameter that determines candidates for RSTP fast state transition.

- the default link type for full-duplex ports is **point-to-point**.
- the default link type for half-duplex ports is **shared**.

Fast state transitions are allowed on point-to-point links that connect bridges. Fast state transitions are not allowed on shared ports regardless of the duplex setting.

### 22.2.3 BPDUs

Spanning tree rules specify a root bridge, select designated bridges, and assign roles to ports. STP rule implementation requires that network topology information is available to each switch. Switches exchange topology information through bridge protocol data units (BPDUs). Information provided by BPDU packets include bridge IDs and root path costs.

#### 22.2.3.1 BPDU Types

STP defines three BPDU types:

- Configuration BPDU (CBPDU), used for computing the spanning tree.
• Topology Change Notification (TCN) BPDU, announces network topology changes.
• Topology Change Notification Acknowledgment (TCA), acknowledges topology changes.

Bridges enter the following addresses in outbound BPDU frames:
• source address: outbound port’s MAC address.
• destination address: STP multicast address 01:80:C2:00:00:00.

Bridges regularly exchange BPDUs to track network changes that trigger STP recomputations and port activity state transitions. The **hello timer** specifies the period between consecutive BPDU messages; the default is two seconds.

### 22.2.3.2 Bridge Timers

Bridge timers specify parameter values that the switch includes in BPDU packets that it sends as a root bridge. Bridge timers include:

- **hello-time**: transmission interval between consecutive BPDU packets.
- **forward-time**: the period that ports remain in learning state.
- **max-age**: the period that BPDU data remains valid after it is received.
- **max-hop**: the number of bridges in an MST region that a BPDU can traverse before it is discarded.

The switch recomputes the spanning tree topology if it does not receive another BPDU before the max-age timer expires. When **edge** ports and **point-to-point** links are properly configured, RSTP network convergence does not require forward-delay and max-age timers.

### 22.2.3.3 MSTP BPDUs

MSTP BPDUs are targeted at a single instance and provide STP information for the entire region. MSTP encodes a standard BPDU for the IST, then adds region information and MST instance messages for all configured instances, where each message conveys spanning tree data for an instance. Frames assigned to VLANs operate in the instance to which the VLAN is assigned. Bridges enter an MD5 digest of the VLAN-to-instance map table in BPDUs to avoid including the entire table in each BPDU. Recipients use this digest and other administratively configured values to identify bridges in the same MST region.

MSTP BPDUs are compatible with RSTP. RSTP bridges view an MST region as a single-hop RSTP bridge regardless of the number of bridges inside the region because:

- RSTP bridges interpret MSTP BPDUs as RSTP BPDUs.
- RSTP bridges increment the **message age timer** only once while data flows through an MST region; MSTP measures **time to live** with a **remaining hops** variable, instead of the **message age timer**.

Ports at the edge of an MST region connecting to a bridge (RSTP or STP) or to an endpoint are **boundary ports**.
22.3 Configuring a Spanning Tree

These sections describe the following configuration processes:

- Section 22.3.1: Version Configuration and Instance Creation
- Section 22.3.2: Spanning Tree Instance Configuration
- Section 22.3.3: Port Roles and Rapid Convergence
- Section 22.3.4: Configuring BPDU Transmissions

22.3.1 Version Configuration and Instance Creation

The switch supports three STP versions and switchport backup interface pairs. Disabling spanning tree is also supported but not recommended.

The `spanning-tree mode` global configuration command specifies the spanning tree version the switch runs. This section describes command options that enable and configure STP versions.

22.3.1.1 Multiple Spanning Tree (MST)

Multiple Spanning Tree is enabled by the `spanning-tree mode` command with the `mstp` option. MSTP is the default STP version.

**Example**

- This command enables Multiple Spanning Tree.

```
switch(config)#spanning-tree mode mstp
```

**Configuring MST Regions**

All switches in an MST region must have the same name, revision, and VLAN-to-instance map. MST configuration mode commands sets the region parameters. MST configuration mode is a group-change mode where changes are saved by exiting the mode.

**Example**

- The `spanning-tree mst configuration` command places the switch in MST configuration mode.

```
switch(config)#spanning-tree mst configuration
```

The `instance` command assigns VLANs to MST instances. The `name (mst-configuration mode)` and `revision (mst-configuration mode)` commands configure the MST region name and revision.

**Examples**

- These commands assign VLANs 4-7 and 9 to instance 8 and remove VLAN 6 from instance 10.

```
switch(config-mst)#instance 8 vlans 4-7,9
switch(config-mst)#no instance 10 vlans 6
```

- These commands assign the `name (corporate_1)` and `revision (3)` to the switch.

```
switch(config-mst)#name corporate_1
switch(config-mst)#revision 3
```

The `exit (mst-configuration mode)` command transitions the switch out of MST configuration mode and saves all pending changes. The `abort (mst-configuration mode)` command exits MST configuration mode without saving the pending changes.
Example

- This command exits MST configuration mode and saves all pending changes.
  
  switch(config-mst)#exit
  switch(config)#

Configuring MST Instances

These STP commands provide an optional MST instance parameter. These commands apply to instance 0 when the optional parameter is not included.

- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree port-priority`

Examples

- This command configures priority for MST instance 4.
  
  switch(config)#spanning-tree mst 4 priority 4096
  switch(config)#

- Each of these commands configure priority for MST instance 0.
  
  switch(config)#spanning-tree mst 0 priority 4096
  or
  switch(config)#spanning-tree priority 4096

22.3.1.2 Rapid Spanning Tree (RST)

Rapid spanning tree is enabled through the `spanning-tree mode` command with the `rstp` option.

Example

- This command enables Rapid Spanning Tree.
  
  switch(config)#spanning-tree mode rstp
  switch(config)#

These STP commands, when they do not include an optional MST or VLAN parameter, apply to RSTP. Commands that configure MSTP instance 0 also apply to the RSTP instance.

- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree port-priority`

Examples

- These commands apply to the RST instance.
  
  switch(config)#spanning-tree priority 4096
  and
  
  switch(config)#spanning-tree mst 0 priority 4096

- These commands do not apply to the RST instance.
  
  switch(config)#spanning-tree mst 4 priority 4096
  and
  
  switch(config)#spanning-tree VLAN 3 priority 4096
Show commands (such as show spanning-tree) displays the RSTP instance as MST0 (MST instance 0).

**Example**

- This command, while the switch is in RST mode, displays RST instance information.
  ```
  switch(config)#show spanning-tree
  MST0
  Spanning tree enabled protocol rstp <---RSTP mode indicator
  Root ID    Priority    32768
  Address     001c.730c.1867
  This bridge is the root

  Bridge ID  Priority    32768 (priority 32768 sys-id-ext 0)
  Address     001c.730c.1867
  Hello Time  2.000 sec  Max Age 20 sec  Forward Delay 15 sec

  Interface        Role       State      Cost      Prio.Nbr Type
  ---------------- ---------- ---------- --------- -------- ---------------------
  Et51             designated forwarding 2000  128.51   P2p
  ```

22.3.1.3 Rapid Per-VLAN Spanning Tree (Rapid-PVST)

Rapid-PVST mode is enabled by the spanning-tree mode command with the rapid-pvst option.

**Example**

- This command enables Rapid Per-VLAN Spanning Tree.
  ```
  switch(config)#spanning-tree mode rapid-pvst
  switch(config)#
  ```

  These commands provide an optional VLAN parameter for configuring Rapid-PVST instances.

  - spanning-tree priority
  - spanning-tree root
  - spanning-tree port-priority

**Example**

- This command configures bridge priority for VLAN 4.
  ```
  switch(config)#spanning-tree VLAN 4 priority 4096
  switch(config)#
  ```

22.3.1.4 Switchport Backup Mode

Switchport backup interface pairs are enabled through the spanning-tree mode command with the backup option. Enabling switchport backup disables all spanning-tree modes. For loop avoidance under switchport backup mode, use the Loop Protection feature.

**Example**

- This command enables switchport backup.
  ```
  switch(config)#spanning-tree mode backup
  switch(config)#
  ```
The `switchport backup interface` command establishes an interface pair between the command mode interface (primary) and the interface specified by the command (backup).

### Examples

- These commands establish Ethernet interface 7 as the backup port for Ethernet interface 1.

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#switchport backup interface ethernet 7
  switch(config-if-Et1)#
  ```

The `prefer` option of the `switchport backup interface` command establishes a peer relationship between the primary and backup interfaces and specifies VLAN traffic that the backup interface normally carries. If either interface goes down, the other interface carries traffic normally handled by both interfaces.

### Examples

These steps perform the following:

- configures Ethernet interface 1 as a trunk port that handles VLANs 4 through 9 traffic.
- configures Ethernet interface 2 as the backup interface.
- assigns Ethernet 2 as the preferred interface for VLANs 7 through 9.

**Step 1** Enter configuration mode for the primary interface

  ```
  switch(config)#interface ethernet 1
  ```

**Step 2** Configure the primary interface as a trunk port that services VLANs 4-9

  ```
  switch(config-if-Et1)#switchport mode trunk
  switch(config-if-Et1)#switchport trunk allowed vlan 4-9
  ```

**Step 3** Configure the backup interface and specify the VLANs that it normally services.

  ```
  switch(config-if-Et1)#switchport backup Ethernet 2 prefer vlan 7-9
  switch(config-if-Et1)#
  ```
22.3.1.5 Loop Protection

Loop protection is a loop detection and prevention method which is independent of STP and is not disabled when the switch is in switchport backup mode. When loop protection is active on an interface, that interface periodically sends out loop-detection frames; if one is received that originated on the switch, the receiving port is errdisabled until a timeout period has passed or it is manually reset.

Loop protection is configured and enabled per VLAN, but individual ports in a VLAN can be configured to disable loop protection.

Note
Loop protection cannot be enabled on an MLAG peer link.

This feature is disabled by default. To enable it, use the `monitor loop-protection` command to enter loop-protection configuration mode, then use the `no shutdown (Loop-protection)` command to enable the feature. To enable loop protection on a VLAN, use the `protect vlan` command. To exclude a port from loop protection, use the `no loop-protection` command.

The feature is configured with the following additional commands:

- `transmit-interval`
- `disabled-time`
- `rate-limit`

Examples

- This command enters loop protection configuration mode.
  ```
  switch(config)#monitor loop-protection
  switch(config-monitor-loop-protect)#
  ```

- These commands enable loop protection on VLANs 1025-2000.
  ```
  switch(config)#monitor loop-protection
  switch(config-monitor-loop-protect)#no shutdown
  switch(config-monitor-loop-protect)#protect vlan 1025-2000
  switch(config-monitor-loop-protect)#
  ```

- These commands exclude Ethernet interface 38 from loop protection.
  ```
  switch(config)#interface ethernet 38
  switch(config-if-Et38)#no loop-protection
  switch(config-if-Et38)#
  ```

- These commands configure loop protection with a transmission interval of 10 seconds, a disabled time of two days, and a maximum rate of 500 loop detection frames per second.
  ```
  switch(config-monitor-loop-protect)#transmit-interval 10
  switch(config-monitor-loop-protect)#disabled-time 172800
  switch(config-monitor-loop-protect)#rate-limit 500
  switch(config-monitor-loop-protect)#
  ```

22.3.1.6 Disabling Spanning Tree

Spanning tree is disabled by the `spanning-tree mode` command with the `none` option. The switch does not generate STP packets. Switchport interfaces forward packets when connected to other ports. The switch forwards inbound STP packets as multicast data packets on the VLAN where they are received.
Examples

- This command disables all STP functions.
  
  ```
  switch(config)#spanning-tree mode none
  switch(config)#
  ```

22.3.2 Spanning Tree Instance Configuration

A network performs these steps to set up an STP instance:

**Step 1**  The bridge with the lowest ID is elected root bridge.
**Step 2**  Root ports (RP) are selected on all other bridges.
**Step 3**  Designated bridges are selected for each network segment.
**Step 4**  Designated ports (DP) are selected on each designated bridge.
**Step 5**  Networks begin forwarding data through RPs and DPs. All other ports are blocked.

22.3.2.1 Root Bridge Parameters

STPs use bridge IDs for electing the root bridge. Switches denote a bridge ID for each configured Spanning Tree instance. The bridge ID composition is

- **Priority (four bits)**
  Priority is expressed as a multiple of 4096 because it is stored as the four most significant bits of a two-byte number.
- **Protocol Dependent (twelve bits)**
  - Rapid-PVST: VLAN number
  - MST: Instance number
  - RST: 0
- **MAC address of switch (six bytes)**

**Example**

- The switch defines bridge IDs for three MST instances:
  - MST 0: 32768 (Priority (32768)+Instance number(0)) and 001c.7301.23de (MAC address)
  - MST101: 32869 (Priority (32768)+Instance number(101)) and 001c.7301.23de (MAC address)
  - MST102: 32870 (Priority (32768)+Instance number(102)) and 001c.7301.23de (MAC address)

This command displays a table of root bridge information.

```
switch>show spanning-tree root

<table>
<thead>
<tr>
<th>Instance</th>
<th>Priority</th>
<th>MAC addr</th>
<th>Root ID</th>
<th>Root Cost</th>
<th>Hello Time</th>
<th>Max Age</th>
<th>Fwd Dly</th>
<th>Root Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>MST0</td>
<td>32768</td>
<td>001c.7301.23de</td>
<td>001c.7301.23de</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>Po937</td>
</tr>
<tr>
<td>MST101</td>
<td>32869</td>
<td>001c.7301.23de</td>
<td>001c.7301.23de</td>
<td>3998</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Po909</td>
</tr>
<tr>
<td>MST102</td>
<td>32870</td>
<td>001c.7301.23de</td>
<td>001c.7301.23de</td>
<td>3998</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Po911</td>
</tr>
</tbody>
</table>
```

The switch provides two commands that configure the switch priority: `spanning-tree priority` and `spanning-tree root`. The commands differ in the available parameter options:
• **spanning-tree priority** options are integer multiples of 4096 between 0 and 61440.
• **spanning-tree root** options are *primary* and *secondary*.
• *primary* assigns a priority of 8192.
• *secondary* assigns a priority of 16384.

The default priority value is 32768.

The following examples configure bridge IDs with both commands.

**Examples**

• These commands configure MST instance bridge priorities with the **root** command:

```
switch(config)#spanning-tree mst 0 root primary
switch(config)#spanning-tree mst 1 root secondary

switch>show spanning-tree root
```

<table>
<thead>
<tr>
<th>Instance</th>
<th>Root ID</th>
<th>MAC addr</th>
<th>Cost</th>
<th>Hello</th>
<th>Max Age</th>
<th>Fwd Dly</th>
<th>Root Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>MST0</td>
<td>8192</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>None</td>
</tr>
<tr>
<td>MST1</td>
<td>16385</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>None</td>
</tr>
<tr>
<td>MST2</td>
<td>32770</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>None</td>
</tr>
</tbody>
</table>

• Instance 0 root priority is 8192: primary priority plus the instance number of 0.
• Instance 1 root priority is 16385: secondary priority plus the instance number of 1.
• Instance 2 root priority is 32770: default priority plus the instance number of 2.

These priority settings normally program the switch to be the primary root bridge for instance 0, the secondary root bridge for instance 1, and a normal bridge for instance 2. Primary and secondary root bridge elections also depend on the configuration of other network bridges.

• These priority commands configure Rapid-PVST VLAN bridge priorities:

```
switch(config)#spanning-tree vlan 1 priority 8192
switch(config)#spanning-tree vlan 2 priority 16384
switch(config)#spanning-tree vlan 3 priority 8192
switch(config)#no spanning-tree vlan 4 priority
switch(config)#show spanning-tree root
```

<table>
<thead>
<tr>
<th>Instance</th>
<th>Root ID</th>
<th>MAC addr</th>
<th>Cost</th>
<th>Hello</th>
<th>Max Age</th>
<th>Fwd Dly</th>
<th>Root Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>VL1</td>
<td>8193</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>None</td>
</tr>
<tr>
<td>VL2</td>
<td>16386</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>None</td>
</tr>
<tr>
<td>VL3</td>
<td>8195</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>None</td>
</tr>
<tr>
<td>VL4</td>
<td>32788</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>None</td>
</tr>
</tbody>
</table>

• VLAN 1 root priority is 8193: configured priority plus the VLAN number of 1.
• VLAN 2 root priority is 16386: configured priority plus the VLAN number of 2.
• VLAN 3 root priority is 8195: configured priority plus the VLAN number of 3.
• VLAN 4 root priority is 32788: default priority plus the VLAN number of 4.

These priority settings normally program the switch to be the primary root bridge for VLANs 1 and 3, the secondary root bridge for VLAN2, and a normal bridge for VLAN 4. Primary and secondary root bridge elections also depend on the configuration of other network bridges.
22.3.2.2 Path Cost

Spanning tree calculates the costs of all possible paths from each component to the root bridge. The path cost is equal to the sum of the cost assigned to each port in the path. Ports are assigned a cost by default or through CLI commands. Cost values range from 1 to 200000000 (200 million).

The default cost is a function of the interface speed:

- 1 gigabit interfaces have a default cost of 20000.
- 10 gigabit interfaces have a default cost of 2000.

The `spanning-tree cost` command configures the path cost of the configuration mode interface. Costs can be specified for Ethernet and port channel interfaces. The command provides a mode parameter for assigning multiple costs to a port for MST instances or Rapid-PVST VLANs.

**Examples**

- These commands configure a port cost of 25000 to Ethernet interface 5. This cost is valid for RSTP or MSTP instance 0.
  
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree cost 25000
  switch(config-if-Et5)#
  ```

- This command configures a path cost of 300000 to Ethernet interface 5 in MST instance 200.
  
