- Assigning a MAC Address to an Interface
- MAC Address Table

### 11.4.2 Routing

Routing transmits network layer packets over connected independent subnets. Each subnet is assigned an IP address range and each device on the subnet is assigned an IP address from that range. Connected subnets have IP address ranges that do not overlap. A router connects multiple subnets. Routers forward inbound packets to the subnet whose address range includes the packets' destination address.

IPv4 and IPv6 are internet layer protocols that facilitate packet-switched networking, including transmissions across multiple networks.

These chapters describe available IP features:

- **IPv4**
11.4.2.2.1 Static Routing

Static routes are entered through the CLI and are typically used when dynamic protocols are unable to establish routes to a specified destination prefix. Static routes are also useful when dynamic routing protocols are not available or appropriate.

Creating a static route associates a destination IP address with a local interface. The routing table refers to these routes as *connected* routes that are available for redistribution into routing domains defined by dynamic routing protocols.

These sections describe static route configuration commands:

- IPv4 Address Configuration
- Configuring Default and Static IPv6 Routes

11.4.2.2 Dynamic Routing

Dynamic routes are established by dynamic routing protocols. These protocols also maintain the routing table and modify routes to adjust for topology or traffic changes. Routing protocols assist the switch in communicating with other devices to exchange network information, maintaining routing tables, and establishing data paths.

The switch supports these dynamic routing protocols:

- Open Shortest Path First – Version 2
- Open Shortest Path First – Version 3
- Border Gateway Protocol (BGP)
- Routing Information Protocol
- IS-IS

11.4.2.3 Layer 3 Switching

Layer 3 switches establish data paths through routing processes (Layer 3) and transfer data as a switch (Layer 2) through speed-optimized hardware. Layer 3 switches use a control plane (routing) and data plane (switching) to manage these processes.

11.4.2.3.1 Control plane

The control plane builds and maintains the IP routing table, which identifies IP packet routes in terms of destination addresses. The routing table defines a route by its next hop address and the egress interface that accesses the next hop.

The control plane derives routing information from three sources:

- Status of physical and virtual interfaces on the switch.
- Static routes entered through the CLI.
- Routes established through dynamic routing protocols.

**Applying an ACL to the Control Plane**

The control plane supports routing and management functions, handling packets that are addressed to the switch without regard to any switch interface.

To apply an IP ACL to the control plane, enter `ip access-group (Control Plane mode)` in control-plane mode. The `system control-plane` command places the switch in control-plane mode.

ACLs and Route Maps describes access control lists.
Example

These commands place the switch in control-plane mode and assigns **CP-Test1** to the control plane.

```
switch(config)#system control-plane
switch(config-system-cp)#ip access-group CP-Test1 in
switch(config-system-cp)#
```

11.4.2.3.2 Data plane

The data plane routes IP packets based on information derived by the control plane. Each packet’s path includes Layer 2 addresses that reach its next hop destination. The data plane also performs other operations required by IP routing, such as recalculating IP header checksums and decrementing the Time-To-Live (TTL) field.

Arista data planes support these packet forwarding modes:

- **Store and forward**: the switch accumulates entire packets before forwarding them.
- **Cut through**: the switch begins forwarding frames before their reception is complete.

Cut through mode reduces switch latency at the risk of decreased reliability. Packet transmissions can begin immediately after the destination address is processed. Corrupted frames may be forwarded because packet transmissions begin before CRC bytes are received.

Packet forwarding mode availability varies by switch platform:

- **Arad**: store and forward mode only.
- **FM6000**: both modes are available.
- **Petra**: store and forward mode only.
- **Trident**: both modes are available.
- **Trident II**: both modes are available.

The data plane is also referred to as the forwarding plane.

Data Plane Forwarding Mode Configuration

The **switch forwarding-mode** command specifies the forwarding mode of the switch’s data plane. This command is available on Trident, Trident II, and FM6000 platform switches. The forwarding mode is **store-and-forward** on Arad and Petra platform switches.

Examples

- This command changes the forwarding mode to **store-and-forward**.

  ```
  switch(config)#switch forwarding-mode store-and-forward
  switch(config)#
  ```

- The **show switch forwarding-mode** command displays the switch’s forwarding mode.

  ```
  switch(config)#show switch forwarding-mode
  Current switching mode:    store and forward
  Available switching modes: cut through, store and forward
  ```

11.4.3 MAC Address Table

The switch maintains a MAC address table for switching frames efficiently between ports. The MAC address table contains static and dynamic MAC addresses.

- Static MAC addresses are entered into the table through a CLI command.
• Dynamic MAC addresses are entered into the table when the switch receives a frame whose source address is not listed in the MAC address table. The switch builds the table dynamically by referencing the source address of frames it receives.

11.4.3.1 MAC Address Table Configuration

These sections describe MAC address table configuration tasks.

• Static MAC Address Table Entries
• Dynamic MAC Address Table Entries

11.4.3.1.1 Static MAC Address Table Entries

The MAC address table accepts static MAC addresses, including multicast entries. Each table entry references a MAC address, a VLAN, and a list of Layer 2 (Ethernet or port channel) ports. The table supports three entry types: unicast drop, unicast, and multicast.

• A drop entry does not include a port.
• A unicast entry includes one port.
• A multicast entry includes at least one port.

Packets with a MAC address (source or destination) and VLAN specified by a drop entry are dropped. Drop entries are valid for only unicast MAC addresses.

The `mac address-table static` command adds a static entry to the MAC address table.

Examples

• This command adds a static entry for unicast MAC address 0012.3694.03ec to the MAC address table.

```
switch(config)#mac address-table static 0012.3694.03ec vlan 3 interface Ethernet 7
```

```
switch(config)#show mac address-table static
Mac Address Table
------------------------------------------------------------------
Vlan    Mac Address       Type        Ports      Moves   Last Move
----    -----------       ----        -----      -----   ---------
3    0012.3694.03ec    STATIC      Et7
Total Mac Addresses for this criterion: 1
```

• This command adds the static entry for the multicast MAC address 0112.3057.8423 to the MAC address table.

```
switch(config)#mac address-table static 0112.3057.8423 vlan 4 interface port-channel 10 port-channel 12
```

```
switch(config)#show mac address-table
Mac Address Table
------------------------------------------------------------------
Vlan    Mac Address       Type        Ports
----    -----------       ----        ----- 
Total Mac Addresses for this criterion: 0
```
11.4.3.1.2 Dynamic MAC Address Table Entries

**Learning Mode**

The switch maintains a MAC address table for switching frames efficiently between VLAN ports. When the switch receives a frame, it associates the MAC address of the transmitting interface with the recipient VLAN and port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is not enabled, the entry is not added to the table.

The `switchport mac address learning` command enables MAC address learning for the configuration mode interface. MAC address learning is enabled by default on all Ethernet and port channel interfaces.

**Example**

These commands disables MAC address learning for `interface Ethernet 8`, then displays the active configuration for the interface.

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#no switchport mac address learning
switch(config-if-Et8)#show active
interface Ethernet8
no switchport mac address learning
switch(config-if-Et8)#
```

**Aging Time**

Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.

Aging time ranges from **10** to **1000000** seconds with a default of **300** seconds (five minutes).

**Example**

This command sets the MAC address table aging time to two minutes (**120** seconds).

```
switch(config)#mac address-table aging-time 120
switch(config)#
```

The `mac address-table aging-time` command configures the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.
Mac Moves
Secure MAC addresses is allowed to move when they appear on another interface, when configured. By default, secure MAC addresses does not move.

```
switch(config)# default switchport port-security mac address moveable
```

Persistent Port Security
When the persistent PortSec-Protect is enabled, secure MAC addresses persist across device reboots and interface flaps. These MAC addresses can still be aged or moved when configured using the commands `mac address-table aging-time` and `default switchport port-security mac address moveable`. Persistent port security is enabled by default, and can be disabled.

```
switch(config)# default switchport port-security persistence disabled
```

Example

`show port-security` command displays the settings for the new global port security configurations, including MAC aging, MAC moves, and persistent port security.

```
switch(config)#show port-security
Secure address moves: disabled
Secure address aging: disabled
Secure address reboot persistence: enabled
Secure address link down persistence: enabled
Secure Port MaxSecureAddr CurrentAddr SecurityViolation Security Action  
(Count) (Count) (Count)                                                   
-------------------------------------------------------------------------------- 
----- 
-------------------------------------------------------------------------------- 
-----
Total Addresses in System: 0
```

Clearing Dynamic Addresses
The `clear mac address-table dynamic` command removes specified dynamic entries from the MAC address table. Entries are identified by their VLAN and Layer 2 (Ethernet or port channel) interface.

Example
This command clears all dynamic mac address table entries for `port channel 5` on `VLAN 34`.

```
switch(config)#clear mac address-table dynamic vlan 34 interface port-channel 5
```

11.4.3.2 Displaying the MAC Address Table
The `show mac address-table` command displays the specified MAC address table entries.

Example
This command displays the MAC address table.

```
switch#show mac address-table
```
### Mac Address Table

</tr>
</tbody>
</table>

Total Mac Addresses for this criterion: 1
```

### 11.4.3.3 MAC Address Learning Per-VLAN

MAC address learning per-VLAN enables or disables MAC address learning per-VLAN instead of per-port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is disabled, the entry is not added to the table.

```
11.4.3.3.1 MAC Address Learning Configuration

The mac address learning command enables MAC address learning on a VLAN interface. By default, MAC address learning on a VLAN is enabled.

The switch maintains a MAC address table for switching frames between VLAN ports. When the switch receives a frame, it associates the MAC address of the transmitting interface with the recipient VLAN and port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is not enabled, the entry is not added to the table.

To disable MAC learning on a particular VLAN, use no mac address learning command on a VLAN configuration.

Examples

- These commands enable MAC address learning on VLAN 10 configuration.

  switch(config)#vlan 10
• These commands disable MAC address learning on VLAN 10 configuration.

11.4.4 Configuring Ports

This section describes these port properties:

• Port Mirroring
• Storm Control
• Switched and Routed Ports
• Loopback Ports
• MAC Security
• Null0 Interface
• Maximum Transmission Units (MTU)

11.4.4.1 Port Mirroring

Port mirroring, also known as port monitoring, is the duplication of traffic from a collection of source ports to a destination port. A mirror session correlates a set of source ports to a destination port.

Valid mirror sources are Ethernet or port channel interfaces, including port channels which are part of an MLAG. Mirror destination ports are usually Ethernet interfaces; port channel destination ports are also supported on some platforms.

Note: On platforms which support the use of port channels as mirror destinations, a port channel must not be used as a mirror destination if it is a member of an MLAG.

Layer 2 control protocols do not run on destination ports. An interface cannot be in more than one mirror session and cannot simultaneously be a source and destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from only one direction.

• Ingress Mirroring: Packets received by a source port are duplicated, including all valid data frames and L2 control PDUs. Ports mirror data before forwarding logic is applied. Packets subsequently dropped because of forwarding decisions are mirrored.

• Egress Mirroring: Packets transmitted by a source port are duplicated, with these exceptions:
  • Flooded/Multicast Packets: Packets sent to multiple mirror ports generate one copy, except in multi-chip devices when the mirror source and destination ports are on different chips; in this case, an extra copy is generated.
  • Dropped Packets: Packets dropped by forwarding decisions (such as output STP state checks) on egress sources are not duplicated. Packets dropped because of congestion may be duplicated.

• Filtered Mirroring: Specific packets are selected for mirroring based on PERMIT and DENY configurations.

• Mirroring to GRE Tunnel: Mirrored packets are encapsulated with GRE protocols for transiting Layer 3 network.

VLAN tags on duplicate packets from an egress source are identical to tags on inbound source packets.

When a packet’s path through the switch includes multiple mirror source ports in different mirror sessions, the traffic is duplicated once and sent to the destination of the highest numbered session.
11.4.1.1 Port Mirroring Capacity

Port mirroring capacity varies by platform. This section describes session limits for each platform.

**FM6000 Platform Switches**
- **Maximum Number of Sessions**: 4.
- **Session Sources**: Ethernet interfaces (any number), Port channel interfaces (any number).
- **Session Destinations**: Ethernet interfaces (any number), Port channel interfaces (any number), CPU.
- Egress IP ACL on destination port is not supported.

Sessions can mirror Rx, Tx, or both ways without impacting the number of available sessions.

Enabling each of the following features reduces the number of available sessions by one: ACL Logging, MLAG Peer Link, sFlow, VTEP Learning (VXLAN), LANZ Sampling

**Arad Platform Switches**
- **Maximum Number of Sessions**: 14.
- **Session Sources**: Ethernet interfaces (any number), Port channel interfaces (any number).
- **Session Destinations**: Ethernet interfaces (one).
- Egress IP ACL on destination port is not supported.

Sessions can mirror Rx, Tx, or both ways without impacting number of available sessions.

Although the number of configured source interfaces is unlimited, the number of interfaces that can be effectively mirrored is restricted by the destination port speed.

**Petra Platform Switches**
- **Maximum Number of Sessions**: 16.
- **Session Sources**: Ethernet interfaces (eight for Rx or Tx sessions; four for both ways).
- **Session Destinations**: Ethernet interfaces (eight for Rx or Tx sessions; four for both ways).
- Egress IP ACL on destination port is not supported.

Sessions can mirror Rx, Tx, or both ways without impacting number of available sessions.

**Trident Platform Switches**
- **Maximum Number of Sessions**: 4.
- **Session Sources**: Ethernet interfaces (any number), Port channel interfaces (any number).
- **Session Destinations**: Ethernet interfaces (one).
- Egress IP ACL on destination port is supported.

Mirroring Rx or Tx requires one session. Mirroring both ways requires two sessions.

**Trident II Platform Switches**
- **Maximum Number of Sessions**: 4.
- **Session Sources**: Ethernet interfaces (any number), Port channel interfaces (any number).
- **Session Destinations**: Ethernet interfaces (one).
- Egress IP ACL on Destination Port is supported.

Mirroring Rx or Tx requires one session. Mirroring both ways requires two sessions.
11.4.1.2 Configuring Mirror Ports

Mirror sessions associate a set of source ports to a destination port using the monitor session source and monitor session destination commands. An interface cannot be used in more than one mirror session and cannot be simultaneously a source and a destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from one direction. On Trident and Trident II platform switches (DCS-7050, DCS-7050X, DCS-7250X, and DCS-7300X series), all frames mirrored on egress are prefixed with an 802.1Q VLAN tag, even when the egress port is configured as an access port. If the capture device cannot process VLAN tags properly, mirroring should be configured exclusively for ingress traffic by specifying rx in the monitor session source command.

Filtering on TX traffic in a mirror session is not supported.

Example

These commands configure Ethernet interface 7 as the source port and Ethernet interface 8 as the destination port for the redirect_1 mirroring session. The session mirrors ingress and egress traffic.

```
switch(config)#monitor session redirect_1 source ethernet 7
switch(config)#monitor session redirect_1 destination ethernet 8
```

The show monitor session command displays the configuration of the specified port mirroring session.

Example

This command shows the configuration of the redirect_1 mirroring session.

```
switch(config)#show monitor session
Session redirect_1
------------------------
Source Ports
  Both:        Et7
Destination Port: Et8
switch(config)#
```

The monitor session ip access-group command configures an ACL to filter the traffic being mirrored to the destination port.

Example

These commands create an ACL and apply it to filter the traffic mirrored to the destination port by session redirect_1.

```
switch(config)#ip access-list allow-host
switch(config-acl-allow-host)#10 permit ip host 192.168.11.24 host 10.0.215.23
switch(config-acl-allow-host)#20 deny ip any any
switch(config-acl-allow-host)#exit
switch(config)#monitor session redirect_1 ip access-group allow-host
switch(config)#
```
11.4.4.1.3 Configuring Filtered Mirroring

Filtered mirroring allows for configuring IPv4, IPv6, and MAC access lists and then updating a monitor session with corresponding configuration changes. EOS mirrors the packets that match permit statements. EOS does not select those packets for mirroring that match deny statements.

Note: EOS supports all standard IPv4, IPv6, and MAC qualifiers.

On Strata series platforms, packets from a single monitor source can be mirrored in multiple sessions that use the same access-list. You can attach multiple monitor sources with various access-lists to a monitor session. Each monitor session should contain one access-list type only. Hence, IPv4, IPv6, and MAC access-lists from the same monitor source must appear in different monitor sessions.

When multiple IPv6 monitor sessions share the same monitor source, only one of the monitor sessions remains active and others are automatically inactivated. When the active monitor session is removed from the monitor source, the system automatically activates the inactive monitor sessions.

Packets matching both IP and MAC access lists behave differently on various platforms.

<table>
<thead>
<tr>
<th>Platform Series</th>
<th>Behavior of Filtered Mirroring</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCS-7050/7050X, DCS-7250X, and DCS-7300X</td>
<td>When entry packets match both IPv4 and MAC access-lists, mirrored copies are created for both IPv4 and MAC access-lists; and forwarded to configured destinations.</td>
</tr>
</tbody>
</table>
| DCS-7280SE and DCS-7500E         | When entry packets match both IPv4 and MAC access-lists, a mirrored copy is created only for IPv4 access-list. The behavior of filtered mirroring varies in the following ways when a packet matches an entry in both access-list types:  
  • Mirroring is permitted when a packet contradicts with permit and deny configurations.  
  • Mirroring is denied when an entry packet matches deny configurations in both.  
  • IP access-list is prioritized over MAC access-list when an entry packet matches permit configurations in both. |

Note: User-Defined Field (UDF) qualifiers in filtered mirroring access-lists allow matching packets using arbitrary user-defined patterns.

Use the system profile command to enable the Mirroring ACL profile that supports matching on IPv6, MAC and UDFs.

The following table provides the matching types supported in default and Mirroring ACL profiles.

<table>
<thead>
<tr>
<th>Profiles</th>
<th>IPv4</th>
<th>IPv6</th>
<th>MAC</th>
<th>UDF</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Mirroring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Note: MAC mirroring-ACLs do not accept routed IPv4/IPv6 packets and bridged IPv6 packets.

Examples

• These commands create an IPv4 access-list and then attach the access-list to monitor sessions.

```bash
switch(config)#ip access-list acl1
switch(config-acl-acl1)#10 permit tcp any any rst
switch(config-acl-acl1)#20 permit tcp any any syn
```
switch(config-acl-acl1)#30 permit tcp any any ack

switch(config)#monitor session 1 source Ethernet1 rx ip access-group acl1
switch(config)#monitor session 1 source Ethernet2 rx ip access-group acl1
switch(config)#monitor session 1 destination <destination>

- These commands create an IPv6 access-list and then attach the access-list to monitor sessions.

Arista(config)#ipv6 access-list acl2
Arista(config-ipv6-acl-acl2)#10 permit ipv6 any any
Arista(config)#monitor session 2 source Ethernet4 rx ipv6 access-group acl2
Arista(config)#monitor session 2 destination Ethernet5

- These commands configure the same monitor source in multiple monitor sessions.

switch(config)#monitor session 1 source Ethernet1 rx ip access-group acl1
switch(config)#monitor session 1 destination <destination 1>
switch(config)#monitor session 2 source Ethernet1 rx ip access-group acl2
switch(config)#monitor session 2 destination <destination 2>

- This command configures access-list priorities for dictating the matching order across multiple access-lists that are attached to the same monitor source.

switch(config)#monitor session 1 source Ethernet1 rx ip access-group acl1
priority 1
switch(config)#monitor session 1 destination <destination 1>
switch(config)#monitor session 2 source Ethernet1 rx ip access-group acl2
priority 2
switch(config)#monitor session 2 destination <destination 2>

- This command enables the Mirroring ACL profile.

switch(config)#hardware tcam
switch(config-hw-tcam)#system profile mirroring-acl
switch(config-hw-tcam)#show hardware tcam profile

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>FixedSystem</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>mirroring-acl</td>
<td>mirroring-acl</td>
</tr>
</tbody>
</table>

```
switch(config-hw-tcam)#
```

### 11.4.1.4 Filtered Mirroring to CPU

Filtered mirroring to CPU adds a special destination to port mirroring that allows mirrored traffic to be sent to the switch supervisor. The traffic can then be monitored and analyzed locally without the need of a remote port analyzer. Filtered mirroring to CPU can also be used for debugging and troubleshooting configured to mirror RX traffic, TX traffic or both, with up to 14 mirroring profiles used simultaneously. In addition, mirroring to CPU uses control plane protection to limit the rate of the traffic sent to the CPU.
Examples

- These commands configure the source for normal mirroring and the destination to CPU.

```
switch(config)#monitor session mySession source ethernet 3/1 both
switch(config)#monitor session mySession destination cpu
switch(config)#
```

- These commands configure reserved bandwidth and shape rate of mirrored traffic.

```
switch(config)#policy-map type copp copp-system-policy
class copp-system-mirroring
switch(config-pmap-control-plane-copp-system-policy)#bandwidth kbps 2000
switch(config-pmap-c-copp-system-policy-copp-system-mirroring)#shape kbps 4000
```

- These commands show the current status of mirroring to CPU from the CLI, and display the control plane protection configuration for mirroring to CPU.

```
switch(config)#show monitor session
    Session mySession
    ------------------------
    Source Ports:
    Both : Et3/1
    Destination Ports:
    Cpu : active (mirror0)
switch(config)#
```

- These commands show the current status of mirroring to CPU from the CLI, and display the control plane protection configuration for mirroring to CPU.

```
switch(config)#show policy-map type copp copp-system-policy class copp-system-mirroring
    Class-map: copp-system-mirroring (match-any)
        shape : None
        bandwidth : None
switch(config)#
```

11.4.4.1.5 Configuring Filtered Mirroring to GRE Tunnel

The `monitor session source` and `monitor session destination` commands configure source and destination ports to the specified port mirroring session in a GRE tunnel.

On DCS-7010T, DCS-7050/7050X, DCS-7060X, DCS-7250X, DCS-7260X, DCS-7300X, a special GRE tunnel destination is supported to mirror ingress packets that are dropped during ASIC forwarding. This GRE destination is referred as the “forwarding-drop” destination, and the corresponding session is called as the “forwarding-drop” session.
**Note:** Forwarding-drop sessions are the sessions corresponding to forwarding-drop destinations.

**Note:** From Release **EOS 4.25.2F** onwards platforms DCS-7050X, DCS-7060X, DCS-7250X, DCS-7260X, CCS-720X started supporting the **tx** keyword, which specifies that outgoing packets should be mirrored.

### Examples

- These commands configure ingress filtered mirroring to a GRE tunnel.

  ```
  switch(config)#monitor session abc source Ethernet1 rx ip access-group acl1
  switch(config)#monitor session abc destination tunnel mode gre source 1.1.1.1 destination 2.2.2.2 ttl 128 dscp 0 protocol 0x88be
  ```

- These commands configure egress filtered mirroring to a GRE tunnel.

  ```
  switch(config)#monitor session abc source Ethernet1 tx ip access-group acl1
  switch(config)#monitor session abc destination tunnel mode gre source 2.2.2.2 destination 2.2.2.2 ttl 128 dscp 0 protocol 0x88be
  ```

- This command configures forwarding-drop sessions.

  ```
  switch(config)#monitor session 1 forwarding-drop destination tunnel mode gre source 1.1.1.1 destination 2.2.2.2
  ```

- A forwarding-drop session is configured by using the **forwarding-drop** keyword when configuring the GRE destination:

  ```
  switch(config)#monitor session 1 source <source>
  switch(config)#monitor session 1 forwarding-drop destination tunnel mode gre
  ```

- A mirroring to GRE destination can be configured as follows:

  ```
  switch(config)#monitor session 1 source <source> rx | tx
  switch(config)#monitor session 1 destination tunnel mode gre
  ```

The **rx** keyword specifies that incoming packets should be mirrored.

#### 11.4.4.1.6 Security ACL Filtered Mirroring

Security ACL Filtered Mirroring is configured using port security ACLs.
Configuring Security ACL Filtered Mirroring

The following configures Ethernet interface 8 as the destination port for the redirect_1 mirroring session, and Ethernet interface 9 as the destination port for the redirect_2 mirroring session. A source port is not needed to create a mirror session. Other destination options for monitor sessions such as GRE or CPU are also configurable.

```
switch (config)#monitor session redirect_1 destination ethernet 8
switch (config)#monitor session redirect_2 destination ethernet 9
```

Examples

Egress IPv4 ACL

The following commands create an IPv4 access-list, and then attach the access-list to Ethernet interface 7 in the out direction with the following rules.

- matching Rule 10 will be mirrored to Ethernet interface 8.
- matching Rule 20 will not be mirrored.
- matching Rule 30 will be mirrored to Ethernet interface 9.
- matching Rule 40 will be dropped and not mirrored.

Specifying a mirror session in a deny rule for egress ACL has no effect.

```
switch(config)#ip access-list acl1
switch(config-acl-acl1)#10 permit ip host 10.0.0.4 any mirror session redirect_1
switch(config-acl-acl1)#20 permit ip host 10.0.0.5 any
switch(config-acl-acl1)#30 permit ip host 10.0.0.6 any mirror session redirect_2
switch(config-acl-acl1)#40 deny ip any any

switch(config)#interface ethernet 7
switch(config-if-Et7)#ip access-group acl1 out
```

Note: Security ACL Filtered Mirroring has higher priority over standard Port Mirroring.

Using the same configuration as above with Ethernet interface 7 as the source port of redirect_1, the following configuration displays the impact on packets egressing from Ethernet interface 7.

```
switch(config)#monitor session redirect_1 source ethernet 7
```

- matching Rule 10 and Rule 20 will be mirrored to Ethernet interface 8.
- matching Rule 30 will be mirrored to Ethernet interface 9.
- matching Rule 40 will be dropped and not mirrored.

Egress IPv6 ACL

The following commands create an IPv6 access-list, and then attach the access-list to interface ethernet 7 in the egress direction.

```
switch(config)#ipv6 access-list acl1
switch(config-ipv6-acl-acl1)#10 permit ipv6 host 10:0:0:10:10:10:10:10:1 any mirror session redirect1
switch(config-ipv6-acl-acl1)#20 permit ipv6 host 10:0:0:10:10:10:10:10:5 any
switch(config-ipv6-acl-acl1)#30 permit ipv6 host 10:0:0:10:10:10:10:10:6 any mirror session redirect2
switch(config-ipv6-acl-acl1)#40 deny ipv6 any any

switch(config)#interface ethernet 7
```
switch(config-if-Et7)#ipv6 access-group acl1 out

Note: The mirroring behavior of egress IPv6 ACL is identical to egress IPv4 ACL. The egress IPv6 ACL is supported only on R3 Series and forward.

Egress MAC ACL

The following commands create a MAC access-list, and then attach the access-list to Ethernet interface 7 in the out direction. The mirroring behavior of egress MAC ACL is identical to egress IPv4 ACL.

```
switch(config)#mac access-list acl1
switch(config-mac-acl-acl1)#10 permit 0000.1111.4444 0000.0000.0000 any
        mirror session redirect_1
switch(config-mac-acl-acl1)#20 permit 0000.1111.5555 0000.0000.0000 any
        mirror session redirect_2
switch(config-mac-acl-acl1)#30 permit 0000.1111.6666 0000.0000.0000 any
        mirror session redirect_2
switch(config-mac-acl-acl1)#40 deny any any

switch(config)#interface ethernet 7
switch(config-if-Et7)#mac access-group acl1 out
```

Ingress IPv4 ACL

The following commands create an IPv4 access-list, and then attach the access-list to Ethernet interface 7 in the in direction with the following rules.

- matching Rule 10 and Rule 20 will be mirrored to Ethernet interface 8.
- matching Rule 30 will be mirrored to Ethernet interface 9 since Security ACL Filtered Mirroring has higher priority.
- matching Rule 40 will be dropped and mirrored to Ethernet interface 8.

```
switch(config)#ip access-list acl2
switch(config-acl-acl2)#10 permit ip host 10.0.0.4 any mirror session redirect_1
switch(config-acl-acl2)#20 permit ip host 10.0.0.5 any
switch(config-acl-acl2)#30 permit ip host 10.0.0.6 any mirror session redirect_2
switch(config-acl-acl2)#40 deny ip host 10.0.0.7 any mirror session redirect_1

switch(config)#interface ethernet 7
switch(config-if-Et7)#ip access-group acl2 in

switch(config)#monitor session redirect_1 source ethernet 7
```

Note: Unlike egress ACL, mirror session specified in a deny rule for ingress ACL will take effect.

The mirroring behavior of ingress IPv6 and MAC ACLs are identical to ingress IPv4 ACL.

Limitations

- The feature is not supported in AlgoMatch mode.
- Egress Security ACL Filtered Mirroring works on IPv4 - permit rules, and MAC - permit rules.
- By default, egress MAC ACL is disabled. Egress MAC ACL is required to be enabled.
- By default, bridged traffic is not subject to Egress IP ACLs, therefore, the bridged packets will not be mirrored.
- RACL and subinterface ACL are not supported for filtering mirroring.
• If a packet is dropped by an ingress ACL and the destination is GRE, the metadata of the GRE packet cannot be computed as expected.

11.4.4.2 Storm Control

A traffic storm is a flood of packets entering a network, resulting in excessive traffic and degraded performance. Storm control prevents network disruptions by limiting traffic beyond specified thresholds on individual physical LAN interfaces.

Storm control monitors inbound traffic levels over one-second intervals and compares the traffic level with a specified benchmark.

Storm control has three modes:

• **Storm control all**: When inbound traffic exceeds the specified threshold within a one-second control interval, all traffic is dropped until the end of the interval.
• **Storm control broadcast**: When inbound broadcast traffic exceeds the specified threshold within a one-second control interval, broadcast traffic is dropped until the end of the interval.
• **Storm control multicast**: When inbound multicast traffic exceeds the specified threshold within a one-second control interval, multicast traffic is dropped until the end of the interval.

Broadcast and multicast storm control are independent features and can be enabled simultaneously. The **storm control all** threshold overrides broadcast and multicast thresholds.

Storm Control Configuration

The `storm-control` command configures and enables broadcast or multicast storm control on the configuration mode interface. The command provides three mode options:

• **storm-control all** unicast, multicast, and broadcast inbound packet control.
• **storm-control broadcast** broadcast inbound packet control.
• **storm-control multicast** multicast inbound packet control.

An interface configuration can contain three storm-control statements, one with each mode setting. The **storm-control all** threshold overrides broadcast and multicast thresholds.

When storm control is enabled, the switch monitors inbound traffic levels over one second intervals and compares the traffic level with a specified threshold. The threshold is a percentage of the total available port bandwidth and is configurable on each interface for each transmission mode.

Examples

• These commands enable multicast storm control on Ethernet interfaces 2 through 4 and set a threshold of 65%. During each one second interval, the interface drops inbound multicast traffic in excess of 65% of capacity.

```
switch(config)#interface ethernet 2 / 3 / 4
switch(config-if-Et4/4/4)#storm-control multicast level 65
```

• These commands clear multicast storm control on Ethernet interfaces 2 through 4.

```
switch(config)#interface ethernet 2 / 3 / 4
switch(config-if-Et2/3/4)#no storm-control multicast
```

• These commands enable broadcast storm control on Ethernet interfaces 2 through 4 and set broadcast traffic to 50%. During each one second interval, the interface drops inbound multicast traffic in excess of 50% of capacity.

```
switch(config)#interface ethernet 2 / 3 / 4
```
• These commands enable broadcast storm control on Ethernet interfaces 2 through 4 and set a threshold of 5000 packets per second (pps).

Note: User cannot configure a PPS setting and a percentage setting on the same interface at the same time, they are mutually exclusive.

• These commands clear broadcast storm control on Ethernet interfaces 2 through 4.

The `show storm-control` command displays the storm-control level and interface inbound packet capacity for the specified interface.

Examples

• This command displays the storm control configuration for Ethernet ports 2 through 4.

```
switch(config-if-Et2/3/4)#show storm-control
```

<table>

11.4.4.3 Switched and Routed Ports

A switched port is an Ethernet or port channel interface that is configured as a Layer 2 interface. Switched ports bridge frames and are assigned to at least one VLAN. Switched ports are not associated with any IP addresses. By default, Ethernet and port channel interfaces are in switched port mode.

A routed port is an Ethernet or port channel interface that is configured as a Layer 3 interface. Routed ports do not bridge frames and are not members of any VLANs. Routed ports can have IP addresses assigned to them and packets are routed directly to and from the port.

Configuring an interface as a routed port is similar to creating a VLAN with spanning-tree disabled, making the port the only member of that VLAN and configuring the IP address on the switch virtual interface (SVI) associated with the VLAN.

All IP-level interface configuration commands, except `autostate` and `ip virtual-router`, can be used to configure a routed interface. If the interface is reverted to switched port mode, `running-config` maintains IP level interface configuration statements. These changes become active again if the interface is configured back to routed port mode.
A LAG that is created with the `channel-group` command inherits the mode of the member port. A LAG created from a routed port becomes a routed LAG. IP-level configuration is not propagated to the LAG from its component members.

The broadcast queue towards the CPU is shared among all interfaces of the forwarding chip. Broadcast storm on a single port adversely impacts other interfaces of the same chip by potentially dropping even low rate broadcast frames. Routed port storm control attempts to mitigate this effect by performing storm control on the broadcast frames for routed ports.

**Routed Port Configuration**

The switching-routing configuration of Ethernet and port channel interfaces is specified by the `switchport` and `no switchport` commands. These commands only toggle the interface between switched and routed modes. They have no effect on other configuration states.

The `no switchport` command places the configuration mode interface in routed port mode. Routed ports behave as Layer 3 interfaces. They do not bridge packets and are not VLAN members. An IP address can be assigned to a routed port for the direct routing of packets to and from the interface.

When an interface is configured as a routed port, the switch transparently allocates an internal VLAN whose only member is the routed interface. Internal VLANs are created in the range from 1006 to 4094. VLANs that are allocated internally for a routed interface cannot be directly created or configured. *Allocating Internal VLANs* describes VLAN allocation configuration procedures.

**Example**

This command places *Ethernet interface 5* in routed port mode.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
```

**Switched Port Configuration**

The `switchport` command places the configuration mode interface in switched port (Layer 2) mode. Switched ports are configurable as members of one or more VLANs through other `switchport` commands. Switched ports ignore all IP level configuration commands, including IP address assignments. By default, Ethernet and port channel interfaces are switched ports.

**Example**

This command places *Ethernet interface 5* in switched port mode.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport
```

The `switchport default mode routed` command places the configuration mode interface for a switch with all ports in switched port (Layer 3) routed mode, changing the switch with all ports from `switchport default mode access`.

**Examples**

- This command places a switch with all ports in routed mode.

  ```bash
  switch(config)#switchport default mode routed
  ```

- This command places a switch with all ports in access mode.

  ```bash
  switch(config)#switchport default mode access
  ```
11.4.4  Loopback Ports

A loopback interface is a virtual network interface implemented in software and does not connect to any hardware. Traffic sent to the loopback interface is immediately received on the sending interface. The switch provides loopback configuration mode for creating loopback interfaces and modifying their operating parameters.

Internet protocols reserve specific addresses for loopback network segments:

- IPv4 designates 127/8 as loopback subnet, which includes 127.0.0.0 through 127.255.255.255.
- IPv6 designates ::/128 as the loopback address, which includes 0:0:0:0:0:0:0:1 (also written as ::1).

Arista switches support the configuration of 1001 loopback interfaces, numbered from 0 to 1000.

Loopback Interface Configuration

Loopback ports are instantiated by entering loopback interface mode for the desired port number. Loopback interface mode also provides access to loopback configuration commands. Previously instantiated ports are edited by entering loopback interface mode for the specified port.

The `interface loopback` command places the switch in interface-loopback configuration mode for the specified interfaces, creating loopback interfaces for each specified port not previously created.

Example

These commands instantiate loopback interface 2 and assigns it IP address 10.1.1.42/24.

```
switch(config)#interface loopback 2
switch(config-if-Lo2)#ip address 10.1.1.42
switch(config-if-Lo2)#show active
interface Loopback2
  ip address 10.1.1.42/24
switch(config-if-Lo2)#
```

11.4.5  MAC Security

MAC security restricts input to a switched port by limiting the number of MAC addresses that can access the port. Ports with MAC security enabled restrict traffic to a limited number of hosts, as determined by their MAC addresses. When the limit is exceeded, the port becomes errdisabled.

Port Security Configuration

MAC address security is enabled by `switchport port-security`. The default MAC address limit on an interface where port security is enabled is one; to change that default limit, use the `switchport port-security mac-address maximum` command.

Example

These commands enable MAC security on Ethernet interface 7, set the maximum number of assigned MAC addresses to 2, assign two static MAC addresses to the interface, and clear the dynamic MAC addresses for the interface.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#switchport port-security
switch(config-if-Et7)#switchport port-security mac-address maximum 2
switch(config-if-Et7)#exit
switch(config)#mac address-table static 0034.24c2.8f11 vlan 10 interface ethernet 7
switch(config)#mac address-table static 4464.842d.17ce vlan 10 interface ethernet 7
switch(config)#clear mac address-table dynamic interface ethernet 7
```
MAC Security LLDP Bypass

When MAC address security configuration is applied on the interface, it encrypts and decrypts all the other protocols PDU and other data packets. LLDP bypass allows LLDP packets to be sent or received from the port even when the port is not authorized.

The following configuration allows LLDP packets to be received or sent from an interface where the MAC security profile is applied.

```
switch(config)#mac security
switch(config-mac-security)#profile test
switch(config-mac-security-profile-test)#l2-protocol lldp bypass unauthorized
```

`unauthorized` allows the LLDP packet to be received and sent out when MKA session between the MACsec peers is yet to come up.

Show Command

The following command shows LLDP packets is bypassed for encryption or decryption.

```
switch(config)#show mac security interface ethernet 4/4/1 detail
Interface: Ethernet4/4/1
Profile: profile1
SCI: d4:af:f7:2e:67:b0::786
SSCI: 00000002
Controlled port: True
Key server priority: 1
Session rekey period: 30
Traffic: Protected
Bypassed protocols: LLDP
Key in use: c0645d4332ba2e1d4d5fb17f:129
Latest key: None
Old key: c0645d4332ba2e1d4d5fb17f:129(RT)
```

11.4.4.6 Null0 Interface

The null0 interface is a virtual interface that drops all inbound packets. A null0 route is a network route whose destination is null0 interface. Inbound packets to a null0 interface are not forwarded to any valid address. Many interface configuration commands provide null0 as an interface option.