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree mst 200 cost 300000
  switch(config-if-Et5)#
  ```

- This command configures a path cost of 10000 to Ethernet interface 5 in Rapid-PVST VLAN 200-220.
  
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree vlan 200-220 cost 10000
  switch(config-if-Et5)#
  ```

22.3.2.3 Port Priority

STP uses the port priority interface parameter to select ports when resolving loops. The port with the lower port priority numerical value is placed in forwarding mode. When multiple ports are assigned equal port priority numbers, the port with the lower interface number is placed in forwarding mode. Valid port-priority numbers are multiples of 16 between 0 and 240; the default is 128.

The `spanning-tree port-priority` command configures the port-priority number for the configuration mode interface. The command provides a mode option for assigning different priority numbers to a port for multiple MST instances or Rapid-PVST VLANs. Port-priority can be specified for Ethernet and port channel interfaces.

**Examples**

- This command sets the access port priority of 144 for Ethernet 5 interface.
  
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree port-priority 144
  switch(config-if-Et5)#
  ```

- This command sets the access port priority of 144 for Ethernet 5 interface in MST instance 10.
  
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree mst 10 port-priority 144
  switch(config-if-Et5)#
  ```
22.3.3 Port Roles and Rapid Convergence

Spanning Tree provides the following options for controlling port configuration and operation:

- **PortFast**: Allows ports to skip learning state before entering the forwarding state.
- **Port type and link type**: Designates ports for rapid transitions to the forwarding state.
- **Root guard**: Ensures that a port will not become the root port.
- **Loop guard**: Prevents loops resulting from unidirectional failure of links.
- **Bridge assurance**: Prevents loops caused by unidirectional links or a malfunctioning switch.

### 22.3.3.1 PortFast

PortFast allows devices to gain immediate network access before convergence of the spanning tree. Enabling PortFast on ports connected to another switch can create loops.

A **portfast** port that receives a BPDU sets its operating state to **non-portfast** while remaining in **portfast** configured state. In this state, the port is subject to topology changes and can enter the discarding state.

The **spanning-tree portfast** command programs access ports to immediately enter the forwarding state. PortFast connects devices attached to an access port, such as a single workstation, to the network immediately without waiting for STP convergence. PortFast can also be enabled on trunk ports.

**Example**

- This command unconditionally enables portfast on Ethernet 5 interface.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast
switch(config-if-Et5)#
```

### 22.3.3.2 Port Type and Link Type Configuration

RSTP only achieves rapid transition to forwarding state on edge ports and point-to-point links.

**Port Type**

Edge ports are directly connected to end stations. Because edge ports do not create loops, they transition directly to forwarding state when a link is established.

The **spanning-tree portfast <port type>** command sets the configuration mode interface’s port type. Spanning tree ports can be configured as **edge** ports, **network** ports, or **normal** ports. The default port type is **normal**.

- **Edge ports** connect to a host (end station). Configuring a port that connects to a bridge as an edge port may create a loop. Edge ports that receive a BPDU become a normal spanning tree port.
- **Network ports** connect only to a Layer 2 switch or bridge. Configuring a port connected to a host as a network port transitions the port to the discarding state.
- **Normal ports** have an unspecified topology.

**Example**

- This command configures Ethernet 5 interface as a network port.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast network
switch(config-if-Et5)#
```
Auto-edge detection converts ports into edge ports when they do not receive a new BPDU before the current BPDU expires, as measured by the max-age timer. The `spanning-tree portfast auto` command enables auto-edge detection on the configuration mode interface, superseding the `spanning-tree portfast` command. Auto-edge detection is enabled by default.

**Example**
- This command enables auto-edge detection on Ethernet interface 5.
  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree portfast auto
  switch(config-if-Et5)#
  ```

**Link Type**
The switch derives a port’s default link type from its duplex mode:
- full-duplex ports are `point-to-point`.
- half-duplex ports are `shared`.

The `spanning-tree link-type` command specifies the configuration mode interface’s link-type. RSTP fast transition is not allowed on `shared link` ports, regardless of their duplex setting. Because the ports are full-duplex by default, the default link-type setting is `point-to-point`.

**Example**
- This command configures Ethernet 5 interface as a shared port.
  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree link-type shared
  switch(config-if-Et5)#
  ```

22.3.3 Root Guard and Loop Guard

**Root guard** stops a port from becoming a root port, which stops connected switches from becoming root bridges. When a switch detects a new root bridge, its root-guard-enabled ports enter blocked (root-inconsistent) state. When the switch no longer detects a new root, these ports enter learning state.

Root guard is enabled on a per-port basis. The setting applies to all STP instances. Disabling root guard places the port in learning state.

The `spanning-tree guard` command, with the root option, enables root guard on the configuration mode interface.

**Example**
- This command enables root guard on Ethernet 5 interface.
  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree guard root
  switch(config-if-Et5)#
  ```

**Loop guard** prevents loops resulting from unidirectional failure of point-to-point links by verifying that non-designated ports (root, blocked, and alternate) are receiving BPDUs from their designated ports. A loop-guard-enabled root or blocked port that stops receiving BPDUs transitions to the discarding (loop-inconsistent) state. The port recovers from this state when it receives a BPDU.

Loop guard, when enabled globally, applies to all point-to-point ports. Loop guard is configurable on individual ports and applies to all STP instances of an enabled port. Loop-inconsistent ports transition to learning state when loop guard is disabled.
If loop guard is enabled on a root switch, it takes effect only if the switch becomes a nonroot switch.

When using loop guard:

- Do not enable loop guard on portfast-enabled ports.
- Loop guard is not functional on ports not connected to point-to-point links.
- Loop guard has no effect on disabled spanning tree instances.

Loop guard aspects on port channels include:

- BPDUs are sent over the channel’s first operational port. Loop guard blocks the channel if that link becomes unidirectional even when other channel links function properly.
- Creating a new channel destroys state information for its component ports; new channels with loop-guard-enabled ports can enter forwarding state as a DP.
- Dissembling a channel destroys its state information; component ports from a blocked channel can enter the forwarding state as DPs, even if the channel contained unidirectional links.
- If a link on any port of the channel becomes unidirectional, the channel is blocked. Transmission resumes if the port is removed from the channel or the bidirectional communication is restored.

Loop guard configuration commands include:

- `spanning-tree loopguard default` command enables loop guard as a default on all switch ports.
- `spanning-tree guard` control the loop guard setting on the configuration mode interface. This command overrides the default command for the specified interface.

**Examples**

- This command enables loop guard as the default on all switch ports.
  
  ```
  switch(config)#spanning-tree loopguard default
  switch(config)#
  ```
- This command enables loop guard on Ethernet 6 interface.
  
  ```
  switch(config)#interface ethernet 6
  switch(config-if-Et6)#spanning-tree guard loop
  switch(config-if-Et6)#
  ```

**22.3.3.4 Bridge Assurance**

Bridge assurance protects against unidirectional link failures, other software failures, and devices that continue forwarding data traffic after they quit running spanning tree.

Bridge assurance programs the switch to send BPDUs at each hello time period through all bridge assurance-enabled ports (i.e., network ports). Bridge assurance operates only on network ports with point-to-point links, ideally with bridge assurance enabled on each side of the link. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled.

Ports not receiving a BPDU packet within a hello time period enter inconsistent (blocking) state. In this case, the `show spanning-tree bridge assurance` command will show a bridge assurance status of “inconsistent” for the port. If the other side of the link has bridge assurance enabled, or if the other switch is the root bridge, it will send periodic BPDUs, preventing an “inconsistent” blocking state.

Bridge assurance is globally enabled by default, but must also be enabled on a per-port basis by designating the port as a network port with the `spanning-tree portfast <port type>` command. The `no spanning-tree bridge assurance` command disables bridge assurance globally.
Example

- These commands enable bridge assurance on the switch, then enable bridge assurance on Ethernet port 5 by designating it a network port.

  switch(config)#spanning-tree bridge assurance
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree portfast network
  switch(config-if-Et5)#

22.3.4 Configuring BPDU Transmissions

The following sections describe instructions that configure BPDU packet contents and transmissions.

22.3.4.1 Bridge Timers

Bridge timers configure parameter values that the switch includes in BPDU packets that it sends as a root bridge. Bridge timers include:

- **hello-time**: the transmission interval between consecutive outbound BPDU packets.
- **forward-time**: the period that ports are in learning state prior to forwarding packets.
- **max-age**: the period that BPDU data remains valid after it is received. The switch recomputes the spanning tree topology if it does not receive another BPDU packet before the timer expires.
- **max-hop**: the number of bridges in an MST region that a BPDU can traverse before it is discarded.

In standard STP, ports passively wait for **forward_delay** and **max_age** periods before entering the forwarding state. RSTP achieves faster convergence by relying on edge port and link type definitions to start forwarding traffic. When edge ports and link types are properly configured, bridge timers are used in RSTP as backup or when interacting with networks running standard STP.

The **spanning-tree hello-time** command configures the hello time.

Example

- This command configures a hello-time of 1 second (1000 ms).

  switch(config)#spanning-tree hello-time 1000
  switch(config)#

The **spanning-tree max-hops** command specifies the max hop setting that the switch inserts into BPDUs that it sends out as the root bridge.

Example

- This command sets the max hop value to 40.

  switch(config)#spanning-tree max-hops 40
  switch(config)#

The **spanning-tree forward-time** command configures the forward delay setting that the switch inserts into BPDUs that it sends out as the root bridge.

Example

- This command sets the forward delay timer value to 25 seconds.

  switch(config)#spanning-tree forward-time 25
  switch(config)#

The **spanning-tree max-age** command configures the max age setting that the switch inserts into BPDUs that it sends out as the root bridge.
Example

- This command sets the max age timer value to 25 seconds.

  switch(config)#spanning-tree max-age 25
  switch(config)#

22.3.4.2 BPDU Transmit Hold-Count

The `spanning-tree transmit hold-count` command specifies the maximum number of BPDUs per second that the switch can send from an interface. Valid settings range from 1 to 10 BPDUs with a default of 6 BPDUs.

Higher hold-count settings can significantly impact CPU utilization, especially in Rapid-PVST mode. Smaller values can slow convergence in some configurations.

Example

- This command configures a transmit hold-count of 8 BPDUs.

  switch(config)#spanning-tree transmit hold-count 8
  switch(config)#

22.3.4.3 BPDU Guard

PortFast interfaces do not receive BPDUs in a valid configuration. BPDU Guard provides a secure response to invalid configurations by disabling ports when they receive a BPDU. Disabled ports differ from blocked ports in that they are re-enabled only through manual intervention.

- When configured globally, BPDU Guard is enabled on ports in the operational portfast state.
- When configured on an individual interface, BPDU Guard disables the port when it receives a BPDU, regardless of the port's portfast state.

The `spanning-tree portfast bpduguard default` global configuration command enables BPDU guard by default on all portfast ports. BPDU guard is disabled on all ports by default.

The `spanning-tree bpduguard` interface configuration command controls BPDU guard on the configuration mode interface. This command takes precedence over the default setting configured by `spanning-tree portfast bpduguard default`.

- `spanning-tree bpduguard` enables BPDU guard on the configuration mode interface.
- `spanning-tree bpduguard disable` disables BPDU guard on the configuration mode interface.
- `no spanning-tree bpduguard` reverts the configuration mode interface to the default BPDU guard setting.

Example

- These commands enable BPDU guard by default on all portfast ports, then disable BPDU guard on Ethernet 5.

  switch(config)#spanning-tree portfast bpduguard default
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree bpduguard disable
  switch(config-if-Et5)

22.3.4.4 BPDU Filter

BPDU filtering prevents the switch from sending or receiving BPDUs on specified ports. BPDU filtering is configurable on Ethernet and port channel interfaces.
Ports with BPDU filtering enabled do not send BPDUs and drops inbound BPDUs. Enabling BPDU filtering on a port not connected to a host can result in loops as the port continues forwarding data while ignoring inbound BPDU packets.

The `spanning-tree bpdufilter` command controls BPDU filtering on the configuration mode interface. BPDU filtering is disabled by default.

**Example**

- These commands enable BPDU filtering on Ethernet 5.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree bpdufilter enable
  ```

### 22.3.4.5 BPDU Rate Limit

BPDU input rate limiting restricts the number of BPDUs that a port with BPDU guard and BPDU filter disabled can process during a specified interval. The port discards all BPDUs that it receives in excess of the specified limit. Configuring the rate limiter requires two steps:

- Establishing the rate limit threshold.
- Enabling rate limiting.

**Establishing the Rate Limit Threshold**

The `spanning-tree bpduguard rate-limit count (interface)` commands specify BPDU reception rate (quantity per interval) that trigger the discarding of BPDUs. Commands are available in global and interface configuration modes.

- The `spanning-tree bpduguard rate-limit count` global command specifies the maximum reception rate for ports not covered by interface rate limit count commands. The default quantity is 10 times the number of VLANs. The default interval is the hello time (`spanning-tree hello-time`).
- The `spanning-tree bpduguard rate-limit count` interface command defines the maximum BPDU reception rate for the configuration mode interface. The global command specifies the default limit.

**Examples**

- This command configures the global limit of 5000 BPDUs over a four second interval.

  ```
  switch(config)#spanning-tree bpduguard rate-limit count 5000 interval 4
  ```

- These commands configure a limit of 7500 BPDUs over an 8 second interval on Ethernet interface 2.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#spanning-tree bpduguard rate-limit count 7500 interval 8
  ```

**Enabling Rate Limiting**

BPDU rate limiting is enabled globally or on individual ports:

- `spanning-tree bpduguard rate-limit default` enables rate limiting on all ports with no interface rate limiting command. The default setting is `enabled`.
- `spanning-tree bpduguard rate-limit enable / disable` interface command enables or disables BPDU rate limiting on the configuration mode interface. This command has precedence over the global command.
Examples

- This command enables rate limiting on ports not covered by interface rate limit commands.
  
  `switch(config)#spanning-tree bpduguard rate-limit default
  switch(config)#`

- These commands enables rate limiting on Ethernet 15.
  
  `switch(config)#interface ethernet 15
  switch(config-if-Et15)#spanning-tree bpduguard rate-limit enable
  switch(config-if-Et15)#`
22.4 **STP Commands**

**Spanning Tree Commands: Global Configuration**
- `spanning-tree bpduguard rate-limit default`
- `spanning-tree bpduguard rate-limit count (global)`
- `spanning-tree bridge assurance`
- `spanning-tree forward-time`
- `spanning-tree hello-time`
- `spanning-tree loopguard default`
- `spanning-tree max-age`
- `spanning-tree max-hops`
- `spanning-tree mode`
- `spanning-tree mst configuration`
- `spanning-tree portchannel guard misconfig`
- `spanning-tree portfast bpdufilter default`
- `spanning-tree portfast bpduguard default`
- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree transmit hold-count`
- `spanning-tree vlan`

**Loop Protection Commands**
- `disabled-time`
- `loop-protection`
- `monitor loop-protection`
- `protect vlan`
- `rate-limit`
- `shutdown (Loop-protection)`
- `transmit-interval`

**Spanning Tree Commands: Interface Configuration Mode**
- `spanning-tree bpdufilter`
- `spanning-tree bpduguard`
- `spanning-tree bpduguard rate-limit count (interface)`
- `spanning-tree bpduguard rate-limit enable / disable`
- `spanning-tree cost`
- `spanning-tree guard`
- `spanning-tree link-type`
- `spanning-tree port-priority`
- `spanning-tree portfast`
- `spanning-tree portfast auto`
- `spanning-tree portfast <port type>`
- `switchport backup interface`

**MST Configuration Commands**
- `abort (mst-configuration mode)`
- `exit (mst-configuration mode)`
- `instance`
- `name (mst-configuration mode)`
- `revision (mst-configuration mode)`
- `show (mst-configuration mode)`
Display Commands

- show spanning-tree
- show spanning-tree blockedports
- show spanning-tree bridge
- show spanning-tree counters
- show spanning-tree interface
- show spanning-tree mst
- show spanning-tree mst configuration
- show spanning-tree mst interface
- show spanning-tree mst test information
- show spanning-tree root
- show spanning-tree topology status

Clear Commands

- clear spanning-tree counters
- clear spanning-tree counters session
- clear spanning-tree detected-protocols
**abort (mst-configuration mode)**

The `abort` command, in MST-configuration mode, discards pending changes to the MST region configuration, then returns the switch to global configuration mode.

The `exit (mst-configuration mode)` command saves MST region changes to `running-config` before returning the switch to global configuration mode.

**Command Mode**

MST-configuration

**Command Syntax**

`abort`

**Examples**

- This command discards changes to the MST region, then returns the switch to global configuration mode.

  ```
  switch(config-mst)#abort
  switch(config)#
  ```
clear spanning-tree counters

The `clear spanning-tree counters` command resets the BPDU counters for the specified interfaces to zero in all CLI sessions.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
clear spanning-tree counters [INT_NAME]
```

**Parameters**

- `INT_NAME` Interface type and number. Options include:
  - `<no parameter>` resets counters for all interfaces.
  - `interface ethernet e_num` Ethernet interface specified by `e_num`.
  - `interface loopback l_num` Loopback interface specified by `l_num`.
  - `interface management m_num` Management interface specified by `m_num`.
  - `interface port-channel p_num` Port-Channel Interface specified by `p_num`.
  - `interface vlan v_num` VLAN interface specified by `v_num`.

**Examples**

- This command resets the BPDU counters on Ethernet 15 interface.

```
switch#show spanning-tree counters
Port     Sent       Received       Tagged Error    Other Error
---------- ----------------- ----------------- --------------- ---------------
Ethemet15     32721             0                  0              0              0
Port-Channel10       8487             0                  0              0              0

switch#clear spanning-tree counters interface ethernet 15
switch#show spanning-tree counters
Port     Sent       Received       Tagged Error    Other Error
---------- ----------------- ----------------- --------------- ---------------
Ethemet15     11              0                  0              0              0

switch#
```
clear spanning-tree counters session

The clear spanning-tree counter session command resets the BPDU counters to zero on all interfaces in the current CLI session. Counters in other CLI sessions are not affected.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear spanning-tree counters session

**Examples**
- This command resets the BPDU counters in the current CLI session.

```
switch# show spanning-tree counters
-------------------------------------------------------------------------------
<table>
<thead>
<tr>
<th>Port</th>
<th>Sent</th>
<th>Received</th>
<th>Tagged Error</th>
<th>Other Error</th>
</tr>
</thead>
<tbody>

<td>6</td>
<td>0</td>
</tr>
</tbody>
</table>
```

switch#
clear spanning-tree detected-protocols

The clear spanning-tree detected-protocols command restarts the spanning tree protocol (STP) migration state machine on the specified interfaces. The switch is reset to running rapid spanning tree protocol on an interface where it previously detected a bridge running an old version of the protocol.

Command Mode
Privileged EXEC

Command Syntax

```
clear spanning-tree detected-protocols [INT_NAME]
```

Parameters

- **INT_NAME** Interface type and number. Values include:
  - <no parameter> all interfaces.
  - ethernet e_num Ethernet interface specified by e_num.
  - loopback l_num Loopback interface specified by l_num.
  - management m_num Management interface specified by m_num.
  - port-channel p_num Port-Channel Interface specified by p_num.
  - vlan v_num VLAN interface specified by v_num.

Examples

- This command restarts the STP migration machine on all switch interfaces.
  ```
  switch# clear spanning-tree detected-protocols
  switch#
  ```
**disabled-time**

The `disabled-time` command sets the time for which the port remains disabled after a loop is detected by loop protection. The `no disabled-time` and `default disabled-time` commands reset the disabled time to the default of 604800 seconds (seven days).

**Note**

If this value is changed, interfaces that are already disabled by loop protection will remain disabled for the previously configured period.

**Command Mode**

Loop-protection Configuration

**Command Syntax**

```
disabled-time period
no disabled-time [period]
default disabled-time [period]
```

**Parameters**

- `period` Time in seconds for which the port remains disabled. Values range from 0 to 604800 (seven days). Default is 604800. A value of 0 disables the interface until it is manually reset, even if the disabled time is later set to a non-zero value. To restore the port manually, shut it down and then re-enable it.

**Example**

- This command configures loop protection to disable a port on which a loop is detected for a period of two days (172800 seconds).

```
switch(config-monitor-loop-protect)#disabled-time 172800
switch(config-monitor-loop-protect)#
```
exit (mst-configuration mode)

The `exit` command, in MST-configuration mode, saves changes to the MST region configuration, then returns the switch to global configuration mode. MST region configuration changes are also saved by entering a different configuration mode.

**Command Mode**

MST-configuration

**Command Syntax**

`exit`

**Examples**

- This command saves changes to the MST region, then returns the switch to global configuration mode.

  ```
  switch(config-mst)#exit
  switch(config)#
  ```

- This command saves changes to the MST region, then places the switch in Interface-Ethernet mode.

  ```
  switch(config-mst)#interface ethernet 3
  switch(config-if-Et3)#
  ```
instance

The instance command inserts an entry into the VLAN-to-instance map that associates a set of VLANs to an MST instance. In addition to defining the MST topology, the VLAN-to-instance map is one of three parameters, along with the MST name and revision number, that identifies the switch’s MST region.

The no instance command removes specified entries from the VLAN-to-instance map. If the command does not provide a VLAN list, all entries are removed for the specified instance. The no instance and default instance commands function identically.

Command Mode
MST-Configuration

Command Syntax

```
instance mst_inst vlans v_range
no instance mst_inst [vlans v_range]
no default instance mst_inst [vlans v_range]
```

Parameters

- `mst_inst` MST instance number. Value of `mst_inst` ranges from 0 to 4094.
- `v_range` VLAN list. Formats include a number, number range, or comma-delimited list of numbers and ranges.

Examples

- This command maps VLANs 20-39 to MST instance 2
  
  switch(config)#spanning-tree mst configuration
  switch(config-mst)#instance 2 vlans 20-39
  switch(config-mst)#

- This command removes all VLAN mappings to MST instance 10.
  
  switch(config-mst)#no instance 10
  switch(config-mst)#
**loop-protection**

The *loop-protection* command enables loop protection on the configuration mode interface. All interfaces in a VLAN under loop protection have loop protection enabled by default. The *no loop-protection* and *default loop-protection* commands disable loop protection on the interface.

When loop protection is disabled (at the VLAN or interface level), the computed state of the interface is forgotten and packets queued to be sent are dropped. If an interface is err-disabled by loop protection, disabling loop protection removes the err-disable.

**Command Mode**

- Interface-Ethernet Configuration

**Command Syntax**

- *loop-protection*
- *no loop-protection*
- *default loop-protection*

**Example**

- These commands disable loop protection on Ethernet interface 2/4. If the interface is currently err-disabled by loop protection, the err-disable will be removed.

```
switch(config)#interface ethernet 2/4
switch(config-if-Et2/4)#no loop-protection
switch(config-if-Et2/4)#
```
**monitor loop-protection**

The **monitor loop-protection** command places the switch in loop-protection configuration mode.

**Command Mode**
- Global Configuration

**Command Syntax**

```
monitor loop-protection
```

**Commands available in loop-protection configuration mode:**
- `shutdown (Loop-protection)`
- `protect vlan`
- `transmit-interval`
- `disabled-time`
- `rate-limit`

**Example**
- This command places the switch in loop-protection configuration mode.
  ```
  switch(config)#monitor loop-protection
  switch(config-monitor-loop-protect)#
  ```
name (mst-configuration mode)

The `name` command configures the MST region name. The name is one of three parameters, along with the MST revision number and VLAN-to-instance map, that identifies the switch's MST region.

The name has up to 32 characters. The default name is an empty string. The name string accepts all characters except the space.

The `no name` and `default name` commands restore the default name by removing the `name` command from `running-config`.

Command Mode
   MST-Configuration

Command Syntax
   name `label_text`
   no name
   default name

Parameters
   - `label_text` character string assigned to name attribute. Maximum 32 characters. The space character is not permitted in the name string.

Example
   - This command assigns corporate_100 as the MST region name.
     switch(config)#spanning-tree mst configuration
     switch(config-mst)#name corporate_100
     switch(config-mst)#show pending
     Active MST configuration
     Name          [corporate_100]
     Revision 0    Instances configured 1
     Instance Vlans mapped
     --------
     0            1-4094
     

---
**protect vlan**

The *protect vlan* command specifies which VLANs will participate in loop protection. The *no protect vlan* and *default protect vlan* commands remove loop protection from the specified VLANs.

**Command Mode**

Loop-protection Configuration

**Command Syntax**

```
protect vlan vlan-range
```

**Parameters**

- **vlan-range** List of VLANs (number, range, comma-delimited list of numbers and ranges). Numbers range from 1 to 4094.

**Example**

- This command enables loop protection on VLANs 1025-2000.

  ```
  switch(config-monitor-loop-protect)#protect vlan 1025-2000
  switch(config-monitor-loop-protect)#
  ```
rate-limit

The `rate-limit` command sets the maximum number of loop detection frames which can be sent by the switch per second. The `no rate-limit` and `default rate-limit` commands return the rate limit to the default value of 1000.

**Command Mode**
- Loop-protection Configuration

**Command Syntax**

- `rate-limit frames`
- `no rate-limit [frames]`
- `default rate-limit [frames]`

**Parameters**

- `frames` Maximum number of frames sent per second. Values range from 0-1000, default is 1000. A value of zero disables throttling.

**Example**

- This command sets the maximum number of loop detection frames to 500 per second.

  ```
  switch(config-monitor-loop-protect)#rate-limit 500
  switch(config-monitor-loop-protect)#
  ```
revision (mst-configuration mode)

The `revision` command configures the MST revision number. The revision number is one of three parameters, along with the MST name and VLAN-to-instance map, that identifies the switch’s MST region. Revision numbers range from 0 to 65535. The default revision number is 0.

The `no revision` and `default revision` commands restore the revision number to its default value by removing the revision command from `running-config`.

**Command Mode**
- MST-Configuration

**Command Syntax**
```
revision rev_number
no revision
default revision
```

**Parameters**
- `rev_number` revision number. Possible ranges from 0 to 65535 with a default of 0.

**Examples**
- This command sets the revision number to 15.
  
```
switch(config)#spanning-tree mst configuration
switch(config-mst)#revision 15
switch(config-mst)#show pending
```

Active MST configuration
Name   []
Revision 15   Instances configured 1

```
Instance  Vlans mapped
--------  --------------------------------------------
0         1-4094
--------------------------------------------
```
show (mst-configuration mode)

The `show` command displays the current and pending MST configuration:
Exiting MST configuration mode stores all pending configuration changes to `running-config`.

Command Mode
MST-Configuration

Command Syntax
`show [EDIT_VERSION]`

Parameters
- `EDIT_VERSION` specifies configuration version that the command displays. Options include:
  - `<no parameter>` command displays pending MST configuration.
  - `active` command displays MST configuration stored in `running-config`.
  - `current` command displays MST configuration stored in `running-config`.
  - `pending` command displays pending MST configuration.
Example

- These commands contrast the difference between the active and pending configuration by adding MST configuration commands, then showing the configurations.

```
switch(config-mst)#show pending
Active MST configuration
Name       []
Revision   0   Instances configured 1

Instance  Vlans mapped
---------  -------------------------------
0         1-4094                           

# instance 2 vlan 20-29,102
switch(config-mst)#revision 2
switch(config-mst)#name baseline
switch(config-mst)#show pending
Pending MST configuration
Name       [baseline]
Revision   2   Instances configured 2

Instance  Vlans mapped
---------  -------------------------------
0         1-19,30-101,103-4094
2         20-29,102                           

# show active
switch(config-mst)#show active
Active MST configuration
Name       []
Revision   0   Instances configured 1

Instance  Vlans mapped
---------  -------------------------------
0         1-4094                           
```

**show loop-protection**

The `show loop-protection` command displays loop protection status.

**Command Syntax**

```
show loop-protection [detail]
```

**Examples**

- This command displays basic loop protection information.

  ```
  switch> show loop-protection
  Loop protection is enabled
  Transmit interval: 5
  Disable Time: 604800 (or Permanent)
  Packets Transmitted rate: 12/second (or Unthrottled)
  Total: 3 Vlans enabled.
  switch>
  ```

- This command displays detailed information about loop protection.

  ```
  switch> show loop-protection detail
  Loop protection is enabled
  Transmit interval: 5
  Disable Time: 604800
  Packets Transmitted rate: 12/second
  Total: 3 Vlans enabled.
  Destination address: ffff.ffff.ffff
  Ethernet type: 0x88b7
  Receive action: Interface Disable

switch>

show spanning-tree

The show spanning-tree command displays spanning tree protocol (STP) data, organized by instance.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree [VLAN_ID] [INFO_LEVEL]
```

**Parameters**

- **VLAN_ID** specifies the VLANs for which the command displays information. Formats include:
  - `<no parameter>` displays information for all VLANs.
  - `vlan` displays data for instances containing the first VLAN listed in running-config.
  - `vlan v_range` displays data for instances containing a VLAN in the specified range.
- **INFO_LEVEL** specifies level of information detail provided by the command.
  - `<no parameter>` displays table for each instance listing status, configuration, and history.
  - `detail` displays data blocks for each instance and all ports on each instance.

**Display Values**

- **Root ID** Displays information on the ROOT ID (elected spanning tree root bridge ID):
  - **Priority**: Priority of the bridge. Default value is 32768.
  - **Address**: MAC address of the bridge.
- **Bridge ID** bridge status and configuration information for the locally configured bridge:
  - **Priority**: Priority of the bridge. The default priority is 32768.
  - **Address**: MAC address of the bridge.
  - **Hello Time**: Interval (seconds) between bridge protocol data units (BPDUs) transmissions.
  - **Max Age**: Maximum time that a BPDU is saved.
  - **Forward Delay**: Time (in seconds) that is spent in the learning state.
- **Interface** STP configuration participants. Link-down interfaces are not shown.
- **Role** Role of the port as one of the following:
  - **Root**: The best port for a bridge to a root bridge used for forwarding.
  - **Designated**: A forwarding port for a LAN segment.
  - **Alternate**: A port acting as an alternate path to the root bridge.
  - **Backup**: A port acting as a redundant path to another bridge port.
- **State** Displays the interface STP state as one of the following:
  - Learning
  - Discarding
  - Forwarding
- **Cost** STP port path cost value.
- **Prio. Nbr.** STP port priority. Values range from 0 to 240. Default is 128.
- **Type** The link type of the interface (automatically derived from the duplex mode of an interface):
  - **P2p Peer (STP)** Point to point full duplex port running standard STP.
• **shr Peer (STP)**  Shared half duplex port running standard STP.

### Examples

- This command displays STP data, including a table of port parameters.

```plaintext
switch> show spanning-tree vlan 1000

  Po947
  Number of blocked ports (segments) in the system : 22
  switch>
  ```
show spanning-tree bridge

The **show spanning-tree bridge** command displays spanning tree protocol bridge configuration settings for each instance on the switch. The display includes Bridge ID, Hello Time, Max Age, and Forward Delay times.

The command also displays the restartability of the STP agent when the **detail** option is selected. A switch can continue support of MLAG operation when its peer is offline and the STP agent is unavailable.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree bridge [INFO_LEVEL]
```

**Parameters**

- **INFO_LEVEL** specifies level of information detail provided by the command.
  - `<no parameter>` command displays information in a data table.
  - **detail** command displays bridge information in data blocks for each instance.

**Examples**

- This command displays a bridge data table.
  
  ```
  switch> show spanning-tree bridge
  Instance Bridge ID Priority MAC addr Hello Max Fwd
  ---------- ----------------- -------------- ----- --- --- ---

  switch>
  ```
show spanning-tree bridge assurance

The `show spanning-tree bridge assurance` command displays spanning tree protocol bridge assurance information for network ports or for all ports. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled, but if they do not receive periodic BPDUs from the other side of the link the `show spanning-tree bridge assurance` command will show a bridge assurance status of “inconsistent” (blocking) for that port.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show spanning-tree bridge assurance INFO_LEVEL
```

**Parameters**

- `INFO_LEVEL` specifies level of information detail provided by the command.
  - `<no parameter>` command displays bridge assurance information for network ports.
  - `detail` command displays bridge assurance information for all ports.

**Examples**

- This command displays the bridge assurance status of network ports.
  ```plaintext
  switch>show spanning-tree bridge assurance
  Name                     Bridge Assurance Status
  --------------------------------------------
  VL1                      Et5/1       consistent
  
  Number of bridge assurance inconsistent ports in the system : 0
  switch>
  ```
**show spanning-tree counters**

The **show spanning-tree counters** command displays the number of BPDU transactions on each interface running spanning tree.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree counters
```

**Example**

- This command displays the BPDU counter status on each interface running spanning tree.

```
switch>show spanning-tree counters

switch>
```
show spanning-tree interface

The **show spanning-tree interface** command displays spanning tree protocol information for the specified interface.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree interface INT_NAME [INFO_LEVEL]
```

**Parameters**

- **INT_NAME**  Interface type and number. Values include:
  - `ethernet e_num`  Ethernet interface specified by `e_num`.
  - `peerethernet e_num`  Ethernet interface specified by `e_num`.
  - `port-channel p_num`  Port-Channel Interface specified by `p_num`.
  - `peerport-channel p_num`  Port-Channel Interface specified by `p_num`.