11.4.4.7 Maximum Transmission Units (MTU)

The MTU of a communications protocol refers to the size in bytes of the largest frame (Ethernet) or packet (IP) that can be sent on the network.
Different protocols support a variety of MTU sizes. Most IP over Ethernet implementations use the Ethernet V2 frame format, which specifies an MTU of 1500 bytes. Jumbo frames are Ethernet frames containing more than 1500 bytes.

11.4.4.7.1 Switching interface MTU size

On Arista devices, layer two interfaces (either trunk or access ports) are set with a default ethernet MTU of 9236 bytes. This value cannot be changed and is derived as follows: 9214 + 6 (source MAC) + 6 (dst MAC) + 4 (VLAN tag) + 2 (ether type) + 4 (crc) totals 9236 bytes.

The output of a show interfaces command for a layer two interface displays the following:

**Trunk**

```
Ethernet1 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.731c.5073 (bia 001c.731c.5073)
  Ethernet MTU 9214 bytes, BW 1000000 kbit
```

**Access**

```
Ethernet3 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.731c.5075 (bia 001c.731c.5075)
  Ethernet MTU 9214 bytes, BW 1000000 kbit
```

11.4.4.7.2 Routing Interface MTU Size

The MTU size on Layer 3 interfaces varies between a minimum of 68 to the maximum 9214 bytes. The default size is 1500 bytes. The show interface output for a Layer 3 interface displays the following:

**VLAN Routed Interface**

```
Vlan100 is up, line protocol is up (connected)
  Hardware is Vlan, address is 001c.731c.5072 (bia 001c.731c.5072)
  Internet address is 10.1.1.2/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 9214 bytes
```

**Physical Routed Interface**

```
Ethernet4 is down, line protocol is down (connect)
  Hardware is Ethernet, address is 001c.731c.5072
  Internet address is 10.10.10.10/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 9214 bytes
```

A routed interface fragments packets that exceed the configured IP MTU on the interface. For example, if a 2000 byte packet is received on routed interface 1 and is forwarded from routed interface 2 then routed interface 2 fragments the packet into a 1500 byte packet plus an additional packet containing the remaining data. This fragmentation should be avoided by configuring a consistent IP MTU across all systems within the operational domain.

The IP MTU set on a routed interface is valid for both IPv4 and IPv6 packets.
MTU Configuration

The `mtu` command configures the IPv4 and IPv6 Maximum Transmission Unit (MTU) size for the configuration mode interface. An interface's MTU value is displayed with the `show interface` command. The command is valid for all routable interfaces.

Examples

- This command sets the MTU size of 1492 bytes on VLAN interface 20.

  ```
  switch(config-if-Vl20)# mtu 1492
  switch(config-if-Vl20)#
  ```

- This command displays status for a routed interface.

  ```
  switch(config-if-Et3)# show interface e3
  Ethernet3 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.731c.5072
  Internet address is 10.1.1.2/24
  Broadcast address is 255.255.255.255
  Address determined by manual configuration
  IP MTU 1500 bytes , BW 1000000 kbit
  Full-duplex, 10b/s, auto negotiation: on, uni-link: unknown
  Up 22 days, 7 hours, 47 minutes, 58 seconds
  switch(config)#
  ```

- Using ping on a Linux host, you can test the maximum transmission through the interface.

  ```
  [user@linux ~]$ ping -M do -s 1472 10.1.1.2
  PING 10.1.1.2 (10.1.1.2) 1472(1500) bytes of data.
  1480 bytes from 10.1.1.2: icmp_seq=1 ttl=64 time=0.206 ms
  1480 bytes from 10.1.1.2: icmp_seq=2 ttl=64 time=0.191 ms
  --- 10.1.1.2 ping statistics ---
  2 packets transmitted, 2 received, 0% packet loss, time 999ms
  rtt min/avg/max/mdev = 0.191/0.198/0.206/0.015 ms
  ```

  The size 1472 has 8 bytes of ICMP information added and 20 bytes of IP headers added, generating a total packet size of 1500 bytes.

  - The option `-M do` specifies that fragmentation is prohibited for this test.
  - The option `-s` specifies the size of the packet being generated.
  - A capture of the frame displays total length of 1514 bytes on the wire which includes the Ethernet headers and type field.

11.4.5 Monitoring Links

These section describes link monitoring and object tracking processes:

- Object Tracking
- Errdisabled Ports
- Error Disable Detect Cause for ACL
- Configuring Error Disable Recovery Interval for each Cause
- Link Flap Monitoring
- Fabric Link Monitoring
- Rapid Automated Indication of Link-Loss
11.4.5.1 Object Tracking

Object tracking makes it possible for the switch to take action in response to changes in specific switch properties by creating an object to track those properties. When the tracked property changes, the object then changes state, allowing configured agents to react accordingly.

Object Tracking Configuration

The `track` command creates an object that changes state to reflect changes in a specific switch property. Agents configured to track that object are then able to react to the change.

**Example**

These commands create an object that tracks the line protocol state on *Ethernet interface 8*, then configures *Ethernet interface 5* to disable VRRP when that tracked object changes state to *down*.

```plaintext
switch(config)# track ETH8 interface ethernet 8 line-protocol
switch(config)# interface ethernet 5
switch(config-if-Et5)# vrrp 1 tracked-object ETH8 shutdown
switch(config-if-Et5)#
```

These commands use object tracking:

- link tracking group
- vrrp tracked-object

11.4.5.2 Errdisabled Ports

The switch places an Ethernet or management interface in *error-disabled* state when it detects an error on the interface. *Error-disabled* is an operational state that is similar to link-down state. Conditions that error-disable an interface include:

- `bpduguard`
- `link-flap`
- `no-internal-vlan`
- `portchannelguard`
- `portsec`
- `tapagg`
- `uplink-failure-detection`
- `xcvr_unsupported`

Most conditions are programmed by the configuration of other features, such as Spanning Tree protocol (bpduguard). Link flap error-disabling is configured through errdisable commands or link flap monitor commands (Link Flap Monitoring).

Error-disabled interfaces are recovered either through manual or automated methods.

To manually recover an interface, enter its configuration mode and execute *shutdown* and *no shutdown* commands.

**Example**

These commands manually recover *Ethernet interface 30* from the errdisabe state.

```plaintext
switch(config)# interface ethernet 30
switch(config-if-Et30)# shutdown
switch(config-if-Et30)# no shutdown
switch(config-if-Et30)#
```
Automated recovery of Ethernet interfaces that are error-disabled by a specified condition is enabled by `errdisable recovery cause`. The `errdisable recovery interval` specifies the period that an interface remains disabled until it is enabled and begins operating normally. When the disabling condition persists, recovered interfaces eventually return to the error-disabled state.

**Example**

These commands configure automated recovery for all interfaces that are error-disabled from link flap and `bpduguard` conditions. Automated recovery begins five minutes after the port is disabled.

```
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery cause bpduguard
switch(config)#errdisable recovery interval 300
switch(config)#
```

11.4.5.3 Error Disable Detect Cause for ACL

The `no errdisable detect cause acl` command configures routed ports, subinterfaces, and physical ports to not get into the `errdisabled` state on ACL failure, the default behavior. To reestablish the default behavior, use the `errdisable detect cause acl` command.

The following displays the output when `errdisabling` is enabled for ACLs.

```
switch(config)#show errdisable detect
Errdisable Reason           Detection Status
------------------------------ ----------------
acl                         Enabled
```

The following displays the output when `errdisabling` is disabled for ACLs.

```
switch(config)#show errdisable detect
Errdisable Reason           Detection Status
------------------------------ ----------------
acl                         Disabled
```

11.4.5.4 Configuring Error Disable Recovery Interval for each Cause

The duration after which an interface tries to recover from being error disabled is programmable for each trigger which causes the interface to be error disabled using the `errdisable recovery cause NAME_OF_CAUSE interval DURATION` command. The command applies only to interfaces that are enabled for error recovery after being error disabled.

```
Example
This command configures interfaces to recover in 30 seconds when the cause is `bpduguard`.

switch(config)#errdisable recovery cause bpduguard interval 30
```

```
Example
```

```
```

```
```
Either of these commands revert the interval to the global value when the cause is **bpduguard**.

```
switch(config)#no errdisable recovery cause bpduguard interval
```

```
switch(config)#default errdisable recovery cause bpduguard interval
```

This command displays the status of the interfaces.

```
switch#show errdisable recovery
Errdisable Reason              Timer Status   Timer Interval
------------------------------ ----------------- --------------
   bpduguard                      Disabled                   30
  hitless-reload-down             Disabled                  300
    lacp-no-portid                 Disabled                  N/A
  lacp-rate-limit                 Disabled                  300
   license-enforce                Disabled                  N/A

uplink-failure-detection        Disabled                  300
```

### 11.4.5.5 Link Flap Monitoring

Link flap frequency is the quantity of link flaps (connection state changes) over a specified period. Excessive link flaps result in network stability issues, including spanning tree and routing recalculations. Link flaps are often caused by Layer 1 issues, such as a bad cable or duplex mismatch. Link flap monitoring specifies link flap thresholds and disables a port when a threshold is exceeded.

Link flap monitoring can be enabled on all interfaces through `errdisable link flap` commands or on individual interfaces with the `link flap monitor`.

#### 11.4.5.5.1 Global Link Flap Monitor

Global link flap detection is configured through two global configuration mode commands:

- **errdisable flap-setting cause link-flap** configures the link-flap frequency that defines link-flap errors on an Ethernet interface.
- **errdisable detect cause link-change** enables the error-disabling of Ethernet interfaces that exceed the threshold link flap frequency.

Link-flap detection is enabled by default.

**Example**

These commands sets the link flap error criteria of **15** connection state changes over a **30** second period, then enables error detection on all interfaces.

```
switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
switch(config)#errdisable detect cause link-change
switch(config)#
```
11.4.5.5.2 Interface Link Flap Monitor

An interface is monitored for link flap errors with link flap profiles. A link flap profile specifies conditions that define a link-flap error. Profiles are assigned to Ethernet interfaces. Multiple profiles can be assigned to an interface to monitor a set of error conditions.

The global link flap monitor is used by interfaces that are not individually monitored for link flap errors.

Configuring Link Flap Profiles

Link flap profiles are configuration statements that define a link flap error in terms of these criteria:

- **flaps**  Threshold number of interface state changes.
- **period**  Interval when link flaps accumulate to trigger an error condition.
- **violations**  Number of link flap errors (threshold exceeded over specified period).
- **intervals**  Quantity of periods.

The **monitor link-flap policy** command places the switch in link-flap configuration mode for configuring link flap profiles and compiling a default-profile set. The **profile max-flaps** (Link Flap Configuration) command configures link flap profiles.

The default-profile set is a list of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled but link-flap profiles are not assigned. The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, **errdisable flap-setting cause link-flap** specifies default error-disable criteria. When the default-profile set contains multiple profiles, the criteria is satisfied when conditions match any profile.

Example

These commands enter link flap configuration mode and create four link flap profiles.

```bash
switch(config)#monitor link-flap policy
switch(config-link-flap)#profile LF01 max-flaps 15 time 60 intervals 10
switch(config-link-flap)#profile LF02 max-flaps 10 time 30 violations 5 intervals 6
switch(config-link-flap)#profile LF03 max-flaps 20 time 75 violations 2 intervals 10
switch(config-link-flap)#profile LF04 max-flaps 30 time 100 violations 4 intervals 7
switch(config-link-flap)#show active
monitor link-flap policy
  profile LF01 max-flaps 15 time 60 violations 1 intervals 1
  profile LF02 max-flaps 10 time 30 violations 5 intervals 10
  profile LF02 max-flaps 20 time 75 violations 2 intervals 6
  profile LF02 max-flaps 30 time 100 violations 4 intervals 7
switch(config-link-flap)#
```

The **default-profiles** command specifies the set of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled without a link flap profile assignment. Entering a **default-profile** command replaces the current default-profile statement in **running-config**.

The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, **errdisable flap-setting cause link-flap** specifies default error-disable criteria. When the default-profile set contains multiple profiles, error-disable criteria is satisfied when conditions match any profile. Multiple profiles are assigned to the default-profile set through a single **default-profiles** command.

Example

This command assigns configurations **LF01** and **LF02** as the default-profile set.

```bash
switch(config)#monitor link-flap policy
```
Interface Link Flap Profile Assignments

Link flap monitoring is enabled on individual Ethernet interfaces and can optionally specify one or more profiles to define link-flap error-disabling criteria. When link flap monitoring is enabled on an interface, the link-flap conditions determine when the interface is error-disabled. Multiple profiles can be assigned to an interface to monitor a set of error conditions; a port is disabled when conditions match any of the profiles assigned to an interface.

The monitor link-flap profiles command controls link-flap monitoring on a configuration mode interface. The command provides these link flap detection options:

- **monitor link-flap (no profiles listed):** Interface detects link flaps using default-profile set criteria.
- **monitor link-flap (at least one profile listed):** Interface detects link flaps using listed profile criteria.
- **default monitor link-flap:** The interface uses global link flap monitor commands (Global Link Flap Monitor).
- **no monitor link-flap:** The interface does not detect link flaps.

Examples

- This command assigns LF03 and LF04 link flap profiles to Ethernet interface 33.

```
switch(config)#interface ethernet 33
switch(config-if-Et33)#monitor link-flap profiles LF03 LF04
switch(config-if-Et33)#show active
interface Ethernet33
    monitor link-flap profiles LF04 LF03
switch(config-if-Et33)#
```

- This command disables link-flap monitoring on Ethernet interface 34.

```
switch(config)#interface ethernet 34
switch(config-if-Et34)#no monitor link-flap
switch(config-if-Et34)#show active
interface Ethernet34
    no monitor link-flap
switch(config-if-Et34)#
```

- This command assigns the default-profile set to Ethernet interface 35.

```
switch(config)#interface ethernet 35
switch(config-if-Et35)#monitor link-flap
switch(config-if-Et35)#show active
interface Ethernet35
    monitor link-flap
switch(config-if-Et35)#
```

- This command configures Ethernet interface 36 to use the global link flap monitoring commands.

```
switch(config)#interface ethernet 36
```
11.4.5.6 **Fabric Link Monitoring**

Fabric link monitoring enables EOS to monitor low error rate errors on all fabric links for long durations, and automatically isolates fabric links on consistent error detection over an extended time interval. Isolated fabric links are restored when the error rate drops below a configured threshold.

The error rate over each configurable polling interval is derived by comparing the number of cells with CRC errors against the total number of received cells. Links are automatically isolated when the error rate is above the configured threshold for the configured consecutive number of polling intervals.

On an isolated fabric link, control cells (but not data cells) are sent. Once the error rate drops below a set threshold for the configured consecutive number of polling intervals, EOS revives the fabric link to continue sending data traffic.

11.4.5.6.1 **Configuring Fabric Link Monitoring**

Configuration mode commands globally enable and disable fabric link monitoring and syslog messages for the settings described below.

The `no platform sand monitor` command disables fabric link monitoring.

**Generate Serdes Error Syslog**

The `platform sand monitor serdes error log` command generates syslog fabric link monitoring for serdes error logging.

**Example**

This command enables the serdes error log for fabric link monitoring.

```
switch(config)#platform sand monitor serdes error log
switch(config)#
```

The following syslog messages are not enabled by default. Fabric link monitoring syslog is enabled by configuring the `platform sand monitor serdes error log` command.

**Examples**

- The following Syslog message is generated when a fabric link for serdes is automatically withdrawn:

  `%SAND-4-SERDES_WITHDRAWN_FROM_FABRIC: Serdes withdrawn from the switch fabric.`

- Here is another instance where a Syslog message is generated when a fabric link is automatically withdrawn:

  `%SAND-4-SERDES_WITHDRAWN_FROM_FABRIC: Serdes Arad10/5-FabricSerdes-11 withdrawn from the switch fabric.`

- The following Syslog message is generated when a fabric link is restored:

  `%SAND-4-SERDES_RESTORED_TO_FABRIC: Serdes restored to the switch fabric.`
• Here is another instance where a Syslog message is generated when a fabric link is restored:

```
%SAND-4-SERDES_RESTORED_TO_FABRIC: Serdes Arad10/5-FabricSerdes-11
restored to the switch fabric.
```

**Generate Serdes Error Threshold**

The `platform sand monitor serdes error threshold` command generates a fabric link monitoring serdes error threshold.

**Example**

This command monitors serdes error thresholds over the specified number of received cells, resulting in the isolation of a fabric link between 200 and 30000 received cells.

```
switch(config)#platform sand monitor serdes error threshold 200 30000
switch(config)#
```

**Enable Serdes Poll Period**

The `platform sand monitor serdes poll period` command sets the serdes poll period.

**Example**

This command changes the serdes polling period for fabric link monitoring to 6 seconds.

```
switch(config)#platform sand monitor serdes poll period 6
switch(config)#
```

**Monitor Serdes Poll Threshold Isolation**

The `platform sand monitor serdes poll threshold isolation` command sets and enables fabric link monitoring for serdes poll threshold isolation.

**Example**

This command changes the number of consecutive polls in which the threshold needs to be detected to isolate a link. In this case the number is 5 consecutive polls.

```
switch(config)#platform sand monitor serdes poll threshold isolation 5
switch(config)#
```

**Monitor Serdes Poll Threshold Recovery**

The `platform sand monitor serdes poll threshold recovery` command sets and enables fabric link monitoring for serdes poll threshold recovery.

**Example**

This command changes the number of consecutive serdes polls used for threshold recovery to 6 seconds.

```
switch(config)#platform sand monitor serdes poll threshold recovery 6
switch(config)#
```
Show Fabric Monitoring Health

The show fabric monitoring health command displays the fabric monitoring connected state status with isolated links.

Example

When fabric links are isolated, their connected state status is shown with isolated links.

```
switch(config)# show platform sand health
Fabric serdes isolated by fabric monitoring: (36 total)
Arad5/0 serdes [0-1, 10-19, 2, 20-29, 3, 30-35, 4-9]
Top fabric serdes list by number of times isolated by monitoring:
Arad5/0 serdes 0: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 1: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 10: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 11: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 12: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 13: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 14: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 15: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 16: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 17: 1 (last occurred: 0:01:04 ago)
```

11.4.5.7 Rapid Automated Indication of Link-Loss

Rapid Automated Indication of Link-Loss (RAIL) is a software feature that reduces the wait time of applications on hosts that are blocked due to a failed link. When a link goes down because of link-flapping or the unavailability of a directly connected server, the switch drops all traffic to servers whose next-hop destination was learned on the port connected to the link. Applications that drive the traffic (clients on source hosts) are blocked because of the dropped edge-switch traffic. Connection timeout varies by application and is usually measured in seconds or minutes.

RAIL is functional on a switch if it is routing-enabled and available for servers that set the switch as the default router.

11.4.5.7.1 RAIL Method

When a link monitored by RAIL goes down, the switch performs these steps for servers that the switch proxies:

1. IP addresses of servers on the failed link are extracted from ARP cache. The interface that accesses the server is determined by searching for the MAC address in the hardware MAC address tables.
2. Upon link shutdown, a dynamic MAC entry is added in the MAC address table for each server that was learned on the failed interface. Each new entry lists its interface as CPU.

The figure below titled RAIL Scenarios depicts three switch-server scenarios: link is up, link is down with RAIL disabled, and link is down with RAIL enabled. A failed link with RAIL enabled results in these behaviors:

1. All ingress packets whose destination MAC address matches an address added to the MAC address table are sent to the CPU.
2. For packets scheduled to be forwarded to the source address, the switch sends one of the following, based on the type of received segment:
   - TCP: TCP RST segment to the source IP address and port.
• **UDP**: ICMP unreachable segment to the source IP address and port.

3. The client closes the socket associated with the transmitted segment and notifies the application. The application reacts immediately instead of maintaining the block until connection timeout expiry.

![Figure 25: RAIL Scenarios](image)

### 11.4.5.7.2 RAIL Implementation

RAIL defines a state machine that manages the RAIL activity level relative to a specified server. The state machine consists of four states:

- **Up**: Transitions to this state from **Inactive** when ARP and MAC entries are added for the server.
- **Proxying**: Transitions to this state from **Up** when Link Down is detected and RAIL proxying is enabled. The switch is a proxy for messages to the server.
- **Down**: Transitions to this state from **Up** when Link Down is detected and RAIL proxying is not enabled. Messages from the client remain unanswered and the application recovers only after timeout expiry.
- **Inactive**: Transitions to this state upon any of the following conditions:
  - Server’s MAC address or ARP entry is deleted (from any state).
  - Proxy timeout expiry (from **Proxying** state).
  - Link down timeout expiry (from **Down** state).

### 11.4.5.7.3 RAIL Configuration

Server-failure configuration mode commands globally enable RAIL and configure RAIL parameters. RAIL is functional on individual interfaces only when it is globally enabled and enabled on the interface. RAIL monitors an interface for link errors when RAIL is globally enabled and enabled on the interface.

#### Entering Server-failure Configuration Mode

The `monitor server-failure` command places the switch in server-failure configuration mode. The `exit` command returns the switch to global configuration mode. Server-failure mode is not a group change mode; `running-config` is changed when commands are entered and not affected by exiting the mode.

The `no monitor server-failure` deletes all server-failure mode commands from `running-config`.

#### Examples

- These commands place the switch in the `server-failure` configuration mode.

```
switch(config)#monitor server-failure
switch(config-server-failure)#
```
• This command deletes all server-failure configuration mode commands from running-config.

```
switch(config)#no monitor server-failure
switch(config)#
```

Enabling RAIL on the Switch

RAIL is disabled by default and is enabled by no shutdown (server-failure configuration mode). The shutdown command disables RAIL without removing RAIL commands from running-config.

Examples

• These commands enable RAIL globally.

```
switch(config)#monitor server
switch(config-server-failure)#no shutdown
switch(config-server-failure)#show active
monitor server-failure
   no shutdown
switch(config-server-failure)#
```

• This command disables RAIL globally.

```
switch(config-server-failure)#shutdown
switch(config-server-failure)#
```

Enabling Proxy Mode

The proxy (server-failure configuration mode) command sets the RAIL proxy setting to enabled and specifies the interval that RAIL responds to messages sent to servers on failed links. The proxy timeout is measured individually for each server whose link has failed. The switch enters RAIL proxy state only when the proxy setting is enabled.

When RAIL is enabled but the proxy setting is disabled, the switch maintains a list of unavailable servers without responding to messages sent to the servers. The RAIL proxy setting is disabled by default. When RAIL proxy is enabled, the default period is three minutes.

The no proxy and default proxy commands return the RAIL proxy setting to disabled. The no proxy lifetime and default proxy lifetime commands set the proxy timeout to its default of three minutes if the RAIL proxy setting is enabled. The lifetime commands have no effect if RAIL proxy is disabled.

Examples

• These commands enable the RAIL proxy and sets the proxy timeout period of 10 minutes.

```
switch(config)#monitor server
switch(config-server-failure)#proxy lifetime 10
switch(config-server-failure)#show active
monitor server-failure
   proxy lifetime 10
switch(config-server-failure)#
```

• This command sets the proxy timeout period to its default value of 3 minutes.

```
switch(config-server-failure)#no proxy lifetime
switch(config-server-failure)#show active
monitor server-failure
   proxy
```

1237
Selecting Networks to Monitor

The **network** (server-failure configuration mode) command specifies the IPv4 network space that Rapid Automated Indication of Link-Loss (RAIL) monitors for failed links to connected servers. **Running-config** can contain multiple **network** statements, allowing RAIL to monitor multiple disjoint network spaces.

When a server on the specified network is blocked because of a failed Ethernet or port channel link, the switch becomes a proxy for the unavailable server and responds with **TCP RST** or **ICMP Unreachable** segments to devices sending packets to the unavailable server.

Example

These commands specify two IPv4 network spaces that RAIL monitors for server failures.

```
switch(config)#monitor server
switch(config-server-failure)#network 10.1.1.0/24
switch(config-server-failure)#network 10.2.1.96/28
switch(config-server-failure)#show active
monitor server-failure
  network 10.2.1.96/28
  network 10.1.1.0/24
switch(config-server-failure)#
```

Enabling RAIL on an Interface

RAIL monitors an interface for link errors only when RAIL is globally enabled and enabled for the interface. The **monitor server-failure link** command enables RAIL on the configuration mode interface. Configuration settings are effective for all Ethernet and port channel interfaces that enable RAIL.

Example

These commands enable RAIL on **port channel interface 100**.

```
switch(config)#interface port-channel 100
switch(config-if-Po100)#monitor server-failure link
switch(config-if-Po100)#show active
interface Port-Channel100
  monitor server-failure link
switch(config-if-Po100)#
```

11.4.5.7.4 Displaying RAIL Status

The switch provides commands to display RAIL configuration and status information:

Displaying RAIL Configuration settings

The **show monitor server-failure** command displays Rapid Automated Indication of Link-Loss (RAIL) configuration settings and the number of servers on each monitored network.
**Example**

This command displays RAIL configuration status and lists the number of servers that are on each monitored network.

```bash
switch> show monitor server-failure
Server-failure monitor is enabled
Proxy service: disabled
Networks being monitored: 3
  10.2.1.96/28    : 0 servers
  10.1.1.0/24     : 0 servers
  10.3.0.0/16     : 3 servers
switch>
```

**Displaying RAIL History for All Connected Servers**

The `show monitor server-failure history` command displays the time of all link failures detected by Rapid Automated Indication of Link-Loss (RAIL) and includes the interface name for each failure.

**Example**

This command displays the link failure history from the time RAIL is instantiated on the switch.

```bash
switch> show monitor server-failure history
Total server failures: 4
Server IP   Server MAC              Interface           Last Failed
----------- -----------------       -----------         --------------
10.1.67.92  01:22:ab:cd:ee:ff       Ethernet17          2013-02-02
11:26:22
44.11.11.7  ad:3e:5f:dd:64:cf       Ethernet23          2013-02-10
00:07:56
10.1.1.1    01:22:df:42:78:cd       Port-Channel6       2013-02-09
19:36:09
00:03:39
switch>
```

**Displaying Server Configuration and Status**

The `show monitor server-failure servers` command displays status and configuration data about each server that RAIL monitors. The display format depends on the parameter specified by the command:

**Examples**

- This command displays RAIL information for the server at IP address `10.11.11.7`.

```bash
switch> show monitor server-failure servers 10.11.11.7
Server information:
  Server Ip Address      : 10.11.11.7
  MAC Address            : ad:3e:5f:dd:64:cf
  Current state          : down
  Interface              : Ethernet23
  Last Discovered        : 2013-01-06 06:47:39
  Last Failed            : 2013-02-10 00:07:56
  Last Proxied           : 2013-02-10 00:08:33
  Last Inactive          : 2013-02-09 23:52:21
  Number of times failed : 3
  Number of times proxied: 1
  Number of times inactive: 18
```
• This command displays RAIL information for the all servers on configured interfaces.

```
switch>
show monitor server-failure servers all
```

Total servers monitored: 5

11.4.6 PHY test pattern CLI

Use the Ethernet Physical Layer (PHY) test pattern CLI to check the quality of the physical layer for an Ethernet interface. You can do this by generating a specific test pattern to a peer, and having the peer check the test pattern that is received, and vice versa. Because the test pattern is a well-known sequence of bits, the peer can check that the pattern received matches this well-known sequence; any difference is a bit error introduced by the peculiarities of the physical layer. The quality of the link is determined based on the acceptable bit errors, as published by the hardware vendors.

To enable the test pattern generator, configure a specific test pattern on the transmitter side of an interface. The test pattern checker is enabled by configuring the test pattern to be checked on the receiver side of the interface. PRBS is the test pattern supported by EOS.

**Note:** Physical links are bidirectional; to test both directions, the generator and checker both need to be enabled on both sides of the link. Both directions can be tested simultaneously or separately. The order of testing does not matter.

11.4.6.1 Configuration

You can configure a test pattern is configured using the `phy diag` interface configuration mode command.

1. Enter interface configuration mode, entering the targeted interface name.

```
switch(config)#interface interfaceName
```

2. Enable a test pattern on an interface using the `phy diag` command. You can select the transmitter or the receiver. To display the available interfaces, select `test pattern ?`.

```
switch(config-if)#phy diag [transmitter | receiver] test pattern ?
PRBS11  Configure the PRBS11 test pattern
PRBS15  Configure the PRBS15 test pattern
PRBS23  Configure the PRBS23 test pattern
PRBS31  Configure the PRBS31 test pattern
PRBS49  Configure the PRBS49 test pattern
PRBS58  Configure the PRBS58 test pattern
PRBS7   Configure the PRBS7 test pattern
PRBS9   Configure the PRBS9 test pattern
```

3. To disable a test pattern on an interface, enter the following command. You can select the transmitter or the receiver, as well as the selected named test pattern.

```
switch(config-if)#no phy diag [transmitter|receiver] test pattern TestPattern
```
4. By default, a test pattern is disabled.

   switch(config-if)#default phy diag [transmitter|receiver] test pattern

5. The following command clears the recorded test pattern status data for all the interfaces. Upon running the command, all the counter values are set to 0 and link states are marked as not locked.

   switch#clear phy diag test pattern

11.4.6.2 Show Commands

To display the configured and operational test pattern, as well as the test patterns available for an interface, use the `show interfaces` command.

In the following example, interfaces `ethernet 36/1` and `ethernet 31/1` are selected for display. The user-configured test pattern is displayed under the `Configured` column, which is divided based on transmitter and receiver configuration. The currently operational test pattern is displayed under the `Operational` column. The `Available` column lists the test patterns available for the interface.

```
switch#show interfaces ethernet 26/1,31/1 phy diag test pattern

Interface           Configured       Operational        Available
            Transmitter Receive Transmitter Receive
----------------------------------------
Ethernet26/1              PRBS15   PRBS15   PRBS15   PRBS15
                        7,9,11,15,23,31,58
Ethernet31/1              PRBS7    PRBS31   PRBS7    PRBS31
                        7,9,11,15,23,31,58
```

Use the `show interfaces [<interface range>] phy detail` command to display the operational test pattern for an interface. In the example below, the `Test pattern` field will not be available, on disabling the test pattern.

Note: This command is not available on DCS-7060PX4 and DCS-7060DX4.

```
switch#show interfaces ethernet 26/1 phy detail | i Test pattern
Test pattern                   enabled
switch#show interfaces ethernet 31/1 phy detail | i Test pattern
Test pattern                   enabled
```

Use the `show interfaces [<interface range>] phy diag test pattern counters` command to display the test pattern link state and error information.

Available error information:

- **Link state**: whether or not the checker locked on to the configured test pattern.
- **Bit Errors**: the accumulated number of bit errors.
- **Largest Burst**: the largest burst of errors that occurred.
- **Burst Count**: the number of occurrences of errors.
• **Last Error Time**: the last time an error has occurred, ‘never’ if no errors have occurred.

Use the `show interfaces [<interface range>] phy diag test pattern counters` command to display the lock state of an interface along with a detailed information on the recorded bit errors.

Available detailed information:

- **Last clear**: the time when the test pattern results were last cleared.
- **Operational test pattern**: the test pattern operational at the receiver side.
- **Bit rate**: the transmission bit rate.
- **Lock state**: the current lock status, number of times it changed and the last time the lock status got changed.
  - **locked**: receiver is able to lock on to the incoming test pattern.
  - **not locked**: receiver is not able to lock on to the incoming test pattern.
- **Largest burst**: the largest burst of errors that occurred.
- **Bit errors***: the accumulated number of errors, number of occurrences of errors, and last time errors were captured. The * suffix, indicating that data may not be accurate due to loss of lock, is applied if the current lock status is not locked or if the lock status has changed more than once. This suffix is cleared when the test pattern status data is cleared via the CLI listed above.
- **Total Bits**: the total bits received.
- **Bit error rate (BER)***: the ratio of captured bit errors to the total bit received. The * suffix, indicating that data may not be accurate due to loss of lock, is applied if the current lock status is not locked or if the lock status has changed more than once. This suffix is cleared when the test pattern status data is cleared via the CLI listed above.
- **Bit errors since last lock**: the accumulated number of errors since last time lock was gained.
- **Total bits since last lock**: the total bits received since last lock.
- BER since last lock: the ratio of captured bit errors to the total bit received since last lock.

11.4.6.3  Bit Error Rate (BER)

Bit error rate is the ratio of the recorded bit errors to the total bits received for the duration of the test run. To achieve a reliable transmission, BER should be relatively small. As per IEEE 802.3 standard, the minimum BER requirement for Ethernet links is 1E-12. Therefore, links with BER lower than 1E-12 are to be considered reliable.

The BER reported by the test pattern CLI is the pre-FEC (Forward Error Correction) BER. For links that have FEC enabled, it is expected to see a higher BER, in the range of 1E-4 to 1E-8, because they are calculated before FEC is applied on the link. Based on the type of FEC applied on the link, these errors could get corrected to achieve the minimum BER requirement of 1E-12 or less.

11.4.6.4  Limitations

The configuration of test patterns is supported only on a few types of ports. The available test patterns that may be configured on an interface are found in the Available field of the show interfaces phy diag test pattern CLI command.

The test pattern CLI calculates only pre-FEC BER.

If one end of the system is from another vendor, consult the vendor’s documentation for the equivalent command(s) to achieve the appropriate behavior.
11.4.7 Data Transfer Commands

Control Plane and Data Plane Commands
- ip access-group (Control Plane mode)
- show switch forwarding-mode
- switch forwarding-mode
- system control-plane

Errdisable Commands
- errdisable detect cause link-change
- errdisable flap-setting cause link-flap
- errdisable recovery cause
- errdisable recovery interval
- show errdisable recovery

Fabric Link Monitoring Commands
- platform sand monitor serdes error log
- platform sand monitor serdes error threshold
- platform sand monitor serdes poll period
- platform sand monitor serdes poll threshold isolation
- platform sand monitor serdes poll threshold recovery
- show fabric monitoring health
- show platform trident mirroring

RAIL Commands
- clear server-failure servers inactive
- monitor server-failure
- monitor server-failure link
- network (server-failure configuration mode)
- proxy (server-failure configuration mode)
- show monitor server-failure
- show monitor server-failure history
- show monitor server-failure servers
- shutdown (server-failure configuration mode)

Link Flap Monitor Commands
- default-profiles
- monitor link-flap policy
- monitor link-flap profiles
- profile max-flaps (Link Flap Configuration)

MAC Address Table Commands
- clear mac address-table dynamic
- mac address-table aging-time
- mac address-table static
- show bridge mac-address-table aging timeout
- show mac address-table
• show mac address-table count
• show mac address-table mlag-peer
• show mac address-table multicast
• show mac address-table multicast brief
• switchport mac address learning

Port Configuration Commands
• clear counters
• description
• interface loopback
• load interval
• mtu
• phy diag
• show interfaces
• show interfaces description
• show interfaces phy diag
• switchport
• switchport default mode access
• switchport default mode routed

Port Mirroring Commands
• monitor session destination
• monitor session destination cpu
• monitor session forwarding-drop
• monitor session ip access-group
• monitor session source
• monitor session source ip access-group
• monitor session truncate
• no monitor session
• show monitor session

Port Security Commands
• show port-security
• show port-security interface
• show port-security mac-address
• switchport port-security
• switchport port-security mac-address maximum
• switchport port-security violation

Storm Control Commands
• show storm-control
• storm-control

Tracking Commands
• links minimum
• link tracking group
• link tracking group (interface)
• show link tracking group
• show track
• track
• traffic-loopback
11.4.7.1 clear counters

The clear counters command resets the counters to zero for the specified interfaces. The command provides the following options:

- **No parameter**: When no option is selected, the counters are reset on the switch.
- **Session parameter**: The command resets the counters in software for the current CLI session, establishing a baseline upon which subsequent show interfaces or show interfaces counters commands are relative. Counters are not affected for other CLI sessions.

**Note**: The clear counters command (and other commands that reset counters to zero) do not reset SNMP counters (such as IF-MIB::ifInOctets). As specified in RFC 2578, sections 7.1.6 and 7.1.10, a single value of a counter in SNMP has no information content. Instead, meaningful information is given by the difference between two separate fetches of a particular counter. SNMP counters automatically reset to 0 when they reach their maximum values.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear counters [INTERFACE][SCOPE]

**Parameters**

- **INTERFACE** Interface type and number. Options include:
  - no parameter Display information for all interfaces.
  - ethernet e_range Ethernet interface range specified by e_range.
  - loopback l_range Loopback interface specified by l_range.
  - management m_range Management interface range specified by m_range.
  - port-channel p_range Port-Channel Interface range specified by p_range.
  - vlan v_range VLAN interface range specified by v_range.
  - vxlan vx_range VXLAN interface range specified by vx_range.

- **SCOPE** Duration of the reset results. Options include:
  - no parameter counters are cleared on the switch.
  - session counters are reset only for the current session.

**Example**

These commands display interface counters, clear the counters, then display the counters again.

```
switch#show interfaces ethernet 1
Ethernet1 is up, line protocol is up (connected)
  Hardware is Ethernet, address is 001c.7302.2fff (bia 001c.7302.2fff)
  MTU 9212 bytes, BW 10000000 Kbit
  Full-duplex, 10Gb/s, auto negotiation: off

switch##
11.4.7.2 clear mac address-table dynamic

The clear mac address-table dynamic command removes specified dynamic entries from the MAC address table. Entries are identified by their VLAN and Layer 2 (Ethernet or port channel) interface.

- To remove a specific entry, include its VLAN and interface in the command.
- To remove all dynamic entries for a VLAN, do not specify an interface.
- To remove all dynamic entries for an interface, do not specify a VLAN.
- To remove all dynamic entries, do not specify a VLAN or an interface.

Command Mode
Privileged EXEC

Command Syntax

clear mac address-table dynamic [VLANS][INTERFACE]

Parameters
- **VLANS** Table entries are cleared for specified VLANs. Options include:
  - no parameter all VLANs.
  - vlan v_num VLAN specified by v_num.
- **INTERFACE** Table entries are cleared for specified interfaces. Options include:
  - no parameter all Ethernet and port channel interfaces.
  - interface ethernet e_range Ethernet interfaces specified by e_range.
  - interface port-channel p_range port channel interfaces specified by p_range.
  - vxlan vx_range VXLAN interfaces specified by vx_range.

Valid range formats include number, range, or comma-delimited list of numbers and ranges.

Example

This command clears all dynamic mac address table entries for port channel 5 on VLAN 34.