- **INFO_LEVEL**  specifies level of detail provided by the output. Options include:
  - `<no parameter>`  command displays a table of STP data for the specified interface.
  - `detail`  command displays a data block for the specified interface.

**Examples**

- This command displays an STP table for Ethernet interface 5.

  ```
  switch> show spanning-tree interface ethernet 5
  Instance Role State Cost Prio.Nbr Type
  -------------- ---------- ---------- --------- -------- -------------------
  MST0 designated forwarding 20000 128.5 P2p
  switch>
  ```

- This command displays a data block for Ethernet interface 5.

  ```
  switch> show spanning-tree interface ethernet 5 detail
  Port 5 (Ethernet5) of MST0 is designated forwarding
  Port path cost 20000, Port priority 128, Port Identifier 128.5.
  Designated root has priority 32768, address 001c.7301.07b9
  Designated bridge has priority 32768, address 001c.7304.195b
  Designated port id is 128.5, designated path cost 1999 (Ext) 0 (Int)
  Timers: message age 1, forward delay 15, hold 20
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default, Internal
  BPDU: sent 1008766, received 0, taggedErr 0, otherErr 0, rateLimiterCount 0
  Rate-Limiter: enabled, Window: 10 sec, Max-BPDU: 400
  ```

  ```
  switch>
  ```
**show spanning-tree mst**

The `show spanning-tree mst` command displays configuration and state information for Multiple Spanning Tree Protocol (MST) instances.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree mst [INSTANCE] [INFO_LEVEL]
```

**Parameters**

- **INSTANCE** – MST instance for which the command displays information. Options include:
  - `<no parameter>` all MST instances.
  - `mst_inst` MST instance number. Value of `mst_inst` ranges from 0 to 4094.
- **INFO_LEVEL** – type and amount of information in the output. Options include:
  - `<no parameter>` output is interface data in tabular format.
  - `detail` output is a data block for each interface.

**Examples**

- This command displays interface data blocks for MST instance 3.

```
switch>show spanning-tree mst 3 detail
##### MST3    vlans mapped:    3

show spanning-tree mst configuration

The **show spanning-tree mst configuration** command displays information about the MST region’s VLAN-to-instance mapping. The command provides two display options:

- **default** displays a table that lists the instance to VLAN map.
- **digest** displays the configuration digest.

The configuration digest is a 16-byte hex string calculated from the md5 encoding of the VLAN-to-instance mapping table. Switches with identical mappings have identical digests.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show spanning-tree mst configuration [INFO_LEVEL]
```

**Parameters**

- **INFO_LEVEL** specifies data provided by the output. Options include:
  - `<no parameter>` command displays VLAN-to-instance map.
  - **digest** command displays the MST configuration digest.

**Examples**

- This command displays the MST region’s VLAN-to-instance map.
  ```plaintext
  switch>show spanning-tree mst configuration
  Name []
  Revision 0  Instances configured 3
  
  Instance  Vlans mapped
  -------
  0         1,4-4094
  2         2
  3         3
  
  switch>
  ```

- This command displays the MST region’s configuration digest.
  ```plaintext
  switch>show spanning-tree mst configuration digest
  Name []
  Revision 0  Instances configured 1
  Digest 0xAC36177F50283CD4B83821D8AB26DE62
  switch>
  ```
show spanning-tree mst interface

The `show spanning-tree mst interface` command displays Multiple Spanning Tree Protocol (MSTP) information for a specified interface on the specified MST instances.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree mst [INSTANCE] interface INT_NAME [INFO_LEVEL]
```

**Parameters**

- **INSTANCE** MST instance for which the command displays information. Options include:
  - <no parameter> all MST instances.
  - `mst_inst` denotes a single MST instance. Value of `mst_inst` ranges from 0 to 4094.
- **INT_NAME** Interface type and number. Values include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `peerethernete_num` Ethernet interface specified by `e_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `peerport-channelp_num` Port-channel interface specified by `p_num`.
- **INFO_LEVEL** specifies level of detail provided by the output. Options include:
  - <no parameter> command displays a table of STP instance data for the specified interface
  - `detail` command displays a data block for all specified instance-interface combinations.

**Examples**

- This command displays an table of STP instance data for Ethernet 1 interface:
  ```
  switch>show spanning-tree mst interface ethernet 1
  Ethernet1 of MST0 is root forwarding
  Edge port: no                              bpdu guard: disabled
  Link type: point-to-point
  Boundary : Internal
  Bpdus sent 2120, received 2164, taggedErr 0, otherErr 0
  Instance Role Sts Cost      Prio.Nbr Vlans mapped
  ------ ---- --------- -------- -------------------------------
  0        Root FWD 2000      128.1    1,4-4094
  2        Desg FWD 2000      128.1    2
  3        Root FWD 2000      128.1    3
  ```

- This command displays blocks of STP instance information for Ethernet 1 interface.
  ```
  switch>show spanning-tree mst 3 interface ethernet 1 detail
  Ethernet1 of MST3 is root forwarding
  Port info             port id          128.1  priority    128 cost        2000
  Designated root       address 0011.2233.4401  priority  32768 cost           0
  Designated bridge     address 0011.2233.4401  priority  32768 port id    128.1
  ```
show spanning-tree mst test information

The `show spanning-tree mst test information` displays diagnostic spanning tree protocol information.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree mst test information
```

**Examples**

- This command displays diagnostic STP information.

```bash
switch>show spanning-tree mst test information
bi = MstInfo.BridgeInfo( "dut" )
bi.stpVersion = "rstp"
bi.mstpRegionId = ""
bv.bridgeAddr = "00:1c:73:01:60:17"
si = MstInfo.BridgeStpiInfo( "Mst" )
bi.stpiInfoIs( "Mst", si )
si.cistRoot = Tac.Value( "Stp::BridgeId", priority=32768, systemId=0,
address='00:1c:73:01:60:17' )

bmii.operIntPathCost = 1999
bmii.fdbFlush = 1
bmii.mstiIntfInfoIs( "Port-Channel10", bmii )
bii = MstInfo.BridgeIntfInfo( "Port-Channel10" )
bii.operExtPathCost = 1999
si.intfInfoIs( "Port-Channel10", bi )
switch>
```
show spanning-tree root

The `show spanning-tree root` command displays the Bridge-ID, cost to the root bridge, root port, and the root bridge timer settings for all instances.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree root [INFO_LEVEL]
```

**Parameters**

- `INFO_LEVEL` specifies output format. Options include:
  - `<no parameter>` output displays data in tabular format.
  - `detail` output displays a data block for each instance.

**Examples**

- This command displays a table of root bridge information.

  ```
  switch>show spanning-tree root
  Instance          Root ID     Root Priority    MAC addr     Hello Cost  Max Fwd  Age  Dly  Root Port
  --------           ----------- -----------          ---------  ---  ---  ---  ----------------

  Hello Time 0.000 sec Max Age 0 sec Forward Delay 0 sec
  switch>
  ```
show spanning-tree topology status

The `show spanning-tree topology status` command displays the forwarding state of ports on the specified VLANs.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree topology [VLAN_NAME] status [INFO_LEVEL]
```

**Parameters**

- **VLAN_NAME** specifies the VLANs that the output displays. Options include:
  - `<no parameter>` output includes all VLANs.
  - `vlan` output includes all VLANs.
  - `vlan v_num` command includes specified VLAN; `v_num` ranges from 1 to 4094.

- **INFO_LEVEL** specifies information provided by output. Options include:
  - `<no parameter>` output lists forwarding state of interfaces.
  - `detail` output lists forwarding state and change history of interfaces.

**Examples**

- This command displays forwarding state for ports mapped to all VLANs.

  ```
  switch>show spanning-tree topology status
  Topology: Cist
  Mapped Vlans: 1-4,666,1000-1001,1004-1005
  Cpu: forwarding
  Ethernet2: forwarding
  Ethernet3: forwarding
  Ethernet4: forwarding
  Ethernet5: forwarding
  Ethernet6: forwarding
  Ethernet8: forwarding
  Ethernet10: forwarding
  Port-Channel1: forwarding
  Port-Channel2: forwarding
  Port-Channel3: forwarding
  switch>
  ```

- This command displays forwarding state and history for ports mapped to VLAN 1000.

  ```
  switch>show spanning-tree topology vlan 1000 status detail
  Topology: Cist
  Mapped Vlans: 1000
  Cpu: forwarding (1 changes, last 23 days, 22:54:43 ago)
  Ethernet2: forwarding (3 changes, last 23 days, 22:48:59 ago)
  Ethernet4: forwarding (3 changes, last 10 days, 19:54:17 ago)
  Ethernet5: forwarding (3 changes, last 23 days, 22:54:38 ago)
  Ethernet6: forwarding (3 changes, last 19 days, 15:49:10 ago)
  Ethernet10: forwarding (3 changes, last 9 days, 7:37:05 ago)
  Port-Channel1: forwarding (3 changes, last 23 days, 22:54:34 ago)
  Port-Channel3: forwarding (5 changes, last 21 days, 4:56:41 ago)
  switch>
  ```
**shutdown (Loop-protection)**

The `shutdown (Loop-protection)` command disables loop protection globally. The feature is disabled by default, and is enabled by using the `no shutdown (Loop-protection)` command.

**Note**
To function, loop protection must also be enabled on a per-VLAN basis using the `protect vlan` command.

**Command Mode**
Loop-protection Configuration

**Command Syntax**

```
  shutdown  
  no shutdown  
```

**Example**

- This command enables loop protection globally on the switch.

  ```
  switch(config-monitor-loop-protect)#no shutdown  
  switch(config-monitor-loop-protect)#
  ```
spanning-tree bpdufilter

The spanning-tree bpdufilter command controls bridge protocol data unit (BPDU) filtering on the configuration mode interface. BPDU filtering is disabled by default.

- spanning-tree bpdufilter enabled enables BPDU filtering.
- spanning-tree bpdufilter disabled disables BPDU filtering by removing the spanning-tree bpdufilter command from running-config.

The BPDU filter default setting for portfast ports is configured by the spanning-tree portfast bpdufilter default command; BPDU filter is disabled by default on all non-portfast ports.

The no spanning-tree bpdufilter and default spanning-tree bpdufilter commands restore the global BPDU filter setting on the configuration mode interface by removing the corresponding spanning-tree bpdufilter command from running-config.

Command Mode
 Interface-Ethernet Configuration
 Interface-Port-Channel Configuration

Command Syntax
  spanning-tree bpdufilter FILTER_STATUS
  no spanning-tree bpdufilter
  default spanning-tree bpdufilter

Parameters
- FILTER_STATUS  BPDU filtering status. Options include:
  - enabled  BPDU filter is enabled on the interface.
  - disabled  BPDU filter is disabled on the interface.

Examples
- This command enables BPDU filtering on Ethernet 5 interface.
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree bpdufilter enabled
  switch(config-if-Et5)#
The `spanning-tree bpduguard` command controls BPDU guard on the configuration mode interface. A BPDU guard-enabled port is disabled when it receives a BPDU packet.

The BPDU guard default setting for portfast ports is configured by the `spanning-tree portfast bpduguard default` command; BPDU guard is disabled by default on all non-portfast ports.

The `no spanning-tree bpduguard` and `default spanning-tree bpduguard` commands restore the global BPDU guard setting on the configuration mode interface by removing the corresponding `spanning-tree bpduguard` command from `running-config`.

### Command Mode
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

### Command Syntax
```
spanning-tree bpduguard GUARD_ACTION
no spanning-tree bpduguard
default spanning-tree bpduguard
```

### Parameters
- **GUARD_ACTION**  
  - **disable**  
    - Disable bpduguard 
  - **enable**  
    - Enable bpduguard 
  - **rate-limit**  
    - BPDU Input Rate Limiter options

### Examples
- These commands enable BPDU guard on Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree bpduguard enabled
  switch(config-if-Et5)
  ```
spanning-tree bpduguard rate-limit count (global)

The `spanning-tree bpduguard rate-limit count` command sets the maximum BPDU reception rate (quantity per interval) for ports not covered by a `spanning-tree bpduguard rate-limit count (interface)` command.

- The default quantity is 10 times the number of VLANs.
- The default interval is the hello time (`spanning-tree hello-time`).

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limiting is enabled or disabled by `spanning-tree bpduguard rate-limit enable / disable` commands.

The `no spanning-tree bpduguard rate-limit count` and `default spanning-tree bpduguard rate-limit count` commands restore the global setting to its default value by removing the `spanning-tree bpduguard rate-limit count` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
```
spanning-tree bpduguard rate-limit count max_bpdu [TIMER]
no spanning-tree bpduguard rate-limit count
default spanning-tree bpduguard rate-limit count
```

**Parameters**
- `max_bpdu` BPDU quantity. Value ranges from 1 to 20000.
- `TIMER` BPDU reception interval (seconds). Options include:
  - `<no parameter>` reception interval defaults to `hello-time`.
  - `interval period` Value of `period` ranges from 1 to 15.

**Example**
- This command configures the global rate limit as 5000 BPDUs per four second period.

```
switch(config)#spanning-tree bpduguard rate-limit count 5000 interval 4
switch(config)#
```
spanning-tree bpduguard rate-limit count (interface)

The `spanning-tree bpduguard rate-limit count` command configures the maximum BPDU reception rate for the configuration mode interface. The default rate limit is specified by the `spanning-tree bpduguard rate-limit count (global)` command.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limiting is enabled or disabled by `spanning-tree bpduguard rate-limit enable / disable` commands.

The `no spanning-tree bpduguard rate-limit count` and `default spanning-tree bpduguard rate-limit count` commands restore the interface value to the global setting by removing the corresponding `spanning-tree bpduguard rate-limit count` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```plaintext
spanning-tree bpduguard rate-limit count max_bpdu [TIMER]
no spanning-tree bpduguard rate-limit count
default spanning-tree bpduguard rate-limit count
```

**Parameters**

- `max_bpdu`  BPDU quantity. Value ranges from 1 to 20,000.
- `TIMER`  BPDU reception interval (seconds). Options include:
  - `<no parameter>`  reception interval defaults to `hello-time`.
  - `interval period`  Value of `period` ranges from 1 to 15.

**Example**

- These commands configure rate limit as 7500 BPDUs per 8 second period on Ethernet 2.

```plaintext
switch(config)#interface ethernet 2
switch(config-if-Et2)#spanning-tree bpduguard rate-limit count 7500 interval 8
switch(config-if-Et2)#
```
spanning-tree bpduguard rate-limit default

The spanning-tree bpduguard rate-limit default command configures the global BPDU rate limit setting. The global BPDU rate limit setting provides the default for individual ports whose configuration does not include a spanning-tree bpduguard rate-limit enable / disable command. The default global setting is enabled.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limits are established by spanning-tree bpduguard rate-limit count (global) commands.

The no spanning-tree bpduguard rate-limit default sets the global BPDU rate limit setting to disabled. The spanning-tree bpduguard rate-limit default and default spanning-tree bpduguard rate-limit default commands restore the default global rate limit setting to enabled by removing the no spanning-tree bpduguard rate-limit default command from running-config.

Command Mode
Global Configuration

Command Syntax
  spanning-tree bpduguard rate-limit default
  no spanning-tree bpduguard rate-limit default
  default spanning-tree bpduguard rate-limit default

Example
- This command enables rate limiting on all ports not covered by an interface rate limit command.

  switch(config)#spanning-tree bpduguard rate-limit default
  switch(config)#
spanning-tree bpduguard rate-limit enable / disable

These commands enable and disable BPDU rate limiting on the configuration mode interface:

- `spanning-tree bpduguard rate-limit enable` enables BPDU rate limiting.
- `spanning-tree bpduguard rate-limit disable` disables BPDU rate limiting.

The `spanning-tree bpduguard rate-limit default` command enables BPDU rate limiting on all ports not configured with a `spanning-tree bpduguard rate-limit` command.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limits are established by `spanning-tree bpduguard rate-limit count (interface)` commands.

The `no spanning-tree bpduguard rate-limit` and `default spanning-tree bpduguard rate-limit` commands restore the global rate limit setting on the configuration mode interface by removing the corresponding `spanning-tree bpduguard rate-limit` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree bpduguard rate-limit enable`
- `spanning-tree bpduguard rate-limit disable`
- `no spanning-tree bpduguard rate-limit`
- `default spanning-tree bpduguard rate-limit`

**Example**

- These commands enable rate limiting on Ethernet 15.
  ```
  switch(config)#interface ethernet 15
  switch(config-if-Et15)#spanning-tree bpduguard rate-limit enable
  switch(config-if-Et15)#
  ```
spanning-tree bridge assurance

The **spanning-tree bridge assurance** command enables bridge assurance globally, which enables bridge assurance on all ports with a port type of `network`. Bridge assurance protects against unidirectional link failure, other software failure, and devices that quit running a spanning tree algorithm.

Bridge assurance is available only on point-to-point links on spanning tree `network` ports. Both ends of the link should ideally have bridge assurance enabled. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled, but if they do not receive periodic BPDUs from the other side of the link the **show spanning-tree bridge assurance** command will show a bridge assurance status of “inconsistent” (blocking) for that port.

The **no spanning-tree bridge assurance** command disables bridge assurance.

The **spanning-tree bridge assurance** and **default spanning-tree bridge assurance** commands restore the default behavior by removing the **no spanning-tree bridge assurance** command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**

```
spanning-tree bridge assurance
no spanning-tree bridge assurance
default spanning-tree bridge assurance
```

**Example**

- This command enables bridge assurance on the switch.

  ```
  switch(config)# spanning-tree bridge assurance
  switch(config)#
  ```
spanning-tree cost

The spanning-tree cost command configures the path cost of the configuration mode interface. Cost values range from 1 to 200000000 (200 million). The default cost depends on the interface speed:

- 1 gigabit interface: cost = 20000
- 10 gigabit interface: cost = 2000

The spanning-tree cost command provides a mode option:

- RST instance cost is configured by not including a mode.
- MST instance 0 cost is configured by not including a mode or with the mst mode option.
- MST instance cost is configured with the mst mode option.
- Rapid-PVST VLAN cost is configured with the vlan mode option.

The no spanning-tree cost and default spanning-tree cost commands restore the default cost on the configuration mode interface by removing the corresponding spanning-tree cost command from running-config.

Command Mode

| Interface-Ethernet Configuration |
| Interface-Port-Channel Configuration |

Command Syntax

- spanning-tree MODE cost value
- no spanning-tree MODE cost
- default spanning-tree MODE cost

Parameters

- **MODE** specifies the spanning tree instances for which the cost is configured. Values include:
  - <no parameter> RST instance, MST instance 0, or all Rapid-PVST instances permitted on the interface.
  - mst m_range specified MST instances. m_range formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - vlan v_range specified Rapid-PVST instances. v_range formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
  - value path cost assigned to interface. Values range from 1 to 200000000 (200 million). Default values are 20000 (1 G interfaces) or 2000 (10 G interfaces).

Examples

- These commands configure a port cost of 25000 for Ethernet interface 5 when configured as an RST port, as a port in MST instance 0, or all unconfigured Rapid-PVST instances that are not explicitly configured.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning tree cost 25000
  ```

- This command configures a port cost of 30000 for Ethernet interface 5 when configured as a port in MST instance 200.

  ```
  switch(config-if-Et5)#spanning tree mst 200 cost 30000
  ```
This command configures a port cost of 100000 for Ethernet interface 5 when configured as a port in VLANs 200-220.

```
switch(config-if-Et5)#spanning tree vlan 200-220 cost 100000
switch(config-if-Et5)#
```
spanning-tree forward-time

The `spanning-tree forward-time` command configures the forward delay timer. Forward delay is the time that a port is in learning state before it begins forwarding data packets.

The switch inserts the forward delay timer value in BPDU packets it sends as the root bridge. The forward delay value ranges from 4 to 30 seconds with a default of 15 seconds.

The `no spanning-tree forward-time` and `default spanning-tree forward-time` commands restore the forward delay timer default of 15 seconds by removing the `spanning-tree forward-time` command from `running-config`.

Command Mode

- Global Configuration

Command Syntax

```
spanning-tree forward-time period
no spanning-tree forward-time
default spanning-tree forward-time
```

Parameters

- `period` forward delay timer (seconds). Value ranges from 4 to 30. Default is 15.

Examples

- This command sets the forward delay timer value to 25 seconds.
  ```
  switch(config)#spanning-tree forward-time 25
  switch(config)#
  ```

spanning-tree guard

The `spanning-tree guard` command enables root guard or loop guard on the configuration mode interface. The `spanning-tree loopguard default` command configures the global loop guard setting.

- Root guard prevents a port from becoming a root or blocked port. A root guard port that receives a superior BPDU transitions to the root-inconsistent (blocked) state.
- Loop guard protects against loops resulting from unidirectional link failures on point-to-point links by preventing non-designated ports from becoming designated ports. When loop guard is enabled, a root or blocked port transitions to loop-inconsistent (blocked) state if it stops receiving BPDUs from its designated port. The port returns to its prior state when it receives a BPDU.

The `no spanning-tree guard` and `default spanning-tree guard` commands sets the configuration mode interface to the global loop guard mode by removing the `spanning-tree guard` statement from `running-config`. The `spanning-tree guard none` command disables loop guard and root guard on the interface, overriding the global setting.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree guard PORT_MODE
no spanning-tree guard
default spanning-tree guard
```

**Parameters**

- `PORT_MODE` the port mode. Options include:
  - `loop` enables loop guard on the interface.
  - `root` enables root guard on the interface.
  - `none` disables root guard and loop guard.

**Examples**

- This command enables root guard on Ethernet 5 interface.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree guard root
  switch(config-if-Et5)#
  ```
spanning-tree hello-time

The `spanning-tree hello-time` command configures the hello time, which specifies the transmission interval between consecutive bridge protocol data units (BPDU) that the switch sends as a root bridge. The hello time is also inserted in outbound BPDUs.

This hello time ranges from 0.2 seconds to 10 seconds with a default of 2 seconds.

The `no spanning-tree hello-time` and `default spanning-tree hello-time` commands restore the hello time default of 2 seconds by removing the `spanning-tree hello-time` command from `running-config`.

Command Mode
Global Configuration

Command Syntax
```
spanning-tree hello-time period
no spanning-tree hello-time
default spanning-tree hello-time
```

Parameters
- `period` hello-time (milliseconds). Value ranges from 200 to 10000. Default is 2000.

Examples
- This command configures a hello-time of one second.
  ```
  switch(config)#spanning-tree hello-time 1000
  switch(config)#
  ```
spanning-tree link-type

The spanning-tree link-type command specifies the configuration mode interface’s link type, which is normally derived from the port’s duplex setting. The default setting depends on a port’s duplex mode:

- full-duplex ports are *point-to-point*.
- half-duplex ports are *shared*.

The no spanning-tree link-type and default spanning-tree link-type commands restore the default link type on the configuration mode interface by removing the corresponding spanning-tree link-type command from *running-config*.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree link-type TYPE
no spanning-tree link-type
default spanning-tree link-type
```

**Parameters**

- **TYPE**  link type of the configuration mode interface. Options include:
  - *point-to-point*
  - *shared*

**Examples**

- This command configures Ethernet 5 interface as a shared port.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree link-type shared
  switch(config-if-Et5)#
  ```
spanning-tree loopguard default

The *spanning-tree loopguard default* command configures the global loop guard setting as *enabled*. Ports not covered by a *spanning-tree guard* command use the global loop guard setting. Loop guard prevents blocked or root ports from becoming a designated port due to failures resulting in a unidirectional link. The *spanning-tree guard* interface configuration statement overrides the global setting for a specified interface. The default global loop guard setting is *disabled*.

The *no spanning-tree loopguard default* and *default spanning-tree loopguard default* commands restore the global loop guard setting of *disabled* by removing the *spanning-tree loopguard default* command from *running-config*.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree loopguard default
no spanning-tree loopguard default
default spanning-tree loopguard default
```

**Examples**

- This command enables loop guard as the default on all switch ports.
  
  ```
  switch(config)#spanning-tree loopguard default
  switch(config)#
  ```
**spanning-tree max-age**

The `spanning-tree max-age` command configures the switch's max age timer, which specifies the max age value that the switch inserts in outbound BPDU packets it sends as a root bridge. The max-age time value ranges from 6 to 40 seconds with a default of 20 seconds.

Max age is the interval, specified in the BPDU, that BPDU data remains valid after its reception. The bridge recomputes the spanning tree topology if it does not receive a new BPDU before max age expiry.

The `no spanning-tree max-age` and `default spanning-tree max-age` commands restore the max-age default of 20 seconds by removing the `spanning-tree max-age` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree max-age period
no spanning-tree max-age
default spanning-tree max-age
```

**Parameters**

- `period`  max age period (seconds). Value ranges from 6 to 40. Default is 20.

**Examples**

- This command sets the max age timer value to 25 seconds.

```
switch(config)#spanning-tree max-age 25
switch(config)#
```
spanning-tree max-hops

The `spanning-tree max-hops` command specifies the max hop setting that the switch inserts into BPDUs that it sends out as the root bridge. The max hop setting determines the number of bridges in an MST region that a BPDU can traverse before it is discarded. The max-hop value ranges from 1 to 40 with a default of 20.

The `no spanning-tree max-hops` and `default spanning-tree max-hops` commands restore the max-hops setting to its default value of 20 by removing the `spanning-tree max-hops` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**
- `spanning-tree max-hops ports`
- `no spanning-tree max-hops`
- `default spanning-tree max-hops`

**Parameters**
- `ports` max hops (bridges). Value ranges from 1 to 40. Default is 20.

**Example**
- This command sets the max hop value to 40.
  ```
  switch(config)#spanning-tree max-hop 40
  switch(config)#
  ```
spanning-tree mode

The spanning-tree mode command specifies the spanning tree protocol version that the switch runs. The default mode is Multiple Spanning Tree (mstp).

The no spanning-tree mode and default spanning-tree mode commands restore the default spanning tree protocol version.

Caution
The spanning-tree mode command may disrupt user traffic. When the switch starts a different STP version, all spanning-tree instances are stopped, then restarted in the new mode.

Command Mode
Global Configuration

Command Syntax
spanning-tree mode VERSION
no spanning-tree mode
default spanning-tree mode

Parameters
- **VERSION** spanning tree version that the switch runs. Options include:
  - **mstp** multiple spanning tree protocol described in the IEEE 802.1Q-2005 specification and originally specified in the IEEE 802.1s specification.
  - **rstp** rapid spanning tree protocol described in the IEEE 802.1D-2004 specification and originally specified in the IEEE 802.1w specification.
  - **rapid-pvst** rapid per-VLAN spanning tree protocol described in the IEEE 802.1D-2004 specification and originally specified in the IEEE 802.1w specification.
  - **backup** disables STP and enables switchport interface pairs configured with the switchport backup interface command.
  - **none** disables STP. The switch does not generate STP packets. Each switchport interface forwards data packets to all connected ports and forwards STP packets as multicast data packets on the VLAN where they are received.

Guidelines
Backup mode is not available on Trident platform switches.

Example
- This command configures the switch to run multiple spanning tree protocol.
  
  ```
  switch(config)#spanning-tree mode mstp
  switch(config)#
  ```
spanning-tree mst configuration

The `spanning-tree mst configuration` command places the switch in MST-configuration mode, which is the group change mode where MST region parameters are configured.

Changes made in a group change mode are saved by leaving the mode through the `exit` command or by entering another configuration mode. To discard changes from the current edit session, leave the mode with the `abort` command.

These commands are available in MST-configuration mode:

- `abort (mst-configuration mode)`
- `exit (mst-configuration mode)`
- `instance`
- `name (mst-configuration mode)`
- `revision (mst-configuration mode)`
- `show (mst-configuration mode)`

The `no spanning-tree mst configuration` and `default spanning-tree mst configuration` commands restore the MST default configuration.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree mst configuration
no spanning-tree mst configuration
default spanning-tree mst configuration
```

**Examples**

- This command enters MST configuration mode.
  
  ```
  switch(config)#spanning-tree mst configuration
  switch(config-mst)#
  ```

- This command exits MST configuration mode, saving MST region configuration changes to `running-config`.
  
  ```
  switch(config-mst)#exit
  switch(config)#
  ```

- This command exits MST configuration mode without saving MST region configuration changes to `running-config`.
  
  ```
  switch(config-mst)#abort
  switch(config)#
  ```
spanning-tree portchannel guard misconfig

The `spanning-tree portchannel guard misconfig` command enables the switch to detect misconfigured port channels that may cause network loops by monitoring inbound BPDUs. When a port channel receives 75 inconsistent BPDUs within 30 seconds, the switch error disables the port. When a port channel receives 5 BPDUs with the same source BPDU during the 30 second measurement interval, the error counter is reset and the port continues normal port channel operation. Misconfigured port channel detection is disabled by default.

The `no spanning-tree portchannel guard misconfig` and `default spanning-tree portchannel guard misconfig` commands disables the detection of misconfigured port channels by removing the `spanning-tree portchannel guard misconfig` statement from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree portchannel guard misconfig
no spanning-tree portchannel guard misconfig
default spanning-tree portchannel guard misconfig

spanning-tree etherchannel guard misconfig
no spanning-tree etherchannel guard misconfig
default spanning-tree etherchannel guard misconfig
```

**Guidelines**

The `spanning-tree portchannel guard misconfig` and `spanning-tree etherchannel guard misconfig` commands are equivalent.

**Examples**

- This command enables port channel misconfiguration detection on the switch.

  ```
  switch(config)#spanning-tree portchannel guard misconfig
  switch(config)#show running-config
  
  !
  spanning-tree mode mstp
  spanning-tree portchannel guard misconfig
  
  <-------OUTPUT OMITTED FROM EXAMPLE------->

  !
  end
  switch(config)#
  ```

- This command disables port channel misconfiguration detection on the switch.

  ```
  switch(config)#no spanning-tree portchannel guard misconfig
  switch(config)#show running-config
  
  !
  spanning-tree mode mstp
  !
  
  <-------OUTPUT OMITTED FROM EXAMPLE------->

  !
  end
  switch(config)#
  ```
spanning-tree portfast

The `spanning-tree portfast` command programs configuration mode ports to immediately enter forwarding state when they establish a link. PortFast ports are included in spanning tree topology calculations and can enter discarding state. This command overrides the `spanning-tree portfast auto` command.

The `no spanning-tree portfast` and `default spanning-tree portfast` commands remove the corresponding `spanning-tree portfast` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree portfast
no spanning-tree portfast
default spanning-tree portfast
```

**Example**

- This command unconditionally enables portfast on Ethernet 5.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast
switch(config-if-Et5)#
```
spanning-tree portfast auto

The `spanning-tree portfast auto` command enables auto-edge detection on the configuration mode interface. When auto-edge detection is enabled, the port is configured as an edge port if it does not receive a new BPDU before the current BPDU expires. Auto-edge detection is enabled by default. The `spanning-tree portfast` command, when configured, has priority over this command.

The `no spanning-tree portfast auto` command disables auto-edge port detection. This command is removed from `running-config` with the `spanning-tree portfast auto` and `default spanning-tree portfast auto` commands.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree portfast auto`
- `no spanning-tree portfast auto`
- `default spanning-tree portfast auto`

**Example**

- This command enables auto-edge detection on Ethernet interface 5.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree portfast auto
  switch(config-if-Et5)#
  ```
spanning-tree portfast bpdufilter default

The `spanning-tree portfast bpdufilter default` command configures the global BPDU filter setting as `enabled`. Ports not covered by a `spanning-tree bpdufilter` command use the global BPDU filter setting.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree portfast bpdufilter default
no spanning-tree portfast bpdufilter default
default spanning-tree portfast bpdufilter default
```

**Example**

- This command configures the BPDU filter global setting to `enabled`.

  ```
  switch(config)#spanning-tree portfast bpdufilter default
  switch(config)#
  ```
spanning-tree portfast bpduguard default

The `spanning-tree portfast bpduguard default` command sets the global BPDU guard setting as `enabled`. Ports not covered by a `spanning-tree bpduguard` command use the global BPDU guard setting.

**Command Mode**
Global Configuration

**Command Syntax**
- `spanning-tree portfast bpduguard default`
- `no spanning-tree portfast bpduguard default`
- `default spanning-tree portfast bpduguard default`

**Example**
- This command configures the global BPDU guard setting to `enabled`.
  ```
  switch(config)#spanning-tree portfast bpduguard default
  switch(config)#
  ```
spanning-tree portfast <port type>

The spanning-tree portfast <port-type> command specifies the STP port mode for the configuration mode interface. Default port mode is normal.

Port modes include:

- **Edge**: Edge ports connect to hosts and transition to the forwarding state when the link is established. An edge port that receives a BPDU becomes a normal port.
- **Network**: Network ports connect only to switches or bridges and support bridge assurance. Network ports that connect to hosts or other edge devices transition to the discarding state.
- **Normal**: Normal ports function as normal STP ports and can connect to any type of device.

The no spanning-tree portfast <port-type> and default spanning-tree portfast <port-type> commands restore the default port mode of normal by removing the corresponding spanning-tree portfast <port-type> command from running-config.

Command Mode

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

Command Syntax

```
spanning-tree portfast PORT_MODE
no spanning-tree portfast PORT_MODE
default spanning-tree portfast PORT_MODE
```

Parameters

- **PORT_MODE**: STP port mode. Options include:
  - edge
  - network
  - normal

  The normal option is not available for the no and default commands.

Related Commands

The spanning-tree portfast <port-type> command also affects the spanning-tree portfast auto and spanning-tree portfast configuration for the configuration mode interface:

- spanning-tree portfast normal: spanning-tree portfast auto is enabled.
- spanning-tree portfast edge: spanning-tree portfast is enabled.
- spanning-tree portfast network: spanning-tree portfast auto is disabled.