```
switch# clear mac address-table dynamic vlan 34 interface port-channel 5
switch#
```
**clear server-failure servers inactive**

The `clear server-failure servers inactive` command removes all inactive server entries from the server failed history list. The switch maintains this list, even after a server’s ARP entry is removed, to maintain a list of servers that are connected to the switch and log the most recent time of the failure of the link that connects the switch to the server.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear server-failure servers inactive`

**Related Command**
`show monitor server-failure history`

**Example**
This command clears the inactive servers from the server failed history list.

```
switch#clear server-failure servers inactive
switch#
```
11.4.7.4 **default-profiles**

The **default-profiles** command specifies the set of link-flap profiles that define error-disable criteria for interfaces where link flap monitoring is enabled without a link flap profile assignment. Entering a **default-profile** command replaces the current default-profile statement in **running-config**.

The default-profile set may contain zero, one, or multiple profiles. When the default-profile set is empty, **errdisable flap-setting cause link-flap** specifies default error-disable criteria. When the default-profile set contains multiple profiles, error-disable criteria is satisfied when conditions match any profile. Multiple profiles are assigned to the default-profile set through a single **default-profiles** command.

The **no default-profiles** and **default default-profiles** commands restore the empty default-profile set by deleting the **default-profiles** command from **running-config**.

**Command Mode**

Link-flap Configuration

**Command Syntax**

```
default-profiles [LF_PROFILES]
no default-profiles
default default-profiles
```

**Parameters**

- **LF_PROFILES** Name of link-flap profiles assigned to default profile set. Parameter may contain zero, one, or multiple link-flap profile names:
  - **no parameter** default-profile set is empty.
  - **profile** name of single link-flap profile.
  - **profile_1 profile_2 ... profile_N** list of link-flap profile names.

**Related Commands**

- **monitor link-flap policy** places the switch in **link-flap-profiles** configuration mode.
- **profile max-flaps (Link Flap Configuration)** configures link flap profiles.

**Guidelines**

The **errdisable flap-setting cause link-flap** statement is also configurable through the **profile max-flaps (Link Flap Configuration)** command.

**Example**

This command assigns configures **LF01** and **LF02** as the default-profile set.

```
switch(config)#monitor link-flap policy
switch(config-link-flap)#default-profiles LF01 LF02
switch(config-link-flap)#show active
monitor link-flap policy
  profile LF01 max-flaps 15 time 60 violations 1 intervals 1
  profile LF02 max-flaps 10 time 30 violations 5 intervals 10
  profile LF03 max-flaps 25 time 100 violations 2 intervals 12
  profile LF04 max-flaps 5 time 15 violations 1 intervals 3
default-profiles LF01 LF02
switch(config-link-flap)#
```
11.4.7.5  description

The `description` command adds comment text for the configuration mode interface. The text provides information about the interface and has no effect on interface functions. The `show interfaces description` command displays interface description text.

The `no description` command removes the description text for the configuration mode interface from `running-config`.

Command Mode
Interface-Ethernet Configuration  
Interface-Loopback Configuration  
Interface-Management Configuration  
Interface-Port-channel Configuration  
Interface-VLAN Configuration  
Interface-VXLAN Configuration

Command Syntax

description label_text

no description

default description

Parameters

`label_text` character string assigned to description attribute.

Example

These commands add description text to `interface Ethernet 23`, then displays the text through a `show interfaces description` command.

```
switch(config)#interface ethernet 23
switch(config-if-Et23)#description external line
switch(config-if-Et23)#show interfaces ethernet 23 description
<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
<th>Protocol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et23</td>
<td>up</td>
<td>up</td>
<td>external line</td>
</tr>
</tbody>
</table>
```
11.4.7.6  **errdisable detect cause link-change**

The **errdisable detect cause link-change** command enables the error-disabling of Ethernet interfaces when the switch detects a link flap error on the interface. The **errdisable flap-setting cause link-flap** command defines a link flap error in terms of the frequency of connection state changes.

The switch places an interface in **error-disabled** state when it detects an error on the interface. **Error-disabled** is an operational state that is similar to link-down state. To re-enable an error-disabled interface, enter **shutdown** and **no shutdown** command in the configuration mode for the interface.

By default, link flap detection is enabled. The **no errdisable detect cause link-change** command disables the triggering of error-disable actions. The **errdisable detect cause link-change** and **default errdisable detect cause link-change** commands enable the triggering of error-disable actions by removing the **no errdisable detect cause link-change** command from **running-config**.

**Command Mode**
Global Configuration

**Command Syntax**

- errdisable detect cause link-change
- no errdisable detect cause link-change
- default errdisable detect cause link-change

**Examples**

- This command disables error detection on the switch.

```
switch(config)#no errdisable detect cause link-change
switch(config)#
```

- These commands sets the link flap error criteria of **15** connection state changes over a **30** second period, then enables error detection on the switch.

```
switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
switch(config)#errdisable detect cause link-change
switch(config)#
```
11.4.7.7 **errdisable flap-setting cause link-flap**

The `errdisable flap-setting cause link-flap` command configures the link-flap frequency that defines an link-flap error on an Ethernet interface. The `errdisable detect cause link-change` command uses this criteria to trigger an error-disable action.

The link-flap frequency is defined by the quantity of link flaps (connection state changes) over a specified period. The default settings are five link flaps and ten seconds.

The `no errdisable flap-setting cause link-flap` and `default errdisable flap-setting cause link-flap` commands restore the default link flap cause settings by removing the `errdisable flap-setting cause link-flap` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
errdisable flap-setting cause link-flap max-flaps quantity time period
no errdisable flap-setting cause link-flap
default errdisable flap-setting cause link-flap
```

**Parameters**

- `quantity` Number of link flaps. Value ranges from 1 to 100. Default value is 5.
- `period` Interval over which link flaps accumulate to trigger an error condition (seconds). Value ranges from 1 to 1800. Default value is 10.

**Example**

This command sets the link flap error criteria of 15 connection state changes over 30 second periods.

```
switch(config)#errdisable flap-setting cause link-flap max-flaps 15 time 30
switch(config)#
```
11.4.7.8 errdisable recovery cause

The **errdisable recovery cause** command enables the automated recovery of error-disabled Ethernet interfaces. An interface that is disabled as a result of a specified condition attempts normal operation after a specified interval. When the disabling condition persists, recovered interfaces eventually return to the error-disabled state.

When automated recovery is not enabled, interfaces are recovered manually by entering `shutdown` and `no shutdown` from the interface’s configuration mode.

**Running-config** can simultaneously store `errdisable recovery cause` statements for each error-disable condition. By default, error-disable recovery is disabled for all conditions.

The `no errdisable recovery cause` and `default errdisable recovery cause` commands disable automated recovery for interfaces disabled by the specified condition by removing the corresponding `errdisable recovery cause` command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
errdisable recovery cause CONDITION
no errdisable recovery cause CONDITION
default errdisable recovery cause CONDITION
```

**Parameters**

**CONDITION**  Disabling condition for which command automates recovery. Options include:

- arp-inspection
- bpduguard
- link-flap
- no-internal-vlan
- portchannelguard
- portsec
- tapagg
- uplink-failure-detection
- xcvr_unsupported

**Related Command**

`errdisable recovery interval` configures the period that an ethernet interface remains disabled before automated recovery begins.

**Example**

This command enables error-disable recovery for interfaces that are disabled by link-flap and bpduguard conditions and sets the errdisable recovery period at 10 minutes.

```
switch(config)#errdisable recovery cause bpduguard
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery interval 600
switch(config)#show running-config
! Command: show running-config

errdisable recovery cause bpduguard
errdisable recovery cause link-flap
errdisable recovery interval 600
!
```
switch(config)#
11.4.7.9 \texttt{errdisable recovery interval}

The \texttt{errdisable recovery interval} command specifies the period that an error-disabled Ethernet interface remains disabled before automated errdisable recovery begins. This command affects only interfaces whose automated recovery is enabled for the disabling condition (\texttt{errdisable recovery cause}). When automated recovery is not enabled, interfaces are recovered manually by entering \texttt{shutdown} and \texttt{no shutdown} from the interface’s configuration mode.

The \texttt{no errdisable recovery interval} and \texttt{default errdisable recovery interval} commands restore the default error recovery period of 300 seconds by removing the \texttt{errdisable recovery interval} command from \textit{running-config}.

\textbf{Command Mode}

Global Configuration

\textbf{Command Syntax}

\texttt{errdisable recovery interval period}
\texttt{no errdisable recovery interval}
\texttt{default errdisable recovery interval}

\textbf{Parameters}

\texttt{period} \quad \text{Error disable recovery period (seconds). Value ranges from 30 to 86400. Default value is 300.}

\textbf{Related Command}

\texttt{errdisable recovery cause} enables the automated recovery of error-disabled Ethernet interfaces.

\textbf{Example}

This command enables error-disable recovery for interfaces that are disabled by link-flap conditions and sets the errdisable recovery period at 10 minutes.

\begin{verbatim}
switch(config)#errdisable recovery cause link-flap
switch(config)#errdisable recovery interval 600
switch(config)#show running-config

! Command: show running-config

! errdisable recovery cause link-flap
errdisable recovery interval 600
!

!
switch(config)#
\end{verbatim}
11.4.7.10  interface loopback

The **interface loopback** command places the switch in loopback-interface configuration mode for the specified interfaces. The command creates loopback interfaces for previously unconfigured interfaces.

The command can specify a single interface or multiple interfaces:

- **Single interface**: Command creates an interface if it specifies one that was not previously created.
- **Multiple interfaces**: Command is valid only if all specified interfaces were previously created.

The **no interface loopback** command removes the specified interfaces from **running-config**, including all interface configuration statements. The **default interface loopback** command removes all configuration statements for the specified loopback interface without deleting the loopback interface from **running-config**.

The following commands are available in loopback configuration mode:

- description
- exit
- ip address
- ip proxy-arp
- ipv6 address
- ipv6 enable
- load interval
- logging event
- mtu
- shutdown (Interfaces)
- snmp trap

**Command Mode**
Global Configuration

**Command Syntax**

```
interface loopback l_range
no interface loopback l_range
default interface loopback l_range
```

**Parameters**

*l_range*  Loopback interfaces (number, range, or comma-delimited list of numbers and ranges). Loopback number ranges from 0 to 1000.

**Examples**

- This command enters interface configuration mode for loopback interfaces 1 through 5.

```
switch(config)#interface loopback 1-5
switch(config-if-Lo1-5)#
```

- This command creates **interface 23** and enters interface configuration mode.

```
switch(config)#interface loopback 23
switch(config-if-Lo23)#
```

- This command removes loopback interfaces 5 through 7 from **running-config**.

```
switch(config)#no interface loopback 5-7
switch(config)#
```
11.4.7.11  ip access-group (Control Plane mode)

The `ip access-group` command applies an IPv4 or standard IPv4 access control list (ACL) to the control plane.

The `no ip access-group` and `default ip access-group` commands remove the corresponding `ip access-group` command from `running-config`.

**Command Mode**
Control-plane Configuration

**Command Syntax**
`ip access-group list_name [VRF_INSTANCE] DIRECTION`
`no ip access-group [list_name][VRF_INSTANCE] DIRECTION`
`default ip access-group [list_name][VRF_INSTANCE] DIRECTION`

**Parameters**
- `list_name` name of ACL assigned to interface.
- `VRF_INSTANCE` specifies the VRF instance being modified.
  - `no parameter` changes are made to the default VRF.
  - `vrf vrf_name` changes are made to the specified user-defined VRF.
- `DIRECTION` transmission direction of packets, relative to interface. Valid options include:
  - `in` inbound packets.

**Example**
These commands apply the IPv4 ACL named `test2` to the control plane.

```
switch(config)# system control-plane
switch(config-system-cp)# ip access-group test2 in
switch(config-system-cp)#
```
The `link tracking group` command adds the configuration mode interface to a link-state group and specifies whether it is upstream or downstream.

The `no link tracking group` and `default link tracking group` commands remove the specified link-state group assignment for the configuration mode interface.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration
- Interface-VXLAN Configuration

**Command Syntax**
```
link tracking group group_name DIRECTION
no link tracking group [group_name]
default link tracking group [group_name]
```

**Parameters**
- `group_name` link tracking group name.
- `DIRECTION` position of the interface in the link-state group. Valid options include:
  - `upstream`
  - `downstream`

**Example**
These commands create link-state group “xyz” and add VLAN interface 100 to the group as an upstream interface.

```
switch(config)#link tracking group xyz
switch(config-link-state-xyz)#show active
link tracking group xyz
switch(config-link-state-xyz)#exit
switch(config)#interface vlan 100
switch(config-if-Vl100)#link tracking group xyz upstream
switch(config-if-Vl100)#show active
interface Vlan100
   link state group xyz upstream
switch(config-if-Vl100)#
```
11.4.7.13  link tracking group

The `link tracking group` command creates and enables a link-state group and places the switch in link-state-group configuration mode. A link-state group consists of “upstream” interfaces (connections to servers) and “downstream” interfaces (connections to switches and clients). In the event of a failure of all upstream interfaces in the link-state group, the downstream interfaces are shut down.

The `no link tracking group` and `default link tracking group` commands delete the link tracking group from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
link tracking group group_name
no link tracking group group_name
default link tracking group group_name
```

**Parameters**

- `group_name` link-state group name.

**Commands available in link-state Configuration Mode**

- `links minimum` configures the minimum number of links that the link-state group requires.

**Example**

This command creates and enables `link-state group 1`.

```
switch(config)#link tracking group 1
switch(config-link-state-1)#
```
The `links minimum` command specifies the minimum number of links the configuration mode link-state group requires.

The `no links minimum` and `default links minimum` commands restore the default minimum value of 1 by deleting the corresponding `links minimum` statement from `running-config`.

**Command Mode**

Link-State Configuration

**Command Syntax**

```
links minimum quantity
no links minimum
default links minimum
```

**Parameters**

`quantity` Minimum number of links. Value ranges from 1 to 100000. Default value is 1.

**Related Commands**

- `link tracking group` creates and enables a link-state group and places the switch in `link-state` configuration mode.
- `link tracking group (interface)` adds the configuration mode interface to the specified link-state group.

**Example**

These commands configure link-state tracking group `link-a` to have at least 60 links.

```
switch(config)#link tracking group link-a
switch(config-link-state-link-a) links minimum 60
switch(config-link-state-link-a)
```
11.4.7.15 load interval

The `load-interval` command changes the load interval for the configuration mode interface. Load interval is the time period over which data is used to compute interface rate counters. Interface rates are exponentially weighted moving averages; recent data samples have greater influence than older samples. Statistics calculated with shorter load intervals are usually more sensitive to short traffic bursts.

The `no load-interval` and `default load-interval` commands restore the default value of 300 seconds by removing the corresponding `load-interval` statement from `running-config`.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration
Interface-VXLAN Configuration

Command Syntax
`load-interval delay`
`no load-interval`
`default load-interval`

Parameters
`delay` Load interval delay. Values range from 5 to 600 (seconds). Default value is 300 (five minutes).

Example
These commands set the load interval for *Ethernet interface 7* at 60 seconds.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#load-interval 60
switch(config-if-Et7)#
```
11.4.7.16  mac address learning

The **mac address learning** command enables MAC address learning on a VLAN configuration mode. By default, MAC address learning is enabled by on a VLAN.

The **no mac address learning** command disables MAC address learning for the VLAN configuration mode. The **mac address learning** and **default mac address learning** commands enable MAC address learning for the VLAN configuration mode by deleting the corresponding **no mac address learning** command from the **running-config**.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

```plaintext
mac address learning local limit
no mac address learning local limit
default mac address learning local limit
```

**Parameter**

- **local limit** Maximum number of locally learned dynamic hosts. Range **0-10000**. To reset the learning limit threshold to have no limit, use the **mac address learning** command.

**Examples**

- These commands enable MAC address learning on **VLAN 10** configuration.

```plaintext
switch(config)#vlan 10
switch(config-vlan-10)#mac address learning
```

- These commands disable MAC address learning on **VLAN 10** configuration.

```plaintext
switch(config)#vlan 10
switch(config-vlan-10)#no mac address learning
```

- An example for **5,000** MACs:

```plaintext
switch(config-vlan-10)#mac address learning local limit 5000 hosts
```

Mac address learning local limit **5000** host.

No mac address learning local limit **5000** host.

Default mac address learning local limit **5000** host.
11.4.7.17  **mac address-table aging-time**

The **mac address-table aging-time** command configures the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries when their presence in the MAC address table exceeds the aging time.

The **no mac address-table aging-time** and **default mac address-table aging-time** commands reset the aging time to its default by removing the **mac address-table aging-time** command from **running-config**.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
mac-address-table aging-time period
no mac-address-table aging-time
default mac-address-table aging-time
```

**Parameters**
- **period**  MAC address table aging time. Default is 300 seconds. Options include:
  - 0  disables deletion of table entries on the basis of aging time.
  - 10 through 1000000 (one million) aging period (seconds).

**Example**
This command sets the MAC address table aging time to two minutes (120 seconds).

```plaintext
switch(config)#mac address-table aging-time 120
switch(config)#
```
11.4.7.18  mac address-table static

The `mac address-table static` command adds a static entry to the MAC address table. Each table entry references a MAC address, a VLAN, and a list of Layer 2 (Ethernet or port channel) ports. The table supports three entry types: unicast drop, unicast, and multicast.

- A drop entry does not include a port.
- A unicast entry includes one port.
- A multicast entry includes at least one port.

Packets with a MAC address (source or destination) and VLAN specified by a drop entry are dropped. Drop entries are valid for only unicast MAC addresses.

The command replaces existing dynamic or static table entries with the same VLAN-MAC address. Static entries are not removed by aging (`mac address-table aging-time`). Static MAC entries for mirror destinations or LAG members are typically avoided.

The most important byte of a MAC address distinguishes it as a unicast or multicast address:

- **Unicast**: most significant byte is an even number. Examples: `0200.0000.0000` `1400.0000.0000`.
- **Multicast**: most significant byte is an odd number. Examples: `0300.0000.0000` `2500.0000.0000`.

The `no mac address-table static` and `default mac address-table static` commands remove corresponding `mac address-table static` commands from `running-config` and MAC address table entries.

**Command Mode**

Global Configuration

**Command Syntax**

```
mac address-table static mac_address vlan v_num [DESTINATION]
```

```
o mac address-table static mac_address vlan v_num [DESTINATION]
```

```
default mac address-table static mac_address vlan v_num [DESTINATION]
```

**Parameters**

- `mac_address`  Table entry’s MAC address (dotted hex notation – H.H.H).
- `v_num`  Table entry’s VLAN.
- `DESTINATION`  Table entry’s port list.

For multicast MAC address entries, the command may contain multiple ports, listed in any order. The CLI accepts only one interface for unicast entries.

- `drop`  creates drop entry in table. Valid only for unicast addresses.
  - `interface ethernet e_range`  Ethernet interfaces specified by `e_range`.
  - `interface port-channel p_range`  Port channel interfaces specified by `p_range`.
  - `no parameter`  Valid for `no` and `default` commands that remove multiple table entries.

`e_range` and `p_range` formats include number, range, comma-delimited list of numbers and ranges.

**Examples**

- This command adds a static entry for unicast MAC address `0012.3694.03ec` to the MAC address table.

  ```
  switch(config)#mac address-table static 0012.3694.03ec vlan 3
  interface Ethernet 7
  switch(config)#show mac address-table static
  Mac Address Table
  ```
• These commands adds a static drop entry for MAC address **0012.3694.03ec** to the MAC address table, then displays the entry in the MAC address table.

```plaintext
switch(config)#mac address-table static 0012.3694.03ec vlan 3 drop
switch(config)#show mac address-table static
```

```
Vlan Mac Address Type Ports Moves Last Move
---- ----------- ---- ----- ----- 
 1 0012.3694.03ec STATIC Et7 
```

```
switch(config)#
```

• This command adds a static entry for the multicast MAC address **0112.3057.8423** to the MAC address table.

```plaintext
switch(config)#mac address-table static 0112.3057.8423 vlan 4
interface port-channel 10 port-channel 12
switch(config)#show mac address-table
```

```
Vlan Mac Address Type Ports Moves Last Move
---- ----------- ---- ----- ----- 
 4 0112.3057.8423 STATIC Po10 Po12 
```

```
switch(config)#
```
11.4.7.19  monitor link-flap policy

The monitor link-flap policy command places the switch in link-flap configuration mode for configuring link flap profiles and compiling a default-profile set. Link-flap configuration mode is not a group change mode; running-config is changed immediately after commands are executed. The exit command does not affect the configuration.

Link flap profiles are assigned to Ethernet interfaces and specify conditions that define a link-flap error. When link flap monitoring is enabled on an interface, the link-flap conditions determine when the interface is error-disabled. Multiple profiles can be assigned to an interface to monitor a set of error conditions.

Command Mode
Global Configuration

Command Syntax

monitor link-flap policy

Commands Available in link-flap Configuration Mode

• default-profiles configures the set of profiles that define the default-profile set.
• profile max-flaps (Link Flap Configuration) configures a link-flap profile.

Examples

• These commands place the switch in link-flap configuration mode.
  
  switch(config)#monitor link-flap policy
  switch(config-link-flap)#

• This command returns the switch to global configuration mode.
  
  switch(config-link-flap)#exit
  switch(config)#
11.4.7.20  **monitor link-flap profiles**

The **monitor link-flap profiles** command enables link-flap monitoring on the configuration mode interface and specifies the error-disable criteria for the interface. Entering a **monitor link-flap profiles** command replaces the corresponding statement in **running-config**.

The command enables the following link flap detection options:

- **monitor link-flap** *(no profiles listed)*: The interface detects link flaps using the criteria defined by the default-profile set (**default-profiles**).
- **monitor link-flap profiles** *(at least one profile listed)*: The interface detects link flaps using the criteria of the listed profiles. Error-disable criteria require conditions that match at least one profile.
- **default monitor link-flap**: The interface detects link flaps using the **errdisable flap-setting cause link-flap** and **errdisable recovery cause** commands.
- **no monitor link-flap**: The interface does not detect link flaps.
- **Default monitor link flap** is the default setting.

**Command Mode**

Interface-Ethernet Configuration
Interface-Management Configuration

**Command Syntax**

```
monitor link-flap [LF_PROFILES]
no monitor link-flap
default monitor link-flap
```

**Parameters**

- **LF_PROFILES**  Name of link-flap profiles assigned to interface. Parameter may contain zero, one, or multiple link-flap profile names:
  - **no parameter**  Link flap criteria determined by default-profile set.
  - **profiles profile_name**  Name of single link-flap profile.
  - **profiles profile_name_1 profile_name_2 ... profile_name_N**  List of link-flap profile names.

**Examples**

- This command applies the **LF03** and **LF04** link flap profiles to **Ethernet interface 33**.

  ```
  switch(config)#interface ethernet 33
  switch(config-if-Et33)#monitor link-flap profiles LF03 LF04
  switch(config-if-Et33)#show active
  interface Ethernet33
  monitor link-flap profiles LF04 LF03
  switch(config-if-Et33)#
  ```

- This command disables link-flap monitoring on **Ethernet interface 34**.

  ```
  switch(config)#interface ethernet 34
  switch(config-if-Et34)#no monitor link-flap
  switch(config-if-Et34)#show active
  interface Ethernet34
  no monitor link-flap
  switch(config-if-Et34)#
  ```
11.4.7.21  monitor server-failure link

The monitor server-failure link command enables Rapid Automated Indication of Link-Loss (RAIL) on the configuration mode interface. RAIL must be properly configured globally or this command has no effect on switch operation.

When an interface monitored by RAIL goes down, the switch performs these steps for servers that the switch accesses from the interface:

1. IP addresses of the servers are removed from ARP cache.
2. A dynamic MAC entry is added to the MAC address table for each server. The port for each entry is listed as CPU.

The no monitor server-failure link and default monitor server-failure link commands disable RAIL on the configuration mode interface by deleting the corresponding monitor server-failure link command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

Command Syntax

monitor server-failure link
no monitor server-failure link
default monitor server-failure link

Related Commands

monitor server-failure places the switch in server-failure configuration mode for configuring RAIL.

Example

These commands enable RAIL on port-channel interface 100.

```
switch(config)#interface port-channel 100
switch(config-if-Po100)#monitor server-failure link
switch(config-if-Po100)#show active
interface Port-Channel100
    monitor server-failure link
switch(config-if-Po100)#
```
11.4.7.22  monitor server-failure

The monitor server-failure command places the switch in server-failure configuration mode. Rapid Automated Indication of Link-Loss (RAIL) settings are configured in server-failure configuration mode. RAIL is disabled by default and is enabled by the no shutdown command in server-failure configuration mode.

The no monitor server-failure and default monitor server-failure commands disable RAIL and restore all settings to their default state by removing all server-failure configuration mode statements from running-config.

Server-failure configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting server-failure configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax

monitor server-failure
no monitor server-failure
default monitor server-failure

Commands Available in server-failure Configuration Mode

• network (server-failure configuration mode)
• proxy (server-failure configuration mode)
• shutdown (server-failure configuration mode)

Examples

• These commands place the switch in server-failure configuration mode and enables RAIL.

```
switch(config)#monitor server-failure
switch(config-server-failure)#show active
switch(config-server-failure)#no shutdown
switch(config-server-failure)#show active
monitor server-failure
    no shutdown
switch(config-server-failure)#
```

• This command deletes all server-failure configuration mode commands from running-config.

```
switch(config)#no monitor server-failure
switch(config)#
```
11.4.7.23 monitor session destination cpu

The `monitor session destination cpu` command configures the CPU as the destination port of a specified port mirroring session. The `monitor session source` command configures the source port of the mirroring session. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from one direction.

The CPU can only be configured as a destination for a mirroring session, not as a source. However, the CPU can serve as the destination for multiple mirroring sessions. Traffic mirrored to the CPU can be viewed using tcpdump.

The `no monitor session destination cpu` and `default monitor session destination cpu` commands remove the mirror session destination assignment by deleting the corresponding `monitor session destination cpu` command from `running-config`. The `no monitor session` command removes the entire mirror session.

**Command Mode**

Global Configuration

**Command Syntax**

```
monitor session session_name destination cpu
no monitor session session_name destination cpu
default monitor session session_name destination cpu
```

**Parameters**

`session_name`  Label assigned to port mirroring session.

**Guidelines**

To view the traffic mirrored to the CPU from a source port, use tcpdump from the Bash shell, with the source interface as an argument. This causes tcpdump to capture packets from the kernel interface of the source port.

**Examples**

- These commands configure *Ethernet interface 35* as the source and the CPU as the destination port for the `redirect_1` mirroring session, then display the mirror interface.

```
switch(config)# monitor session redirect_1 destination cpu
switch(config)# monitor session redirect_1 source ethernet 35
switch(config)# show monitor session
Session redirect_1
------------------------
Source Ports:          
   Both:       Et35
Destination Ports:     
   Cpu : active (mirror0)
switch(config)#
```

- This command uses tcpdump to view the traffic mirrored by the `redirect_1` mirroring session. The CPU mirror interface specified in the previous output must be used in the tcpdump expression (in this case, *mirror0*).

```
switch# bash tcpdump -i mirror0
tcpdump: WARNING: mirror0: no IPv4 address assigned
```
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on mirror0, link-type EN10MB (Ethernet), capture size 65535 bytes
09:51:12.478363 00:1c:73:27:a6:d3 (oui Arista Networks) > 01:80:c2:00:00:00 (oui Unknown), 802.3, length 119: LLC, dsap STP (0x42) Individual, ssap STP (0x42) Command, ctrl 0x03: STP 802.1s, Rapid STP, CIST Flags [Proposal, Learn, Forward, Agreement], length 102

switch#
monitor session destination

The `monitor session destination` command configures an interface as the destination port of a specified port mirroring session. The destination is usually an Ethernet interface, but other options are available on certain platforms (see Guidelines). The `monitor session source` command configures the source port of the mirroring session.

An interface cannot be used in more than one mirror session and cannot be simultaneously used as both source and destination. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic only from one direction.

Note: On platforms which support the use of port channels as mirror destinations, a port channel must not be used as a mirror destination if it is a member of an MLAG.

The `no monitor session destination` and `default monitor session destination` commands remove the mirroring session destination assignment by deleting the corresponding `monitor session destination` command from `running-config`. The `no monitor session` removes the entire mirroring session.

Command Mode
Global Configuration

Command Syntax

```
monitor session session_name destination { cpu | ethernet e_range | port-channel p_range | tunnel mode }
no monitor session session_name destination
default monitor session session_name destination
```

Parameters

- `session_name` label assigned to the port mirroring session.
- `cpu` configures a CPU as the destination interface.
- `ethernet e_range` configures Ethernet interfaces specified by `e_range` as the destination interface. The ethernet interface value ranges from 1 to 50.
- `port-channel p_range` configures port channel interfaces specified by `p_range` as the destination interface. The port-channel value ranges from 1 to 2000.
- `tunnel mode` configures a tunnel as the destination interface. Option includes:
  - `gre` configures GRE-tunnel as the destination interface.

Guidelines
Tunnel mode is supported on select platforms only.

Port mirroring capacity varies by platforms. The session destination capacity of switches on each platform is listed below:

- **Arad Platform:** Ethernet interfaces (one).
- **FM6000 Platform:** Ethernet interfaces (any count), Port channel interfaces (any count), CPU.
- **Petra Platform:** Ethernet interfaces (eight for Rx or Tx sessions; four for both ways).
- **Trident Platform:** Ethernet interfaces (one).
- **Trident II Platform:** Ethernet interfaces (one).

When there are multiple transmit (Tx) sources in a monitor session, mirrored frames use Tx properties of the lowest numbered Tx mirror source configured. Packets are modified based on properties.

Allowed VLANs on the `ethernet8` source interface are 10, 20, and 30. Allowed VLANs on `ethernet9` source interface are 30, 40, and 50. The frames going out of `ethernet9` tagged with 10, 20, and 30 appears at the mirrored destination as tagged frames. The tagged frames with 40 or 50 on `ethernet9`
appears at the mirrored destination as untagged frames. Since ethernet8 is the lowest numbered source interface, all Tx frames on ethernet8 are tagged in the mirrored destination.

Examples

• This command configures Ethernet interface 8 as the destination port for the redirect_1 mirroring session.

```bash
switch(config)#monitor session redirect_1 destination ethernet 2
switch(config)#show monitor session

Session redirect_1
--------------------
Source Ports:
Destination Ports:
    Et2 : active
switch(config)#
```

• This command configures a GRE tunnel with source and destination addresses as 1.1.1.1 and 2.2.2.2 respectively as the destination interface for the redirect_2 mirroring.

```bash
switch(config)#monitor session redirect_2 destination tunnel mode gre source 1.1.1.1 destination 2.2.2.2
switch(config)#show monitor session

Session redirect_2
--------------------
Source Ports:
Destination Ports:
    status  source    dest    TTL  DSCP  proto    VRF     fwd-drop
    Gre1 : active  1.1.1.1   2.2.2.2 128  0     0x88be   default no
switch(config)#
```
11.4.7.25  monitor session forwarding-drop

The `monitor session forwarding-drop` command configures a forwarding-drop session for mirroring ingress packets that are dropped during ASIC forwarding.

The `no monitor session forwarding-drop` and `default monitor session forwarding-drop` commands delete the current forwarding-drop configuration.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
monitor session session_name forwarding-drop destination tunnel mode
go no monitor session session_name forwarding-drop destination tunnel mode
default monitor session session_name forwarding-drop destination tunnel mode
```

**Parameters**

- `destination` specifies to mirror packets at destination.
- `tunnel mode` specifies to mirror packets that pass through a tunnel. Options include:
  - `gre` configures GRE-tunnel as the destination interface.

**Related Commands**

- `monitor session destination`
- `monitor session destination cpu`
- `show monitor session`

**Guidelines**

The forwarding-drop configuration is supported on select platforms only.

**Example**

This command configurations a forwarding-drop session to `1.1.1.1` as the destination.

```
switch(config)#monitor session 1 forwarding-drop destination tunnel mode
  gre source 1.1.1.1 destination 2.2.2.2

switch(config)#show monitor session
Session 1
------------------------
Programmed in HW: No
Source Ports:
Destination Ports:
status source dest TTL DSCP proto VRF
fwd-drop Gre1: active 1.1.1.1 2.2.2.2 128 0 0x88be default
yes
```

switch(config)#
11.4.7.26  monitor session ip access-group

The `monitor session ip access-group` command configures an ACL to filter the traffic being mirrored to the destination port. ACLs applied to a source port affect the RX side of the interface, and do not impact the TX side of the interface. TX mirrored packets cannot be filtered, and will continue to be sent to the mirror destination.

The `no monitor session ip access-group` and `default monitor session ip access-group` commands remove the filter from the specified mirror session by deleting the corresponding `monitor session ip access-group` command from `running-config`. The `no monitor session` command removes the entire mirror session.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
monitor session session_name ip access-group acl_name
no monitor session session_name ip access-group
default monitor session session_name ip access-group
```

**Parameters**

- `session_name`  Label assigned to port mirroring session.
- `acl_name`  The ACL to be applied to filter traffic for the specified session.

**Examples**

- These commands create an ACL and apply it to filter the traffic mirrored to the destination port by session `redirect_1`.

  ```plaintext
  switch(config)#ip access-list allow-host
  switch(config-acl-allow-host)#10 permit ip host 192.168.11.24 host 10.0.215.23
  switch(config-acl-allow-host)#20 deny ip any any
  switch(config-acl-allow-host)#exit
  switch(config)#
  switch(config)#monitor session redirect_1 ip access-group allow-host
  switch(config)#
  ```

- Use the `show monitor session` command to verify the configuration.

  ```plaintext
  switch#show monitor session
  Session redirect_1
  ------------------------
  Source Ports:
  Both:  Et35(Acl:allow-host)
  Destination Ports:
  Cpu :  active (mirror0)
  ip access-group: allow-host
  switch#
  ```
11.4.7.27  monitor session source ip access-group

The `monitor session source ip access-group` command configures an ACL to filter the traffic being mirrored from a specific source port. This enables the ability to filter traffic using a different ACL on each source port and have the combined matched traffic sent to the destination port.

The `no monitor session source ip access-group` and `default monitor session source ip access-group` commands remove the filter from the specified mirror session by deleting the corresponding `monitor session source ip access-group` command from `running-config`. The `no monitor session` command removes the entire mirror session.

Command Mode
Global Configuration

Command Syntax

```
monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
no monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
default monitor session s_name source INT_NAME [DIRECT] ip access-group acl_name
```

Parameters

- **s_name**  Label assigned to port mirroring session.
- **INT_NAME**  Source interface for the mirroring session.
  - **ethernet e_range**  Ethernet interfaces specified by `e_range`.
  - **port-channel p_range**  Port channel interfaces specified by `p_range`.
- **DIRECT**  Transmission direction of traffic to be mirrored. Options include:
  - **no parameter**  mirrors received traffic only.
  - **rx**  mirrors received traffic only.
- **acl_name**  The ACL to be applied to filter traffic for the specified session.

Example

These commands create ACLs and apply them to filter the traffic mirrored from two source ports by session `redir_1`.

```
switch(config)#ip access-list allow-host-x
switch(config-acl-allow-host-x)#10 permit ip host 192.168.11.24 host 10.0.215.23
switch(config-acl-allow-host-x)#20 deny ip any any
switch(config-acl-allow-host-x)#exit
switch(config)#ip access-list allow-host-y
switch(config-acl-allow-host-y)#10 permit ip host 172.16.233.80 host 10.0.215.23
switch(config-acl-allow-host-y)#20 deny ip any any
switch(config-acl-allow-host-y)#exit
switch(config)#monitor session redir_1 source ethernet 5,9 rx
switch(config)#monitor session redir_1 source ethernet 5 ip access-group allow-host-x
switch(config)#monitor session redir_1 source ethernet 9 ip access-group allow-host-y
switch(config)#
```
11.4.7.28  monitor session source

The `monitor session source` command configures the source port of a specified port mirroring session. The `monitor session destination` or `monitor session destination cpu` command configures the destination port of the mirroring session.

An interface cannot be used in more than one mirror session and cannot be simultaneously a source and a destination. An interface which is part of a port channel cannot be used as a source, but a port channel which is a member of an MLAG can be used. By default, mirror sessions duplicate ingress and egress traffic but are configurable to mirror traffic from only one direction.

The `no monitor session source` and `default monitor session source` commands remove the mirroring session source assignment by deleting the corresponding `monitor session source` command from `running-config`. The `no monitor session` removes entire the mirroring session.

**Command Mode**

Global Configuration

**Command Syntax**

```
monitor session session_name source INT_NAME DIRECTION
```

```
no monitor session session_name source INT_NAME DIRECTION
```

```
default monitor session session_name source INT_NAME DIRECTION
```

**Parameters**

- `session_name`  Label assigned to port mirroring session.
- `INT_NAME` Source interface for the mirroring session.
  - `ethernet e_range` Ethernet interfaces specified by `e_range`.
  - `port-channel p_range` Port channel interfaces specified by `p_range`.
- `DIRECTION` transmission direction of traffic to be mirrored.
  - `no parameter` mirrors transmitted and received traffic.
  - `both` mirrors transmitted and received traffic.
  - `rx` mirrors received traffic only.
  - `tx` mirrors transmitted traffic only.

**Guidelines**

On DCS-7050, DCS-7050X, DCS-7250X, and DCS-7300X series, due to limitations of the switch ASIC, all frames mirrored on egress are prefixed with an 802.1Q VLAN tag, even when the egress port is configured as an access port. If the capture device is unable to process VLAN tags in a desirable manner mirroring should be configured exclusively for ingress traffic by specifying `rx`.

**Restrictions**

Port mirroring capacity varies by platform. Session source capacity for each platform is listed below:

- **FM6000 Platform:** Ethernet interfaces (any number), port channel interfaces (any number).
- **Arad Platform:** Ethernet interfaces (any number), port channel interfaces (any number).
- **Petra Platform:** Ethernet interfaces (eight for Rx or Tx sessions; four for both ways).
- **Trident Platform:** Ethernet interfaces (any number), port channel interfaces (any number).
- **Trident II Platform:** Ethernet interfaces (any number), port channel interfaces (any number).

The number of interfaces that can be effectively mirrored is restricted by the destination port speed.

**Example**
This command configures *Ethernet interface 7* as the source port for *redirect_1* mirroring session.

```
switch(config)#monitor session redirect_1 source ethernet 7
switch(config)#
```
11.4.7.29  **monitor session truncate**

The *monitor session truncate* command configures a port mirroring session to truncate mirrored packets, retaining only the first 160 bytes. Packet truncation can be used to prevent oversubscription of the session’s destination port.