Example

- This command configures Ethernet 5 interface as a network port.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree portfast network
  switch(config-if-Et5)#
  ```
spanning-tree port-priority

The `spanning-tree port-priority` command specifies the configuration mode interface's port-priority number. The switch uses this number to determine which interface it places into forwarding mode when resolving a loop. Valid settings are all multiples of 16 between 0 and 240. Default value is 128. Ports with lower numerical priority values are selected over other ports.

The `no spanning-tree port-priority` and default spanning-tree port-priority commands restore the default of 128 for the configuration mode interface by removing the `spanning-tree port-priority` command from `running-config`.

The `spanning-tree port-priority` command provides a mode option:

- RST instance port-priority is configured by not including a mode.
- MST instance 0 port-priority is configured by not including a mode or with the `mst` mode option.
- MST instance port-priority is configured with the `mst` mode option.
- Rapid-PVST VLAN port-priority is configured with the `vlan` mode option.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

Command Syntax

```
spanning-tree [MODE] port-priority value
no spanning-tree [MODE] port-priority
default spanning-tree [MODE] port-priority
```

Parameters

- `MODE` specifies the spanning tree instances for which the cost is configured. Values include:
  - `<no parameter>` RST instance or MST instance 0.
  - `mst m_range` specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - `vlan v_range` specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
  - `value` bridge priority number. Values range from 0 to 240 and must be a multiple of 16.

Example

- This command sets the port priority of Ethernet 5 interface to 144.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree port-priority 144
switch(config-if-Et5)#
```
spanning-tree priority

The `spanning-tree priority` command configures the bridge priority number. The bridge priority is the four most significant digits of the bridge ID, which is used by spanning tree algorithms to select the root bridge and choose among redundant links. Bridge ID numbers range from 0 to 65535 (16 bits); bridges with smaller bridge IDs are elected over other bridges.

Because bridge priority sets the four most significant bits of the bridge ID, valid settings include all multiples of 4096 between 0 and 61440. Default value is 32768.

The `spanning-tree priority` command provides a mode option:
- RST instance priority is configured by not including a mode.
- MST instance 0 priority is configured by not including a mode or with the `mst` mode option.
- MST instance priority is configured with the `mst` mode option.
- Rapid-PVST VLAN priority is configured with the `vlan` mode option.

The `no spanning-tree priority` and `default spanning-tree priority` commands restore the bridge priority default of 32768 for the specified mode by removing the corresponding `spanning-tree priority` command from `running-config`.

Another method of adding `spanning-tree priority` commands to the configuration is through the `spanning-tree root` command. Similarly, the `no spanning-tree root` command removes the corresponding `spanning-tree priority` command from `running-config`.

**Command Mode**
- Global Configuration

**Command Syntax**
```
spanning-tree [MODE] priority level
no spanning-tree [MODE] priority
default spanning-tree [MODE] priority
```

**Parameters**
- **MODE** spanning tree instances for which the command configures priority. Options include:
  - `<no parameter>` RST instance or MST instance 0.
  - `mst m_range` specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - `vlan v_range` specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
- **level** priority number. Values include multiples of 4096 between 0 and 61440. Default is 32768.

**Examples**
- This command configures a bridge priority value of 20480 for Rapid-PVST VLANs 20, 24, 28, and 32.
  ```
  switch(config)#spanning-tree vlan 20,24,28,32 priority 20480
  switch(config)#
  ```
- This command configures a bridge priority value of 36864 for the RST instance. When MST is enabled, this command configures a priority of 36864 for MST instance 0.
  ```
  switch(config)#spanning-tree priority 36864
  switch(config)#
  ```
spanning-tree root

The `spanning-tree root` command configures the bridge priority number by adding a `spanning-tree priority` command to the configuration. Parameter settings set the following priority values:

- **primary** sets the bridge priority to 8192.
- **secondary** sets the bridge priority to 16384.

The bridge priority is the four most significant digits of the bridge ID, which is used by spanning tree algorithms to select the root bridge and choose among redundant links. Bridge ID numbers range from 0 to 65535 (16 bits); bridges with smaller bridge IDs are elected over other bridges.

When no other switch in the network is similarly configured, assigning the primary value to the switch facilitates its selection as the root switch. Assigning the secondary value to the switch facilitates its selection as the backup root in a network that contains one switch with a smaller priority number.

The `spanning-tree root` command provides a mode option:

- RST instance priority is configured by not including a mode.
- MST instance 0 priority is configured by not including a mode or with the `mst` mode option.
- MST instance priority is configured with the `mst` mode option.
- Rapid-PVST VLAN priority is configured with the `vlan` mode option.

The `no spanning-tree root` and `default spanning-tree root` commands restore the bridge priority default of 32768 by removing the corresponding `spanning-tree priority` command from `running-config`. The `no spanning-tree root`, `no spanning-tree priority`, `default spanning-tree root` and `default spanning-tree priority` commands perform the same function.

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree [MODE] root TYPE
no spanning-tree [MODE] root
default spanning-tree [MODE] root
```

**Parameters**

- **MODE** specifies the spanning tree instances for which priority is configured. Values include:
  - `<no parameter>` RST instance or MST instance 0.
  - `mst m_range` specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - `vlan v_range` specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
- **TYPE** sets the bridge priority number. Values include:
  - `primary` sets the bridge priority to 8192.
  - `secondary` sets the bridge priority to 16384.
Examples

- This command configures a bridge priority value of 8192 for Rapid-PVST VLANs 20-36.
  
  ```
  switch(config)#spanning-tree vlan 20-36 root primary
  ```

- This command configures a bridge priority value of 16384 for the RSTP instance and MST instance 0.

  ```
  switch(config)#spanning-tree root secondary
  ```
spanning-tree transmit hold-count

The `spanning-tree transmit hold-count` command specifies the maximum number of BPDUs per second that the switch can send from an interface. Valid settings range from 1 to 10 BPDUs with a default of 6 BPDUs.

The `no spanning-tree transmit hold-count` and `default spanning-tree transmit hold-count` commands restore the transmit hold count default of 6 BPDUs by removing the `spanning-tree transmit hold-count` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
spanning-tree transmit hold-count max_bpdu
no spanning-tree transmit hold-count
default spanning-tree transmit hold-count
```

Parameters
- `max_bpdu` BPDUs. Value ranges from 1 to 10. Default is 6.

Examples
- This command configures a transmit hold-count of 8 BPDUs.

```
switch(config)#spanning-tree transmit hold-count 8
switch(config)#
```
spanning-tree vlan

The `spanning-tree vlan` command enables Spanning Tree Protocol (STP) on specified VLANs by removing the corresponding `no spanning-tree vlan` statements from `running-config`. Spanning-tree is enabled on all VLANs by default.

The `no spanning-tree vlan` and `default spanning-tree` commands disable STP on the specified interfaces.

**Warning**
Disabling STP is not recommended, even in topologies free of physical loops; STP guards against configuration mistakes and cabling errors. When disabling STP, ensure that there are no physical loops in the VLAN.

**Important!**
When disabling STP on a VLAN, ensure that all switches and bridges in the network disable STP for the same VLAN. Disabling STP on a subset of switches and bridges in a VLAN may have unexpected results because switches and bridges running STP will have incomplete information regarding the network's physical topology.

The following STP global configuration commands provide a `vlan` option for configuring Rapid-PVST VLAN instances:

- `spanning-tree priority`
- `spanning-tree root`

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree vlan v_range
no spanning-tree vlan v_range
default spanning-tree vlan v_range
```

**Parameters**
- `v_range` VLAN list. Formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.

**Examples**

- This command disables STP on VLANs 200-205
  ```
  switch(config)#no spanning-tree vlan 200-205
  switch(config)#
  ```

- This command enables STP on VLAN 203
  ```
  switch(config)#spanning-tree vlan 203
  switch(config)#
  ```
**switchport backup interface**

The `switchport backup interface` command establishes a primary-backup configuration for forwarding VLAN traffic between the command mode interface and a specified interface. The `show interfaces switchport backup` command displays the state of backup interface pairs on the switch:

- the primary interface is the command mode interface.
- the backup interface is the interface specified in the command.

The following guidelines apply to primary and backup interfaces:

- Ethernet and Port Channels can be primary interfaces.
- Ethernet, Port Channel, Management, Loopback, and VLANs can be backup interfaces.
- The primary and backup interfaces can be different interface types.
- Interface pairs should be similarly configured to ensure consistent behavior.
- An interface can be associated with a maximum of one backup interface.
- An interface can back up a maximum of one interface.
- Any Ethernet interface configured in an interface pair cannot be a port channel member.
- The STP mode is backup.
- Static MAC addresses should be configured after primary-backup pairs are established.

When load balancing is not enabled, the primary and backup interfaces cannot simultaneously forward VLAN traffic. When the primary interface is forwarding VLAN traffic, the backup interface drops all traffic. If the primary interface fails, the backup interface forwards VLAN traffic until the primary interface is functional.

The `prefer vlan` option balances the load across the primary and backup interfaces. When the command includes the `prefer vlan` option, each interface is the primary for a subset of the vlans carried by the pair. When both interfaces are up, prefer option vlans are forwarded on the backup interface and all other configured vlans are carried by the primary interface.

The `no switchport backup interface` and `default switchport backup interface` commands remove the primary-backup configuration for the command mode interface.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port Channel Configuration

**Command Syntax**

```
switchport backup interface INT_NAME [BALANCE]
no switchport backup interface
default switchport backup interface
```

**Parameters**

- **INT_NAME** the backup interface. Options include:
  - ethernet `e_num` Ethernet interface specified by `e_num`.
  - loopback `l_num` Loopback interface specified by `l_num`.
  - management `m_num` Management interface specified by `m_num`.
  - port-channel `p_num` Channel group interface specified by `p_num`.
  - vlan `v_num` VLAN interface specified by `v_num`.
  - vxlan `vx_num` VXLAN interface specified by `vx_num`.
- **BALANCE** VLANs whose traffic is normally handled on the backup interfaces. Values include:
• <no parameter> backup interface handles no traffic if the primary interface is operating.
• prefer vlan v-range list of VLANs whose traffic is handled by backup interface.

Examples
• These commands establish Ethernet interface 7 as the backup port for Ethernet interface 1.
  
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#switchport backup interface ethernet 7
  switch(config-if-Et1)#
  
  These commands configure the following:
  • Ethernet interface 1 as a trunk port that handles VLAN 4 through 9 traffic.
  • Ethernet interface 2 as its backup interface.
  • Ethernet 2 as the preferred interface for VLANs 7 through 9.
  
  switch(config-if-Et1)#switchport mode trunk
  switch(config-if-Et1)#switchport trunk allowed vlan 4-9
  switch(config-if-Et1)#switchport backup Ethernet 2 prefer vlan 7-9
  switch(config-if-Et1)#
transmit-interval

The `transmit-interval` command sets the interval at which loop detection packets are transmitted. The `no transmit-interval` and `default transmit-interval` commands restore the transmission interval to the default of 5 seconds.

**Command Mode**

Loop-protection Configuration

**Command Syntax**

```plaintext
transmit-interval interval
```

**Parameters**

- `interval` Interval in seconds at which loop-detection packets are transmitted. Values range from 1 to 10; default is 5.

**Example**

- This command sets the loop detection packet transmission interval to 10 seconds.

```plaintext
switch(config-monitor-loop-protect)#transmit-interval 10
switch(config-monitor-loop-protect)#
```
This chapter describes Arista’s Quality of Service (QoS) implementation, including configuration instructions and command descriptions. Topics covered by this chapter include:

- Section 23.1: Quality of Service Conceptual Overview
- Section 23.2: QoS Configuration: Arad Platform Switches
- Section 23.3: QoS Configuration: Jericho Platform Switches
- Section 23.4: QoS Configuration: FM6000 Platform Switches
- Section 23.5: QoS Configuration: Petra Platform Switches
- Section 23.6: QoS Configuration: Trident Platform Switches
- Section 23.7: QoS Configuration: Trident-II and Helix Platform Switches
- Section 23.8: Quality of Service Configuration Commands

23.1 Quality of Service Conceptual Overview

QoS processes apply to traffic that flows through Ethernet ports and control planes. These processes can modify data fields (CoS or DSCP) or assign data streams to traffic classes for prioritized handling. Transmission queues are configurable for individual Ethernet ports to shape traffic based on its traffic class. Many switches also support traffic policies that apply to data that is filtered by access control lists.

The following sections describe QoS features:

- Section 23.1.1: QoS Data Fields and Traffic Classes
- Section 23.1.2: Transmit Queues and Port Shaping
- Section 23.1.3: Explicit Congestion Notification (ECN)

23.1.1 QoS Data Fields and Traffic Classes

Quality of Service defines a method of differentiating data streams to provide varying levels of service to the different streams. Criteria determining a packet’s priority level include packet field contents and the port where data packets are received. QoS settings are translated into traffic classes, which are then used by switches to manage all traffic flows. Traffic flow management varies with each switch platform.

23.1.1.1 QoS Data Fields

Quality of service decisions are based on the contents of the following packet fields:

- CoS (three bits): Class of service (CoS) is a 3-bit field in Ethernet frame headers using VLAN tagging. The field specifies a priority value between zero and seven. Class of service operates at layer 2.
• DSCP (six bits): Differentiated Service Code Point (DSCP) is a 6-bit field in the Type Of Service (TOS) field of IP packet headers.

23.1.1.2 Port Settings – Trust Mode and Traffic Class
Ethernet and port channel interfaces support three QoS trust modes:
• CoS Trust: Ports use inbound packet CoS field contents to derive the traffic class.
• DSCP Trust: Ports use inbound packets DSCP field contents to derive the traffic class.
• Untrusted: Ports use their default values to derive the traffic class, ignoring packet contents.
The default mode setting is CoS trust for switched ports and DSCP trust for routed ports.

Port Settings – Trust Mode and Traffic Class

23.1.1.2 Port Settings – Trust Mode and Traffic Class
Ethernet and port channel interfaces support three QoS trust modes:
• CoS Trust: Ports use inbound packet CoS field contents to derive the traffic class.
• DSCP Trust: Ports use inbound packets DSCP field contents to derive the traffic class.
• Untrusted: Ports use their default values to derive the traffic class, ignoring packet contents.
The default mode setting is CoS trust for switched ports and DSCP trust for routed ports.

23.1.1.3 Rewriting CoS and DSCP

CoS Rewrite
Switches can rewrite the CoS field for outbound tagged packets. The new CoS value is configurable, and is derived from a data stream’s traffic class as specified by the traffic class-to-CoS rewrite map. CoS rewrite is disabled on all the traffic received on CoS trusted ports.

On Arad, Jericho, FM6000, Trident, Trident-II, and Helix platform switches, CoS rewrite can be enabled or disabled on DSCP trusted ports and untrusted ports.
• CoS rewrite is globally enabled by default for packets received on untrusted ports and DSCP trusted ports if at least one port is explicitly configured in DSCP trust or untrusted mode.
• CoS rewrite is globally disabled by default for packets received on untrusted ports and DSCP trusted ports if there are no ports explicitly configured in DSCP trust or untrusted mode.

On Petra platform switches, CoS rewrite is always enabled on DSCP trusted ports and untrusted ports.

DSCP Rewrite
Switches can rewrite the DSCP field for outbound IP packets. On FM6000, Trident, Trident-II, and Helix platform switches, DSCP rewrite is disabled by default on all ports and always disabled for traffic received on DSCP trusted ports. On Petra, Arad, and Jericho platform switches, DSCP rewrite is always disabled.

FM6000, Trident, Trident-II, and Helix platform switches provide a command that enables or disables DSCP rewrite for packets received on CoS trusted ports and untrusted ports. The new DSCP value is configurable, based on the data stream’s traffic class, as specified by the traffic class-to-DSCP rewrite map.

These sections describe procedures for rewriting CoS and DSCP fields:
• Section 23.2.3: CoS Rewrite – Arad Platform Switches
• Section 23.4.3: CoS and DSCP Rewrite – FM6000 Platform Switches
23.1.1.4 Traffic Classes

Data stream distribution is based on their traffic classes. Data stream management varies by switch platform. Traffic classes are derived from these data stream, inbound port, and switch attributes:

- CoS field contents
- DSCP field contents
- Inbound port trust setting
- CoS default setting (Arad, Jericho, FM6000, Trident, Trident-II, and Helix platform switches)
- DSCP default setting (Arad, Jericho, FM6000, Trident, and Trident-II platform switches)
- Traffic class default setting (Petra platform switches)

When a port is configured to derive a data stream’s traffic class from the CoS or DSCP value associated with the stream, the traffic class is determined from a conversion map.

- A CoS-to-traffic class map derives a traffic class from a CoS value.
- A DSCP-to-traffic class map derives a traffic class from a DSCP value.

Map entries are configurable through CLI commands. Default maps determine the traffic class value when CLI map entry commands are not configured. Default maps vary by switch platform.

These sections describe traffic class configuration procedures:

- Section 23.2.2: Traffic Class Derivations – Arad Platform Switches
- Section 23.3.2: Traffic Class Derivations – Jericho Platform Switches
- Section 23.4.2: Traffic Class Derivations – FM6000 Platform Switches
- Section 23.5.2: Traffic Class Derivations – Petra Platform Switches
- Section 23.6.2: Traffic Class Derivations – Trident Platform Switches
- Section 23.7.2: Traffic Class Derivations – Trident-II and Helix Platform Switches

23.1.2 Transmit Queues and Port Shaping

Transmit queues are logical partitions of an Ethernet port’s egress bandwidth. Data streams are assigned to queues based on their traffic class, then sent as scheduled by port and transmit settings. Support varies by switch platform. A queue’s label determines its priority: queues with the suffix “0” have the lowest priority.

Parameters that determine transmission schedules include:

- Traffic class-to-transmit queue mapping determines the transmit queue for transmitting data streams based on traffic class. The set of available transmit maps vary by switch platforms:
  - Arad, Jericho, FM6000, Trident-II, and Helix platforms: one map for all unicast and multicast traffic.
  - Trident platform: one map for unicast traffic and one map for multicast traffic.
  - Petra platform: one map for unicast traffic. Queue shaping is not available for multicast traffic.

- Port shaping specifies a port’s maximum egress bandwidth.

- Queue shaping specifies a transmit queue’s maximum egress bandwidth, and implementation varies by platform.
• Trident platform: queue shaping is configurable separately for unicast and multicast queues.
• Trident-II platform: queue shaping is configurable for transmit queues. Port shaping and queue shaping are supported only in store-and-forward switching mode.
• Petra platform: queue shaping is not available for multicast traffic.
• Helix platform: queue shaping is configurable for transmit queues.
• FM6000 platform: switches do not support simultaneous port shaping and queue shaping. Enabling port shaping on an FM6000 switch disables queue shaping, regardless of the previous configuration.

**Guaranteed bandwidth** guarantees the allocation of a specified bandwidth for a transmit queue. Guaranteed bandwidth is supported only on Trident-II platforms.

**Queue priority** specifies the priority at which a transmit queue is serviced. The switch defines two queue priority types:

- **Strict priority** queues are serviced in the order of their priority rank - subject to each queue’s configured maximum bandwidth. Data is not handled for a queue until all queues with higher priority are emptied or their transmission limit is reached. These queues typically carry low latency real time traffic and require highest available priority.

- **Round robin** queues are serviced simultaneously subject to assigned bandwidth percentage and configured maximum bandwidth. All round robin queues have lower priority than strict priority queues. Round robin queues can be starved by strict priority queues.

• Queue scheduling determines how packets from different transmit queues are serviced to be sent out on the port.

**Queue bandwidth allocation** specifies the time slice (percentage) assigned to a round robin queue, relative to all other round robin queues.

These sections describe transmit queue and port shaping configuration procedures:

- Section 23.2.4: Transmit Queues and Port Shaping – Arad Platform Switches
- Section 23.3.4: Transmit Queues and Port Shaping – Jericho Platform Switches
- Section 23.4.4: Transmit Queues and Port Shaping – FM6000 Platform Switches
- Section 23.5.4: Transmit Queues and Port Shaping – Petra Platform Switches
- Section 23.6.4: Transmit Queues and Port Shaping – Trident Platform Switches
- Section 23.7.4: Transmit Queues and Port Shaping – Trident-II and Helix Platform Switches

### 23.1.3 Explicit Congestion Notification (ECN)

Explicit Congestion Notification (ECN) is an IP and TCP extension that facilitates end-to-end network congestion notification without dropping packets. ECN recognizes early congestion and sets flags that signal affected hosts. Trident, Trident II, and Helix platform switches extend ECN support to non-TCP packets.

ECN usage requires that it is supported and enabled by both endpoints. Although only unicast flows are modified by ECN markers, the multicast, broadcast, and unmarked unicast flows can affect network congestion and influence the indication of unicast packet congestion.

#### 23.1.3.1 ECN Conceptual Overview

The ECN field in the IP header (bits 6 and 7 in the IPv4 TOS or IPv6 traffic class octet) advertises ECN capabilities:

• 00: Router does not support ECN.
• 10: Router supports ECN.
• 01: Router supports ECN.
• 11: Congestion encountered.

Networks typically signal congestion by dropping packets. After an ECN-capable host negotiates ECN, it signals impending congestion by marking the IP header of packets encountering the congestion instead of dropping the packets. The recipient echoes the congestion indication back to the sender, which reduces its transmission rate as if it had detected a dropped packet.

Switches support ECN for unicast queues through Weighted Random Early Detection (WRED), an active queue management (AQM) algorithm that extends Random Early Detection (RED) to define multiple thresholds for an individual queue. WRED determines congestion by comparing average queue size with queue thresholds. Average queue size depends on the previous average and current queue size:

\[
\text{average queue size} = (\text{old_avg} \times (1 - 2^{-\text{weight}})) + (\text{current_queue_size} \times 2^{-\text{weight}})
\]

where weight is the exponential weight factor used for averaging the queue size.

Packets are marked based on WRED as follows:

• If average queue size is below the minimum threshold, packets are queued as in normal operation without ECN.
• If average queue size is greater than the maximum threshold, packets are marked for congestion.
• If average queue size is between minimum and maximum queue threshold, packets are either queued or marked. The proportion of packets that are marked increases linearly from 0% at the minimum threshold to 100% at the maximum threshold.

Treatment of packets marked as not ECN capable varies by platform.

These sections describe ECN configuration procedures:

• Section 23.2.5: ECN Configuration – Arad Platform Switches
• Section 23.6.5: ECN Configuration – Trident Platform Switches

### 23.1.4 ACL Policing

Access Control List (ACL) policing for ingress ACL support provides the ability to monitor the data rates for a particular class of traffic, and perform actions when that traffic exceeds user-configured values. This allows the user to control ingress bandwidth based on packet classification. Ingress policing is done by policing meters, which mark incoming traffic and perform actions based on the results.

ACL policing on Arista switches uses a single-rate, two-color marker system. The flow mode for single-rate two-color marker is as follows:

• One meter – one token bucket.
• Packet is marked green if there are enough tokens in the bucket to allow the packet, otherwise it is marked red.

ACL policing is supported on Trident, Trident-II, Trident+, FM6000, Arad, and Jericho platforms. Policing on LAG interfaces is not supported.

These sections describe ACL policing configuration procedures:

• Section 23.2.6: ACL Policing – Arad Platform Switches
• Section 23.3.5: ACL Policing – Jericho Platform Switches
23.2 QoS Configuration: Arad Platform Switches
Implementing QoS on an Arad platform switch consists of configuring port trust settings, default port settings, conversion maps, and transmit queues.

- Section 23.2.1: CoS and DSCP Port Settings – Arad Platform Switches
- Section 23.2.2: Traffic Class Derivations – Arad Platform Switches
- Section 23.2.3: CoS Rewrite – Arad Platform Switches
- Section 23.2.4: Transmit Queues and Port Shaping – Arad Platform Switches
- Section 23.2.5: ECN Configuration – Arad Platform Switches

Note QoS traffic policy is supported on Trident, Trident-II, FM6000, Arad, and Jericho.

23.2.1 CoS and DSCP Port Settings – Arad Platform Switches
Section 23.1.1.2 describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings
The `qos trust` command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is `CoS`. The port-trust default for routed ports is `DSCP`.

- `qos trust cos` specifies `CoS` as the port’s port-trust mode.
- `qos trust dscp` specifies `DSCP` as the port’s port-trust mode.
- `no qos trust` specifies `untrusted` as the port’s port-trust mode.

The `show qos interfaces trust` command displays the trust mode of specified interfaces.

Example
- These commands configure and display the following trust modes:
  - Ethernet 3/5/1: dscp
  - Ethernet 3/5/2: untrusted
  - Ethernet 3/5/3: cos
  - Ethernet 3/5/4: default as a switched port
• Ethernet 3/6/1: default as a routed port

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#qos trust dscp
switch(config-if-Et3/5/1)#interface ethernet 3/5/2
switch(config-if-Et3/5/2)#no qos trust
switch(config-if-Et3/5/2)#interface ethernet 3/5/3
switch(config-if-Et3/5/3)#qos trust cos
switch(config-if-Et3/5/3)#interface ethernet 3/5/4
switch(config-if-Et3/5/4)#switchport
switch(config-if-Et3/5/4)#default qos trust
switch(config-if-Et3/5/4)#interface ethernet 3/6/1
switch(config-if-Et3/5/4)#no switchport
switch(config-if-Et3/5/4)#default qos trust
switch(config-if-Et3/5/4)#show qos interface ethernet 3/5/1 - 3/6/1 trust
```

<table>

```

### Configuring Default Port Settings

Default CoS and DSCP values are assigned to each Ethernet and port channel interface. These commands specify the configuration mode interface commands specify the port’s default CoS and DSCP values.

- `qos cos` configures a port's default CoS value.
- `qos dscp` configures a port's default DSCP value.

### Example

These commands configure default CoS (4) and DSCP (44) values on Ethernet interface 3/6/2.

```
switch(config)#interface ethernet 3/6/2
switch(config-if-Et3/6/2)#qos cos 4
switch(config-if-Et3/6/2)#qos dscp 44
switch(config-if-Et3/6/2)#show active
```

```
interface Ethernet3/6/2:
  qos cos 4
  qos dscp 44
```

```
switch(config-if-Et3/6/2)#show qos interfaces ethernet 3/6/2
```

```
Ethernet3/6/2:
  Trust Mode: COS
  Default COS: 4
  Default DSCP: 44
```

```
<--------OUTPUT OMITTED FROM EXAMPLE-------->
```

```
switch(config-if-Et3/6/2)#
```

23.2.2 Traffic Class Derivations – Arad Platform Switches

Section 23.1.1.4 describes traffic classes.
Traffic Class Derivation Source

Table 23-1 displays the source for deriving a data stream’s traffic class.

Section 23.2.1 describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The `qos map cos` command assigns a traffic class to a list of CoS values. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet’s CoS field or the chip upon which it is received.

**Example**
- This command assigns the traffic class of 5 to the classes of service 1, 3, 5, and 7.

```
switch(config)# qos map cos 1 3 5 7 to traffic-class 5
switch(config)# show qos maps
    Number of Traffic Classes supported: 8
    <--------OUTPUT OMITTED FROM EXAMPLE--------->
    Cos-tc map:
        cos:  0  1  2  3  4  5  6  7
        tc:   1  5  2  5  4  5  6  5
    <--------OUTPUT OMITTED FROM EXAMPLE--------->
```

Table 23-2 displays the default CoS to Traffic Class map on Arad platform switches.

Mapping DSCP to Traffic Class

The `qos map dscp` command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet’s DSCP field or the chip upon which it is received.
Example

- This command assigns the traffic class of 0 to DSCP values of 12, 24, 41, and 44-47.

  `switch(config)#qos map dscp 12 24 41 44 45 46 47 to traffic-class 0`

  `switch(config)#show qos maps`

  Number of Traffic Classes supported: 8

  <--------OUTPUT OMITTED FROM EXAMPLE-------->

23.2.3 CoS Rewrite – Arad Platform Switches

Section 23.1.1.3 describes the CoS rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream’s traffic class, as specified by the traffic class-CoS rewrite map. The `qos map traffic-class to cos` command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

- This command assigns the CoS of two to traffic classes 1, 3, and 5.

  `switch(config)#qos map traffic-class 1 3 5 to cos 2`

  `switch(config)#show qos maps`

  Number of Traffic Classes supported: 8

  <--------OUTPUT OMITTED FROM EXAMPLE-------->

  Tc-cos map:

  tc: 0 1 2 3 4 5 6 7
  --------------------------
  cos: 1 2 2 2 4 2 6 7

  <--------OUTPUT OMITTED FROM EXAMPLE-------->

  switch(config)#

</tbody>
</table>

Traffic Class to DSCP Rewrite Map

DSCP rewrite is always disabled on Arad platform switches.

23.2.4 Transmit Queues and Port Shaping – Arad Platform Switches

Section 23.1.2 describes transmit queues and port shaping.

Arad platform switches provide 16 physical queues for each egress port: eight unicast and eight multicast queues. Data is scheduled to the physical queues based on transmit queue assignments.

Multicast queue capacity that remains after multicast traffic is serviced is available for unicast traffic of a corresponding priority. Similarly, unicast queue capacity that remains after unicast traffic is serviced is available for overflow multicast traffic. Under conditions of unicast and multicast congestion, egress traffic is evenly split between unicast and multicast traffic.

A data stream’s traffic class determines the transmit queue it uses. The switch defines a single traffic class–transmit queue map for unicast and multicast traffic on all Ethernet and port channel interfaces. The `show qos maps` command displays the traffic class–transmit queue map.

Table 23-5 displays the default traffic class to transmit queue map on Arad platform switches.

<table>
<thead>
<tr>
<th>Traffic Class</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmit Queue</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

Transmit queue parameters are configured in `tx-queue configuration command mode`, which is entered from interface-ethernet configuration mode.

Mapping Traffic Classes to a Transmit Queue

The `qos map traffic-class to tx-queue` command assigns traffic classes to a transmit queue. Multiple commands complete the traffic class-transmit queue map. Traffic class 7 and transmit queue 7 are always mapped to each other. This association is not editable.
Example

- These commands assign traffic classes of 1, 3, and 5 to transmit queue 1, traffic classes 2, 4, and 6 to transmit queue 2, and traffic class 0 to transmit queue 0, then display the resultant map.

  switch(config)#qos map traffic-class 1 3 5 to tx-queue 1
  switch(config)#qos map traffic-class 2 4 6 to tx-queue 2
  switch(config)#qos map traffic-class 0 to tx-queue 0
  switch(config)#show qos maps
  Number of Traffic Classes supported: 8
  Number of Transmit Queues supported: 8
  <--------OUTPUT OMITTED FROM EXAMPLE-------->

  Tc - tx-queue map:
  tc:           0 1 2 3 4 5 6 7
  ---------------------------
  tx-queue: 0 1 2 1 2 1 2 7

  switch(config)#

Entering Tx-Queue Configuration Mode

The tx-queue (Arad/Jericho) command places the switch in tx-queue configuration mode to configure a transmit queue on the configuration mode interface. Tx-queue 7 is not configurable. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

- This command enters Tx-queue configuration mode for transmit queue 4 of Ethernet interface 3/3/3.

  switch(config)#interface ethernet 3/3/3
  switch(config-if-Et3/3/3)#tx-queue 4
  switch(config-if-Et3/3/3-txq-4)#

Configuring the Shape Rate – Port and Transmit Queues

A port’s shape rate specifies its maximum outbound traffic bandwidth. A transmit queue’s shape rate specifies the queue’s maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

- To configure a port’s shape rate, enter shape rate (Interface – Arad/Jericho) from the port’s interface configuration mode.

- To configure a transmit queue’s shape rate, enter shape rate (Tx-queue – Arad/Jericho) from the queue’s tx-queue configuration mode.
Examples

- This command configures a port shape rate of 5 Gbps on Ethernet interface 3/5/1.

  ```
  switch(config)#interface ethernet 3/5/1
  switch(config-if-Et3/5/1)#shape rate 5000000
  switch(config-if-Et3/5/1)#show qos interfaces ethernet 3/5/1
  Ethernet3/5/1:
  Port shaping rate: 5000012 / 5000000 kbps
  ```

- These commands configure a shape rate of 1 Gbps on transmit queues 3 and 4 of Ethernet interface 3/4/1.

  ```
  switch(config)#interface ethernet 3/4/1
  switch(config-if-Et3/4/1)#tx-queue 4
  switch(config-if-Et3/4/1-txq-4)#shape rate 1000000 kbps
  switch(config-if-Et3/4/1-txq-4)#tx-queue 3
  switch(config-if-Et3/4/1-txq-3)#shape rate 1000000 kbps
  switch(config-if-Et3/4/1-txq-3)#show qos interface ethernet 3/4/1
  Ethernet3/4/1:
  Port shaping rate: disabled
  ```

Configuring Queue Priority

The **priority** (**Arad/Jericho**) command configures a transmit queue’s priority type:

- The **priority strict** command configures the queue as a strict priority queue.
- The **no priority** command configures the queue as a round robin queue.

A queue’s configuration as **round robin** also applies to all lower priority queues regardless of other configuration statements.

The **bandwidth percent** (**Arad/Jericho**) command configures a round robin queue’s bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port’s operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.
Example

- These commands configure queues 0 through 3 (Ethernet interface 3/5/1) as round robin, then allocate bandwidth for three queues at 30% and one queue at 10%.

The no priority statement for queue 3 also configures queues 0, 1, and 2 as round robin queues. Removing this statement reverts the other queues to strict priority type unless running-config contains a no priority statement for one of these queues.

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#tx-queue 3
switch(config-if-Et3/5/1-txq-3)#no priority
switch(config-if-Et3/5/1-txq-3)#bandwidth percent 10
switch(config-if-Et3/5/1-txq-3)#tx-queue 2
switch(config-if-Et3/5/1-txq-2)#bandwidth percent 30
switch(config-if-Et3/5/1-txq-2)#tx-queue 1
switch(config-if-Et3/5/1-txq-1)#bandwidth percent 30
switch(config-if-Et3/5/1-txq-1)#tx-queue 0
switch(config-if-Et3/5/1-txq-0)#bandwidth percent 30
switch(config-if-Et3/5/1-txq-0)#show qos interfaces ethernet 3/5/1
```

```
switch(config-if-Et3/5/1-txq-3)#
```

### 23.2.5 ECN Configuration – Arad Platform Switches

Section 23.1.3 describes Explicit Congestion Notification (ECN).