Packet truncation applies to the mirroring session as a whole, and cannot be applied to individual source ports.

The `no monitor session truncate` and `default monitor session truncate` commands restores mirroring of full packets by deleting the corresponding `monitor session truncate` command from *running-config*. The `no monitor session` removes the entire mirroring session.

**Command Mode**
Global Configuration

**Command Syntax**

```bash
monitor session session_name truncate
no monitor session session_name truncate
default monitor session session_name truncate
```

**Parameters**

*session_name*  
Label assigned to port mirroring session.

**Example**

This command configures mirroring session *redirect_1* to truncate mirrored packets.

```
switch(config)#monitor session redirect_1 truncate
switch(config)#
```
The `mtu` command configures the IPv4 and IPv6 Maximum Transmission Unit (MTU) size for the configuration mode interface. The switch fragments IP packets that are larger than the MTU value for the outbound interface. An interface's MTU value is displayed with the `show interfaces` command.

MTU is independently configurable on all routable interfaces.

The `no mtu` and `default mtu` commands restore the interface’s MTU to the default value by removing the corresponding `mtu` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `mtu bytes`
- `no mtu`
- `default mtu`

**Parameters**

- `bytes` MTU size (bytes). Values range from 68 to 9214. The default MTU size is 1500 bytes.

**Example**

This command sets the MTU size of 1492 bytes on VLAN interface 20.

```
switch(config)#interface vlan 20
switch(config-if-Vl20)#mtu 1492
switch(config-if-Vl20)#
```
11.4.7.31 network (server-failure configuration mode)

The `network` command specifies the IPv4 network space that Rapid Automated Indication of Link-Loss (RAIL) monitors for failed links to connected servers. RAIL reduces the wait time for applications on directly connected servers that are blocked due to a failed link. `Running-config` supports simultaneous network command, allowing RAIL to monitor multiple disjoint network spaces.

When a server on the specified network is blocked because of a failed Ethernet or port channel link, the switch becomes a proxy for the unavailable server and responds with TCP RST or ICMP Unreachable segments to devices sending packets to the unavailable server.

The `no network` and `default network` commands terminate the RAIL monitoring of the specified IPv4 address space by deleting the corresponding `network` command from `running-config`.

Command Mode
Server-failure Configuration

Command Syntax
```
network netv4_address
no network netv4_address
default network netv4_address
```

Parameters

`netv4_addr` IPv4 subnet address to be monitored (CIDR or address-mask notation).

Related Command

`monitor server-failure` places the switch in server-failure configuration mode.

Example

This command specifies two IPv4 network spaces that RAIL monitors for server failures.

```
switch(config)#monitor server
switch(config-server-failure)#network 10.1.1.0/24
switch(config-server-failure)#network 10.2.1.96/28
switch(config-server-failure)#show active
monitor server-failure
    network 10.2.1.96/28
    network 10.1.1.0/24
switch(config-server-failure)#
```
11.4.7.32  no monitor session

The no monitor session and default monitor session commands remove the specified monitor session from the switch by deleting all corresponding monitor commands from running-config. Commands that remove or alter individual commands within a session configuration are described in the monitor session destination and monitor session source commands.

Command Mode
Global Configuration

Command Syntax

no monitor session session_name

default monitor session session_name

Parameters

session_name  Label assigned to port mirroring session.

Example

This command displays the configuration of the redirect_1 mirroring session, deletes the session, then confirms that the session was removed.

```
switch(config)#show monitor session redirect_1
Session redirect_1
------------------------
Source Ports
  Both:        Et7
Destination Port: Et8
switch(config)#no monitor session redirect_1
switch(config)#show monitor session redirect_1
Session not created
```

switch(config)#
11.4.7.33 phy diag

Use the **phy diag** command to configure a test pattern in the interface configuration mode. The **no** and **default** forms of the command disables the test pattern.

**Command Mode**
Interface configuration mode

**Command Syntax**

- **phy diag** [transmitter | receiver] test pattern *TestPattern*
- **no phy diag** [transmitter | receiver] test pattern *TestPattern*
- **default phy diag** [transmitter | receiver] test pattern *TestPattern*

**Parameters**
- **transmitter** Configures the physical transmitter.
- **receiver** Configures the physical receiver.
- **test pattern** *TestPattern* Configures the named test pattern.

**Examples**

- Enable a test pattern on an interface using the **phy diag** command. You can select the transmitter or the receiver. To display the available interfaces, select **test pattern ?**.

  ```
  switch(config-if)# phy diag [ transmitter | receiver ] test pattern ?
  PRBS11  Configure the PRBS11 test pattern
  PRBS15  Configure the PRBS15 test pattern
  PRBS23  Configure the PRBS23 test pattern
  PRBS31  Configure the PRBS31 test pattern
  PRBS49  Configure the PRBS49 test pattern
  PRBS58  Configure the PRBS58 test pattern
  PRBS7   Configure the PRBS7 test pattern
  PRBS9   Configure the PRBS9 test pattern
  ```

- To disable a test pattern on an interface, enter the following command. You can select the transmitter or the receiver, as well as the selected named test pattern.

  ```
  switch(config-if)# no phy diag [ transmitter | receiver ] test pattern *TestPattern*
  ```

- By default, a test pattern is disabled.

  ```
  switch(config-if)# default phy diag [ transmitter | receiver ] test pattern
  ```

- The following command clears the recorded test pattern status data for all the interfaces. Upon running the command, all the counter values are set to 0 and link states are marked as **not locked**.

  ```
  switch# clear phy diag test pattern
  ```
11.4.7.34  platform sand monitor serdes error log

The platform sand monitor serdes error log command is used for enabling the serdes error log for fabric link monitoring.

Command Mode
Global Configuration

Command Syntax
platform sand monitor serdes error log

Example
This command enables the serdes error log for fabric link monitoring.

switch(config)#platform sand monitor serdes error log
switch(config)#
11.4.7.35  platform sand monitor serdes error threshold

The platform sand monitor serdes error threshold command is used for generating a fabric link monitoring serdes error threshold.

**Command Mode**

Global Configuration

**Command Syntax**

`platform sand monitor serdes error threshold`

**Example**

This command monitors serdes error thresholds over the specified number of received cells, resulting in the isolation of a fabric link between 200 and 30000 received cells.

```
switch(config)#platform sand monitor serdes error threshold 200 30000
switch(config)#
```
11.4.7.36  platform sand monitor serdes poll period

The `platform sand monitor serdes poll period` command is used to enable the serdes poll period.

**Command Mode**
Global Configuration

**Command Syntax**
`platform sand monitor serdes poll period`

**Example**
This command changes the serdes polling period for fabric link monitoring to **6** seconds.

```
switch(config)#platform sand monitor serdes poll period 6
switch(config)#
```
11.4.7.37 platform sand monitor serdes poll threshold isolation

The platform sand monitor serdes poll threshold isolation command is used to set and enables fabric link monitoring for serdes poll threshold isolation.

Command Mode
Global Configuration

Command Syntax
platform sand monitor serdes poll threshold isolation

Example
This command changes the number of consecutive polls in which the threshold needs to be detected to isolate a link. In this case the number is 5 consecutive polls.

```
switch(config)#platform sand monitor serdes poll threshold isolation 5
switch(config)#
```
11.4.7.38 platform sand monitor serdes poll threshold recovery

The **platform sand monitor serdes poll threshold recovery** command is used to set and enable fabric link monitoring for serdes poll threshold recovery.

**Command Mode**
Global Configuration

**Command Syntax**
`platform sand monitor serdes poll threshold recovery`

**Example**
This command changes the number of consecutive serdes polls used for threshold recovery to 6 seconds.

```
switch(config)#platform sand monitor serdes poll threshold recovery 6
switch(config)#
```
11.4.7.39 profile max-flaps (Link Flap Configuration)

The `profile max-flaps` command creates a link flap profile that, when assigned to an Ethernet interface, specifies the conditions that result in an error-disable action. Link flap profile parameters include:

- **flaps**  Threshold number of interface state changes.
- **period** Interval when link flaps accumulate to trigger an error condition.
- **violations** Number of link flap errors (threshold exceeded over specified period).
- **intervals** Quantity of periods.

By default, violations and intervals are each set to one, resulting in a profile that triggers a link-flap error when the specified frequency is exceeded once. By configuring violations and intervals, link-flap errors are defined when the frequency is exceeded multiple times over a specified set of intervals.

**Default** is a reserved profile name that modifies the `errdisable flap-setting cause link-flap` statement in `running-config`. When configuring the default profile, violations and intervals are disregarded.

The `no profile max-flaps` command removes the specified profile by deleting the corresponding `profile max-flaps` command from `running-config`. The `no profile max-flaps default` command restores default `errdisable flap-setting cause link-flap` values by removing that command from `running-config`.

**Command Mode**
Link-flap Configuration

**Command Syntax**
```
profile PROFILE_NAME max-flaps flap_max time period [EXTENSIONS]
no profile LF_PROFILE
```

**Parameters**
- **PROFILE_NAME**  Name of link flap profile. Options include:
  - **default**  command modifies default values (`errdisable flap-setting cause link-flap`).
  - **profile_name**  command modifies specified link-flap profile.
  - **flap_max**  Threshold number of interface state changes. Value ranges from 1 to 100.
  - **period**  Interval when flaps accumulate toward threshold (seconds). Value ranges from 1 to 1800.
- **EXTENSIONS**  Configures multi-flap triggers. Options include:
  - **no parameter**  Sets errors and episodes to default values (one).
  - **violations errors intervals episodes**  Link flap errors (errors) and number of periods (episodes).
    - **Errors**  range is 1 to 1000. Default value is 1.
    - **Episodes**  range is 1 to 1000. Default value is 1.

**Related Command**
`monitor link-flap policy` places the switch in link-flap configuration mode.

**Example**
These commands create two link flap profiles with various trigger settings.

```
switch(config)#monitor link-flap policy
switch(config-link-flap)#profile LF01 max-flaps 15 time 60
switch(config-link-flap)#profile LF02 max-flaps 10 time 30 violations 5 intervals 10
switch(config-link-flap)#show active
```
monitor link-flap policy
    profile LF01 max-flaps 15 time 60 violations 1 intervals 1
    profile LF02 max-flaps 10 time 30 violations 5 intervals 10
switch(config-link-flap)#
11.4.7.40  proxy (server-failure configuration mode)

The `proxy` command enables the Rapid Automated Indication of Link-Loss (RAIL) proxy setting and specifies the interval that RAIL responds to messages sent to servers on failed links, starting from when the switch detects the failed link. The RAIL state machine is in the proxying state during the timeout interval this command specifies. When RAIL proxy is not enabled, the switch maintains a list of unavailable servers without responding to messages sent the servers. The switch can enter RAIL proxy state only when this command is enabled.

The RAIL proxy setting is **disabled** by default. When RAIL proxy is enabled, the default period is three minutes.

The `no proxy` and `default proxy` commands return the RAIL proxy setting to disabled by removing the proxy statement from `running-config`.

The `no proxy lifetime` and `default proxy lifetime` command sets the proxy time setting to its default value of three minutes if the RAIL proxy setting is **enabled**. These commands have no effect if the RAIL proxy setting is **disabled**.

**Command Mode**

Server-failure Configuration

**Command Syntax**

```
proxy
no proxy
default proxy
```

**Parameters**

`timespan` proxy timeout period (minutes). Value ranges from 1 to 10080. Default value is 3.

**Related Command**

`monitor server-failure` places the switch in server-failure configuration mode.

**Examples**

- These commands enable the RAIL proxy and sets the proxy timeout period of 10 minutes.

````
switch(config)#monitor server
switch(config-server-failure)#proxy lifetime 10
switch(config-server-failure)#show active
```

- This command sets the proxy timeout period to its default value of 3 minutes.

````
switch(config-server-failure)#no proxy lifetime
switch(config-server-failure)#show active
```

- This command disables the RAIL proxy.

````
switch(config-server-failure)#no proxy
switch(config-server-failure)#show active
```

1295
The `show bridge mac-address-table aging timeout` command displays the aging time for MAC address table dynamic entries. Aging time defines the period an entry is in the table, as measured from the most recent reception of a frame on the entry’s VLAN from the specified MAC address. The switch removes entries that exceed the aging time.

Aging time ranges from 10 seconds to 1000000 seconds with a default of 300 seconds (five minutes).

**Command Mode**

EXEC

**Command Syntax**

`show bridge mac-address-table aging timeout`

**Example**

This command shows the MAC address table aging time.

```
switch>show bridge mac-address-table aging timeout
Global Aging Time: 120
switch>
```
11.4.7.42  show errdisable recovery

The `show errdisable recovery` command displays information about the recovery intervals and error disable causes.

Command Mode

EXEC

Command Syntax

`show errdisable recovery`

Parameters

- **no parameter** state of the system.

The following output is for a system where the causes are listed and interval timer for each cause is identified along with the timer status.

```
switch#show errdisable recovery
Errdisable Reason        Timer Status     Timer Interval
------------------------ ----------------- ---------------
bpdu guard              Disabled           30
hitless-reload-down    Disabled           300
lacp-no-portid          Disabled           N/A
lacp-rate-limit         Disabled           300
license-enforce         Disabled           N/A
link-flap               Disabled           300
no-internal-vlan        Disabled           300
uplink-failure-detection Disabled           300
```
11.4.7.43  **show fabric monitoring health**

The `platform sand monitor health` command is used to display the fabric monitoring connected state status with isolated links.

**Command Mode**
Global Configuration

**Command Syntax**
`platform sand monitor health`

**Example**
This command displays the connected state status with isolated links.

```
switch(config)#show platform sand health
Fabric serdes isolated by fabric monitoring: (36 total)
Arad5/0 serdes [0-1, 10-19, 2, 20-29, 3, 30-35, 4-9]

Top fabric serdes list by number of times isolated by monitoring:
Arad5/0 serdes 0: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 1: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 10: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 11: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 12: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 13: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 14: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 15: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 16: 1 (last occurred: 0:01:04 ago)
Arad5/0 serdes 17: 1 (last occurred: 0:01:04 ago)

switch(config)#`
```
11.4.7.44  show interfaces

The `show interfaces` command displays operational status and configuration information of specified interfaces. The output includes speed, duplex, flow control information and basic interface statistics.

The input and output bit rates, as displayed, do not include framing bits that are part of the Ethernet standard, the inter-frame gap and preamble that total 20 bytes per packet. The percentage number includes those framing bits to provide a better link utilization estimate.

**Command Mode**
EXEC

**Command Syntax**
```
show interfaces [INT_NAME]
```

**Parameters**

*INT_NAME*  Interface type and numbers. Options include:

* no parameter  all interfaces.
* ethernet _e_range_  Ethernet interface range specified by _e_range_.
* loopback _l_range_  Loopback interface specified by _l_range_.
* management _m_range_  Management interface range specified by _m_range_.
* port-channel _p_range_  Port-Channel Interface range specified by _p_range_.
* vlan _v_range_  VLAN interface range specified by _v_range_.
* vxlan _vx_range_  VXLAN interface range specified by _vx_range_.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**
This command display configuration and status information for Ethernet interface 1 and 2.

```
switch>show interfaces ethernet 1-2
Ethernet1 is up, line protocol is up (connected)
    Hardware is Ethernet, address is 001c.2481.7647 (bia 001c.2481.7647)
    Description: mkt.1
    MTU 9212 bytes, BW 10000000 Kbit
    Full-duplex, 10Gb/s, auto negotiation: off
    Last clearing of "show interface" counters never
    5 seconds input rate 33.5 Mbps (0.3% with framing), 846 packets/sec
    5 seconds output rate 180 kbps (0.0% with framing), 55 packets/sec

switch>
11.4.7.45  show interfaces description

The `show interfaces description` command displays the status and description text of the specified interfaces. The `description` command configures an interface’s description parameter.

**Command Mode**
EXEC

**Command Syntax**
```
show interfaces [INT_NAME] description
```

**Parameters**

INT_NAME  Interface type and labels. Options include:
- no parameter  all interfaces.
- ethernet e_range  Ethernet interface range specified by `e_range`.
- loopback l_range  Loopback interface specified by `l_range`.
- management m_range  Management interface range specified by `m_range`.
- port-channel p_range  Port-Channel Interface range specified by `p_range`.
- vlan v_range  VLAN interface range specified by `vx_range`.
- vxlan vx_range  VXLAN interface range specified by `vx_range`.

Range formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

This command displays description text and status of `ethernet interfaces 1-10`.

```
switch>show interfaces ethernet 1-10 description
Interface     Status  Protocol  Description
Et1           up       up        ctar_01
Et2           up       up        ctar_02
Et3           up       up        ctar_03
Et4           up       up        fobd_01
Et5           up       up        fobd_02
Et6           up       up        yzrq_01
Et7           up       up        yzrq_02
Et8           down     down      yzrq_03
Et9           up       up        yzrq_04
Et10          up       up        yzrq_05
switch>
```
11.4.7.46 show interfaces phy diag

Command Mode
EXEC

Command Syntax
show interfaces [interface type interface range] phy diag [error-correction | test pattern]

Parameters
• interface type interface range Type of interface and range.
• error-correction Forwards error correction.
• test pattern Displays test patterns.

Guidelines
The user-configured test pattern is displayed under the Configured column, which is divided based on transmitter and receiver configuration. The currently operational test pattern is displayed under the Operational column. The Available column lists the test patterns available for the interface.

Example
• In this example, interfaces ethernet 26/1 and ethernet 31/1 in the show interfaces ethernet 26/1,31/1 phy diag test pattern command are selected to display the configured and operational test pattern, and the available test patterns.

```
switch#show interfaces ethernet 26/1,31/1 phy diag test pattern
Configured       Operational
Interface     Transmit Receive Transmit Receive Available
------------- -------- ------- -------- ------- -----------------------
Ethernet26/1  PRBS15   PRBS15  PRBS15   PRBS15  PRBS 7,9,11,15,23,31,58
Ethernet31/1  PRBS7    PRBS31  PRBS7    PRBS31  PRBS 7,9,11,15,23,31,58
```

The user-configured test pattern is displayed under the Configured column, which is divided based on transmitter and receiver configuration. The currently operational test pattern is displayed under the Operational column. The Available column lists the test patterns available for the interface.

• In this example, the show interfaces ethernet 26/1 phy detail | i Test pattern command displays the operational test pattern for an interface. Here the Test pattern field will not be available, on disabling the test pattern.

```
switch#show interfaces ethernet 26/1 phy detail | i Test pattern
Test pattern                enabled
switch#show interfaces ethernet 31/1 phy detail | i Test pattern
Test pattern                enabled
```

• In this example, the show interfaces ethernet 26/1,31/1 phy diag test pattern counters command displays test pattern link state and error information.

The following information is listed in the display output:
• Link state: whether or not the checker locked on to the configured test pattern.
• Bit Errors: the accumulated number of bit errors.
• Largest Burst: the largest burst of errors that occurred.
• Burst Count: the number of occurrences of errors.
• Last Error Time: the last time an error has occurred, ‘never’ if no errors have occurred.

```
switch#show interfaces ethernet 26/1,31/1 phy diag test pattern counters
Interface     Lane  Link State  Bit Errors  Burst Count  Last Error Time
--------------- ----- -------------- ----------- ---------- ----------------
Ethernet26/1  0     locked      409266  409266       1       0:21:27 ago
```

1302
In this example, the `show interfaces ethernet 26/1,31/1 phy diag test pattern counters` command displays the lock state of an interface along with a detailed information on the recorded bit errors.

The following information is listed in the display output:

- **Last clear**: the time when the test pattern results were last cleared.
- **Operational test pattern**: the test pattern operational at the receiver side.
- **Bit rate**: the transmission bit rate.
- **Lock state**: the current lock status, number of times it changed and the last time the lock status got changed.
  - **locked**: receiver is able to lock on to the incoming test pattern.
  - **not locked**: receiver is not able to lock on to the incoming test pattern.
- **Largest burst**: the largest burst of errors that occurred.
- **Bit errors**: the accumulated number of errors, number of occurrences of errors, and last time errors were captured. The * suffix, indicating that data may not be accurate due to loss of lock, is applied if the current lock status is not locked or if the lock status has changed more than once. This suffix is cleared when the test pattern status data is cleared via the CLI listed above.
- **Total Bits**: the total bits received.
- **Bit error rate (BER)**: the ratio of captured bit errors to the total bit received. The * suffix, indicating that data may not be accurate due to loss of lock, is applied if the current lock status is not locked or if the lock status has changed more than once. This suffix is cleared when the test pattern status data is cleared via the CLI listed above.
- **Bit errors since last lock**: the accumulated number of errors since last time lock was gained.
- **Total bits since last lock**: the total bits received since last lock.
- **BER since last lock**: the ratio of captured bit errors to the total bit received since last lock.

```
switch#show interfaces ethernet 26/1,31/1 phy diag test pattern counters detail
*: Data may not be accurate due to loss of lock.

11.4.7.47  **show link tracking group**

The `show link tracking group` command displays information about a specified link-state group or about all groups.

**Command Mode**

EXEC

**Command Syntax**

`show link tracking group [DATA_LEVEL][GROUPS]`

**Parameters**

- **DATA_LEVEL**  device for which the command provides data. Options include:
  - `no parameter`  information about all groups in group list.
  - `detail`  detailed information about all groups in group list.
- **GROUPS**
  - `no parameter`  all link-state groups.
  - `group_name`  link-state group name.

**Example**

This command displays all the link-state group information.

```
switch#show link tracking group detail
Link State Group: 1 Status: up
Upstream Interfaces : Vlan100
Downstream Interfaces : Vlan200
Number of times disabled : 2
Last disabled 0:10:29 ago

Link State Group: group3 Status: down
Upstream Interfaces : Ethernet24
Downstream Interfaces : Ethernet8
Number of times disabled : 2
Last disabled 0:30:35 ago

Link State Group: 2 Status: up
Upstream Interfaces : Ethernet2 Ethernet5
Downstream Interfaces : Ethernet12
Number of times disabled : 0
Last disabled never
switch#
```
11.4.7.48  show mac address-table count

The `show mac-address-table count` command displays the number of entries in the MAC address table for the specified VLAN or for all VLANs.

**Command Mode**

EXEC

**Command Syntax**

`show mac address-table count [VLANS]`

**Parameters**

**VLANS**  The VLANs for which the command displays the entry count.

- `no parameter`  all configured VLANs.
- `vlan v_num`  VLAN interface specified by `v_num`.

**Example**

This command displays the number of entries on **VLAN 39**.

```
switch>show mac address-table count vlan 39
Mac Entries for Vlan 39:
------------------------
Dynamic Address Count    : 1
Unicast Static Address Count : 1
Multicast Static Address Count : 0
Total Mac Addresses      : 2

switch>
```
11.4.7.49  show mac address-table mlag-peer

The `show mac address-table mlag-peer` command displays the specified MAC address table entries learned from the MLAG peer switch.

**Command Mode**
EXEC

**Command Syntax**
```
show mac address-table mlag-peer [ENTRY_TYPE] [MAC_ADDR] [INTF_1 ... INTF_N] [VLANS]
```

**Parameters**
- **ENTRY_TYPE** command filters display by entry type. Entry types include mlag-peer, dynamic, static, unicast, multicast entries, and configured.
  - **no parameter** all MLAG peer entries.
  - **configured** static entries on MLAG peer; includes unconfigured VLAN entries.
  - **dynamic** entries learned on MLAG peer.
  - **static** MLAG entries entered by CLI commands and include a configured VLAN.
  - **unicast** MLAG entries with unicast MAC address.
- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - **no parameter** all MAC addresses table entries.
  - **address mac_address** displays entries with specified address (dotted hex notation – H.H.H).
- **INTF_X** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - **no parameter** all Ethernet and port channel interfaces.
  - **ethernet e_range** Ethernet interfaces specified by `e_range`.
  - **port-channel p_range** Port channel interfaces specified by `p_range`.
- **VLANS** command filters display by VLAN.
  - **no parameter** all VLANs.
  - **vlan v_num** VLANs specified by `v_num`.

**Related Commands**
- `show mac address-table`
- `show mac address-table multicast`
show mac address-table multicast brief

The `show mac-address-table` command displays a summary of multicast MAC address table entries.

**Command Mode**

EXEC

**Command Syntax**

`show mac address-table multicast [VLANS] brief`

**Parameters**

- **VLANS** command filters display by VLAN.
  - *no parameter* all VLANs.
  - *vlan v_num* VLANs specified by `v_num`.

**Related Command**

`show mac address-table multicast`.
11.4.7.51 show mac address-table multicast

The `show mac-address-table` command displays the specified multicast MAC address table entries.

**Command Mode**
EXEC

**Command Syntax**
`show mac address-table multicast [MAC_ADDR][INTF][VLANS]

**Parameters**
- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - *no parameter* all MAC addresses table entries.
  - *address mac_address* displays entries with specified address (dotted hex notation – H.H.H).
- **INTF** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - *no parameter* all Ethernet and port channel interfaces.
  - *ethernet e_range* Ethernet interfaces specified by `e_range`.
  - *port-channel p_range* Port channel interfaces specified by `p_range`.
- **VLANS** command filters display by VLAN.
  - *no parameter* all VLANs.
  - *vlan v_num* VLANs specified by `v_num`.

**Related Commands**
- `show mac address-table`
- `show mac address-table multicast brief`
show mac address-table

The `show mac address-table` command displays the specified MAC address table entries.

**Command Mode**

EXEC

**Command Syntax**

`show mac address-table [ENTRY_TYPE][MAC_ADDR][INTF_1 ... INTF_N][VLANS]`

**Parameters**

- **ENTRY_TYPE** command filters display by entry type. Entry types include mlag-peer, dynamic, static, unicast, multicast entries, and configured.
  - *no parameter* all table entries.
  - *configured* static entries; includes unconfigured VLAN entries.
  - *dynamic* entries learned by the switch.
  - *static* entries entered by CLI commands and include a configured VLAN.
  - *unicast* entries with unicast MAC address.
- **MAC_ADDR** command uses MAC address to filter displayed entries.
  - *no parameter* all MAC addresses table entries.
  - *address mac_address* displays entries with specified address (dotted hex notation – H.H.H).
- **INTF_X** command filters display by port list. When parameter lists multiple interfaces, command displays all entries containing at least one listed interface.
  - *no parameter* all Ethernet and port channel interfaces.
  - *ethernet e_range* Ethernet interfaces specified by `e_range`.
  - *port-channel p_range* Port channel interfaces specified by `p_range`.
- **VLANS** command filters display by VLAN.
  - *no parameter* all VLANs.
  - *vlan v_num* VLANs specified by `v_num`.

**Related Commands**

- `show mac address-table mlag-peer`
- `show mac address-table multicast`

**Examples**

- This command displays the MAC address table.

```
switch>show mac address-table

11.4.7.53  show monitor server-failure history

The `show monitor server-failure history` command displays the time of all link failures detected by Rapid Automated Indication of Link-Loss (RAIL) and includes the interface name for each failure.

The history is cleared by removing RAIL from the switch (`no monitor server-failure`).

**Command Mode**

EXEC

**Command Syntax**

`show monitor server-failure history`

**Related Command**

`clear server-failure servers inactive`

**Example**

This command displays the Fast Server Failure link failure history from the time RAIL is instantiated on the switch.

```
switch> show monitor server-failure history
Total server failures: 4

  Server IP   Server MAC           Interface       Last Failed

switch>
```
show monitor server-failure servers

The `show monitor server-failure servers` command displays status and configuration information about each server that RAIL is monitoring. The display format depends on the parameter specified by the command:

- **single IP address**: command displays information about the server at the specified address, including IP address, MAC address, RAIL state, the time of most recent entry of all RAIL states, and the number of failed, proxied, and inactive state entries.
- **no parameter, key specifying a server list**: command displays a table. Each row corresponds to a monitored server. Information that the command displays includes IP address, MAC address, RAIL state, the time of most recent link failure.

**Command Mode**

EXEC

**Command Syntax**

`show monitor server-failure servers [SERVER_LIST]`

**Parameters**

**SERVER_LIST**  Servers for which command displays information. Valid options include:

- **no parameter**  all servers in up, down, and proxying states.
- **ipv4_addr**  individual server; command displays detailed information.
- **all**  all servers on monitored networks.
- **inactive**  all servers in inactive state.
- **proxying**  all servers in proxying state.

**Examples**

- This command displays RAIL information for the server at IP address *10.11.11.7*.

  ```
  switch>show monitor server-failure servers 10.11.11.7
  Server information:
  Server Ip Address : 10.11.11.7
  MAC Address : ad:3e:5f:dd:64:cf
  Current state : down
  Interface : Ethernet23
  Last Discovered : 2013-01-06 06:47:39
  Last Failed : 2013-02-10 00:07:56
  Last Proxied : 2013-02-10 00:08:33
  Last Inactive : 2013-02-09 23:52:21
  Number of times failed : 3
  Number of times proxied : 1
  Number of times inactive : 18
  ```

- This command displays RAIL data for all servers in monitored networks that are in inactive state.

  ```
  switch>show monitor server-failure servers inactive
  Inactive servers: 1
  Server IP    Server MAC    Interface    State    Last Failed
  ------ ------ --------------- ------- -------------
  10.1.67.92   01:22:ab:cd:ee:ff Ethernet17 inactive 7 days, 12:48:06 ago
  ```
• This command displays RAIL information for all servers in monitored networks that are in up, down, and proxying states.

```
switch>show monitor server-failure servers
Active servers: 4

```
11.4.7.55 show monitor server-failure

The `show monitor server-failure` command displays Rapid Automated Indication of Link-Loss (RAIL) configuration settings and the number of servers on each monitored network.

**Command Mode**

EXEC

**Command Syntax**

`show monitor server-failure`

**Example**

This command displays RAIL configuration status and lists the number of servers that are on each monitored network.

```
switch>show monitor server-failure
Server-failure monitor is enabled
Proxy service: disabled
Networks being monitored: 3
  10.2.1.96/28      : 0 servers
  10.1.1.0/24       : 0 servers
  10.3.0.0/16       : 3 servers
switch>
```
11.4.7.56 show monitor session

The `show monitor session` command displays the configuration of the specified port mirroring session. The command displays the configuration of all mirroring sessions on the switch when the session name parameter is omitted.

**Command Mode**
EXEC

**Command Syntax**
```
show monitor session SESSION_NAME
```

**Parameters**

- **SESSION_NAME** Port mirroring session identifier. Options include:
  - **no parameter** displays configuration for all sessions.
  - **label** command displays configuration of the specified session.

**Example**
This command displays the mirroring configuration of the specified monitor session.

```
switch>show monitor session redirect_1
Session redirect_1
------------------------
Source Ports
  Both:        Et7
Destination Port: Et8
switch(config)>
```
11.4.7.57  show platform trident mirroring

The `show platform trident mirroring` command displays current parameters of all configured mirroring sessions in Trident series platforms.

**Command Mode**
Privileged EXEC

**Command Syntax**
`show platform trident mirroring [detail | session]`

**Parameters**
- `detail` displays the detailed information of all configured mirroring sessions.
- `session session_name` displays the information of specified mirroring session.

**Guidelines**
This command is supported on DCS-7050/7050X, DCS-7250X, and DCS-7300X devices only.

**Examples**
- This command displays the detailed information of all configured mirroring sessions.

```plaintext
switch(config)#show platform trident mirroring detail

switch(config)#
11.4.7.58  show port-channel load-balance

The `show port-channel load-balance` command displays the traffic distribution between the member ports of the specified port channels. The command displays distribution for unicast, multicast, and broadcast streams.

The distribution values displayed are based on the total interface counters which start from zero at boot time or when the counters are cleared. For more current traffic distribution values, clear the interface counters of the member interfaces using the `clear counters` command.

**Command Mode**

EXEC

**Command Syntax**

`show port-channel load-balance [MEMBERS]`

**Parameters**

**MEMBERS** List of port channels for which information is displayed. Options include:

- **no parameter** All configured port channels.
- **c_range** Ports in specified channel list (number, number range, or list of numbers and ranges).

**Example**

This command displays traffic distribution for all configured port channels.

```
switch>show port-channel load-balance
ChanId  Port  Rx-Ucst Tx-Ucst Rx-Mcst Tx-Mcst Rx-Bcst Tx-Bcst
-------- --------- ------- ------- ------- ------- ------- -------

switch>
```
11.4.7.59  show port-security interface

The show port-security interface command displays the switchport port-security status of all specified interfaces.

Command Mode
EXEC

Command Syntax
show port-security interface [INT_NAME]

Parameters

INT_NAME  Interface type and numbers. Options include:
  • no parameter  Display information for all interfaces.
  • ethernet e_range  Ethernet interface range specified by e_range.
  • loopback l_range  Loopback interface specified by l_range.
  • management m_range  Management interface range specified by m_range.
  • port-channel p_range  Port-Channel Interface range specified by p_range.
  • vlan v_range  VLAN interface range specified by v_range.
  • vxlan vx_range  VXLAN interface range specified by vx_range.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

Example

This command display port-security configuration and status for the specified interfaces.

```
switch>show port-security interface ethernet 7-8
Interface                  : Ethernet7
Port Security              : Enabled
Port Status                : Secure-down
Violation Mode             : Shutdown
Maximum MAC Addresses      : 5
Aging Time                 : 5 mins
Aging Type                 : Inactivity
SecureStatic Address Aging : Disabled
Total MAC Addresses        : 3
Configured MAC Addresses   : 3
Learn/Move/Age Events      : 5
Last Source Address:Vlan   : 164f.29ae.4e14:10
Last Address Change Time   : 0:39:47 ago
Security Violation Count   : 0
Interface                  : Ethernet8
Port Security              : Disabled
Port Status                : Secure-down
Violation Mode             : Shutdown
Maximum MAC Addresses      : 1
Aging Time                 : 5 mins
Aging Type                 : Inactivity
SecureStatic Address Aging : Disabled
switch>
```
11.4.7.60  **show port-security mac-address**

The `show port-security mac-address` command displays static unicast MAC addresses assigned to interfaces where switchport port security is enabled.

**Command Mode**

EXEC

**Command Syntax**

`show port-security mac-address`

**Example**

This command displays MAC addresses assigned to port-security protected interfaces.

```
switch>**show port-security mac-address**
Secure Mac Address Table
-----------------------------------------------
Vlan | Mac Address       | Type                | Ports | Remaining Age (mins)
-----|-------------------|---------------------|-------|---------------------
 10  | 164f.29ae.4e14    | SecureConfigured    | Et7   | N/A
 10  | 164f.29ae.4f11    | SecureConfigured    | Et7   | N/A
 10  | 164f.320a.3a11    | SecureConfigured    | Et7   | N/A
-----------------------------------------------
Total Mac Addresses for this criterion: 3
switch>
```
11.4.7.61  **show port-security**

The `show port-security` command displays a summary of MAC address port security configuration and status on each interface where switchport port security is enabled.

**Command Mode**

EXEC

**Command Syntax**

`show port-security`

**Display Values**

Each column corresponds to one physical interface. The table displays interfaces with port security enabled.

- **Secure Port**: Interface with switchport port-security enabled.
- **MaxSecureAddr**: Maximum quantity of MAC addresses that the specified port can process.
- **CurrentAddr**: Static MAC addresses assigned to the interface.
- **SecurityViolation**: Number of frames with unsecured addresses received by port.
- **Security Action**: Action triggered by a security violation.

These are the value displayed by the command.

- **Aging Time**: Age of Mac address.
- **MAC Moveable**: Mac address movement.
- **Port Security**: Enabled or disabled status

**Examples**

- This command displays switchport port security configuration and status data.

```
switch>show port-security
Secure Port    MaxSecureAddr  CurrentAddr  SecurityViolation  Security Action
               (Count)      (Count)          (Count)                
----------------------------------------------------------------------------
Et7              5             3            0            Shutdown
Et10             1             0            0            Shutdown
----------------------------------------------------------------------------
Total Addresses in System: 3
```

- From **EOS Release 4.26.0F**, `show port-security` command displays the settings for the new global port security configurations, including MAC aging, MAC moves, and persistent port security.

```
switch(config)#show port-security
Secure address moves: disabled
Secure address aging: disabled
Secure address reboot persistence: enabled
Secure address link down persistence: enabled
Secure Port    MaxSecureAddr  CurrentAddr  SecurityViolation  Security Action
               (Count)      (Count)          (Count)                
----------------------------------------------------------------------------
Et7              5             3            0            Shutdown
Et10             1             0            0            Shutdown
----------------------------------------------------------------------------
Total Addresses in System: 0
```
show storm-control

The `show storm-control` command displays the storm-control level and interface inbound packet capacity for the specified interface.

The configured value (storm-control) differs from the programmed threshold in that the hardware accounts for Interframe Gaps (IFG) based on the minimum packet size. This command displays the broadcast or multicast rate after this adjustment.

**Command Mode**
Privileged EXEC

**Command Syntax**

`show storm-control [INT_NAME]`

**Parameters**

- **no parameter** Command returns data for all interfaces configured for storm control.
- **INT_NAME** interface type and port range. Settings include:
  - **ethernet e_range** Ethernet interfaces that `e_range` denotes.
  - **port-channel p_range** Port channel interfaces that `p_range` denotes.

When storm control commands exist for a port-channel and an Ethernet port that is a member of the port channel, the command for the port-channel takes precedence.

Valid `range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

This command displays the storm control configuration for **Ethernet port 2** through **Ethernet port 4**.

```
switch# show storm-control
Port   Type  Level Rate(Mbps)  Status   Drops Reason
Et10/2 all   75    7500   active   0
Et10/3 multicast 55   5500   active   0
Et10/4 broadcast 50   5000   active   0
switch#
```
11.4.7.63  show switch forwarding-mode

The `show switch forwarding-mode` command displays the switch's current and available forwarding plane hardware modes.

**Command Mode**
EXEC

**Command Syntax**
`show switch forwarding-mode`

**Related Command**
`switch forwarding-mode` configures the switch's forwarding mode setting.

**Example**
This command changes the switch's forward mode to **store-and-forward**, then displays the forwarding mode.

```
switch(config)#switch forwarding-mode store-and-forward
switch(config)#show switch forwarding-mode
Current switching mode: store and forward
Available switching modes: cut through, store and forward
```
11.4.7.64  show track

The show track command displays information about tracked objects configured on the switch.

Command Mode
EXEC

Command Syntax
show track [OBJECT][INFO_LEVEL]

Parameters
• OBJECT tracked object for which information is displayed. Options include:
  • no parameter displays information for all tracked objects configured on the switch.
  • object_name displays information for the specified object.
• INFO_LEVEL amount of information that is displayed. Options include:
  • no parameter displays complete information including object status, number of status changes, time since last change, and client process tracking the object (if any).
  • brief displays brief list of all tracked objects and their current status.