ECN is independently configurable on all egress queues of each Ethernet interface. ECN settings for Port-Channels are applied on each of the channel’s member Ethernet interfaces. Average queue length is tracked for transmit queues. When it reaches maximum threshold, all subsequent packets are marked.

Although the switch does not limit the number of queues that can be configured for ECN, hardware table limitations restrict the number of queues that can simultaneously implement ECN.

The **random-detect ecn** (Arad/Jericho) command enables ECN marking for the configuration mode unicast transmit queue and specifies threshold queue sizes.

**Example**

- These commands enable ECN marking of unicast packets from unicast transmit queue 4 of Ethernet interface 3/5/1, setting thresholds at 128 kbytes and 1280 kbytes.

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#tx-queue 4
switch(config-if-Et3/5/1-txq-4)#random-detect ecn minimum-threshold 128 kbytes maximum-threshold 1280 kbyte
switch(config-if-Et3/5/1-txq-4)#show active
interface Ethernet3/5/1
    tx-queue 4
        random-detect ecn minimum-threshold 128 kbytes maximum-threshold 1280 kbytes
switch(config-if-Et3/5/1-txq-4)#
```

### 23.2.6 ACL Policing – Arad Platform Switches

Section 23.1.4 describes ACL policing.
Implementing ACL policing consists of configuring the following:

- policy-map settings
- class-name
- committed information rate (CIR) the data speed committed to any given circuit regardless of the number of users
- burst size the maximum burst size in bytes the network commits to moving under normal conditions

The default unit for the metering rate CIR is bits per second; the default unit for the burst size is bytes.

The policer is applied to the class inside the policy map. Policy maps can contain one or more policy map classes, each with different match criteria and policer.

Default behavior and available policing actions are as follows:

- Policy map can be applied on multiple interfaces. Interfaces on the same chip will share the policer. (Applicable for Arad only.)
- If there is no policer configured within a class, all traffic is transmitted without any policing.
- If there are any actions configured, the configured actions are applied:
  - Conform-action (green): transmit (default)
  - Violate-action (red): drop (default)

**Example**

These commands configure ACL policing in single-rate, two-color mode.

```
switch(config)#class-map type qos match-any class1
switch(config-cmap-class1)#match ip access-group acl1
switch(config-cmap-class1)#exit
switch(config)#policy-map type qos policy1
switch(config-policy1)#class class1
switch(config-policy1-class1)#police cir 512000 bc 96000
switch(config-policy1-class1)#exit
switch(config-policy1)#exit
switch(config)#show policy-map
Service-policy policy1

Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes

Class-map: class-default (match-any)
```

switch(config)#
Displaying ACL Policing Information

Example

This command shows the interface specific police counters.

```
switch(config)#show policy-map interface Ethernet 1 input counters
Service-policy input: policy1
Hardware programming status: Successful

Class-map: class1 (match-any) Match: ip access-group name acl1
Police cir 512000 bps bc 96000 bytes Conformed 4351 packets, 1857386 bytes
Conformed 2536 packets, 3384260 bytes

Class-map: class-default (match-any) matched packets: 0
```

Example

This command configures ACL policing.

```
switch(config)#show policy-map [type qos] p1 input counters
Service-policy input: p1 Class-map: c1 (match-any)
Match: ip access-group name a1
Police cir 512000 bps bc 96000 bytes Interface: Ethernet1
Conformed 4351 packets, 1857386 bytes
Exceeded 2536 packets, 3384260 bytes
Interface: Ethernet2
Conformed 2351 packets, 957386 bytes
Exceeded 1536 packets, 1384260 bytes
Class-map: class-default (match-any)
Matched packets: 3229
```

Example

This command configures ACL policing.

```
switch(config)#show policy-map interface Ethernet 1 input [type qos]
Interface: Ethernet 1 Service-policy input: policy1
Hardware programming status: Successful Class-map: class1 (match-any)
Match: ip access-group name acl1
Police cir 512000 bps bc 9000 bytes
Class-map: class2 (match-any)
Match: ip access-group name acl2 set dscp 2
Class-map: class3 (match-any) Match: ip access-group name acl3
Police cir 1280000 bps bc 9000 bytes
Class-map: class-default (match-any)
```

switch(config)#
23.3  QoS Configuration: Jericho Platform Switches
Implementing QoS on a Jericho platform switch consists of configuring port trust settings, default port settings, default traffic classes, conversion maps, and transmit queues.

- Section 23.2.1: CoS and DSCP Port Settings – Arad Platform Switches
- Section 23.2.2: Traffic Class Derivations – Arad Platform Switches
- Section 23.2.3: CoS Rewrite – Arad Platform Switches
- Section 23.2.4: Transmit Queues and Port Shaping – Arad Platform Switches
- Section 23.2.5: ECN Configuration – Arad Platform Switches

Note  QoS traffic policy is supported on Trident, Trident-II, FM6000, Arad, and Jericho.

23.3.1 CoS and DSCP Port Settings – Jericho Platform Switches
Section 23.1.1.2 describes port trust and default port CoS and DSCP values.

Configuring Port Trust Settings
The `qos trust` command configures the QoS port trust mode for the configuration mode interface. Trust enabled ports use packet CoS or DSCP values to classify traffic. The port-trust default for switched ports is `CoS`. The port-trust default for routed ports is `DSCP`.

- `qos trust cos` specifies `CoS` as the port’s port-trust mode.
- `qos trust dscp` specifies `DSCP` as the port’s port-trust mode.
- `no qos trust` specifies `untrusted` as the port’s port-trust mode.

The `show qos interfaces trust` command displays the trust mode of specified interfaces.

Example
- These commands configure and display the following trust modes:
  - Ethernet 3/5/1: dscp
  - Ethernet 3/5/2: untrusted
  - Ethernet 3/5/3: cos
  - Ethernet 3/5/4: default as a switched port
- Ethernet 3/6/1: default as a routed port

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#qos trust dscp
switch(config-if-Et3/5/1)#interface ethernet 3/5/2
switch(config-if-Et3/5/2)#no qos trust
switch(config-if-Et3/5/2)#interface ethernet 3/5/3
switch(config-if-Et3/5/3)#qos trust cos
switch(config-if-Et3/5/3)#interface ethernet 3/5/4
switch(config-if-Et3/5/4)#switchport
switch(config-if-Et3/5/4)#default qos trust
switch(config-if-Et3/5/4)#interface ethernet 3/6/1
switch(config-if-Et3/6/1)#no switchport
switch(config-if-Et3/6/1)#default qos trust
switch(config-if-Et3/6/1)#show qos interface ethernet 3/5/1 - 3/6/1 trust
```

<table>

</table>

```
switch(config-if-Et3/6/1)#
```

**Configuring Default Port Settings**

Default CoS and DSCP values are assigned to each Ethernet and port channel interface. These commands specify the configuration mode interface commands specify the port’s default CoS and DSCP values.

- `qos cos` configures a port's default CoS value.
- `qos dscp` configures a port's default DSCP value.

**Example**

These commands configure default CoS (4) and DSCP (44) values on Ethernet interface 3/6/2.

```
switch(config)#interface ethernet 3/6/2
switch(config-if-Et3/6/2)#qos cos 4
switch(config-if-Et3/6/2)#qos dscp 44
switch(config-if-Et3/6/2)#show active interface Ethernet3/6/2

qos cos 4
t-default dscp 44

switch(config-if-Et3/6/2)#show qos interfaces ethernet 3/6/2
```

```
Ethernet3/6/2:
  Trust Mode: COS
  Default COS: 4
  Default DSCP: 44

<-------OUTPUT OMITTED FROM EXAMPLE--------->
```

```
switch(config-if-Et3/6/2)#
```

**23.3.2 Traffic Class Derivations – Jericho Platform Switches**

Section 23.1.1.4 describes traffic classes.
Traffic Class Derivation Source

Table 23-1 displays the source for deriving a data stream’s traffic class.

Table 23-6 Traffic Class Derivation Source: Jericho Platform Switches

<table>
<thead>

<td>CoS (packet)</td>
<td>DSCP (packet)</td>
</tr>
</tbody>
</table>

Section 23.2.1 describes the default CoS and DSCP settings for each port.

Mapping CoS to Traffic Class

The `qos map cos` command assigns a traffic class to a list of CoS values. Multiple commands create a complete CoS to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet’s CoS field or the chip upon which it is received.

Example

- This command assigns the traffic class of 5 to the classes of service 1, 3, 5, and 7.

  switch(config)#qos map cos 1 3 5 7 to traffic-class 5
  switch(config)#show qos maps
  Number of Traffic Classes supported: 8
  <------OUTPUT OMITTED FROM EXAMPLE------>
  Cos-tc map:
  cos: 0 1 2 3 4 5 6 7
  tc: 1 5 2 5 4 5 6 5

Mapping DSCP to Traffic Class

The `qos map dscp` command assigns a traffic class to a set of DSCP values. Multiple commands create a complete DSCP to traffic class map. The switch uses this map to assign a traffic class to data packets on the basis of the packet’s DSCP field or the chip upon which it is received.
Example

- This command assigns the traffic class of 0 to DSCP values of 12, 24, 41, and 44-47.

  switch(config)# qos map dscp 12 24 41 44 45 46 47 to traffic-class 0
  switch(config)# show qos maps

23.3.3 CoS Rewrite – Jericho Platform Switches

Section 23.1.1.3 describes the CoS rewrite functions.

Traffic Class to CoS Rewrite Map

The CoS rewrite value is configurable and based on a data stream’s traffic class, as specified by the traffic class-CoS rewrite map. The qos map traffic-class to cos command assigns a CoS rewrite value to a list of traffic classes. Multiple commands create the complete traffic class–CoS rewrite map.

Example

- This command assigns the CoS of two to traffic classes 1, 3, and 5.

  switch(config)# qos map traffic-class 1 3 5 to cos 2
  switch(config)# show qos map
  Number of Traffic Classes supported: 8
  <-------OUTPUT OMITTED FROM EXAMPLE-------->

  Tc-cos map:
  tc: 0 1 2 3 4 5 6 7
  ------------------------
  cos: 1 2 2 2 4 2 6 7

  <-------OUTPUT OMITTED FROM EXAMPLE-------->

  switch(config)#
Table 23-4 displays the default Traffic Class to CoS rewrite value map on Jericho platform switches.

Table 23-4 Default Traffic Class to CoS Rewrite Value Map: Jericho Platform Switches

<table>
<thead>
<tr>
<th>Traffic Class</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoS Rewrite Value</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

Traffic Class to DSCP Rewrite Map

DSCP rewrite is always disabled on Jericho platform switches.

23.3.4 Transmit Queues and Port Shaping – Jericho Platform Switches

Section 23.1.2 describes transmit queues and port shaping.

Jericho platform switches provide 16 physical queues for each egress port: eight unicast and eight multicast queues. Data is scheduled to the physical queues based on transmit queue assignments.

Multicast queue capacity that remains after multicast traffic is serviced is available for unicast traffic of a corresponding priority. Similarly, unicast queue capacity that remains after unicast traffic is serviced is available for overflow multicast traffic. Under conditions of unicast and multicast congestion, egress traffic is evenly split between unicast and multicast traffic.

A data stream’s traffic class determines the transmit queue it uses. The switch defines a single traffic class–transmit queue map for unicast and multicast traffic on all Ethernet and port channel interfaces. The `show qos maps` command displays the traffic class–transmit queue map.

Table 23-5 displays the default traffic class to transmit queue map on Jericho platform switches.

Table 23-5 Default Traffic Class to Transmit Queue Map: Jericho Platform Switches

<table>
<thead>
<tr>
<th>Traffic Class</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmit Queue</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

Transmit queue parameters are configured in `tx-queue` configuration command mode, which is entered from interface-ethernet configuration mode.

Mapping Traffic Classes to a Transmit Queue

The `qos map traffic-class to tx-queue` command assigns traffic classes to a transmit queue. Multiple commands complete the traffic class-transmit queue map. Traffic class 7 and transmit queue 7 are always mapped to each other. This association is not editable.
Example

- These commands assign traffic classes of 1, 3, and 5 to transmit queue 1, traffic classes 2, 4, and 6 to transmit queue 2, and traffic class 0 to transmit queue 0, then display the resultant map.

  switch(config)#qos map traffic-class 1 3 5 to tx-queue 1
  switch(config)#qos map traffic-class 2 4 6 to tx-queue 2
  switch(config)#qos map traffic-class 0 to tx-queue 0
  switch(config)#show qos maps
  Number of Traffic Classes supported: 8
  Number of Transmit Queues supported: 8

  Tc - tx-queue map:
  tc:  0  1  2  3  4  5  6  7
  ---------------------------------
  tx-queue:  0  1  2  1  2  1  2  7

  switch(config)#

Entering Tx-Queue Configuration Mode

The tx-queue (Arad/Jericho) command places the switch in tx-queue configuration mode to configure a transmit queue on the configuration mode interface. Tx-queue 7 is not configurable. The show qos interfaces displays the transmit queue configuration for a specified port.

Example

- This command enters Tx-queue configuration mode for transmit queue 4 of Ethernet interface 3/3/3.

  switch(config)#interface ethernet 3/3/3
  switch(config-if-Et3/3/3)#tx-queue 4
  switch(config-if-Et3/3/3-txq-4)#

Configuring the Shape Rate – Port and Transmit Queues

A port’s shape rate specifies its maximum outbound traffic bandwidth. A transmit queue’s shape rate specifies the queue’s maximum outbound bandwidth. Shape rate commands specify data rates in kbps.

- To configure a port’s shape rate, enter shape rate (Interface – Arad/Jericho) from the port’s interface configuration mode.
- To configure a transmit queue’s shape rate, enter shape rate (Tx-queue – Arad/Jericho) from the queue’s tx-queue configuration mode.
Examples

- This command configures a port shape rate of 5 Gbps on Ethernet interface 3/5/1.

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#shape rate 5000000
switch(config-if-Et3/5/1)#show qos interfaces ethernet 3/5/1
```

--- OUTPUT OMITTED FROM EXAMPLE ---

```
Port shaping rate: 5000012 / 5000000 kbps

<table>
<thead>
<tr>

<th>ECN</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>- / -</td>
<td>- / -</td>
<td>SP / SP</td>
<td>D</td>
</tr>
</tbody>
</table>
```

switch(config-if-Et3/5/1)#

- These commands configure a shape rate of 1 Gbps on transmit queues 3 and 4 of Ethernet interface 3/4/1.

```
switch(config)#interface ethernet 3/4/1
switch(config-if-Et3/4/1)#tx-queue 4
switch(config-if-Et3/4/1-txq-4)#shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-4)#tx-queue 3
switch(config-if-Et3/4/1-txq-3)#shape rate 1000000 kbps
switch(config-if-Et3/4/1-txq-3)#show qos interface ethernet 3/4/1
```

--- OUTPUT OMITTED FROM EXAMPLE ---

```
Port shaping rate: disabled

</tbody>
</table>
```

switch(config-if-Et3/4/1-txq-3)#

Configuring Queue Priority

The `priority (Arad/Jericho)` command configures a transmit queue’s priority type:

- The `priority strict` command configures the queue as a strict priority queue.
- The `no priority` command configures the queue as a round robin queue.

A queue’s configuration as round robin also applies to all lower priority queues regardless of other configuration statements.

The `bandwidth percent (Arad/Jericho)` command configures a round robin queue’s bandwidth share. The cumulative operational bandwidth of all round robin queues is always less than or equal to 100%. If the cumulative configured bandwidth is greater than 100%, each port’s operational bandwidth is its configured bandwidth divided by the cumulative configured bandwidth.
Example

- These commands configure queues 0 through 3 (Ethernet interface 3/5/1) as round robin, then allocate bandwidth for three queues at 30% and one queue at 10%.

The **no priority** statement for queue 3 also configures queues 0, 1, and 2 as round robin queues. Removing this statement reverts the other queues to **strict priority** type unless **running-config** contains a **no priority** statement for one of these queues.

```
switch(config)#interface ethernet 3/5/1
switch(config-if-Et3/5/1)#tx-queue 3
switch(config-if-Et3/5/1-txq-3)#no priority
switch(config-if-Et3/5/1-txq-3)#bandwidth percent 10
switch(config-if-Et3/5/1-txq-3)#tx-queue 2
switch(config-if-Et3/5/1-txq-2)#bandwidth percent 30
switch(config-if-Et3/5/1-txq-2)#tx-queue 1
switch(config-if-Et3/5/1-txq-1)#bandwidth percent 30
switch(config-if-Et3/5/1-txq-1)#tx-queue 0