Examples
• This command displays all information for tracked object ETH8.

switch#show track ETH8
Tracked object ETH8 is up
  Interface Ethernet8 line-protocol
   4 change, last change time was 0:36:12 ago
  Tracked by:
   Ethernet5/1 vrrp instance 50
switch#

• This command displays summary information for all tracked objects.

switch#show track brief
Tracked object ETH2 is up
Tracked object ETH4 is down
Tracked object ETH6 is up
Tracked object ETH8 is up
switch#
11.4.7.65  **shutdown (server-failure configuration mode)**

The `shutdown` command disables Rapid Automated Indication of Link-Loss (RAIL). By default, RAIL is disabled.

After entering server-failure configuration mode, a `no shutdown` command is required to enable RAIL.

The `no shutdown` command enables RAIL on the switch. The `shutdown` and `default shutdown` commands disable RAIL by removing the shutdown command from `running-config`.

**Command Mode**

Server-failure Configuration

**Command Syntax**

`shutdown`

`no shutdown`

`default shutdown`

**Examples**

- **This command enables RAIL on the switch.**

  ```
  switch(config)#monitor server
  switch(config-server-failure)#no shutdown
  switch(config-server-failure)#show active
  monitor server-failure
  no shutdown
  switch(config-server-failure)#
  ```

- **This command disables RAIL on the switch.**

  ```
  switch(config-server-failure)#shutdown
  switch(config-server-failure)#show active
  monitor server-failure
  switch(config-server-failure)#
  ```
11.4.7.66 storm-control

The `storm-control` command configures and enables storm control on the configuration mode physical interface. The command provides three mode options:

- `storm-control all` unicast, multicast, and broadcast inbound packet control.
- `storm-control broadcast` broadcast inbound packet control.
- `storm-control multicast` multicast inbound packet control.

An interface configuration can contain three storm-control statements, one with each mode setting. The `storm-control all` threshold overrides broadcast and multicast thresholds.

The threshold is a percentage of the available port bandwidth and is configurable on each interface for each transmission mode.

The `no storm-control` and `default storm-control` commands remove the corresponding `storm-control` statement from `running-config`, disabling storm control for the specified transmission type on the configuration mode interface.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

**Command Syntax**

```
storm-control MODE level threshold
no storm-control MODE
default storm-control MODE
```

**Parameters**

- **MODE** packet transmission type. Options include:
  - *all*
  - *broadcast*
  - *multicast*
- **threshold** Inbound packet level that triggers storm control, as a percentage of port capacity. Value ranges from 0.01 to 100. Storm control is suppressed by a level of 100.

  The configured value differs from the programmed threshold in that the hardware accounts for Interframe Gaps (IFG) based on the minimum packet size. The `show storm-control` command displays the broadcast or multicast rate after this adjustment.

**Restrictions**

The `storm-control all` option is not available on Arad platform switches.

**Example**

These commands enable multicast and broadcast storm control on **Ethernet port 20** and sets thresholds of 65% (multicast) and 50% (broadcast). During each one second interval, the interface drops inbound multicast traffic and broadcast traffic in excess of the specified thresholds.

```
switch(config)#interface ethernet 20
switch(config-if-Et20)#storm-control multicast level 65
switch(config-if-Et20)#storm-control broadcast level 50
switch(config-if-Et20)#show active
interface Ethernet20
  storm-control broadcast level 50
  storm-control multicast level 65
switch(config-if-Et20)#
```
11.4.7.67 switch forwarding-mode

The `switch forwarding-mode` command specifies the mode of the switch’s forwarding plane hardware. The default forwarding mode is `cut through`.

The `no switch forwarding-mode` and `default switch forwarding-mode` commands restore the default forwarding mode by removing the `switch forwarding-mode` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
switch forwarding-mode MODE_SETTING
no switch forwarding-mode
default switch forwarding-mode
```

Parameters

`MODE_SETTING` Specifies the switch’s forwarding plane hardware mode. Options include:
- `cut-through` the switch begins forwarding frames before their reception is complete.
- `store-and-forward` the switch accumulates entire packets before forwarding them.

Guidelines
The forwarding plane mode is `store-and-forward` on Petra and Arad platform switches.

Related Command

`show switch forwarding-mode` displays the current forwarding mode.

Example
This command changes the forwarding mode to `store-and-forward`.

```
switch(config)#switch forwarding-mode store-and-forward
switch(config)#
```
11.4.7.68 switchport default mode access

The `switchport default mode access` command places the configuration mode interface in `switched port default access` (Layer 3) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

**Command Mode**
Global Configuration

**Command Syntax**
`switchport default mode access`

**Related Command**
`switchport default mode routed` puts a switch with all ports in routed port mode.

**Example**
This command puts a switch with all ports in access port mode.

```plaintext
switch(config)#switchport default mode access
```
11.4.7.69 switchport default mode routed

The `switchport default mode routed` command places the configuration mode interface in `switched port default routed` (Layer 3) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

By default, on a switch with default startup config or no config, all ports come up in access mode. By adding the CLI command `switchport default mode routed` to kickstart config, all ports will come up in routed mode after boot up. On boot up, Zero Touch Provisioning (ZTP) is enabled by default if the startup config (/mnt/flash/startupconfig) is deleted. ZTP can be disabled by setting DISABLE=True in ZTP config (/mnt/flash/zerotouchconfig). Kickstart config (/mnt/flash/kickstart-config) is used when startup config is missing and ZTP is disabled.

**Command Mode**
Global Configuration

**Command Syntax**

```
switchport default mode routed
```

**Related Command**

`switchport default mode access` puts a switch with all ports in access port mode.

**Example**

This command puts a switch with all ports in routed port mode.

```
switch(config)#switchport default mode routed
```
11.4.70  **switchport mac address learning**

The **switchport mac address learning** command enables MAC address learning for the configuration mode interface. MAC address learning is enabled by default on all Ethernet and port channel interfaces.

The switch maintains a MAC address table for switching frames between VLAN ports. When the switch receives a frame, it associates the MAC address of the transmitting interface with the recipient VLAN and port. When MAC address learning is enabled for the recipient port, the entry is added to the MAC address table. When MAC address learning is not enabled, the entry is not added to the table.

The **no switchport mac address learning** command disables MAC address learning for the configuration mode interface. The **switchport mac address learning** and **default switchport mac address learning** commands enable MAC address learning for the configuration mode interface by deleting the corresponding **no switchport mac address learning** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port Channel Configuration

**Command Syntax**

```
switchport mac address learning
no switchport mac address learning
default switchport mac address learning
```

**Example**

These commands disables MAC address learning for Ethernet interface 8, then displays the active configuration for the interface.

```
switch(config)#interface ethernet 8
switch(config-if-Et8)#no switchport mac address learning
switch(config-if-Et8)#show active
interface Ethernet8
  no switchport mac address learning
switch(config-if-Et8)#
```
11.4.7.71  switchport port-security mac-address maximum

The `switchport port-security mac-address maximum` command specifies the maximum MAC address limit for the configuration mode interface when configured as a secure port. When port security is enabled, the port accepts traffic and adds source addresses to the MAC table until the maximum is reached. Once the maximum is reached, if any traffic arrives from a source not already in the MAC table for the secure port, the port becomes errdisabled. The `switchport port-security` command configures an interface as a secure port.

The `no switchport port-security mac-address maximum` and `default switchport port-security mac-address maximum` commands restore the maximum MAC address limit of one on the configuration mode interface by removing the corresponding `switchport port-security mac-address maximum` command from `running-config`.

Command Mode
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

Command Syntax
- `switchport port-security mac-address maximum max_addr`
- `no switchport port-security mac-address maximum`
- `default switchport port-security mac-address maximum`

Parameters
- `max_addr` maximum number of MAC addresses. Value ranges from 1 to 1000. Default value is 1.

Example

These commands configure a maximum of five incoming addresses for secure `port channel interface 14`.

```
switch(config)#interface port-channel 14
switch(config-if-Po14)#switchport port-security mac-address maximum 5
switch(config-if-Po14)#
```
11.4.7.72 switchport port-security violation

The `switchport port-security violation` command configures port security in protect mode (with the option of enabling logging) or the shutdown mode.

The `no switchport port-security` and `no switchport port-security violation protect log` commands disable port security protect mode and port security protect mode logging on the configuration mode interface.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port Channel Configuration

**Command Syntax**

```
switchport port-security violation { protect [log] | shutdown }
no switchport port-security violation protect log
default switchport port-security violation protect log
```

**Parameters**

- `protect` configures the port security in the protect mode.
- `shutdown` configures the port security in the shutdown mode.
- `log` the log of new addresses seen after limit is reached in the protect mode.

**Guidelines**

When port security is enabled, the port accepts traffic and adds source addresses to the MAC table until the maximum is reached. The `switchport port-security` command configures an interface as a secure port.

In the protect mode, the ACLs are dynamically created to block incoming MAC addresses when the configured maximum MAC value is reached.

In the shutdown mode, once the maximum is reached, if any traffic arrives from a source not already in the MAC table for the secure port, the port is set to be errdisabled.

**Examples**

- These commands configure port security violation protect mode for `secure port channel interface 14`.

  ```
  switch(config)#interface port-channel 14
  switch(config-if-Po14)#switchport port-security violation protect
  switch(config-if-Po14)#
  ```

- These commands configure port security violation protect logging mode for `secure port channel interface 14`.

  ```
  switch(config)#interface port-channel 14
  switch(config-if-Po14)#switchport port-security violation protect log
  switch(config-if-Po14)#
  ```

- These commands configure port security violation shutdown mode for `secure port channel interface 15`.

  ```
  switch(config)#interface port-channel 15
  switch(config-if-Po15)#switchport port-security violation shutdown
  switch(config-if-Po15)#
  ```
11.4.7.73 switchport port-security

The **switchport port-security** command enables MAC address port security on the configuration mode interface. Ports with port security enables restrict traffic to a limited number of hosts, as determined by their MAC addresses. On enabling the **switchport port-security** command, the port-security mode would be 'shutdown', by default.

The **switchport port-security mac-address maximum** command specifies the maximum number of MAC addresses. The **switchport port-security violation** command enables port security in protect mode.

The **no switchport port-security** and **default switchport port-security** commands disable port security on the configuration mode interface by removing the corresponding **switchport port-security** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port Channel Configuration

**Command Syntax**

**switchport port-security**

**no switchport port-security**

**default switchport port-security**

**Example**

These commands enable port security on **ethernet interface 7**.

```
switch(config)#interface ethernet 7
switch(config-if-Et7)#switchport port-security
switch(config-if-Et7)#
```
11.4.7.74  switchport

The `switchport` command places the configuration mode interface in **switched port** (Layer 2) mode. Switched ports are configurable as members of one or more VLANs through other switchport commands. Switched ports ignore all IP level configuration commands, including IP address assignments.

The `no switchport` command places the configuration mode interface in **routed port** (Layer 3) mode. Routed ports are not members of any VLANs and do not switch or bridge packets. All IP level configuration commands, including IP address assignments, apply directly to the routed port interface.

By default, Ethernet and Port Channel interfaces are in switched port mode. The `default switchport` command also places the configuration mode interface in switched port mode by removing the corresponding `no switchport` command from `running-config`.

These commands only toggle the interface between switched and routed modes. They have no effect on other configuration states.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port Channel Configuration

**Command Syntax**
- `switchport`
- `no switchport`
- `default switchport`

**Guidelines**

When an interface is configured as a routed port, the switch transparently allocates an internal VLAN whose only member is the routed interface. Internal VLANs are created in the range from 1006 to 4094. VLANs that are allocated internally for a routed interface cannot be directly created or configured. The `vlan internal order` command specifies the method that VLANs are allocated.

All IP-level configuration commands, except `autostate` and `ip virtual-router`, can be used to configure a routed interface. Any IP-level configuration changes made to a routed interface are maintained when the interface is toggled to switched port mode.

A LAG that is created with the `channel-group` command inherits the mode of the member port. A LAG created from a routed port becomes a routed LAG. IP-level configuration statements are not propagated to the LAG from its component members.

**Examples**
- These commands put *Ethernet interface 5* in routed port mode.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
switch(config-if-Et5)#
```

- These commands returns *Ethernet interface 5* to switched port mode.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport
switch(config-if-Et5)#
```
11.4.7.75 system control-plane

The system control-plane command places the switch in control-plane configuration mode. Control-plane mode is used for assigning an ACL (access control list) to the control plane.

The control-plane configuration mode is not a group change mode; running-config is changed immediately after commands are executed. Exiting control-plane configuration mode does not affect the configuration.

The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
system control-plane

Command Available in control-plane Configuration Mode
ip access-group (Control Plane mode)

Examples

- This command places the switch in the control plane mode.

```
switch(config)# system control-plane
switch(config-system-cp)
```

- This command assigns the control-plane-2 ACL to the control plane.

```
switch(config-system-cp)# ip access-group control-plane-2
switch(config-system-cp)
```

- This command exits the control plane mode.

```
switch(config-system-cp)# exit
switch(config)
```
11.4.7.76  track

The `track` command creates an object whose state changes to provide information to a client process. The client process must be separately configured for object tracking to have an effect on the switch.

The `no track` and `default track` commands remove the specified tracked object by removing the corresponding `track` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
track object_name interface INTERFACE_NAME PROPERTY
no track object_name
default track object_name
```

**Parameters**

- `object_name`  User-created name for the tracked object.
- `INTERFACE_NAME`  Interface associated with the tracked object. Options include:
  - `ethernet e_num`  Ethernet interface specified by `e_num`.
  - `loopback l_num`  Loopback interface specified by `l_num`.
  - `management m_num`  Management interface specified by `m_num`.
  - `port-channel p_num`  Port-channel interface specified by `p_num`.
  - `vlan v_num`  VLAN interface specified by `v_num`.
  - `vxlan vx_num`  VXLAN interface specified by `vx_num`.
- `PROPERTY`  Tracked property. Options include:
  - `line-protocol`  Object changes when the state of the associated interface changes.

**Example**

This command creates a tracked object which tracks the state of the line protocol on `Ethernet interface 8`.

```
switch(config)# track ETH8 interface ethernet 8 line-protocol
switch(config)#
```
11.4.7.77  traffic-loopback

The `traffic-loopback` command is used to create loopbacks to verify the functionality of interfaces and partner links. The `source` determines whether outgoing traffic is being looped back to the interface (system) to test the interface itself, or incoming traffic is being looped back to the link partner (network) to test the link between the systems. The `device` determines whether system traffic is looped on the physical level (phy) or Layer-2 level (mac). Only the phy level is available for network traffic.

The `no traffic-loopback` command deletes the loopback configuration.

**Command Mode**

Interface Configuration

**Command Syntax**

```
traffic-loopback source [system|network] device [phy|mac]
```

**Parameters**

- `system` loops outgoing traffic back to the interface.
- `network` loops incoming traffic back to the link partner.
- `phy` implements loopback in the physical layer.
- `mac` implements loopback in the MAC layer (available only for system traffic).

**Examples**

- These commands cause outgoing traffic on *Ethernet interface 1* to be looped back to the interface at the MAC level.

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#traffic-loopback source system device mac
  switch(config-if-Et1)#
  ```

- These commands cause incoming traffic on *Ethernet interface 1* to be looped back to the link partner at the physical level.

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#traffic-loopback source network device phy
  switch(config-if-Et1)#
  ```

- These commands delete the loopback configuration from *Ethernet interface 1*.

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#no traffic-loopback
  switch(config-if-Et1)#
  ```
11.5 Octal Port Renumber to Four Interfaces

For an octal port such as a QSFPDD or OSFP, this feature rennumbers the ports on a system to have 4 configurable interfaces instead of eight. The original octal would have had eight interfaces named \(x/1\) to \(x/8\) where \(x\) is the front panel port number.

The four interfaces created by this feature are named \(x/1\) to \(x/4\) instead and each interface has two transceiver lanes attached to it. Thus each interface can be configured to two-lane, four-lane or eight-lanes speeds as appropriate. However, the interfaces are restricted from any single-lane speeds and are not capable of a full breakout.

The entire chassis must be renumbered. This feature is not supported on a per-line card or per-port basis. Any cards in the same chassis that do not support this feature are unaffected. For affected line cards, both the configurable speeds and the default speeds of all interfaces are affected.

 Supported Speeds

11.5.1 Configuring Octal Port Renumber to 4 Interfaces

In order to configure a chassis to octal port renumbering with four interfaces, a boot command is used.

The boot command is different from a standard CLI command since it takes effect very early in the boot process but can be configured in the same way. Therefore it requires a reboot after the CLI command in order to take effect.

Since the ports will be renumbered for all cards that support the feature, the current configuration of the switch may no longer make sense after the reboot. Please ensure all interface configurations reflect the new naming scheme. The following items should be addressed prior to enabling or disabling the feature and performing a reboot:

1. Change interface naming appropriately.
2. Review interface speeds to ensure they are supported with the feature.
3. Review change in interface defaults to ensure the feature’s defaults are desired.
4. Review changes to SNMP OIDs for affected interfaces.

From the CLI configuration mode, use the following command to enable the feature:

```
switch(config)#boot port numbering octal interfaces 4
```
The command warns that the switch needs to be rebooted for the command to take effect. Reboot the box afterward.

From the CLI configuration mode, use the following command to disable the feature:

```
switch(config)#no boot port numbering octal interfaces 4
```

The command warns that the switch needs to be rebooted for the command to take effect. Reboot the box afterward.

### 11.5.2 Show Commands

To confirm the command has taken effect, expose inactive interfaces with the `service interface inactive expose` CLI command and confirm the affected linecards only have four interfaces for each front panel port.

```
switch#(config-if-Et16/1,16/3)#show interfaces et15/1-16/1 status
```

<table>
<thead>
<tr>

<td>full</td>
<td>400G</td>
<td>400G</td>
<td>400GBase-CR8</td>
<td></td>
</tr>
</tbody>
</table>

### 11.5.3 Limitations

- A config replace of the startup config does not affect the configuration of this feature.
- Since the feature is stored in flash:boot-config, removing or overwriting the boot-config can affect the presence of the feature on the next reboot.
11.5.4 Commands

- boot port numbering octal interfaces 4
11.5.4.1  boot port numbering octal interfaces 4

The `boot port numbering octal interfaces 4` command configures a chassis to octal port renumbering with four interfaces.

The `no boot port numbering octal interfaces 4` command disable the `boot port numbering octal interfaces 4` configuration from the `running-config`.

**Command Mode**

Global Configuration Mode

**Command Syntax**

`boot port numbering octal interfaces 4`

`no boot port numbering octal interfaces 4`

**Example**

To enable `boot port numbering octal interfaces 4`, use the following command:

```
switch(config)#boot port numbering octal interfaces 4
```
Layer 2 Configuration

This chapter contains the following sections:

- Spanning Tree Protocol
- Link Layer Discovery Protocol
- Virtual LANs (VLANs)
- DCBX and Flow Control
- IP Locking
- L2 Protocol Forwarding
- Layer 2 Subinterfaces

12.1 Spanning Tree Protocol

Spanning Tree Protocols prevent bridging loops in Layer 2 Ethernet networks. Arista switches support Rapid Spanning Tree, Multiple Spanning Tree, and Rapid-Per VLAN Spanning Tree protocols.

These sections describe the Arista Spanning Tree Protocol implementation.

- Introduction to Spanning Tree Protocols
- Spanning Tree Overview
- Configuring a Spanning Tree
- STP Commands

12.1.1 Introduction to Spanning Tree Protocols

Arista switches support the leading spanning tree protocols: RSTP, MST and Rapid-PVST. This variety of options simplifies integration into existing networks without compromising network reliability, scalability or performance.

12.1.2 Spanning Tree Overview

An Ethernet network functions properly when only one active path exists between any two stations. A spanning tree is a loop-free subset of a network topology. STP is a L2 network protocol that ensures a loop-free topology for any bridged Ethernet LAN. STP allows a network to include spare links as automatic backup paths that are available when an active link fails without creating loops or requiring manual intervention. The original STP is standardized as IEEE 802.1D.

Several variations to the original STP improve performance and add capacity. Arista switches support these STP versions:

- Rapid Spanning Tree (RSTP)
- Multiple Spanning Tree (MSTP)
- Rapid Per-VLAN Spanning Tree (Rapid-PVST)

The Overview contains the following sections:

- Spanning Tree Protocol Versions
- Structure of a Spanning Tree Instance
- BPDUs
12.1.2.1 Spanning Tree Protocol Versions

STP versions supported by Arista switches address two limitations of the original Spanning Tree protocol that was standardized as IEEE 802.1D:

- Slow convergence to the new spanning tree topology after a network change.
- The entire network is covered by one spanning tree instance.

The following sections describe the supported STP versions, compatibility issues in networks containing switches running different STP versions, and supported alternatives to spanning tree.

12.1.2.1.1 Rapid Spanning Tree Protocol (RSTP)

RSTP is specified in 802.1w and supersedes STP. RSTP provides rapid convergence after network topology changes. Similar to STP, RSTP provides a single instance of spanning tree for the entire network. Standard 802.1D-2004 incorporates RSTP and obsoletes STP.

The RSTP instance is the base unit of MST and Rapid-PVST spanning trees.

12.1.2.1.2 Rapid Per-VLAN Spanning Tree Protocol (Rapid-PVST)

Rapid Per-VLAN Spanning Tree (PVST) extends the original STP to support a spanning tree instance on each VLAN in the network. The maximum number of PVST instances that can be created on a switch depends on the hardware platform. In most of the cases, it is 510. PVST can load balance Layer-2 traffic without creating a loop because it handles each VLAN as a separate network. However, PVST does not address slow network convergence after a network topology change.

Arista switches support Rapid-PVST, which is a variation of PVST based on RSTP instances. Rapid-PVST provides rapid connectivity recovery after the failure of a bridge, port, or LAN. Rapid-PVST can be enabled or disabled on individual VLANs.

12.1.2.1.3 Multiple Spanning Tree Protocol (MSTP)

MST extends Rapid Spanning Tree Protocol (RSTP) to support multiple spanning tree instances on a network, but is still compatible with RSTP. By default, Arista switches use MSTP.

MST supports multiple spanning tree instances, similar to Rapid PVST. However, MST associates an instance with multiple VLANs. This architecture supports load balancing by providing numerous forwarding paths to data traffic. Network fault tolerance is improved because failures in one instance do not affect other instances.

MST Regions

An MST region is a group of connected switches with identical MST configuration. Each region can support a maximum of 65 spanning-tree instances. MST regions are identified by a version number, name, and VLAN-to-instance map. You must configure identical parameters on all switches in the regions. Only MST region members participate with the MST instances defined in the region. A VLAN can be simultaneously assigned to only one spanning-tree instance. MST does not specify the maximum number of regions that a network can contain.

MST Instances

Each MST instance is identified by an instance number that ranges from 0 to 4094 and is associated with a set of VLANs. An MST region contains two types of spanning tree instances: an Internal Spanning Tree Instance (IST) and Multiple Spanning Tree Instances (MSTI).

- IST is the default spanning tree instance in MST regions; and is always zero. It gives a root switch to the region that contains all VLANs configured across all switches in the region but not assigned to a MST instance. IST considers all interfaces regardless of the VLAN membership.
• Multiple Spanning Tree instances (MSTIs) consist of VLANs that are assigned through MST configuration statements. VLANs assigned to an MSTI are removed from the IST instance. VLANs in an MSTI operate as a part of a single Spanning Tree topology. Because each VLAN can belong to only one instance, MST instances (and the IST) are topologically independent.

MSTP-Rapid PVST+ Interoperation

MSTP-Rapid PVST+ interoperation allows protocol-level interaction between MSTP and Rapid PVST+ by consuming and transmitting PVST BPDUs through MSTP at the border ports. While transmitting from Rapid PVST+ to MSTP or vice-versa, you can deploy MSTP in certain regions and Rapid PVST+ in other regions based on their merits or other factors. MSTP-Rapid PVST+ interoperation allows MSTP to work with any Rapid PVST+ implementation.

MSTP inter-operation can be viewed as bi-directional BPDU conversion occurring at MSTP PVST+ border ports as following:

• The outgoing Common Internal Spanning Tree (CIST) BPDU is projected as Rapid PVST+ BPDUs across various VLANs.
• Incoming PVST+ topology BPDU is mapped to corresponding MSTI based on incoming VLAN.

The following restrictions are enforced based on port role. These are relevant only for border ports with roles designated or root (for CIST) that can potentially forward.

• Case (A): If the MSTP-Rapid PVST+ border port role is designated for CIST, it should not receive any superior PVST BPDU (with respect to CIST). Root of all VLANs in the PVST region should be towards the MSTP region.
• Case (B): If the MSTP-Rapid PVST+ border port role is root for CIST, it should not receive any inferior Rapid PVST+ BPDU (with respect to CIST). Root of all VLANs in the Rapid PVST+ region should be within the PVST+ region.

Note: If the restrictions are violated, the port enters blocking state. The BPDU translation occurs only on MSTP-Rapid PVST+ border ports with the forwarding state for CIST.

It is desirable to configure multiple MSTP-Rapid PVST+ border ports confirming to Case(A) for a specified Rapid PVST+ region as it allows VLAN load balancing across the ports. This can be achieved by adjusting the per-VLAN port cost towards the Rapid PVST+ region such that the per-VLAN root port is evenly distributed across the border ports.

12.1.2.1.4 Version Interoperability

A network can contain switches running different spanning tree versions. The Common Spanning Tree (CST) is a single forwarding path the switch calculates for STP, RSTP, MSTP, and Rapid-PVST topologies in networks containing multiple spanning tree variations.

In multi-instance topologies, the following instances correspond to the CST:

• Rapid-PVST: VLAN 1
• MST: IST (instance 0)

RSTP and MSTP are compatible with other spanning tree versions:

• An RSTP bridge sends 802.1D (original STP) BPDUs on ports connected to an STP bridge.
• RSTP bridges operating in 802.1D mode remain in 802.1D mode even after all STP bridges are removed from their links.
• An MST bridge detects a port is at a region boundary when it receives an STP BPDU or an MST BPDU from a different region.
• MST ports assume they are boundary ports when the bridges to which they connect join the same region.

The clear spanning-tree detected-protocols command forces MST ports to renegotiate with their neighbors.
12.1.2.1.5  Switchport Interface Pairs

Switchport interface pairs associate two interfaces in a primary-backup configuration. When the primary interface is functioning, the backup interface remains dormant in standby mode. When the primary interface stops functioning, the backup interface handles the traffic.

An alternative implementation balances traffic between the primary and backup interfaces. If either interface shuts down, the other handles traffic addressed to the pair.

The following guidelines apply to switchport interface pairs.

- Ethernet and Port Channels can be primary interfaces.
- Ethernet, Port Channel, Management, Loopback, and VLAN interfaces can be backup interfaces.
- The primary and backup interfaces can be different interface types.
- Interface pairs should be similarly configured to ensure consistent behavior.
- An interface can be associated with a maximum of one backup interface.
- An interface can back up a maximum of one interface.
- Any Ethernet interface configured in an interface pair cannot be a port channel member.
- STP is disabled on ports configured as primary or backup interfaces.
- Static MAC addresses should be configured after primary-backup pairs are established.

12.1.2.2  Structure of a Spanning Tree Instance

A Layer 2 network consists of bridges and network segments. A loop exists when multiple active paths connect two components. Spanning tree protocols allow only one active path between any two network components. Loops are removed by blocking selected ports that connect bridges to network segments.

Ports are assigned cost values that reflect their transmission speed and any other criteria selected by the administrator. Ports with faster transmission speeds and other desirable characteristics are assigned lower costs. High cost ports are blocked in deference to lower cost ports.

A network topology defines multiple possible spanning trees. Network bridges collectively compute and implement one spanning tree to maintain connectivity between all network components while blocking ports that could result in loops. Administrators improve network performance by adjusting parameter settings to select the most efficient spanning tree.

Spanning tree bridges continuously transmit topology information to notify all other bridges on the network when topology changes are required, such as when a link fails. Bridge Protocol Data Units (BPDUs) are STP information packets that bridges exchange.

The following sections describe spanning tree configuration parameters.

12.1.2.2.1  Root and Designated Bridges

The root bridge is the center of the STP topology. A spanning tree instance has one root bridge. Spanning tree bases path calculations on each network components distance from the root bridge.

All other network bridges calculate paths to the root bridge when selecting spanning tree links. STP calculates the distance to the root bridge to build a loop-free topology that features the shortest distance between devices among all possible paths.

Each switch is assigned a unique bridge ID number for each instance. All network switches collectively elect the root bridge by comparing bridge IDs. The root bridge is the switch with the lowest bridge ID.

The bridge ID contains the following eight bytes, in order of decreasing significance:

- Port priority (four bits)
- Instance number (12 bits): VLAN number (Rapid-PVST); instance number (MST); 0 (RST)
- MAC address of switch (six bytes)
A designated bridge is defined for each network segment as the switch that provides the segments shortest path to the root bridge. A designated bridge is selected for each segment after a root bridge is selected; a switch can be a designated bridge for multiple segments.

The following network calculations in Spanning Tree Network Example assume that each path has the same cost:

- **Switch B** is the root bridge its bridge ID is lowest because it has the smallest port priority.
- **Switch A** is the designated bridge for VLAN 11.
- **Switch B** is the designated bridge for VLAN 10, VLAN 13, VLAN 16, VLAN 18, VLAN 19.
- **Switch C** is the designated bridge for VLAN 25.
- **Switch D** is the designated bridge for VLAN 21, VLAN 23.

Figure 26: Spanning Tree Network Example

### 12.1.2.2.2 Port Roles

Messages from connected devices to the root bridge traverse a least-cost path, which has the smallest cost among all possible paths to the root bridge. The cost of a path is the sum of the costs of all path segments, as defined through port cost settings.

Active ports in a least cost-path fulfill one of two possible roles: root port and designated port. STP blocks all other network ports. STP also defines alternate and backup ports to handle traffic when an active port is inaccessible.

- Root Port (RP) accesses the bridges least-cost path to the root bridge. Each bridge selects its root port after calculating the cost of each possible path to the root bridge.

  The following ports in Spanning Tree Network Example are root ports:

  - **Switch A**: port 2
  - **Switch C**: port 1
  - **Switch D**: port 3

- Designated Port (DP) accesses a network segments designated bridge. Each segment defines one DP. Switches can provide DPs for multiple segments. All ports on the root bridge are DPs.
The following ports in **Spanning Tree Network Example** are designated ports:

- **Switch A**: port 4 (VLAN 11)
- **Switch B**: port 2 (VLAN 13), port 4 (VLAN 18), port 5 (VLAN 10), port 6 (VLAN 19), port 8 (VLAN 16)
- **Switch C**: port 2 (VLAN 25)
- **Switch D**: port 2 (VLAN 23), port 6 (VLAN 21)

- Alternate ports provide backup paths from their bridges to the root bridge. An alternate port is blocked until a network change transforms it into a root port.
- Backup ports provide alternative paths from VLANs to their designated bridges. A backup port is blocked until a network change transforms it into a designated port.

### 12.1.2.2.3 Port Activity States

A port's activity state defines its current STP activity level. STP monitors BPDUs for network changes that require an activity state transition.

STP defines three port activity states:

- **Forwarding**: The port receives and sends data. Root ports and designated ports are either in, or transitioning to, this state.
- **Discarding**: The port does not receive or send data. Blocked ports receive BPDU packets. All ports except RPs and DPs are blocked, including alternate and backup ports.
- **Learning**: The transitional post-discarding state where the port prepares to forward frames by adding source addresses from inbound data packets to the switching database.

### 12.1.2.2.4 Port Types

Port type is a configurable parameter that reflects the type of network segment that is connected to the port. Proper port type configuration results in rapid convergence after network topology changes. RSTP port types include normal, network, and edge ports. **Normal** is the default port type.

- **Normal** ports have an unspecified topology.
- **Network** ports connect only to switches or bridges.
  - RSTP immediately transitions network ports to the discarding state.
- **Edge** ports connect directly to end stations.
  - Edge ports transition directly to forwarding state because they do not create loops. An edge port becomes a normal port when it receives a BPDU.

### 12.1.2.2.5 Link Types

Link type is a configurable parameter that determines candidates for RSTP fast state transition.

- The default link type for full-duplex ports is **point-to-point**.
- The default link type for half-duplex ports is **shared**.

Fast state transitions are allowed on point-to-point links that connect bridges. Fast state transitions are not allowed on shared ports regardless of the duplex setting.

### 12.1.2.3 BPDUs

Spanning tree rules specify a root bridge, select designated bridges, and assign roles to ports. STP rule implementation requires that network topology information is available to each switch.

Switches exchange topology information through Bridge Protocol Data Units (BPDUs). Information provided by BPDU packets include bridge IDs and root path costs.
12.1.2.3.1 BPDU Types

STP defines three BPDU types:

- Configuration BPDU (CBPDU), used for computing the spanning tree.
- Topology Change Notification (TCN) BPDU, announces network topology changes.
- Topology Change Notification Acknowledgment (TCA), acknowledges topology changes.

Bridges enter the following addresses in outbound BPDU frames:

- Source address: outbound port’s MAC address.
- Destination address: STP multicast address 01:80:C2:00:00:00.

Bridges regularly exchange BPDUs to track network changes that trigger STP recomputations and port activity state transitions. The **hello timer** specifies the period between consecutive BPDU messages; the default is two seconds.

12.1.2.3.2 Bridge Timers

Bridge timers specify parameter values that the switch includes in BPDU packets that it sends as a root bridge. Bridge timers include:

- **hello-time**: transmission interval between consecutive BPDU packets.
- **forward-time**: the period that ports remain in learning state.
- **max-age**: the period that BPDU data remains valid after it is received.
- **max-hop**: the number of bridges in an MST region that a BPDU can traverse before it is discarded.

The switch recomputes the spanning tree topology if it does not receive another BPDU before the max-age timer expires. When **edge** ports and **point-to-point** links are properly configured, RSTP network convergence does not require forward-delay and max-age timers.

12.1.2.3.3 MSTP BPDUs

MSTP BPDUs are targeted at a single instance and provide STP information for the entire region. MSTP encodes a standard BPDU for the IST, then adds region information and MST instance messages for all configured instances, where each message conveys spanning tree data for an instance. Frames assigned to VLANs operate in the instance to which the VLAN is assigned. Bridges enter an MD5 digest of the VLAN-to-instance map table in BPDUs to avoid including the entire table in each BPDU. Recipients use this digest and other administratively configured values to identify bridges in the same MST region.

MSTP BPDUs are compatible with RSTP. RSTP bridges view an MST region as a single-hop RSTP bridge regardless of the number of bridges inside the region because:

- RSTP bridges interpret MSTP BPDUs as RSTP BPDUs.
- RSTP bridges increment the **message age timer** only once while data flows through an MST region; MSTP measures **time to live** with a **remaining hops** variable, instead of the message age timer.

Ports at the edge of an MST region connecting to a bridge (RSTP or STP) or to an endpoint are **boundary ports**.

12.1.3 Configuring a Spanning Tree

These sections describe the following configuration processes:

- Version Configuration and Instance Creation
- Spanning Tree Instance Configuration
- Port Roles and Rapid Convergence
- Configuring BPDU Transmissions
12.1.3.1 Version Configuration and Instance Creation

The switch supports three STP versions and switchport backup interface pairs. Disabling spanning tree is also supported but not recommended.

The spanning-tree mode global configuration command specifies the spanning tree version the switch runs. This section describes command options that enable and configure STP versions.

12.1.3.1.1 Multiple Spanning Tree (MST)

Multiple Spanning Tree is enabled by the spanning-tree mode command with the mstp option. MSTP is the default STP version.

Example

This command enables Multiple Spanning Tree.

```
switch(config)#spanning-tree mode mstp
switch(config)#
```

Configuring MST Regions

All switches in an MST region must have the same name, revision, and VLAN-to-instance map. MST configuration mode commands sets the region parameters. The MST configuration mode is a group-change mode where changes are saved by exiting the mode.

Example

The spanning-tree mst configuration command places the switch in the MST configuration mode.

```
switch(config)#spanning-tree mst configuration
switch(config-mst)#
```

The instance command assigns VLANs to MST instances. The name (mst-configuration mode) and revision (mst-configuration mode) commands configure the MST region name and revision.

Examples

- These commands assign VLANs 4-7 and 9 to instance 8 and remove VLAN 6 from instance 10.
  
  ```
  switch(config-mst)#instance 8 vlans 4-7,9
  switch(config-mst)#no instance 10 vlans 6
  switch(config-mst)#
  
  switch(config-mst)#{instance 8 vlans 4-7,9
  switch(config-mst)#no instance 10 vlans 6
  switch(config-mst)#
  ```

- These commands assign the name (corporate_1) and revision (3) to the switch.
  
  ```
  switch(config-mst)#name corporate_1
  switch(config-mst)#revision 3
  switch(config-mst)#
  
  switch(config-mst)#name corporate_1
  switch(config-mst)#revision 3
  switch(config-mst)#
  ```

The exit (mst-configuration mode) command transitions the switch out of the MST configuration mode and saves all pending changes. The abort (mst-configuration mode) command exits the MST configuration mode without saving the pending changes.

Example

This command exits the MST configuration mode and saves all pending changes.

```
switch(config-mst)#exit
switch(config)#
```
Configuring MST Instances
These STP commands provide an optional MST instance parameter. These commands apply to instance 0 when the optional parameter is not included.

- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree port-priority`

Examples
- This command configures priority for MST instance 4.
  ```
  switch(config)#spanning-tree mst 4 priority 4096
  switch(config)#
  ```
- Each of these commands configure priority for MST instance 0.
  ```
  switch(config)#spanning-tree mst 0 priority 4096
  or
  switch(config)#spanning-tree priority 4096
  ```

12.1.3.1.2 Rapid Spanning Tree (RST)
Rapid spanning tree is enabled through the `spanning-tree mode` command with the `rstp` option.

Example
- This command enables Rapid Spanning Tree.
  ```
  switch(config)#spanning-tree mode rstp
  switch(config)#
  ```

These STP commands, when they do not include an optional MST or VLAN parameter, apply to RSTP. Commands that configure MSTP instance 0 also apply to the RSTP instance.

- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree port-priority`

Examples
- These commands apply to the RST instance.
  ```
  switch(config)#spanning-tree priority 4096
  and
  switch(config)#spanning-tree mst 0 priority 4096
  ```
- These commands do not apply to the RST instance.
  ```
  switch(config)#spanning-tree mst 4 priority 4096
  and
  switch(config)#spanning-tree vlan-id 3 priority 4096
  ```

Show commands (such as `show spanning-tree`) displays the RSTP instance as MST0 (MST instance 0).
Example

- This command, while the switch is in RST mode, displays RST instance information.

```snippet
switch(config)# show spanning-tree
MST0
  Spanning tree enabled protocol rstp<---RSTP mode indicator
  Root ID  Priority  32768
  Address  001c.730c.1867
  This bridge is the root

  Bridge ID  Priority  32768 (priority 32768 sys-id-ext 0)
  Address  001c.730c.1867
  Hello Time  2.000 sec  Max Age 20 sec  Forward Delay 15 sec

  Interface        Role       State      Cost      Prio.Nbr Type
  ---------------- ---------- ---------- --------- -------- -----
  Et51             designated forwarding 2000      128.51   P2p

switch(config)#
```

12.1.3.1.3 Rapid Per-VLAN Spanning Tree (Rapid-PVST)

Rapid-PVST mode is enabled by the `spanning-tree mode rapid-pvst` command with the `rapid-pvst` option.

**Example**

- This command enables Rapid Per-VLAN Spanning Tree.

```snippet
switch(config)# spanning-tree mode rapid-pvst
switch(config)#
```

These commands provide an optional VLAN parameter for configuring Rapid-PVST instances.

- `spanning-tree priority`
- `spanning-tree root`
- `spanning-tree port-priority`
- `spanning-tree mst pvst border`

**Examples**

- This command configures bridge priority for VLAN 4.

```snippet
switch(config)# spanning-tree vlan-id 4 priority 4096
switch(config)#
```

- This command enables MSTP PVST+ border ports. The command is effective only if spanning-tree mode is MSTP.

```snippet
switch(config)# spanning-tree mst pvst border
```

12.1.3.1.4 Switchport Backup Mode

Switchport backup interface pairs are enabled through the `spanning-tree mode` command with the `backup` option. Enabling switchport backup disables all spanning-tree modes. For loop avoidance under switchport backup mode, use the Loop Protection feature.

**Example**

```
This command enables switchport backup.

```yaml
switch(config)#spanning-tree mode backup
```

The `switchport backup-link` command establishes an interface pair between the command mode interface (primary) and the interface specified by the command (backup).

**Example**

These commands establish *Ethernet interface 7* as the backup port for *Ethernet interface 1*.

```yaml
switch(config)#interface ethernet 1
switch(config-if-Et1)#switchport backup-link ethernet 7
switch(config-if-Et1)#
```

The `prefer` option of the `switchport backup-link` command establishes a peer relationship between the primary and backup interfaces and specifies VLAN traffic that the backup interface normally carries. If either interface goes down, the other interface carries traffic normally handled by both interfaces.

**Examples**

These steps perform the following:

- configures *Ethernet interface 1* as a trunk port that handles VLANs 4 through 9 traffic.
- configures *Ethernet interface 2* as the backup interface.
- assigns *Ethernet 2* as the preferred interface for VLANs 7 through 9.

1. Enter configuration mode for the primary interface.

   ```yaml
   switch(config)#interface ethernet 1
   ```

2. Configure the primary interface as a trunk port that services VLANs 4-9

   ```yaml
   switch(config-if-Et1)#switchport mode trunk
   switch(config-if-Et1)#switchport trunk allowed vlan 4-9
   ```

3. Configure the backup interface and specify the VLANs that it normally services.

   ```yaml
   switch(config-if-Et1)#switchport backup-link Ethernet 2 prefer vlan 7-9
   switch(config-if-Et1)#
   ```

12.1.3.1.5  **Loop Protection**

Loop protection is a loop detection and prevention method which is independent of STP and is not disabled when the switch is in switchport backup mode. When loop protection is active on an interface, that interface periodically sends out loop-detection frames; if one is received that originated on the switch, the receiving port is errdisabled until a timeout period has passed or it is manually reset.

Loop protection is configured and enabled per VLAN, but individual ports in a VLAN can be configured to disable loop protection.

**Note:** Loop protection cannot be enabled on an MLAG peer link.

This feature is disabled by default. To enable it, use the `monitor loop-protection` command to enter loop-protection configuration mode, then use the `no shutdown (Loop-protection)` command to enable the feature. To enable loop protection on a VLAN, use the `protect vlan` command. To exclude a port from loop protection, use the `no loop-protection` command.

The feature is configured with the following additional commands:
- `transmit-interval`
- `disabled-time`
- `rate-limit`

**Examples**

- This command enters loop protection configuration mode.

```plaintext
switch(config)#monitor loop-protection
switch(config-monitor-loop-protect)#
```

- These commands enable loop protection on VLANs **1025-2000**.

```plaintext
switch(config)#monitor loop-protection
switch(config-monitor-loop-protect)#no shutdown
switch(config-monitor-loop-protect)#protect vlan 1025-2000
switch(config-monitor-loop-protect)#
```

- These commands exclude *Ethernet interface 38* from loop protection.

```plaintext
switch(config)#interface ethernet 38
switch(config-if-Et38)#no loop-protection
switch(config-if-Et38)#
```

- These commands configure loop protection with a transmission interval of **10** seconds, a disabled time of two days, and a maximum rate of **500** loop detection frames per second.

```plaintext
switch(config-monitor-loop-protect)#transmit-interval 10
switch(config-monitor-loop-protect)#disabled-time 172800
switch(config-monitor-loop-protect)#rate-limit 500
switch(config-monitor-loop-protect)#
```

**12.1.3.1.6 Disabling Spanning Tree**

Spanning tree is disabled by the `spanning-tree mode` command with the `none` option. The switch does not generate STP packets. Switchport interfaces forward packets when connected to other ports. The switch forwards inbound STP packets as multicast data packets on the VLAN where they are received.

**Example**

This command disables all STP functions.

```plaintext
switch(config)#spanning-tree mode none
switch(config)#
```

**12.1.3.2 Spanning Tree Instance Configuration**

A network performs these steps to set up an STP instance:

1. The bridge with the lowest ID is elected root bridge.
2. Root ports (RP) are selected on all other bridges.
3. Designated bridges are selected for each network segment.
4. Designated ports (DP) are selected on each designated bridge.
5. Networks begin forwarding data through RPs and DPs. All other ports are blocked.
12.1.3.2.1 Root Bridge Parameters

STPs use bridge IDs for electing the root bridge. Switches denote a bridge ID for each configured Spanning Tree instance. The bridge ID composition is:

- **Priority** (four bits)
  
  Priority is expressed as a multiple of 4096 because it is stored as the four most significant bits of a two-byte number.

- **Protocol Dependent** (twelve bits)
  
  - **Rapid-PVST**: VLAN number
  - **MST**: Instance number
  - **RST**: 0
  - **MAC address of switch** (six bytes)

**Example**

The switch defines bridge IDs for three MST instances:

- **MST 0**: **32768** (Priority (**32768**) + Instance number(**0**)) and **001c.7301.23de** (MAC address)
- **MST101**: **32869** (Priority (**32768**) + Instance number(**101**)) and **001c.7301.23de** (MAC address)
- **MST102**: **32870** (Priority (**32768**) + Instance number(**102**)) and **001c.7301.23de** (MAC address)

This command displays a table of root bridge information.

The switch provides two commands that configure the switch priority: **spanning-tree priority** and **spanning-tree root**. The commands differ in the available parameter options:

- **spanning-tree priority** options are integer multiples of **4096** between **0** and **61440**.
- **spanning-tree root** options are **primary** and **secondary**.
  - **primary** assigns a priority of **8192**.
  - **secondary** assigns a priority of **16384**.
- The default priority value is **32768**.

The following examples configure bridge IDs with both commands.

**Examples**

- These commands configure MST instance bridge priorities with the **root** command:

  ```
  switch(config)#spanning-tree mst 0 root primary
  switch(config)#spanning-tree mst 1 root secondary
  ```

<table>
<thead>
<tr>
<th>Instance</th>
<th>Priority</th>
<th>MAC addr</th>
<th>Cost</th>
<th>Time</th>
<th>Age</th>
<th>Dly</th>
<th>Root Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>MST0</td>
<td>32768</td>
<td>001c.7301.23de</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>Po937</td>
</tr>
<tr>
<td>MST101</td>
<td>32869</td>
<td>001c.7301.23de</td>
<td>3998</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Po909</td>
</tr>
<tr>
<td>MST102</td>
<td>32870</td>
<td>001c.7301.23de</td>
<td>3998</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Po911</td>
</tr>
</tbody>
</table>

  - Instance **0** root priority is **8192**: primary priority plus the instance number of **0**.
  - Instance **1** root priority is **16385**: secondary priority plus the instance number of **1**.
  - Instance **2** root priority is **32770**: default priority plus the instance number of **2**.
These priority settings normally program the switch to be the primary root bridge for instance 0, the secondary root bridge for instance 1, and a normal bridge for instance 2. Primary and secondary root bridge elections also depend on the configuration of other network bridges.

- These priority commands configure Rapid-PVST VLAN bridge priorities:

```
switch(config)#spanning-tree vlan-id 1 priority 8192
switch(config)#spanning-tree vlan-id 2 priority 16384
switch(config)#spanning-tree vlan-id 3 priority 8192
switch(config)#no spanning-tree vlan-id 4 priority
switch(config)#show spanning-tree root
```

<table>
<thead>
<tr>
<th>Instance</th>
<th>Priority</th>
<th>Root ID</th>
<th>Root</th>
<th>Hello</th>
<th>Max</th>
<th>Fwd</th>
</tr>
</thead>
<tbody>
<tr>
<td>VL18193</td>
<td>8192</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
</tr>
<tr>
<td>VL216386</td>
<td>16384</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
</tr>
<tr>
<td>VL38195</td>
<td>8195</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
</tr>
<tr>
<td>VL432788</td>
<td>32788</td>
<td>001c.7301.6017</td>
<td>0</td>
<td>2</td>
<td>20</td>
<td>15</td>
</tr>
</tbody>
</table>

- VLAN 1 root priority is 8193: configured priority plus the VLAN number of 1.
- VLAN 2 root priority is 16386: configured priority plus the VLAN number of 2.
- VLAN 3 root priority is 8195: configured priority plus the VLAN number of 3.

These priority settings normally program the switch to be the primary root bridge for VLANs 1 and 3, the secondary root bridge for VLAN2, and a normal bridge for VLAN 4. Primary and secondary root bridge elections also depend on the configuration of other network bridges. VLAN 4 root priority is 32788: default priority plus the VLAN number of 4.

### 12.1.3.2.2 Path Cost

Spanning tree calculates the costs of all possible paths from each component to the root bridge. The path cost is equal to the sum of the cost assigned to each port in the path. Ports are assigned a cost by default or through CLI commands. Cost values range from 1 to 200000000 (200 million).

The default cost is a function of the interface speed:

- 1 gigabit interfaces have a default cost of 20000.
- 10 gigabit interfaces have a default cost of 2000.

The `spanning-tree cost` command configures the path cost of the configuration mode interface. Costs can be specified for Ethernet and port channel interfaces. The command provides a mode parameter for assigning multiple costs to a port for MST instances or Rapid-PVST VLANs.

**Examples**

- These commands configure a port cost of 25000 to Ethernet interface 5. This cost is valid for RSTP or MSTP instance 0.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree cost 25000
switch(config-if-Et5)#
```

- This command configures a path cost of 300000 to Ethernet interface 5 in MST instance 200.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree mst 200 cost 300000
switch(config-if-Et5)#
```

- This command configures a path cost of 10000 to Ethernet interface 5 in Rapid-PVST VLAN 200-220.

```
switch(config)#interface ethernet 5
```
12.1.3.2.3 Port Priority

STP uses the port priority interface parameter to select ports when resolving loops. The port with the lower port priority numerical value is placed in forwarding mode. When multiple ports are assigned equal port priority numbers, the port with the lower interface number is placed in forwarding mode. Valid port-priority numbers are multiples of 16 between 0 and 240; the default is 128.

The `spanning-tree port-priority` command configures the port-priority number for the configuration mode interface. The command provides a mode option for assigning different priority numbers to a port for multiple MST instances or Rapid-PVST VLANs. Port-priority can be specified for Ethernet and port channel interfaces.

**Examples**

- This command sets the access port priority of 144 for Ethernet 5 interface.
  
  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree port-priority 144
  switch(config-if-Et5)#
  
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning-tree mst 10 port-priority 144
  switch(config-if-Et5)#
  ```

12.1.3.3 Port Roles and Rapid Convergence

Spanning Tree provides the following options for controlling port configuration and operation:

- **portfast**: Allows ports to skip learning state before entering the forwarding state.
- **port type** and **link type**: Designates ports for rapid transitions to the forwarding state.
- **root guard**: Ensures that a port will not become the root port.
- **loop guard**: Prevents loops resulting from unidirectional failure of links.
- **bridge assurance**: Prevents loops caused by unidirectional links or a malfunctioning switch.

12.1.3.3.1 PortFast

PortFast allows devices to gain immediate network access before convergence of the spanning tree. Enabling PortFast on ports connected to another switch can create loops.

A portfast port that receives a BPDU sets its operating state to non-portfast while remaining in portfast configured state. In this state, the port is subject to topology changes and can enter the discarding state.

The `spanning-tree portfast` command programs access ports to immediately enter the forwarding state. PortFast connects devices attached to an access port, such as a single workstation, to the network immediately without waiting for STP convergence. PortFast can also be enabled on trunk ports.

**Example**

This command unconditionally enables portfast on `interface ethernet 5`.

```plaintext
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast
switch(config-if-Et5)#
```
12.1.3.3.2 Port Type and Link Type Configuration

RSTP only achieves rapid transition to forwarding state on edge ports and point-to-point links.

Port Type

Edge ports are directly connected to end stations. Because edge ports do not create loops, they transition directly to forwarding state when a link is established.

The `spanning-tree portfast <port type>` command sets the configuration mode interfaces port type. Spanning tree ports can be configured as edge ports, network ports, or normal ports. The default port type is normal.

- **edge ports** connect to a host (end station). Configuring a port that connects to a bridge as an edge port may create a loop. Edge ports that receive a BPDU become a normal spanning tree port.
- **network ports** connect only to a Layer 2 switch or bridge. Configuring a port connected to a host as a network port transitions the port to the discarding state.
- **normal ports** have an unspecified topology.

Examples

- This command configures `interface ethernet 5` as a network port.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast network
switch(config-if-Et5)#
```

- Auto-edge detection converts ports into edge ports when they do not receive a new BPDU before the current BPDU expires, as measured by the max-age timer. The `spanning-tree portfast auto` command enables auto-edge detection on the configuration mode interface, superseding the `spanning-tree portfast` command. Auto-edge detection is enabled by default.

This command enables auto-edge detection on `interface ethernet 5`.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast auto
switch(config-if-Et5)#
```

Link Type

The switch derives a ports default link type from its duplex mode:

- full-duplex ports are **point-to-point**.
- half-duplex ports are **shared link**.

The `spanning-tree link-type` command specifies the configuration mode interfaces link-type. RSTP fast transition is not allowed on **shared link** ports, regardless of their duplex setting. Because the ports are full-duplex by default, the default link-type setting is **point-to-point**.

Example

This command configures `interface ethernet 5` as a shared port.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree link-type shared
switch(config-if-Et5)#
```

12.1.3.3.3 Root Guard and Loop Guard

**Root guard** stops a port from becoming a root port, which stops connected switches from becoming root bridges. When a switch detects a new root bridge, its root-guard-enabled ports enter blocked
Layer 2 Configuration

(root-inconsistent) state. When the switch no longer detects a new root, these ports enter learning state.

Root guard is enabled on a per-port basis. The setting applies to all STP instances. Disabling root guard places the port in learning state.

The **spanning-tree guard** command, with the root option, enables root guard on the configuration mode interface.

**Example**

This command enables root guard on *interface ethernet 5*.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree guard root
switch(config-if-Et5)#
```

**Loop guard** prevents loops resulting from unidirectional failure of point-to-point links by verifying that non-designated ports (root, blocked, and alternate) are receiving BPDUs from their designated ports. A loop-guard-enabled root or blocked port that stops receiving BPDUs transitions to the discarding (loop-inconsistent) state. The port recovers from this state when it receives a BPDU.

Loop guard, when enabled globally, applies to all point-to-point ports. Loop guard is configurable on individual ports and applies to all STP instances of an enabled port. Loop-inconsistent ports transition to learning state when loop guard is disabled.

If loop guard is enabled on a root switch, it takes effect only if the switch becomes a nonroot switch.

When using loop guard:

- Do not enable loop guard on portfast-enabled ports.
- Loop guard is not functional on ports not connected to point-to-point links.
- Loop guard has no effect on disabled spanning tree instances.

Loop guard aspects on port channels include:

- BPDUs are sent over the channels first operational port. Loop guard blocks the channel if that link becomes unidirectional even when other channel links function properly.
- Creating a new channel destroys state information for its component ports; new channels with loop-guard-enabled ports can enter forwarding state as a DP.
- Dissembling a channel destroys its state information; component ports from a blocked channel can enter the forwarding state as DPs, even if the channel contained unidirectional links.
- If a link on any port of the channel becomes unidirectional, the channel is blocked. Transmission resumes if the port is removed from the channel or the bidirectional communication is restored.

Loop guard configuration commands include:

- **spanning-tree guard loop default** command enables loop guard as a default on all switch ports.
- **spanning-tree guard** control the loop guard setting on the configuration mode interface. This command overrides the default command for the specified interface.

**Examples**

- This command enables loop guard as the default on all switch ports.
  
  ```
  switch(config)#spanning-tree guard loop default
  switch(config)#
  ```

- This command enables loop guard on *interface ethernet 6*.
  
  ```
  switch(config)#interface ethernet 6
  switch(config-if-Et6)#spanning-tree guard loop
  ```
12.1.3.3.4 Bridge Assurance

Bridge assurance protects against unidirectional link failures, other software failures, and devices that continue forwarding data traffic after they quit running spanning tree.

Bridge assurance programs the switch to send BPDUs at each hello time period through all bridge assurance-enabled ports (i.e., network ports). Bridge assurance operates only on network ports with point-to-point links, ideally with bridge assurance enabled on each side of the link. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled.

Ports not receiving a BPDU packet within a hello time period enter inconsistent (blocking) state. In this case, the `show spanning-tree transmit active` command will show a bridge assurance status of inconsistent for the port. If the other side of the link has bridge assurance enabled, or if the other switch is the root bridge, it will send periodic BPDUs, preventing an inconsistent blocking state.

Bridge assurance is globally enabled by default, but must also be enabled on a per-port basis by designating the port as a network port with the `spanning-tree portfast <port type>` command. The `no spanning-tree transmit active` command disables bridge assurance globally.

Example

These commands enable bridge assurance on the switch, then enable bridge assurance on interface `ethernet 5` by designating it a network port.

```
switch(config)#spanning-tree transmit active
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast network
switch(config-if-Et5)#
```

12.1.3.4 Configuring BPDU Transmissions

The following sections describe instructions that configure BPDU packet contents and transmissions.

12.1.3.4.1 Configuring Bridge Timers

Bridge timers specify parameter values that the switch includes in BPDU packets that it sends as a root bridge. Bridge timers include:

- **hello-time**: transmission interval between consecutive BPDU packets.
- **forward-time**: the period that ports remain in learning state.
- **max-age**: the period that BPDU data remains valid after it is received.
- **max-hop**: the number of bridges in an MST region that a BPDU can traverse before it is discarded.

In standard STP, ports passively wait for `forward_delay` and `max_age` periods before entering the forwarding state. RSTP achieves faster convergence by relying on edge port and link type definitions to start forwarding traffic. When edge ports and link types are properly configured, bridge timers are used in RSTP as backup or when interacting with networks running standard STP.

The `spanning-tree hello-time` command configures the hello time.

Examples

- This command configures a hello-time of 1 second (1000 ms).

```
switch(config)#spanning-tree hello-time 1000
switch(config)#
```
The `spanning-tree max-hops` command specifies the max hop setting that the switch inserts into BPDUs that it sends out as the root bridge.

- This command sets the max hop value to **40**.

```
switch(config)#spanning-tree max-hops 40
switch(config)#
```

The `spanning-tree forward-time` command configures the forward delay setting that the switch inserts into BPDUs that it sends out as the root bridge.

- This command sets the forward delay timer value to **25** seconds.

```
switch(config)#spanning-tree forward-time 25
switch(config)#
```

The `spanning-tree max-age` command configures the max age setting that the switch inserts into BPDUs that it sends out as the root bridge.

- This command sets the max age timer value to **25** seconds.

```
switch(config)#spanning-tree max-age 25
switch(config)#
```

### 12.1.3.4.2 BPDU Transmit Hold-Count

The `spanning-tree bpdu tx hold-count` command specifies the maximum number of BPDUs per second that the switch can send from an interface. Valid settings range from 1 to **10** BPDUs with a default of 6 BPDUs.

Higher hold-count settings can significantly impact CPU utilization, especially in Rapid-PVST mode. Smaller values can slow convergence in some configurations.

**Example**

This command configures a transmit hold-count of **8** BPDUs.

```
switch(config)#spanning-tree bpdu tx hold-count 8
switch(config)#
```

### 12.1.3.4.3 BPDU Guard

PortFast interfaces do not receive BPDUs in a valid configuration. BPDU Guard provides a secure response to invalid configurations by disabling ports when they receive a BPDU. Disabled ports differ from blocked ports in that they are re-enabled only through manual intervention.

- When configured globally, BPDU Guard is enabled on ports in the operational portfast state.
- When configured on an individual interface, BPDU Guard disables the port when it receives a BPDU, regardless of the ports portfast state.

The `spanning-tree edge-port bpdu guard default` global configuration command enables BPDU guard by default on all portfast ports. BPDU guard is disabled on all ports by default.

The `spanning-tree bpdu guard` interface configuration command controls BPDU guard on the configuration mode interface. This command takes precedence over the default setting configured by `spanning-tree edge-port bpdu guard default`.

- `spanning-tree bpdu guard` enables BPDU guard on the configuration mode interface.
- `spanning-tree bpdu guard disable` disables BPDU guard on the configuration mode interface.
• `no spanning-tree bpduguard` reverts the configuration mode interface to the default BPDU guard setting.

**Example**

These commands enable BPDU guard by default on all portfast ports, then disable BPDU guard on *Ethernet 5*.

```plaintext
switch(config)#spanning-tree edge-port bpduguard default
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree bpduguard disable
switch(config-if-Et5)
```

12.1.3.4.4 BPDU Filter

BPDU filtering prevents the switch from sending or receiving BPDUs on specified ports. BPDU filtering is configurable on Ethernet and port channel interfaces.

Ports with BPDU filtering enabled do not send BPDUs and drops inbound BPDUs. Enabling BPDU filtering on a port not connected to a host can result in loops as the port continues forwarding data while ignoring inbound BPDU packets.

The `spanning-tree bpdufilter` command controls BPDU filtering on the configuration mode interface. BPDU filtering is disabled by default.

**Example**

These commands enable BPDU filtering on *Ethernet 5*.

```plaintext
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree bpdufilter enable
switch(config-if-Et5)
```

12.1.3.4.5 BPDU Rate Limit

BPDU input rate limiting restricts the number of BPDUs that a port with BPDU guard and BPDU filter disabled, can process during a specified interval. The port discards all BPDUs that it receives in excess of the specified limit. Configuring the rate limiter requires two steps:

- Establishing the rate limit threshold
- Enabling rate limiting

**Establishing the Rate Limit Threshold**

The `spanning-tree bpduguard rate-limit count (interface)` command specifies the BPDU reception rate (quantity per interval) that triggers the discarding of BPDUs. The command is available in global and interface configuration modes.

- The `spanning-tree bpduguard rate-limit count` global command specifies the maximum reception rate for ports that are not covered by interface rate limit count commands. The global command specifies the default limit.

**Note:** Arista Networks recommends to retain the default values of rate limit. In the PVST mode, when the VLAN membership of a port is changed by a significant margin, it is advisable to disable interface BPDU rate limit on both ends of a port. For example, if three VLANs are present on a port initially, the operator must first add 300 more VLANs on one side of the port and then add the same 300 VLANs on the other side of the port. In this case, if the VLANs are increased towards the root bridge first, then the other side can cross the rate-limit threshold.
• The `spanning-tree bpduguard rate-limit count` interface command defines the maximum BPDU reception rate for ports in the configuration mode interface.

**Examples**

• This command configures the global limit of 5000 BPDUs over a 4 second interval.

  ```
  switch(config)#spanning-tree bpduguard rate-limit count 5000 interval 4
  ```

• These commands configure a limit of 7500 BPDUs over an 8 second interval on the `interface ethernet 2`.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#spanning-tree bpduguard rate-limit count 7500 interval 8
  ```

**Enabling Rate Limiting**

BPDU rate limiting is enabled globally or on individual ports:

• `spanning-tree bpduguard rate-limit default` enables rate limiting on all ports that are not covered by the interface rate limiting command. The default setting is `enabled`.

• `spanning-tree bpduguard rate-limit enable / disable` interface command enables or disables BPDU rate limiting on the configuration mode interface. This command has precedence over the global command.

**Examples**

• This command enables rate limiting on ports that are not covered by interface rate limit commands.

  ```
  switch(config)#spanning-tree bpduguard rate-limit default
  ```

• These commands enable rate limiting on the `interface ethernet 15`.

  ```
  switch(config)#interface ethernet 15
  switch(config-if-Et15)#spanning-tree bpduguard rate-limit enable
  ```
12.1.4 STP Commands

Spanning Tree Commands: Global Configuration

- spanning-tree bpdu tx hold-count
- spanning-tree bpdu guard rate-limit count (global)
- spanning-tree bpdu guard rate-limit default
- spanning-tree edge-port bpdufilter default
- spanning-tree edge-port bpduguard default
- spanning-tree forward-time
- spanning-tree guard loop default
- spanning-tree hello-time
- spanning-tree max-age
- spanning-tree max-hops
- spanning-tree mode
- spanning-tree mst configuration
- spanning-tree mst pvst border
- spanning-tree portchannel guard misconfig
- spanning-tree priority
- spanning-tree root
- spanning-tree transmit active
- spanning-tree vlan-id

Loop Protection Commands

- disabled-time
- loop-protection
- monitor loop-protection
- protect vlan
- rate-limit
- shutdown (Loop-protection)
- show loop-protection
- transmit-interval

Spanning Tree Commands: Interface Configuration Mode

- spanning-tree bpdufilter
- spanning-tree bpdu guard
- spanning-tree bpdu guard rate-limit count (interface)
- spanning-tree bpdu guard rate-limit enable / disable
- spanning-tree cost
- spanning-tree guard
- spanning-tree link-type
- spanning-tree port-priority
- spanning-tree portfast
- spanning-tree portfast auto
- spanning-tree portfast <port type>
- switchport backup-link
**MST Configuration Commands**

- abort (mst-configuration mode)
- exit (mst-configuration mode)
- instance
- name (mst-configuration mode)
- revision (mst-configuration mode)
- show (mst-configuration mode)

**Display Commands**

- show spanning-tree
- show spanning-tree blockedports
- show spanning-tree counters
- show spanning-tree instance
- show spanning-tree instance detail
- show spanning-tree interface
- show spanning-tree mst
- show spanning-tree mst configuration
- show spanning-tree mst interface
- show spanning-tree mst test information
- show spanning-tree root
- show spanning-tree topology status
- show spanning-tree topology status

**Clear Commands**

- clear spanning-tree counters
- clear spanning-tree counters session
- clear spanning-tree detected-protocols
12.1.4.1  abort (mst-configuration mode)

The abort command, in MST-configuration mode, discards pending changes to the MST region configuration, then returns the switch to global configuration mode.

The exit (mst-configuration mode) command saves MST region changes to running-config before returning the switch to global configuration mode.

**Command Mode**

MST-configuration

**Command Syntax**

abort

**Example**

This command discards changes to the MST region, then returns the switch to global configuration mode.

```
switch(config-mst)#abort
switch(config)#
```
12.1.4.2 clear spanning-tree counters session

The `clear spanning-tree counter session` command resets the BPDU counters to zero on all interfaces in the current CLI session. Counters in other CLI sessions are not affected.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear spanning-tree counters session

**Example**
This command resets the BPDU counters in the current CLI session.

```
switch# show spanning-tree counters
                  Port       Sent       Received       Tagged Error  Other
                        Error
-------------------------------------------------------
   Ethernet15        32721             0                  0           0
   Port-Channel10     8487             0                  0           0
switch# clear spanning-tree counters session
switch# show spanning-tree counters
                  Port       Sent       Received       Tagged Error  Other
                        Error
---------------------------------------
   Ethernet15        11              0                  0           0
   Port-Channel10     7               2                  6
```
12.1.4.3 clear spanning-tree counters

The `clear spanning-tree counters` command resets the BPDU counters for the specified interfaces to zero in all CLI sessions.

**Command Mode**

Privileged EXEC

**Command Syntax**

`clear spanning-tree counters [INT_NAME]`

**Parameters**

**INT_NAME** Interface type and number. Options include:

- *no parameter* resets counters for all interfaces.
- *interface ethernet e_num* Ethernet interface specified by `e_num`.
- *interface loopback l_num* Loopback interface specified by `l_num`.
- *interface management m_num* Management interface specified by `m_num`.
- *interface port-channel p_num* Port-Channel Interface specified by `p_num`.
- *interface vlan v_num* VLAN interface specified by `v_num`.

**Example**

This command resets the BPDU counters on `interface ethernet 15`.

```
switch#show spanning-tree counters
Port    Sent       Received   Tagged Error   Other Error
----------------------------------------------------------------------
Ethernet15   32721       0           0              0
Port-Channel10  8487       0           0              0
switch#clear spanning-tree counters interface ethernet 15
switch#show spanning-tree counters
Port    Sent       Received   Tagged Error   Other Error
----------------------------------------------------------------------
Ethernet15    11          0           0              0
Port-Channel10 84942       6           0              0
switch#
```
12.1.4.4  clear spanning-tree detected-protocols

The `clear spanning-tree detected-protocols` command restarts the spanning tree protocol (STP) migration state machine on the specified interfaces. The switch is reset to running rapid spanning tree protocol on an interface where it previously detected a bridge running an old version of the protocol.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear spanning-tree detected-protocols [INT_NAME]`

**Parameters**

**INT_NAME** Interface type and number. Values include:
- `no parameter` all interfaces.
- `ethernet e_num` Ethernet interface specified by `e_num`.
- `loopback l_num` Loopback interface specified by `l_num`.
- `management m_num` Management interface specified by `m_num`.
- `port-channel p_num` Port-Channel Interface specified by `p_num`.
- `vlan v_num` VLAN interface specified by `v_num`.

**Example**
This command restarts the STP migration machine on all switch interfaces.

```
switch#clear spanning-tree detected-protocols
switch#
```
12.1.4.5  disabled-time

The `disabled-time` command sets the time for which the port remains disabled after a loop is detected by loop protection. The `no disabled-time` and `default disabled-time` commands reset the disabled time to the default of 604800 seconds (seven days).

**Note:** If this value is changed, interfaces that are already disabled by loop protection will remain disabled for the previously configured period.

**Command Mode**

Loop-protection Configuration

**Command Syntax**

```
disabled-time [period]
no disabled-time [period]
default disabled-time [period]
```

**Parameters**

`period` Time in seconds for which the port remains disabled. Values range from 0 to 604800 (seven days). Default is 604800. A value of 0 disables the interface until it is manually reset, even if the disabled time is later set to a non-zero value. To restore the port manually, shut it down and then re-enable it.

**Example**

This command configures loop protection to disable a port on which a loop is detected for a period of two days (172800 seconds).

```
switch(config-monitor-loop-protect)#disabled-time 172800
switch(config-monitor-loop-protect)#
```
12.1.4.6  exit (mst-configuration mode)

The `exit` command, in MST-configuration mode, saves changes to the MST region configuration, then returns the switch to global configuration mode. MST region configuration changes are also saved by entering a different configuration mode.

**Command Mode**

MST-configuration

**Command Syntax**

`exit`

**Examples**

- This command saves changes to the MST region, then returns the switch to global configuration mode.

```bash
switch(config-mst)#exit
switch(config)#
```

- This command saves changes to the MST region, then places the switch in Interface-Ethernet mode.

```bash
switch(config-mst)#interface ethernet 3
switch(config-if-Et3)#
```
12.1.4.7 instance

The **instance** command inserts an entry into the VLAN-to-instance map that associates a set of VLANs to an MST instance. In addition to defining the MST topology, the VLAN-to-instance map is one of three parameters, along with the MST name and revision number, that identifies the switch's MST region.

The **no instance** command removes specified entries from the VLAN-to-instance map. If the command does not provide a VLAN list, all entries are removed for the specified instance. The **no instance** and **default instance** commands function identically.

**Command Mode**
MST-Configuration

**Command Syntax**

```
instance mst_inst vlans v_range
no instance mst_inst [vlans v_range]
no default instance mst_inst [vlans v_range]
```

**Parameters**

- **mst_inst** MST instance number. Value of **mst_inst** ranges from 0 to 4094.
- **v_range** VLAN list. Formats include a number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command maps VLANs **20-39** to MST instance **2**.

```
switch(config)#spanning-tree mst configuration
switch(config-mst)#instance 2 vlans 20-39
switch(config-mst)#
```

- This command removes all VLAN mappings to MST instance **10**.

```
switch(config-mst)#no instance 10
switch(config-mst)#
```
12.1.4.8  loop-protection

The `loop-protection` command enables loop protection on the configuration mode interface. All interfaces in a VLAN under loop protection have loop protection enabled by default. The `no loop-protection` and `default loop-protection` commands disable loop protection on the interface.

When loop protection is disabled (at the VLAN or interface level), the computed state of the interface is forgotten and packets queued to be sent are dropped. If an interface is err-disabled by loop protection, disabling loop protection removes the err-disable.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

- `loop-protection`
- `no loop-protection`
- `default loop-protection`

**Example**

These commands disable loop protection on `interface ethernet 2/4`. If the interface is currently errdisenabled by loop protection, the errdis is removed.

```
switch(config)#interface ethernet 2/4
switch(config-if-Et2/4)#no loop-protection
switch(config-if-Et2/4)#
```
12.1.4.9  monitor loop-protection

The `monitor loop-protection` command places the switch in loop-protection configuration mode.

**Command Mode**
Global Configuration

**Command Syntax**

```
monitor loop-protection
```

**Commands available in loop-protection configuration mode:**
- shutdown (Loop-protection)
- protect vlan
- transmit-interval
- disabled-time
- rate-limit

**Example**

This command places the switch in `loop-protection` configuration mode.

```
switch(config)#monitor loop-protection
switch(config-monitor-loop-protect)#
```
12.1.4.10  **name (mst-configuration mode)**

The `name` command configures the MST region name. The name is one of three parameters, along with the MST revision number and VLAN-to-instance map, that identifies the switch's MST region.

The name has up to 32 characters. The default name is an empty string. The name string accepts all characters except the space.

The `no name` and `default name` commands restore the default name by removing the `name` command from `running-config`.

**Command Mode**

MST-Configuration

**Command Syntax**

```
name label_text
no name
default name
```

**Parameters**

*label_text* character string assigned to name attribute. Maximum 32 characters. The space character is not permitted in the name string.

**Example**

This command assigns *corporate_100* as the MST region name.

```
switch(config)# spanning-tree mst configuration
switch(config-mst)# name corporate_100
switch(config-mst)# show pending
Active MST configuration
Name        [corporate_100]
Revision    0    Instances configured 1

Instance  Vlans mapped
---------- -----------------------------------------------
0          1-4094
---------- -----------------------------------------------
```
12.1.4.11  protect vlan

The `protect vlan` command specifies which VLANs participate in loop protection. The `no protect vlan` and `default protect vlan` commands remove loop protection from the specified VLANs.

**Command Mode**
Loop- protección Configuration

**Command Syntax**
`protect vlan vlan-range`

**Parameters**

`vlan-range` List of VLANs (number, range, comma-delimited list of numbers and ranges). Numbers range from 1 to 4094.

**Example**
This command enables loop protection on VLANs 1025-2000.

```
switch(config-monitor-loop-protect)#protect vlan 1025-2000
switch(config-monitor-loop-protect)#
```
12.1.4.12  rate-limit

The `rate-limit` command sets the maximum number of loop detection frames which can be sent by the switch per second. The `no rate-limit` and `default rate-limit` commands return the rate limit to the default value of 1000.

**Command Mode**
Loop-protection Configuration

**Command Syntax**

```
rate-limit [frames]
no rate-limit [frames]
default rate-limit [frames]
```

**Parameters**

- `frames` Maximum number of frames sent per second. Values range from 0-1000, default is 1000. A value of 0 disables throttling.

**Example**

This command sets the maximum number of loop detection frames to 500 per second.

```
switch(config-monitor-loop-protect)#rate-limit 500
switch(config-monitor-loop-protect)#
```
12.1.4.13  Revision (mst-configuration mode)

The `revision` command configures the MST revision number. The revision number is one of three parameters, along with the MST name and VLAN-to-instance map, that identifies the switch's MST region. Revision numbers range from 0 to 65535. The default revision number is 0.

The `no revision` and `default revision` commands restore the revision number to its default value by removing the revision command from `running-config`.

**Command Mode**
MST-Configuration

**Command Syntax**

```
revision rev_number
no revision
default revision
```

**Parameters**

`rev_number` revision number. Possible ranges from 0 to 65535 with a default of 0.

**Example**
This command sets the revision number to 15.

```
switch(config)# spanning-tree mst configuration
switch(config-mst)# revision 15
switch(config-mst)# show pending
Active MST configuration
Name  []
Revision 15
Instances configured 1

Instance  Vlans mapped
---------  -----------------------------------------------
0         1-4094
```

---

1378
12.1.4.14 show (mst-configuration mode)

The `show` command displays the current and pending MST configuration:
Exiting MST configuration mode stores all pending configuration changes to `running-config`.

Command Mode
MST-Configuration

Command Syntax
`show [EDIT_VERSION]`

Parameters

- **EDIT_VERSION** specifies configuration version that the command displays. Options include:
  - *no parameter* command displays pending MST configuration.
  - *active* command displays MST configuration stored in `running-config`.
  - *current* command displays MST configuration stored in `running-config`.
  - *pending* command displays pending MST configuration.

Example

These commands contrast the difference between the active and pending configuration by adding MST configuration commands, then showing the configurations.

```bash
switch(config-mst)#show pending
Active MST configuration
Name    []
Revision 0    Instances configured 1

Instance Vlans mapped
--------------------------------------------------------
  0      1-4094
--------------------------------------------------------

switch(config-mst)#instance 2 vlan 20-29,102
switch(config-mst)#revision 2
switch(config-mst)#name baseline
switch(config-mst)#show pending
Pending MST configuration
Name    [baseline]
Revision 2    Instances configured 2

Instance Vlans mapped
---------------------------------------------------------
  0      1-19,30-101,103-4094
  2      20-29,102
---------------------------------------------------------

switch(config-mst)#show active
Active MST configuration
Name    []
Revision 0    Instances configured 1

Instance Vlans mapped
--------------------------------------------------------
  0      1-4094
--------------------------------------------------------
```
12.1.4.15  show loop-protection

The **show loop-protection** command displays loop protection status.

**Command Syntax**

```plaintext
show loop-protection [detail]
```

**Examples**

- This command displays basic loop protection information.

  ```plaintext
  switch#show loop-protection
  Loop protection is enabled
  Transmit interval: 5
  Disable Time: 604800 (or Permanent)
  Packets Transmitted rate: 12/second (or Unthrottled)
  Total: 3 Vlans enabled.
  switch>
  ```

- This command displays detailed information about loop protection.

  ```plaintext
  switch#show loop-protection detail
  Loop protection is enabled
  Transmit interval: 5
  Disable Time: 604800
  Packets Transmitted rate: 12/second
  Total: 3 Vlans enabled.
  Destination address: ffff.ffff.ffff
  Ethernet type: 0x88b7
  Receive action: Interface Disable
  Vlan  Detected  Loop  Disabled Intfs  Total  Latest
       ----------- --------- ------------- ----- --------------
        1           Yes       Et1-2          20     18:01
        2           No        -              20     -
        3           No        -              20     -
  switch#
  ```

- This command displays loop protection information for the interfaces in VLANS 3-4.

  ```plaintext
  switch#show loop-protection vlan 3-4
  Vlan  Intf  LP  Enabled  State  LP  Disabled  Bring
        ----- ----- ---------- --------- -------  -------- -----
        3     Et1  Yes        shutdown  Yes      17:21   18:21
        3     Et2  Yes        shutdown  No       -        -
        3     Et3  Yes        enabled  No       -        -
        3     Et4  No         -          -        -        -
        4     -     No         -          -        -        -
  switch#
  ```

- This command displays the number of loop detection packets sent and received.

  ```plaintext
  switch#show loop-protection counters
  VLAN  Tx  Rx  Rx-Other
        ----- ----- ----  --------
        2     200  0  100
        3     200  1  0
  Intfs  Tx  Rx  Rx-Other
        ----- ----- ----  --------
  ```

switch#
12.1.4.16  show spanning-tree blockedports

The `show spanning-tree blockedports` command displays the list of blocked (discarding) ports.

**Command Mode**

EXEC

**Command Syntax**

`show spanning-tree blockedports`

**Example**

This command shows the ports that are in discarding state.

```
switch# show spanning-tree blockedports
Name   Blocked Interfaces List
---------------------------------------------------------------------
MST0    Po903, Po905, Po907, Po909, Po911, Po913, Po915, Po917, Po919, Po921, Po923
           Po925, Po927, Po929, Po931, Po933, Po935, Po939, Po941, Po943, Po945, Po947
Number of blocked ports (segments) in the system : 22
switch#
```
12.1.4.17  show spanning-tree counters

The `show spanning-tree counters` command displays the number of BPDU transactions on each interface running spanning tree.

**Command Mode**

EXEC

**Command Syntax**

`show spanning-tree counters`

**Example**

This command displays the BPDU counter status on each interface running spanning tree.

```
switch#show spanning-tree counters

Port      Sent   Received   Tagged Error   Other Error  sinceTimer
---------------------------------------------------------------------

switch#
```
12.1.4.18  show spanning-tree instance

The `show spanning-tree instance` command displays spanning tree protocol bridge configuration settings for each instance on the switch. The display includes **Bridge ID, Hello Time, Max Age, and Forward Delay** times.

The command also displays the restartability of the STP agent when the `detail` option is selected. A switch can continue support of MLAG operation when its peer is offline and the STP agent is unavailable.

**Command Mode**
EXEC

**Command Syntax**
`show spanning-tree instance [INFO_LEVEL]`

**Parameters**
INFO_LEVEL specifies level of information detail provided by the command.

- **no parameter** command displays information in a data table.
- **detail** command displays bridge information in data blocks for each instance.

**Examples**
- This command displays a bridge data table.

```
switch#show spanning-tree instance
Bridge ID          Priority          MAC addr        Hello  Max  Fwd
Instance          --------  ---------------        -----  ---  ---
MST0              32768(32768, sys-id 0 ) 001c.7302.2f98 2000   20  15
MST101            32869(32768, sys-id 101 ) 001c.7302.2f98 2000   20  15
MST102            32870(32768, sys-id 102 ) 001c.7302.2f98 2000   20  15
switch#
```

- This command displays bridge data blocks.

```
switch#show spanning-tree instance detail
Stp Detailed Status:
  Stp agent restartable : True
  MST-PVST interoperation : Disabled
  Stp heartbeat timeout : 2.0
  Last local heartbeat timeout : 0:04:07 ago
  Local heartbeat timeout since reboot : 1

MST0
  Bridge ID Priority  32768 (priority 32768 sys-id-ext 0)
  Address 001c.7302.2f98
  Hello Time 2.000 sec  Max Age 20 sec  Forward Delay 15 sec

MST101
  Bridge ID Priority  32869 (priority 32768 sys-id-ext 101)
  Address 001c.7302.2f98
  Hello Time 2.000 sec  Max Age 20 sec  Forward Delay 15 sec

MST102
  Bridge ID Priority  32870 (priority 32768 sys-id-ext 102)
  Address 001c.7302.2f98
  Hello Time 2.000 sec  Max Age 20 sec  Forward Delay 15 sec
switch#
```
12.1.4.19  show spanning-tree instance detail

The `show spanning-tree instance detail` command displays detailed MST information including MSTP-Rapid PVST+ interoperation status.

**Command Mode**

EXEC

**Command Syntax**

`show spanning-tree instance detail`

**Example**

This command displays detailed MST information.

```
switch# show spanning-tree instance detail
Stp Detailed Status:  
  Stp agent restartable : True
  MST-PVST interoperation : Enabled
  Stp heartbeat timeout : 2.0
  Last local heartbeat timeout : 36 days, 19:10:46 ago
  Local heartbeat timeout since reboot : 1
MST0
  Bridge ID Priority 32768 (priority 32768 sys-id-ext 0)
  Address 001c.7374.8572
  Hello Time 2.000 sec Max Age 20 sec Forward Delay 15 sec
switch#
```
12.1.4.20  show spanning-tree interface

The `show spanning-tree interface` command displays spanning tree protocol information for the specified interface.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree interface INT_NAME [INFO_LEVEL]
```

**Parameters**

- **INT_NAME** Interface type and number. Values include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `peer ethernet e_num` Ethernet interface specified by `e_num`.
  - `port-channel p_num` Port-Channel Interface specified by `p_num`.
  - `peerport-channel p_num` Port-Channel Interface specified by `p_num`.
- **INFO_LEVEL** specifies level of detail provided by the output. Options include:
  - `no parameter` command displays a table of STP data for the specified interface.
  - `detail` command displays a data block for the specified interface.

**Examples**

- This command displays an STP table for Ethernet interface 5.

  ```
  switch#show spanning-tree interface ethernet 5
  Instance    Role     State      Cost      Prio.Nbr     Type
  ----------- -------- ---------- --------- ---------- ----
  MST0        designated forwarding 20000      128.5      P2p
  switch#
  ```

- This command displays a data block for Ethernet interface 5.

  ```
  switch#show spanning-tree interface ethernet 5 detail
  Port 5 (Ethernet5) of MST0 is designated forwarding
  Port path cost 20000, Port priority 128, Port Identifier 128.5.
  Designated root has priority 32768, address 001c.7301.07b9
  Designated bridge has priority 32768, address 001c.7304.195b
  Designated port id is 128.5, designated path cost 1999 (Ext) 0 (Int)
  Timers: message age 1, forward delay 15, hold 20
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default, Internal
  BPDU: sent 1008766, received 0, taggedErr 0, otherErr 0,
  rateLimiterCount 0
  Rate-Limiter: enabled, Window: 10 sec, Max-BPDU: 400
  switch#
  ```
### 12.1.4.21 show spanning-tree mst configuration

The `show spanning-tree mst configuration` command displays information about the MST regions VLAN-to-instance mapping. The command provides two display options:

- **default** displays a table that lists the instance to VLAN map.
- **digest** displays the configuration digest.

The configuration digest is a 16-byte hex string calculated from the md5 encoding of the VLAN-to-instance mapping table. Switches with identical mappings have identical digests.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree mst configuration [INFO_LEVEL]
```

**Parameters**

INFO_LEVEL specifies data provided by the output. Options include:

- **no parameter** command displays VLAN-to-instance map.
- **digest** command displays the MST configuration digest.

**Examples**

- This command displays the MST regions VLAN-to-instance map.

```
switch# show spanning-tree mst configuration
Name      []    Revision 0    Instances configured 3
Instance Vlans mapped
-----------------------------------------------------------
01,4-4094  22
33
-----------------------------------------------------------
switch#
```

- This command displays the MST regions configuration digest.

```
switch# show spanning-tree mst configuration digest
Name      []    Revision 0    Instances configured 1
Digest    0xAC36177F50283CD4B83821D8AB26DE62
switch#
```
12.1.4.22 show spanning-tree mst interface

The `show spanning-tree mst interface` command displays Multiple Spanning Tree Protocol (MSTP) information for a specified interface on the specified MST instances.

**Command Mode**
EXEC

**Command Syntax**
`show spanning-tree mst [INSTANCE] interface INT_NAME [INFO_LEVEL]`

**Parameters**
- **INSTANCE** MST instance for which the command displays information. Options include:
  - *no parameter* all MST instances.
  - *mst_inst* denotes a single MST instance. Value of *mst_inst* ranges from 0 to 4094.
- **INT_NAME** Interface type and number. Values include:
  - *ethernet e_num* Ethernet interface specified by *e_num*.
  - *peerethernet e_num* Ethernet interface specified by *e_num*.
  - *port-channel p_num* Port-channel interface specified by *p_num*.
  - *peerport-channel p_num* Port-channel interface specified by *p_num*.
- **INFO_LEVEL** specifies level of detail provided by the output. Options include:
  - *no parameter* command displays a table of STP instance data for the specified interface.
  - *detail* command displays a data block for all specified instance-interface combinations.

**Examples**
- This command displays an table of STP instance data for interface *ethernet 1*:

```
switch# show spanning-tree mst interface ethernet 1
Ethernet1 of MST0 is root forwarding
Edge port: nobpdu guard: disabled
Link type: point-to-point
Boundary : Internal
Bpdus sent 2120, received 2164, taggedErr 0, otherErr 0

Instance Role Sts Cost Prio Nbr Vlans mapped
-------- ---- ----- ---- --------- -------------------------
0RootFWD 2000 128.11,4-4094
2DesgFWD 2000 128.12
3RootFWD 2000 128.13
```

- This command displays blocks of STP instance information for interface *ethernet 1*.

```
switch# show spanning-tree mst 3 interface ethernet 1 detail
Ethernet1 of MST3 is root forwarding
Vlans mapped to MST3 3
Port infoport id128.1 priority 128 cost 2000
Designated root address 0011.2233.4401 priority 32768 cost 0
Designated bridge address 0011.2233.4401 priority 32768 port id128.1
```
12.1.4.23  show spanning-tree mst test information

The **show spanning-tree mst test information** displays diagnostic spanning tree protocol information.

**Command Mode**

EXEC

**Command Syntax**

`show spanning-tree mst test information`

**Example**

This command displays diagnostic STP information.

```python
switch#show spanning-tree mst test information
bi = MstInfo.BridgeInfo( "dut" )
bi.stpVersion = "rstp"
bm.mstpRegionId = ""
bm.bridgeAddr = "00:1c:73:01:60:17"
si = MstInfo.BridgeStpiInfo( "Mst" )
bi.stpiInfoIs( "Mst", si )
si.cistRoot = Tac.Value( "Stp::BridgeId", priority=32768, systemId=0, address='00:1c:73:01:60:17' )
si.cistPathCost = 0
bm.mstInfoIs( "Mst0", bmi )
bm.bridgeId = Tac.Value( "Stp::BridgeId", priority=32768, systemId=0, address='00:1c:73:01:60:17' )
bm.designatedRoot = Tac.Value( "Stp::BridgeId", priority=32768, systemId=0, address='00:1c:73:01:60:17' )
si.mstiInfoIs( "Mst0", bmi )
bmii = MstInfo.BridgeMstiIntfInfo( "Mst0", "Ethernet15" )
bmii.portId = Tac.Value( "Stp::PortId", portPriority=128, portNumber=15 )
bmii.role = "designated"
bmii.operIntPathCost = 2000
bmii.fdbFlush = 1
bmii.mstiIntfInfoIs( "Ethernet15", bmii )
bii = MstInfo.BridgeIntfInfo( "Ethernet15" )
bii.operExtPathCost = 2000
si.intfInfoIs( "Ethernet15", bi )
bmii = MstInfo.BridgeMstiIntfInfo( "Mst0", "Port-Channel110" )
bmii.portId = Tac.Value( "Stp::PortId", portPriority=128, portNumber=101 )
bmii.role = "designated"
bmii.operIntPathCost = 1999
bmii.fdbFlush = 1
bmii.mstiIntfInfoIs( "Port-Channel110", bmii )
bii = MstInfo.BridgeIntfInfo( "Port-Channel110" )
bii.operExtPathCost = 1999
si.intfInfoIs( "Port-Channel110", bi )
switch>
```
12.1.4.24  **show spanning-tree mst**

The **show spanning-tree mst** command displays configuration and state information for Multiple Spanning Tree Protocol (MST) instances.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show spanning-tree mst [INSTANCE] [INFO_LEVEL]
```

**Parameters**

- **INSTANCE** MST instance for which the command displays information. Options include:
  - *no parameter* all MST instances.
  - *mst_inst* MST instance number. Value of *mst_inst* ranges from 0 to 4094.
- **INFO_LEVEL** type and amount of information in the output. Options include:
  - *no parameter* output is interface data in tabular format.
  - *detail* output is a data block for each interface.

**Examples**

- This command displays interface data blocks for MST instance 3.

```plaintext
switch#show spanning-tree mst 3 detail
##### MST3 vlans mapped:3
Bridgeaddress 0011.2233.4402priority32771 (32768 sysid 3)

12.1.4.25  show spanning-tree root

The show spanning-tree root command displays the Bridge-ID, cost to the root bridge, root port, and the root bridge timer settings for all instances.

Command Mode
EXEC

Command Syntax
show spanning-tree root [INFO_LEVEL]

Parameters
INFO_LEVEL specifies output format. Options include:

- no parameter output displays data in tabular format.
- detail output displays a data block for each instance.

Examples

- This command displays a table of root bridge information.

```
switch#show spanning-tree root

<table>
<thead>
<tr>
<th>Instance</th>
<th>Root ID</th>
<th>Root Priority</th>
<th>Root MAC addr</th>
<th>Hello Cost</th>

```
12.1.4.26  show spanning-tree topology status

The `show spanning-tree topology status` command displays the forwarding state of ports on the specified VLANs.

**Command Mode**

EXEC

**Command Syntax**

```
show spanning-tree topology [VLAN_NAME] status [INFO_LEVEL]
```

**Parameters**

- **VLAN_NAME** specifies the VLANs that the output displays. Options include:
  - *no parameter* output includes all VLANs.
  - *vlan* output includes all VLANs.
  - *vlan v_num* command includes specified VLAN; `v_num` ranges from 1 to 4094.

- **INFO_LEVEL** specifies information provided by output. Options include:
  - *no parameter* output lists forwarding state of interfaces.
  - *detail* output lists forwarding state and change history of interfaces.

**Examples**

- This command displays forwarding state for ports mapped to all VLANs.

```
switch#show spanning-tree topology status
Topology: Cist
Mapped Vlans: 1-4,666,1000-1001,1004-1005
Cpu:               forwarding
Ethernet2:         forwarding
Ethernet3:         forwarding
Ethernet4:         forwarding
Ethernet5:         forwarding
Ethernet6:         forwarding
Ethernet8:         forwarding
Ethernet10:        forwarding
Port-Channel1:     forwarding
Port-Channel2:     forwarding
Port-Channel3:     forwarding

switch>
```

- This command displays forwarding state and history for ports mapped to **VLAN 1000**.

```
switch#show spanning-tree topology vlan 1000 status detail
Topology: Cist
Mapped Vlans: 1000
Cpu:               forwarding (1 changes, last 23 days, 22:54:43 ago)
Ethernet2:         forwarding (3 changes, last 23 days, 22:48:59 ago)
Ethernet4:         forwarding (3 changes, last 10 days, 19:54:17 ago)
Ethernet5:         forwarding (3 changes, last 23 days, 22:54:38 ago)
Ethernet6:         forwarding (3 changes, last 19 days, 15:49:10 ago)
Ethernet10:        forwarding (3 changes, last 9 days, 7:37:05 ago)
Port-Channel1:     forwarding (5 changes, last 21 days, 4:56:41 ago)
Port-Channel3:     forwarding

switch>
```
show spanning-tree transmit active

The `show spanning-tree transmit active` command displays spanning tree protocol bridge assurance information for network ports or for all ports. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled, but if they do not receive periodic BPDUs from the other side of the link the `show spanning-tree transmit active` command will show a bridge assurance status of inconsistent (blocking) for that port.

**Command Mode**

EXEC

**Command Syntax**

`show spanning-tree transmit active INFO_LEVEL`

**Parameters**

- **INFO_LEVEL** specifies level of information detail provided by the command.
  - `no parameter` command displays bridge assurance information for network ports.
  - `detail` command displays bridge assurance information for all ports.

**Example**

This command displays the bridge assurance status of network ports.

```
switch#show spanning-tree transmit active
Name       Bridge Assurance Status
---------------------------------------
VL1           Et5/1         consistent

Number of bridge assurance inconsistent ports in the system: 0
switch>
```
The `show spanning-tree` command displays spanning tree protocol (STP) data, organized by instance.

Command Mode
EXEC

Command Syntax
`show spanning-tree [VLAN_ID][INFO_LEVEL]`

Parameters
- **VLAN_ID** specifies the VLANs for which the command displays information. Formats include:
  - `no parameter` displays information for all VLANs.
  - `vlan` displays data for instances containing the first VLAN listed in running-config.
  - `vlan v_range` displays data for instances containing a VLAN in the specified range.
- **INFO_LEVEL** specifies level of information detail provided by the command.
  - `no parameter` displays table for each instance listing status, configuration, and history.
  - `detail` displays data blocks for each instance and all ports on each instance.

Display Values
- **Root ID** Displays information on the ROOT ID (elected spanning tree root bridge ID):
  - **Priority** Priority of the bridge. Default value is 32768.
  - **Address** MAC address of the bridge.
- **Bridge ID** bridge status and configuration information for the locally configured bridge:
  - **Priority** Priority of the bridge. The default priority is 32768.
  - **Address** MAC address of the bridge.
  - **Hello Time** Interval (seconds) between bridge protocol data units (BPDUs) transmissions.
  - **Max Age** Maximum time that a BPDU is saved.
  - **Forward Delay** Time (in seconds) that is spent in the learning state.
- **Interface** STP configuration participants. Link-down interfaces are not shown.
- **Role** Role of the port as one of the following:
  - **Root** The best port for a bridge to a root bridge used for forwarding.
  - **Designated** A forwarding port for a LAN segment.
  - **Alternate** A port acting as an alternate path to the root bridge.
  - **Backup** A port acting as a redundant path to another bridge port.
- **State** Displays the interface STP state as one of the following:
  - **Learning</br>** Discarding</br>** Forwarding</br>** Cost STP port path cost value.
- **Prio. Nbr.** STP port priority. Values range from 0 to 240. Default is 128.
- **Type** The link type of the interface (automatically derived from the duplex mode of an interface):
  - **P2p Peer** (STP) Point to point full duplex port running standard STP.
  - **shr Peer** (STP) Shared half duplex port running standard STP.

Examples
- This command displays STP data, including a table of port parameters.

```
switch#show spanning-tree vlan 1000
MST0
```
Spanning tree enabled protocol rstp

switch#
12.1.4.29 shutdown (Loop-protection)

The `shutdown` command disables loop protection globally. The feature is disabled by default, and is enabled by using the `no shutdown` command.

**Note:** To function, loop protection must also be enabled on a per-VLAN basis using the `protect vlan` command.

**Command Mode**
Loop-protection Configuration

**Command Syntax**

- `shutdown`
- `no shutdown`

**Example**

This command enables loop protection globally on the switch.

```
switch(config-monitor-loop-protect)#no shutdown
switch(config-monitor-loop-protect)#
```
12.1.4.30  spanning-tree bpdu tx hold-count

The `spanning-tree bpdu tx hold-count` command specifies the maximum number of BPDUs per second that the switch can send from an interface. Valid settings range from 1 to 10 BPDUs with a default of 6 BPDUs.

The `no spanning-tree bpdu tx hold-count` and `default spanning-tree bpdu tx hold-count` commands restore the transmit hold count default of 6 BPDUs by removing the `spanning-tree bpdu tx hold-count` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
spanning-tree bpdu tx hold-count max_bpdu
no spanning-tree bpdu tx hold-count
default spanning-tree bpdu tx hold-count
```

Parameters

`max_bpdu` BPU packets. Value ranges from 1 to 10. Default is 6.

Example

This command configures a transmit hold-count of 8 BPDUs.

```
switch(config)#spanning-tree bpdu tx hold-count 8
switch(config)#
```
12.1.4.31 spanning-tree bpdufilter

The `spanning-tree bpdufilter` command controls bridge protocol data unit (BPDU) filtering on the configuration mode interface. BPDU filtering is disabled by default.

- `spanning-tree bpdufilter enabled` enables BPDU filtering.
- `spanning-tree bpdufilter disabled` disables BPDU filtering by removing the `spanning-tree bpdufilter` command from `running-config`.

The BPDU filter default setting for portfast ports is configured by the `spanning-tree edge-port bpdufilter default` command; BPDU filter is disabled by default on all non-portfast ports.

The `no spanning-tree bpdufilter` and `default spanning-tree bpdufilter` commands restore the global BPDU filter setting on the configuration mode interface by removing the corresponding `spanning-tree bpdufilter` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree bpdufilter FILTER_STATUS
no spanning-tree bpdufilter
default spanning-tree bpdufilter
```

**Parameters**

`FILTER_STATUS`  BPDU filtering status. Options include:

- `enabled`  BPDU filter is enabled on the interface.
- `disabled`  BPDU filter is disabled on the interface.

**Example**

This command enables BPDU filtering on *interface ethernet 5*.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree bpdufilter enabled
switch(config-if-Et5)#
```
12.1.4.32  spanning-tree bpduguard rate-limit count (global)

The spanning-tree bpduguard rate-limit count command sets the maximum BPDU reception rate (quantity per interval) for ports that are not covered by a spanning-tree bpduguard rate-limit count (interface) command.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs they receive in excess of the specified limit. BPDU rate limiting is enabled or disabled by spanning-tree bpduguard rate-limit enable / disable commands.

The no spanning-tree bpduguard rate-limit count and default spanning-tree bpduguard rate-limit count commands restore the global setting to its default value by removing the spanning-tree bpduguard rate-limit count command from running-config.

Command Mode
Global Configuration

Command Syntax

spanning-tree bpduguard rate-limit count max_bpdu [interval period]
no spanning-tree bpduguard rate-limit count
default spanning-tree bpduguard rate-limit count

Parameters

- max_bpdu configures the maximum number of BPDUs per timer interval. The value of BPDU quantity ranges from 1 to 20000.
- interval period configures the timer interval in seconds. The value of period ranges from 1 to 15.

Guidelines
Arista Networks recommends to retain the default values of rate limit.

In the PVST mode, when the VLAN membership of a port is changed by a significant margin, it is advisable to disable interface BPDU rate limit on both ends of a port. For example, if three VLANs are present on a port initially, the operator must first add 300 more VLANs on one side of the port and then add the same 300 VLANs on the other side of the port. In this case, if the VLANs are increased towards the root bridge first, then the other side can cross the rate-limit threshold.

Example
This command configures the global rate limit as 5000 BPDUs per 4 second period.

```bash
switch(config)#spanning-tree bpduguard rate-limit count 5000 interval 4
switch(config)#
```
12.1.4.33 spanning-tree bpduguard rate-limit count (interface)

The spanning-tree bpduguard rate-limit count command configures the maximum BPDU reception rate for the configuration mode interface. The default rate limit is specified by the spanning-tree bpduguard rate-limit count (global) command.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limiting is enabled or disabled by spanning-tree bpduguard rate-limit enable / disable commands.

The no spanning-tree bpduguard rate-limit count and default spanning-tree bpduguard rate-limit count commands restore the interface value to the global setting by removing the corresponding spanning-tree bpduguard rate-limit count command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration

Command Syntax
spanning-tree bpduguard rate-limit count max_bpdu [TIMER]
no spanning-tree bpduguard rate-limit count
default spanning-tree bpduguard rate-limit count

Parameters
- max_bpdu BPDU quantity. Value ranges from 1 to 20000.
- TIMER BPDU reception interval (seconds). Options include:
  - period reception interval defaults to hello-time.
  - interval period Value of period ranges from 1 to 15.

Example
These commands configure rate limit as 7500 BPDU per 8 second period on interface Ethernet 2.

switch(config)#interface ethernet 2
switch(config-if-Et2)#spanning-tree bpduguard rate-limit count 7500
  interval 8
switch(config-if-Et2)#
12.1.4.34  spanning-tree bpduguard rate-limit default

The `spanning-tree bpduguard rate-limit default` command configures the global BPDU rate limit setting. The global BPDU rate limit setting provides the default for individual ports whose configuration does not include a `spanning-tree bpduguard rate-limit enable / disable` command. The default global setting is enabled.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limits are established by `spanning-tree bpduguard rate-limit count (global)` commands.

The `no spanning-tree bpduguard rate-limit default` sets the global BPDU rate limit setting to disabled. The `spanning-tree bpduguard rate-limit default` and `default spanning-tree bpduguard rate-limit default` commands restore the default global rate limit setting to enabled by removing the `nospanning-tree bpduguard rate-limit default` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree bpduguard rate-limit default
no spanning-tree bpduguard rate-limit default
default spanning-tree bpduguard rate-limit default
```

**Example**
This command enables rate limiting on all ports not covered by an interface rate limit command.

```
switch(config)#spanning-tree bpduguard rate-limit default
switch(config)#
```
12.1.4.35  spanning-tree bpduguard rate-limit enable / disable

These commands enable and disable BPDU rate limiting on the configuration mode interface:

- `spanning-tree bpduguard rate-limit enable` enables BPDU rate limiting.
- `spanning-tree bpduguard rate-limit disable` disables BPDU rate limiting.

The `spanning-tree bpduguard rate-limit default` command enables BPDU rate limiting on all ports not configured with a `spanning-tree bpduguard rate-limit` command.

BPDU rate limiting restricts the number of BPDUs that ports with BPDU guard or BPDU filter disabled can process during a specified interval. Ports discard BPDUs it receives in excess of the specified limit. BPDU rate limits are established by `spanning-tree bpduguard rate-limit count (interface)` commands.

The `no spanning-tree bpduguard rate-limit` and `default spanning-tree bpduguard rate-limit` commands restore the global rate limit setting on the configuration mode interface by removing the corresponding `spanning-tree bpduguard rate-limit` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration  
Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree bpduguard rate-limit enable`
- `spanning-tree bpduguard rate-limit disable`
- `no spanning-tree bpduguard rate-limit`
- `default spanning-tree bpduguard rate-limit`

**Example**

These commands enable rate limiting on `interface Ethernet 15`.

```
switch(config)#interface ethernet 15  
switch(config-if-Et15)#spanning-tree bpduguard rate-limit enable  
switch(config-if-Et15)#
```
12.1.4.36  spanning-tree bpduguard

The `spanning-tree bpduguard` command controls BPDU guard on the configuration mode interface. A BPDU guard-enabled port is disabled when it receives a BPDU packet.

The BPDU guard default setting for portfast ports is configured by the `spanning-tree edge-port bpduguard default` command; BPDU guard is disabled by default on all non-portfast ports.

The `no spanning-tree bpduguard` and `default spanning-tree bpduguard` commands restore the global BPDU guard setting on the configuration mode interface by removing the corresponding `spanning-tree bpduguard` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree bpduguard GUARD_ACTION
no spanning-tree bpduguard
default spanning-tree bpduguard
```

**Parameters**

GUARD_ACTION BPDU guard setting. Options include:

- **disable** Disable bpduguard.
- **enable** Enable bpduguard.
- **rate-limit** BPDU Input Rate Limiter options.

**Example**

These commands enable BPDU guard on `interface Ethernet 5`.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree bpduguard enabled
switch(config-if-Et5)
```
spanning-tree cost

The spanning-tree cost command configures the path cost of the configuration mode interface. Cost values range from 1 to 200000000 (200 million). The default cost depends on the interface speed:

- 1 gigabit interface: cost = 20000
- 10 gigabit interface: cost = 2000

The spanning-tree cost command provides a mode option:

- RST instance cost is configured by not including a mode.
- MST instance 0 cost is configured by not including a mode or with the mst mode option.
- MST instance cost is configured with the mst mode option.
- Rapid-PVST VLAN cost is configured with the vlan mode option.

The no spanning-tree cost and default spanning-tree cost commands restore the default cost on the configuration mode interface by removing the corresponding spanning-tree cost command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

Command Syntax

spanning-tree MODE cost value
no spanning-tree MODE cost
default spanning-tree MODE cost

Parameters

- MODE specifies the spanning tree instances for which the cost is configured. Values include:
  - no parameter RST instance, MST instance 0, or all Rapid-PVST instances permitted on the interface.
  - mst m_range specified MST instances. m_range formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - vlan v_range specified Rapid-PVST instances. v_range formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.value path cost assigned to interface. Values range from 1 to 200000000 (200 million). Default values are 20000 (1 G interfaces) or 2000 (10 G interfaces).

Examples

- These commands configure a port cost of 25000 for interface Ethernet 5 when configured as an RST port, as a port in MST instance 0, or all unconfigured Rapid-PVST instances that are not explicitly configured.

  switch(config)#interface ethernet 5
  switch(config-if-Et5)#spanning tree cost 25000

- This command configures a port cost of 30000 for interface Ethernet 5 when configured as a port in MST instance 200.

  switch(config-if-Et5)#spanning tree mst 200 cost 30000

- This command configures a port cost of 100000 for interface Ethernet 5 when configured as a port in VLANs 200-220.

  switch(config-if-Et5)#spanning tree vlan 200-220 cost 100000
switch(config-if-Et5)#
12.1.4.38 spanning-tree edge-port bpdufilter default

The `spanning-tree edge-port bpdufilter default` command configures the global BPDU filter setting as `enabled`. Ports not covered by a `spanning-tree bpdufilter` command use the global BPDU filter setting.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
spanning-tree edge-port bpdufilter default
no spanning-tree edge-port bpdufilter default
default spanning-tree edge-port bpdufilter default
```

**Example**

This command configures the BPDU filter global setting to `enabled`.

```
switch(config)# spanning-tree edge-port bpdufilter default
switch(config)#
```
12.1.4.39 spanning-tree edge-port bpduguard default

The `spanning-tree edge-port bpduguard default` command sets the global BPDU guard setting as **enabled**. Ports not covered by a `spanning-tree bpduguard` command use the global BPDU guard setting.

**Command Mode**
Global Configuration

**Command Syntax**

`spanning-tree edge-port bpduguard default`
`no spanning-tree edge-port bpduguard default`
`default spanning-tree edge-port bpduguard default`

**Example**
This command configures the global BPDU guard setting to enabled.

```
switch(config)#spanning-tree edge-port bpduguard default
switch(config)#
```
12.1.4.40 spanning-tree forward-time

The `spanning-tree forward-time` command configures the forward delay timer. Forward delay is the time that a port is in learning state before it begins forwarding data packets.

The switch inserts the forward delay timer value in BPDU packets it sends as the root bridge. The forward delay value ranges from 4 to 30 seconds with a default of 15 seconds.

The `no spanning-tree forward-time` and `default spanning-tree forward-time` commands restore the forward delay timer default of 15 seconds by removing the `spanning-tree forward-time` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree forward-time period
no spanning-tree forward-time
default spanning-tree forward-time
```

**Parameters**

`period` forward delay timer (seconds). Value ranges from 4 to 30. Default is 15.

**Example**

This command sets the forward delay timer value to 25 seconds.

```
switch(config)#spanning-tree forward-time 25
switch(config)#
```
12.1.4.41 spanning-tree guard loop default

The `spanning-tree guard loop default` command configures the global loop guard setting as enabled. Ports not covered by a `spanning-tree guard` command use the global loop guard setting. Loop guard prevents blocked or root ports from becoming a designated port due to failures resulting in a unidirectional link. The `spanning-tree guard` interface configuration statement overrides the global setting for a specified interface. The default global loop guard setting is disabled.

The `no spanning-tree guard loop default` and `default spanning-tree guard loop default` commands restore the global loop guard setting of disabled by removing the `spanning-tree guard loop default` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree guard loop default
no spanning-tree guard loop default
default spanning-tree guard loop default
```

**Example**

This command enables loop guard as the default on all switch ports.

```
switch(config)#spanning-tree guard loop default
switch(config)#
```
**12.1.4.42 spanning-tree guard**

The `spanning-tree guard` command enables root guard or loop guard on the configuration mode interface. The `spanning-tree guard loop default` command configures the global loop guard setting.

- Root guard prevents a port from becoming a root or blocked port. A root guard port that receives a superior BPDU transitions to the root-inconsistent (blocked) state.
- Loop guard protects against loops resulting from unidirectional link failures on point-to-point links by preventing non-designated ports from becoming designated ports. When loop guard is enabled, a root or blocked port transitions to loop-inconsistent (blocked) state if it stops receiving BPDUs from its designated port. The port returns to its prior state when it receives a BPDU.

The `no spanning-tree guard` and `default spanning-tree guard` commands sets the configuration mode interface to the global loop guard mode by removing the `spanning-tree guard` statement from `running-config`. The `spanning-tree guard none` command disables loop guard and root guard on the interface, overriding the global setting.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree guard PORT_MODE
no spanning-tree guard
default spanning-tree guard
```

**Parameters**

- `PORT_MODE` the port mode. Options include:
  - `loop` enables loop guard on the interface.
  - `root` enables root guard on the interface.
  - `none` disables root guard and loop guard.

**Example**

This command enables root guard on interface Ethernet 5.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree guard root
switch(config-if-Et5)#
```
12.1.43 spanning-tree hello-time

The `spanning-tree hello-time` command configures the hello time, which specifies the transmission interval between consecutive bridge protocol data units (BPDU) that the switch sends as a root bridge. The hello time is also inserted in outbound BPDUs.

This hello time ranges from 0.2 seconds to 10 seconds with a default of 2 seconds.

The `no spanning-tree hello-time` and `default spanning-tree hello-time` commands restore the hello time default of 2 seconds by removing the `spanning-tree hello-time` command from `running-config`.

Command Mode
Global Configuration

Command Syntax
```
spanning-tree hello-time period
no spanning-tree hello-time
default spanning-tree hello-time
```

Parameters

`period` hello-time (milliseconds). Value ranges from 200 to 10000. Default is 2000.

Example

This command configures a hello-time of 1 second.

```
switch(config)#spanning-tree hello-time 1000
switch(config)#
```
spanning-tree link-type

The `spanning-tree link-type` command specifies the configuration mode interfaces link type, which is normally derived from the ports duplex setting. The default setting depends on a ports duplex mode:

- full-duplex ports are **point-to-point**.
- half-duplex ports are **shared**.

The `no spanning-tree link-type` and `default spanning-tree link-type` commands restore the default link type on the configuration mode interface by removing the corresponding `spanning-tree link-type` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree link-type TYPE`
- `no spanning-tree link-type`
- `default spanning-tree link-type`

**Parameters**

- **TYPE** link type of the configuration mode interface. Options include:
  - **point-to-point**
  - **shared**

**Example**

This command configures *interface Ethernet 5* as a shared port.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree link-type shared
switch(config-if-Et5)#
```
The `spanning-tree max-age` command configures the switch's max age timer, which specifies the max age value that the switch inserts in outbound BPDU packets it sends as a root bridge. The max-age time value ranges from 6 to 40 seconds with a default of 20 seconds.

Max age is the interval, specified in the BPDU, that BPDU data remains valid after its reception. The bridge recomputes the spanning tree topology if it does not receive a new BPDU before max age expiry.

The `no spanning-tree max-age` and `default spanning-tree max-age` commands restore the max-age default of 20 seconds by removing the `spanning-tree max-age` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**
`spanning-tree max-age period`
`no spanning-tree max-age`
`default spanning-tree max-age`

**Parameters**
`period` max age period (seconds). Value ranges from 6 to 40. Default is 20.

**Example**
This command sets the max age timer value to 25 seconds.

```
switch(config)#spanning-tree max-age 25
switch(config)#
```
12.1.4.46 spanning-tree max-hops

The spanning-tree max-hops command specifies the max hop setting that the switch inserts into BPDUs that it sends out as the root bridge. The max hop setting determines the number of bridges in an MST region that a BPDU can traverse before it is discarded. The max-hop value ranges from 1 to 40 with a default of 20.

The no spanning-tree max-hops and default spanning-tree max-hops commands restore the max-hops setting to its default value of 20 by removing the spanning-tree max-hops command from running-config.

**Command Mode**

Global Configuration

**Command Syntax**

spanning-tree max-hops ports
no spanning-tree max-hops
default spanning-tree max-hops

**Parameters**

*ports* max hops (bridges). Value ranges from 1 to 40. Default is 20.

**Example**

This command sets the max hop value to 40.

```
switch(config)#spanning-tree max-hop 40
switch(config)#
```
12.1.47 spanning-tree mode

The `spanning-tree mode` command specifies the spanning tree protocol version that the switch runs. The default mode is Multiple Spanning Tree (MSTP).

The `no spanning-tree mode` and `default spanning-tree mode` commands restore the default spanning tree protocol version.

**Note:** The `spanning-tree mode` command may disrupt user traffic. When the switch starts a different STP version, all spanning-tree instances are stopped, then restarted in the new mode.

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree mode VERSION
no spanning-tree mode
default spanning-tree mode
```

**Parameters**

`VERSION` spanning tree version that the switch runs. Options include:

- `mstp` multiple spanning tree protocol described in the *IEEE 802.1Q-2005* specification and originally specified in the *IEEE 802.1s* specification.
- `rstp` rapid spanning tree protocol described in the *IEEE 802.1D-2004* specification and originally specified in the *IEEE 802.1w* specification.
- `rapid-pvst` rapid per-VLAN spanning tree protocol described in the *IEEE 802.1D-2004* specification and originally specified in the *IEEE 802.1w* specification.
- `backup` disables STP and enables switchport interface pairs configured with the `switchport backup-link` command.
- `none` disables STP. The switch does not generate STP packets. Each switchport interface forwards data packets to all connected ports and forwards STP packets as multicast data packets on the VLAN where they are received.

**Guidelines**

Backup mode is not available on Trident platform switches.

**Example**

This command configures the switch to run multiple spanning tree protocol.

```
switch(config)#spanning-tree mode mstp
switch(config)#
```
12.1.4.48 spanning-tree mst configuration

The `spanning-tree mst configuration` command places the switch in MST-configuration mode, which is the group change mode where MST region parameters are configured.

Changes made in a group change mode are saved by leaving the mode through the `exit` command or by entering another configuration mode. To discard changes from the current edit session, leave the mode with the `abort` command.

These commands are available in MST-configuration mode:

- `abort (mst-configuration mode)`
- `exit (mst-configuration mode)`
- `instance`
- `name (mst-configuration mode)`
- `revision (mst-configuration mode)`
- `show (mst-configuration mode)`

The `no spanning-tree mst configuration` and `default spanning-tree mst configuration` commands restore the MST default configuration.

**Command Mode**

Global Configuration

**Command Syntax**

`spanning-tree mst configuration`

`no spanning-tree mst configuration`

`default spanning-tree mst configuration`

**Examples**

- This command enters MST configuration mode.

```
switch(config)#spanning-tree mst configuration
switch(config-mst)#
```

- This command exits MST configuration mode, saving MST region configuration changes to `running-config`.

```
switch(config-mst)#exit
switch(config)#
```

- This command exits MST configuration mode without saving MST region configuration changes to `running-config`.

```
switch(config-mst)#abort
switch(config)#
```
12.1.4.49 spanning-tree mst pvst border

The `spanning-tree mst pvst border` command configures MSTP PVST border feature to automatically detect border ports facing PVST+ regions. By default, spanning-tree mst pvst border is disabled.

The `no spanning-tree mst pvst border` and `default spanning-tree mst pvst border` commands restore the default MST configuration.

**Command Mode**

MST Configuration

**Command Syntax**

- `spanning-tree mst pvst border`
- `no spanning-tree mst pvst border`
- `default spanning-tree mst pvst border`

**Example**

This command enters the MST configuration mode.

```
switch(config)#spanning-tree mst configuration
switch(config-mst)#spanning-tree mst pvst border
```
12.1.4.50 spanning-tree portchannel guard misconfig

The `spanning-tree portchannel guard misconfig` command enables the switch to detect misconfigured port channels that may cause network loops by monitoring inbound BPDUs. When a port channel receives 75 inconsistent BPDUs within 30 seconds, the switch error disables the port. When a port channel receives 5 BPDUs with the same source BPDU during the 30 second measurement interval, the error counter is reset and the port continues normal port channel operation. Misconfigured port channel detection is disabled by default.

The `no spanning-tree portchannel guard misconfig` and `default spanning-tree portchannel guard misconfig` commands disable the detection of misconfigured port channels by removing the `spanning-tree portchannel guard misconfig` statement from `running-config`.

Command Mode
Global Configuration

Command Syntax
`spanning-tree portchannel guard misconfig`
`no spanning-tree portchannel guard misconfig`
`default spanning-tree portchannel guard misconfig`

`spanning-tree etherchannel guard misconfig`
`no spanning-tree etherchannel guard misconfig`
`default spanning-tree etherchannel guard misconfig`

Guidelines
The `spanning-tree portchannel guard misconfig` and `spanning-tree etherchannel guard misconfig` commands are equivalent.

Examples
- This command enables port channel misconfiguration detection on the switch.

```
switch(config)# spanning-tree portchannel guard misconfig
switch(config)# show running-config
!
spanning-tree mode mstp
spanning-tree portchannel guard misconfig
!
end
switch(config)#
```

- This command disables port channel misconfiguration detection on the switch.

```
switch(config)# no spanning-tree portchannel guard misconfig
switch(config)# show running-config
!
spanning-tree mode mstp
!
end
switch(config)#
```
12.1.4.51 spanning-tree portfast auto

The `spanning-tree portfast auto` command enables auto-edge detection on the configuration mode interface. When auto-edge detection is enabled, the port is configured as an edge port if it does not receive a new BPDU before the current BPDU expires. Auto-edge detection is enabled by default. The `spanning-tree portfast` command, when configured, has priority over this command.

The `no spanning-tree portfast auto` command disables auto-edge port detection. This command is removed from `running-config` with the `spanning-tree portfast auto` and `default spanning-tree portfast auto` commands.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree portfast auto`
- `no spanning-tree portfast auto`
- `default spanning-tree portfast auto`

**Example**

This command enables auto-edge detection on `interface Ethernet 5`.

```
switch(config)# interface ethernet 5
switch(config-if-Et5)# spanning-tree portfast auto
switch(config-if-Et5)#
```
12.1.4.52  spanning-tree portfast <port type>

The **spanning-tree portfast** command specifies the STP port mode for the configuration mode interface. Default port mode is **normal**.

Port modes include:

- **Edge**: Edge ports connect to hosts and transition to the forwarding state when the link is established. An edge port that receives a BPDU becomes a normal port.
- **Network**: Network ports connect only to switches or bridges and support bridge assurance. Network ports that connect to hosts or other edge devices transition to the discarding state.
- **Normal**: Normal ports function as normal STP ports and can connect to any type of device.

The **no spanning-tree portfast <port-type>** and **default spanning-tree portfast <port-type>** commands restore the default port mode of normal by removing the corresponding **spanning-tree portfast <port-type>** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree portfast PORT_MODE
no spanning-tree portfast PORT_MODE
default spanning-tree portfast PORT_MODE
```

**Parameters**

PORT_MODE STP port mode. Options include:

- edge
- network
- normal

The **normal** option is not available for the **no** and **default** commands.

**Related Commands**

The **spanning-tree portfast** command also affects the **spanning-tree portfast auto** and **spanning-tree portfast** configuration for the configuration mode interface:

- **spanning-tree portfast normal**: **spanning-tree portfast auto** is enabled.
- **spanning-tree portfast edge**: **spanning-tree portfast** is enabled.
- **spanning-tree portfast network**: **spanning-tree portfast auto** is disabled.

**Example**

This command configures **interface Ethernet 5** as a network port.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast network
switch(config-if-Et5)#
```
12.1.4.53 spanning-tree portfast

The **spanning-tree portfast** command programs configuration mode ports to immediately enter forwarding state when they establish a link. PortFast ports are included in spanning tree topology calculations and can enter discarding state. This command overrides the **spanning-tree portfast auto** command.

The no **spanning-tree portfast** and default **spanning-tree portfast** commands remove the corresponding **spanning-tree portfast** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

**Command Syntax**

- `spanning-tree portfast`
- `no spanning-tree portfast`
- `default spanning-tree portfast`

**Example**

This command unconditionally enables portfast on **interface Ethernet 5**.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree portfast
switch(config-if-Et5)#
```
12.1.4.54 spanning-tree port-priority

The `spanning-tree port-priority` command specifies the configuration mode interfaces port-priority number. The switch uses this number to determine which interface it places into forwarding mode when resolving a loop. Valid settings are all multiples of 16 between 0 and 240. Default value is 128. Ports with lower numerical priority values are selected over other ports.

The `no spanning-tree port-priority` and default spanning-tree port-priority commands restore the default of 128 for the configuration mode interface by removing the `spanning-tree port-priority` command from `running-config`.

The `spanning-tree port-priority` command provides a mode option:

- RST instance port-priority is configured by not including a mode.
- MST instance 0 port-priority is configured by not including a mode or with the `mst` mode option.
- MST instance port-priority is configured with the `mst` mode option.
- Rapid-PVST VLAN port-priority is configured with the `vlan` mode option.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration

**Command Syntax**

```
spanning-tree [MODE] port-priority value
no spanning-tree [MODE] port-priority
default spanning-tree [MODE] port-priority
```

**Parameters**

- **MODE** specifies the spanning tree instances for which the cost is configured. Values include:
  - `no parameter` RST instance or MST instance 0.
  - `mst m_range` specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - `vlan v_range` specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
- **value** bridge priority number. Values range from 0 to 240 and must be a multiple of 16.

**Example**

This command sets the port priority of *interface Ethernet 5* to 144.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#spanning-tree port-priority 144
switch(config-if-Et5)#
```
12.1.4.55 spanning-tree priority

The `spanning-tree priority` command configures the bridge priority number. The bridge priority is the four most significant digits of the bridge ID, which is used by spanning tree algorithms to select the root bridge and choose among redundant links. Bridge ID numbers range from 0 to 65535 (16 bits); bridges with smaller bridge IDs are elected over other bridges.

Because bridge priority sets the four most significant bits of the bridge ID, valid settings include all multiples of 4096 between 0 and 61440. Default value is 32768.

The `spanning-tree priority` command provides a mode option:

- RST instance priority is configured by not including a mode.
- MST instance 0 priority is configured by not including a mode or with the `mst` mode option.
- MST instance priority is configured with the `mst` mode option.
- Rapid-PVST VLAN priority is configured with the `vlan` mode option.

The `no spanning-tree priority` and `default spanning-tree priority` commands restore the bridge priority default of 32768 for the specified mode by removing the corresponding `spanning-tree priority` command from `running-config`.

Another method of adding `spanning-tree priority` commands to the configuration is through the `spanning-tree root` command. Similarly, the `no spanning-tree root` command removes the corresponding `spanning-tree priority` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
spanning-tree [MODE] priority level
no spanning-tree [MODE] priority
default spanning-tree [MODE] priority
```

Parameters

- **MODE** spanning tree instances for which the command configures priority. Options include:
  - **no parameter** RST instance or MST instance 0.
  - **mst m_range** specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from 0 to 4094.
  - **vlan v_range** specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.
  - **level** priority number. Values include multiples of 4096 between 0 and 61440. Default is 32768.

Examples

- This command configures a bridge priority value of 20480 for Rapid-PVST VLANs 20, 24, 28, and 32.
  ```
  switch(config)#spanning-tree vlan-id 20,24,28,32 priority 20480
  switch(config)#
  ```

- This command configures a bridge priority value of 36864 for the RST instance. When MST is enabled, this command configures a priority of 36864 for MST instance 0.
  ```
  switch(config)#spanning-tree priority 36864
  switch(config)#
  ```
The `spanning-tree root` command configures the bridge priority number by adding a `spanning-tree priority` command to the configuration. Parameter settings set the following priority values:

- `primary` sets the bridge priority to `8192`.
- `secondary` sets the bridge priority to `16384`.

The bridge priority is the four most significant digits of the bridge ID, which is used by spanning tree algorithms to select the root bridge and choose among redundant links. Bridge ID numbers range from `0` to `65535` (16 bits); bridges with smaller bridge IDs are elected over other bridges.

When no other switch in the network is similarly configured, assigning the primary value to the switch facilitates its selection as the root switch. Assigning the secondary value to the switch facilitates its selection as the backup root in a network that contains one switch with a smaller priority number.

The `spanning-tree root` command provides a mode option:

- RST instance priority is configured by not including a mode.
- MST instance `0` priority is configured by not including a mode or with the `mst` mode option.
- MST instance priority is configured with the `mst` mode option.
- Rapid-PVST VLAN priority is configured with the `vlan` mode option.

The `no spanning-tree root` and `default spanning-tree root` commands restore the bridge priority default of `32768` by removing the corresponding `spanning-tree priority` command from `running-config`. The `no spanning-tree root`, `no spanning-tree priority`, `default spanning-tree root` and `default spanning-tree priority` commands perform the same function.

**Command Mode**
Global Configuration

**Command Syntax**

```
spanning-tree [MODE] root TYPE
no spanning-tree [MODE] root
default spanning-tree [MODE] root
```

**Parameters**

- `MODE` specifies the spanning tree instances for which priority is configured. Values include:
  - `no parameter` RST instance or MST instance `0`.
  - `mst m_range` specified MST instances. `m_range` formats include a number, number range, or comma-delimited list of numbers and ranges. Instance numbers range from `0` to `4094`.
  - `vlan v_range` specified Rapid-PVST instances. `v_range` formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from `1` to `4094`.
- `TYPE` sets the bridge priority number. Values include:
  - `primary` sets the bridge priority to `8192`.
  - `secondary` sets the bridge priority to `16384`.

**Examples**

- This command configures a bridge priority value of `8192` for Rapid-PVST VLANs `20` to `36`.

```
switch(config)#spanning-tree vlan-id 20-36 root primary
```
• This command configures a bridge priority value of **16384** for the RSTP instance and MST instance **0**.

```plaintext
switch(config)#spanning-tree root secondary
```
12.1.4.57 spanning-tree transmit active

The `spanning-tree transmit active` command enables bridge assurance globally, which enables bridge assurance on all ports with a port type of `network`. Bridge assurance protects against unidirectional link failure, other software failure, and devices that quit running a spanning tree algorithm.

Bridge assurance is available only on point-to-point links on spanning tree `network` ports. Both ends of the link should ideally have bridge assurance enabled. Bridge assurance-enabled ports will not necessarily be blocked when they link to a port where bridge assurance is not enabled, but if they do not receive periodic BPDUs from the other side of the link the `show spanning-tree transmit active` command will show a bridge assurance status of inconsistent (blocking) for that port.

The `no spanning-tree transmit active` command disables bridge assurance.

The `spanning-tree transmit active` and `default spanning-tree transmit active` commands restore the default behavior by removing the `no spanning-tree transmit active` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
spanning-tree transmit active
no spanning-tree transmit active
default spanning-tree transmit active
```

**Example**

This command enables bridge assurance on the switch.

```
switch(config)# spanning-tree transmit active
switch(config)#
```
Layer 2 Configuration

12.1.458 spanning-tree vlan-id

The **spanning-tree vlan-id** command enables Spanning Tree Protocol (STP) on specified VLANs by removing any corresponding **no spanning-tree vlan-id** statements from **running-config**. Spanning-tree is enabled on all VLANs by default.

The **no spanning-tree vlan-id** command disables STP on the specified interfaces. The **default spanning-tree vlan-id** enables STP on the specified interfaces.

**Note:** Disabling STP is not recommended, even in topologies free of physical loops; STP guards against configuration mistakes and cabling errors. When disabling STP, ensure that there are no physical loops in the VLAN.

When disabling STP on a VLAN, ensure that all switches and bridges in the network disable STP for the same VLAN. Disabling STP on a subset of switches and bridges in a VLAN may have unexpected results because switches and bridges running STP will have incomplete information regarding the network's physical topology.

The following STP global configuration commands provide a **vlan** option for configuring Rapid-PVST VLAN instances:

- **spanning-tree priority**
- **spanning-tree root**

**Command Mode**

Global Configuration

**Command Syntax**

```
spanning-tree vlan-id v_range

no spanning-tree vlan-id v_range

default spanning-tree vlan-id v_range
```

**Parameters**

**v_range** VLAN list. Formats include a number, number range, or comma-delimited list of numbers and ranges. VLAN numbers range from 1 to 4094.

**Examples**

- This command disables STP on **VLANs 200-205**.
  
  ```
  switch(config)#no spanning-tree vlan-id 200-205
  switch(config)#
  ```

- This command enables STP on **VLAN 203**.
  
  ```
  switch(config)#spanning-tree vlan-id 203
  switch(config)#
  ```
12.1.4.59 switchport backup-link

The `switchport backup-link` command establishes a primary-backup configuration for forwarding VLAN traffic between the command mode interface and a specified interface. The `show interfaces switchport backup-link` command displays the state of backup interface pairs on the switch:

- the primary interface is the command mode interface.
- the backup interface is the interface specified in the command.

The following guidelines apply to primary and backup interfaces:

- Ethernet and Port Channels can be primary interfaces.
- Ethernet, Port Channel, Management, Loopback, and VLANs can be backup interfaces.
- The primary and backup interfaces can be different interface types.
- Interface pairs should be similarly configured to ensure consistent behavior.
- An interface can be associated with a maximum of one backup interface.
- An interface can back up a maximum of one interface.
- Any Ethernet interface configured in an interface pair cannot be a port channel member.
- The STP mode is backup.
- Static MAC addresses should be configured after primary-backup pairs are established.

When load balancing is not enabled, the primary and backup interfaces cannot simultaneously forward VLAN traffic. When the primary interface is forwarding VLAN traffic, the backup interface drops all traffic. If the primary interface fails, the backup interface forwards VLAN traffic until the primary interface is functional.

The `prefer vlan` option balances the load across the primary and backup interfaces. When the command includes the `prefer vlan` option, each interface is the primary for a subset of the vlans carried by the pair. When both interfaces are up, prefer option vlans are forwarded on the backup interface and all other configured vlans are carried by the primary interface.

The `no switchport backup-link` and `default switchport backup-link` commands remove the primary-backup configuration for the configuration mode interface.

Command Mode

Interface-Ethernet Configuration

Interface-Port Channel Configuration

Command Syntax

```
switchport backup-link INT_NAME [BALANCE]
no switchport backup-link
default switchport backup-link
```

Parameters

- `INT_NAME` the backup interface. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Channel group interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.
  - `vxlan vx_num` VXLAN interface specified by `vx_num`.
- `BALANCE` VLANs whose traffic is normally handled on the backup interfaces. Values include:
  - `no parameter` backup interface handles no traffic if the primary interface is operating.
  - `prefer vlan v_range` list of VLANs whose traffic is handled by backup interface.
Examples

- These commands establish *interface Ethernet 7* as the backup port for *interface ethernet 1*.

  ```
  switch(config)#interface ethernet 1
  switch(config-if-Et1)#switchport backup-link ethernet 7
  switch(config-if-Et1)#
  ```

- These commands configure the following:
  - *interface ethernet 1* as a trunk port that handles VLAN 4 through 9 traffic.
  - *interface ethernet 2* as its backup interface.
  - *interface ethernet 2* as the preferred interface for VLANs 7 through 9.

  ```
  switch(config-if-Et1)#switchport mode trunk
  switch(config-if-Et1)#switchport trunk allowed vlan 4-9
  switch(config-if-Et1)#switchport backup-link Ethernet 2 prefer vlan 7-9
  switch(config-if-Et1)#
  ```
12.1.4.60  transmit-interval

The `transmit-interval` command sets the interval at which loop detection packets are transmitted. The `no transmit-interval` and `default transmit-interval` commands restore the transmission interval to the default of 5 seconds.

**Command Mode**
Loop-protection Configuration

**Command Syntax**
`transmit-interval interval`

**Parameters**
`interval` Interval in seconds at which loop-detection packets are transmitted. Values range from 1 to 10; default is 5.

**Example**
This command sets the loop detection packet transmission interval to 10 seconds.

```
switch(config-monitor-loop-protect)# transmit-interval 10
```

```
switch(config-monitor-loop-protect)#
```
12.2 Link Layer Discovery Protocol

This section describes Link Layer Discovery Protocol (LLDP) configuration tasks. Refer to the command descriptions for information about commands used in this chapter.

Topics in this section include:

- LLDP Introduction
- LLDP Overview
- LLDP Configuration Procedures
- LLDP Configuration Commands

12.2.1 LLDP Introduction

Link Layer Discovery Protocol (LLDP) lets Ethernet network devices to advertise details about themselves, such as capabilities, identification, and device configurations to directly connected devices on the network that are also using LLDP.

12.2.2 LLDP Overview

LLDP is a discovery protocol that allows devices to advertise information about themselves to peer devices that are on the same physical LAN and store information about the network. LLDP allows a device to learn higher layer management reachability and connection endpoint information from adjacent devices.

Each switch with an active LLDP agent sends and receives messages on all physical interfaces enabled for LLDP transmission. These messages are sent periodically and are typically configured for short time intervals to ensure that accurate information is always available. These messages are then stored for a configurable period of time, and contained within the received packet. The message information expires and is discarded when the configured value is met. The only other time an advertisement is sent is when a relevant change takes place in the switch. If information changes for any reason, the LLDP agent is notified and sends out and update the new values.

12.2.2.1 LLDP Data Units

A single LLDP Data Unit (LLDPDU) is transmitted in a single 802.3 Ethernet frame. The basic LLDPDU includes a header and a series of type-length-value elements (TLVs). Each TLV advertises different types of information, such as its device ID, type, or management addresses. LLDP advertises the following TLVs by default:

- port-description
- system-capabilities
- system-description
- system-name
- management-address
- port-vlan

12.2.2.2 Transmission and Reception

Every device that uses LLDP has its own LLDP agent. The LLDP agent is responsible for the reception, transmission, and management of LLDP. When LLDP is enabled on a port, transmission and reception of LLDPDUs are both enabled by default, but the agent can be configured to only transmit or only receive.
Transmission
When LLDP transmission is enabled, the LLDP agent advertises information about the switch to
neighbors at regular intervals. Each transmitted LLDPDU contains the mandatory TLVs, and any
enabled optional TLVs.

Reception
When LLDP reception is enabled, the LLDP agent receives and stores advertised information from
neighboring devices.

12.2.2.3 Storing LLDP Information
Whenever the switch receives a valid and current LLDP advertisement from a neighbor, it stores the
information in a Simple Network Management Protocol (SNMP) Management Information Base (MIB).

12.2.4 Guidelines and Limitations
LLDP has the following configuration limitations:
• LLDP must be enabled globally before it can be enabled on an interface.
• LLDP is not supported on virtual interfaces.
• LLDP can discover only one device per port.

12.2.3 LLDP Configuration Procedures
These sections describe the following configuration processes:
• Enabling LLDP Globally
• Enabling LLDP on an Interface
• Optional LLDP Parameters
• Clearing LLDP Statistics
• Displaying LLDP Information

12.2.3.1 Enabling LLDP Globally
The `lldp run` command globally enables LLDP on the Arista switch. Once LLDP is enabled, the switch
will transmit advertisements from the ports that are configured to send TLVs. The neighbor information
table is populated as advertisements from the neighbors arrive on the ports.

Example
This command enables LLDP globally on the Arista switch.

```
switch(config)#lldp run
switch(config)#
```

12.2.3.2 Enabling LLDP on an Interface
When enabling LLDP, it is enabled on all interfaces by default. By using the `lldp transmit` and `lldp
receive` commands, LLDP can be enabled or disabled on individual interfaces or configured to only
send or only receive LLDP packets.

Example
• These commands enable `interface ethernet port 3/1` to transmit LLDP packets.

```
switch(config)#interface ethernet 3/1
switch(config-if-Et3/1)#lldp transmit
```
Layer 2 Configuration

These commands enable **interface ethernet 3/1** to receive LLDP packets.

```plaintext
switch(config)#interface ethernet 3/1
switch(config-if-Et3/1)#lldp receive
```

### 12.2.3.3 Optional LLDP Parameters

The following sections describe these tasks:

- Setting the LLDP Timer
- Setting the LLDP Hold Time
- Setting the LLDP Re-initialization Timer
- Setting the IP Management Address to be used in the TLV
- Selecting the LLDP TLVs
- Configuring LLDP for Power over Ethernet

#### 12.2.3.3.1 Setting the LLDP Timer

The **lldp timer** command specifies the time in seconds between LLDP updates sent by the switch.

**Examples**

- This command specifies that the LLDP updates should be sent every **120** seconds.
  ```plaintext
  switch(config)#lldp timer 120
  switch(config)#
  ```

- This command reverts the LLDP timer to its default value of **30** seconds.
  ```plaintext
  switch(config)#no lldp timer 120
  switch(config)#
  ```

#### 12.2.3.3.2 Setting the LLDP Hold Time

The **lldp hold-time** command sets the amount of time a receiving device should retain the information sent by the device.

**Examples**

- This command specifies that the receiving device should retain the information for **180** seconds before discarding it.
  ```plaintext
  switch(config)#lldp hold-time 180
  switch(config)#
  ```

- This command reverts the LLDP hold time and to the default value of **120** seconds.
  ```plaintext
  switch(config)#no lldp hold-time 180
  switch(config)#
  ```

#### 12.2.3.3.3 Setting the LLDP Re-initialization Timer

The **lldp run** command specifies the amount in time in seconds to delay the re-initialization attempt by the switch.

**Example**
This command specifies that the switch waits 10 seconds before attempting to re-initialize.

```
switch(config)#lldp timer reinitialization 10
switch(config)#
```

### 12.2.3.3.4 Setting the IP Management Address to be used in the TLV

The **lldp management-address** command specifies the IP management address or the IP address of the VRF interface in LLDP type-length-value (TLV) triplets.

**Example**

This command specifies the IP management address to be used in the TLV.

```
switch(config)# lldp management-address ethernet 3/1
switch(config)#
```

### 12.2.3.3.5 Selecting the LLDP TLVs

The **lldp tlv transmit** command specifies which type, length, and value elements (TLVs) are to be included in LLDP packets. The **no lldp tlv transmit** command removes the TLV configuration.

**Example**

This command enables the system descriptions to be included in the TLVs.

```
switch(config)# lldp tlv transmit system-description
switch(config)#
```

### 12.2.3.3.6 Configuring LLDP for Power over Ethernet

Initial power over Ethernet (PoE) power-level negotiation with a powered device (PD) takes place in hardware (see [Configuring Power over Ethernet (PoE)]). Once hardware negotiation has taken place, IEEE 802.3at Power Via MDI type-length-value elements (TLVs) are included by default in LLDP packets sent to connected PDs to allow LLDP to further negotiate power needs. LLDP allows the switch to deal with more granular power requests from PDs, and also allows dynamic power-level setting. TLVs received from connected power-sourcing equipment (PSE) are ignored.

- **Note:** Power Via MDI TLVs are not sent (even when enabled) under the following circumstances:
  1. there is a user-configured power limit on the port, or
  2. hardware negotiation sets the power to higher than class 4 because *IEEE 802.3bt*, which increases the maximum power output for PoE, is not yet supported by LLDP.

To disable Power Via MDI TLVs globally, use the **no lldp tlv transmit** command and specify the Power Via MDI TLV. Hardware negotiation and manual power limits will remain in effect.

**Example**

This command disables the sending of Power Via MDI TLVs globally.

```
switch(config)# no lldp tlv transmit power-via-mdi
switch(config)#
```

To disable Power Via MDI TLVs on an individual interface, use the **poe negotiation lldp disabled** command. Hardware negotiation and manual power limits will remain in effect.

**Example**
These commands disable the sending of Power Via MDI TLVs on interface Ethernet 5.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#poe negotiation lldp disabled
switch(config-if-Et5)#
```

New LLDP Fields Defined by IEEE 802.3at-2009

Arista switches do not support the following new LLDP/SNMP fields defined in IEEE standard 802.3at-2009:

- **Power type** a LldpXdot3RemPowerType
- **Power source** a LldpXdot3RemPowerSource
- **Power priority** a LldpXdot3RemPowerPriority
- **PD requested power value** a LldpXdot3RemPDRequestedPowerValue
- **PSE allocated power value** a LldpXdot3RemPSEAllocatedPowerValue

12.2.3.4 Clearing LLDP Statistics

- clear lldp counters
- clear lldp table

12.2.3.5 Displaying LLDP Information

- Viewing LLDP Global Information
- Viewing LLDP Local Information
- Viewing LLDP Neighbors
- Viewing LLDP Traffic

12.2.3.5.1 Viewing LLDP Global Information

The `show lldp` command displays LLDP information.

**Examples**

- This command displays global information about LLDP.

```
switch#show lldp
 LLDP transmit interval : 60 seconds
 LLDP transmit holdtime : 120 seconds
 LLDP reinitialization delay : 2 seconds
 LLDP Management Address VRF : default
 Enabled optional TLVs:
   Port Description
   System Name
   System Description
   System Capabilities
   Management Address (Management0)
   IEEE802.1 Port VLAN ID
   IEEE802.3 Link Aggregation
   IEEE802.3 Maximum Frame Size
 Port   Tx Enabled  Rx Enabled
 Et3/1   Yes       Yes
```

- This command displays LLDP information.

```
switch#show lldp ethernet interface 3/1
```
LLDP transmit interval : 30 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : default
Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
switch#

12.2.3.5.2 Viewing LLDP Local Information

The `show lldp local-info` command displays the information contained in the LLDP TLVs to be sent about the local system.

Example

This command displays information contained in the TLVs about the local systems.

```
switch#show lldp local-info management 1
Local System:
  - Chassis ID type: MAC address (4)
    Chassis ID     : 001c.730f.11a8
  - System Name: "switch.aristanetworks.com"
  - System Description: "Arista Networks EOS version 4.13.2F running on an Arista Networks DCS-7150S-64-CL"
    - System Capabilities : Bridge, Router
      Enabled Capabilities: Bridge
Interface Management1:
  - Port ID type: Interface name (5)
    Port ID     : "Management1"
  - Port Description: ""
  - Management Address Subtype: IPv4 (1)
    Management Address        : 172.22.30.154
    Interface Number Subtype  : ifIndex (2)
    Interface Number          : 999001
    OID String                :
    - IEEE802.1 Port VLAN ID: 0
    - IEEE802.1/IEEE802.3 Link Aggregation
      Link Aggregation Status: Not Capable (0x00)
    - IEEE802.3 Maximum Frame Size: 1518 bytes
switch(config)#
```

12.2.3.5.3 Viewing LLDP Neighbors

The `show lldp neighbors` command displays information about LLDP neighbors.

Examples

• This command shows information about LLDP neighbors.

```
switch#show lldp neighbor
Last table change time : 0:12:33 ago
Number of table inserts : 33
Number of table deletes  : 0
Number of table drops    : 0
Number of table age-outs : 0
```

1438
Layer 2 Configuration

<table>
<thead>
<tr>
<th>Port</th>
<th>Neighbor Device ID</th>
<th>Neighbor Port ID</th>
<th>TTL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et3/1</td>
<td>tg104.sjc.aristanetworks.com</td>
<td>Ethernet3/2</td>
<td>120</td>
</tr>
<tr>
<td>Ma1/1</td>
<td>dcl-rackll-tor1.sjc</td>
<td>1/1</td>
<td>120</td>
</tr>
</tbody>
</table>

- This command displays detailed information about the neighbor **Ethernet 3/1**.

```shell
switch# show lldp neighbor ethernet 3/1
Last table change time : 0:16:24 ago
Number of table inserts : 33
Number of table deletes : 0
Number of table drops : 0
Number of table age-outs : 0

<td>Ethernet3/2</td>
<td>120</td>
</tr>
</tbody>
</table>

12.2.3.5.4 Viewing LLDP Traffic

The **show lldp counters** command displays the LLDP traffic information for the switch.

**Example**

This command displays the LLDP counters on the switch.

```shell
switch# show lldp counters
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Tx Frames</th>
<th>Tx Length Exceeded</th>

switch#
12.2.4 LLDP Configuration Commands

Global Configuration Commands

- lldp hold-time
- lldp management-address
- lldp management-address vrf
- lldp run
- lldp receive packet tagged drop
- lldp timer
- lldp timer reinitialization
- lldp tlv transmit

Interface Configuration Commands – Ethernet Interface

- lldp receive
- lldp transmit
- poe negotiation lldp disabled

Privileged EXEC Commands

- clear lldp counters
- clear lldp table

EXEC Commands

- show lldp
- show lldp counters
- show lldp local-info
- show lldp neighbors
12.2.4.1  clear lldp counters

The `clear lldp counters` command resets the LLDP counters to zero.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear lldp counters [SCOPE]

**Parameters**

**SCOPE** Session affected by command. Options include:

- *no parameter* command affects counters on all CLI sessions.
- *session* clears LLDP counters for the current CLI session only.

**Examples**

- This command resets all the LLDP counters to zero.

  ```
  switch(config)#clear lldp counters
  switch(config)#
  ```

- This command resets only the LLDP counters for the current CLI session.

  ```
  switch(config)#clear lldp counters session
  switch(config)#
  ```
12.2.4.2 clear lldp table

The `clear lldp table` command clears neighbor information from the LLDP table.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear lldp table

**Example**
This command clears neighbor information from the LLDP table.

```
switch(config)#clear lldp table
switch(config)#
```
12.2.4.3  lldp hold-time

The `lldp hold-time` command specifies the amount of time a receiving device should maintain the information sent by the device before discarding it.

**Command Mode**
Global Configuration

**Command Syntax**
```
lldp hold-time period
no lldp hold-time
default lldp hold-time
```

**Parameters**

`period`  The amount of time a receiving device should hold LLDPDU information before discarding it. Value ranges from 10 to 65535 second; default value is 120 seconds.

**Examples**

- This command sets the amount of time before the receiving device discards LLDPDU information to 180 seconds.

```
switch(config)#lldp hold-time 180
switch(config)#
```

- This command restores the hold-time to its default value of 120 seconds.

```
switch(config)#no lldp hold-time 180
switch(config)#
```
12.2.4.4  lldp management-address vrf

The lldp management-address vrf command enables the user to add the IP address of the VRF interface used in LLDP type-length-value (TLV).

Command Mode
Global Configuration

Command Syntax

```
lldp management-address vrf VRF_INSTANCE
no lldp management-address vrf VRF_INSTANCE
default lldp management-address vrf VRF_INSTANCE
```

Parameters

VRF_INSTANCE specifies the VRF instance.

Examples

- This command specifies the management address VRF to be used in the TLV.
  ```
  switch(config)#lldp management-address vrf test 1
  switch(config)#
  ```

- This command removes the management VRF used in the TLV.
  ```
  switch(config)#no lldp management-address vrf test 1
  switch(config)#
  ```
**12.2.4.5  lldp management-address**

The *lldp management-address* command enables the user to add the IP management address used for LLDP type-length-value (TLV).

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
lldp management-address [INTERFACE]
no lldp management-address [INTERFACE]
default lldp management-address [INTERFACE]
```

**Parameters**

**INTERFACE** Interface type and number. Options include:

- **all**    all interfaces.
- **ethernet e_num** Ethernet interface specified by `e_num`.
- **loopback l_num** Loopback interface specified by `l_num`.
- **management m_num** Management interface specified by `m_num`.
- **port-channel p_num** Port-Channel Interface specified by `p_num`.
- **vlan v_num** VLAN interface specified by `v_num`.

**Examples**

- This command specifies the IP management address to be used in the TLV.

  ```plaintext
  switch(config)#lldp management-address ethernet 3/1
  switch(config)#
  ```

- This command removes the IP management address used in the TLV.

  ```plaintext
  switch(config)#no lldp management-address ethernet 3/1
  switch(config)#
  ```

- This command specifies that VLAN 200 is used in the TLV.

  ```plaintext
  switch(config)#lldp management-address vlan 200
  switch(config)#
  ```

- This command removes the VLAN ID used in the TLV.

  ```plaintext
  switch(config)#no lldp management-address vlan 200
  switch(config)#
  ```
12.2.4.6  lldp receive

The `lldp receive` command enables LLDP packets on an interface. The `no lldp receive` command disables the acceptance of LLDP packets.

**Command Mode**

Interface-Ethernet configuration
Interface-Management configuration

**Command Syntax**

`lldp receive`
`no lldp receive`
`default lldp receive`

**Examples**

- These commands enable the reception of LLDP packets on `interface ethernet 4/1`.

```
switch(config)#interface ethernet 4/1
switch(config-if-Et4/1)#lldp receive
switch(config-if-Et4/1)#
```

- These commands disable LLDP the reception of LLDP packets on `interface ethernet 4/1`.

```
switch(config)#interface ethernet 4/1
switch(config-if-Et4/1)#no lldp receive
switch(config-if-Et4/1)#
```
12.2.4.7  lldp receive packet tagged drop

The `lldp receive packet tagged drop` command is a global configuration command and when configured the LLDP ignores all the packets with VLAN-tag. By default, this command is disabled.

**Command Mode**
Global Configuration

**Command Syntax**
`lldp receive packet tagged drop`

**Example**
This command when configured, the LLDP ignores all the packets with VLAN-tag.

```
switch(config)#lldp receive packet tagged drop
```
12.2.4.8  lldp run

The lldp run command enables LLDP on the switch.

**Command Mode**
Global Configuration

**Command Syntax**

lldp run

no lldp run

default lldp run

**Examples**

- This command enables LLDP globally on the switch.
  ```
  switch(config)#lldp run
  switch(config)#
  ```

- This command disables LLDP globally on the switch.
  ```
  switch(config)#no lldp run
  switch(config)#
  ```
12.2.4.9  lldp timer reinitialization

The `lldp timer reinitialization` command sets the time delay in seconds for LLDP to initialize.

**Command Mode**
Global Configuration

**Command Syntax**

```
lldp timer reinitialization delay
no lldp timer reinitialization
default lldp timer reinitialization
```

**Parameters**

`delay` the amount of time the device should wait before re-initialization is attempted. Value ranges from 1 to 20 seconds; default value is 2 seconds.

**Examples**

- This command specifies that the switch should wait 10 seconds before attempting to re-initialize.

```
switch(config)#lldp timer reinitialization 10
switch(config)#
```

- This command restores the default initialization delay of 2 seconds.

```
switch(config)#no lldp timer reinitialization 10
switch(config)#
```
12.2.4.10  lldp timer

The `lldp timer` command specifies the amount of time a receiving device should maintain the information sent by the device before discarding it. The `no lldp timer` command removes the configured LLDP timer.

**Command Mode**

Global Configuration

**Command Syntax**

```
lldp timer transmission_time
no lldp timer
default lldp timer
```

**Parameters**

- `transmission_time` the period of time at which LLDPDUs are transmitted. Values range from 5 to 32768 seconds; the default is 30 seconds.

**Examples**

- This command configures a period of 180 seconds at which the LLDPDUs are transmitted.
  
  ```
  switch(config)#lldp timer 180
  switch(config)#
  ```

- This command removes the configured period of time at which the LLDPDUs are transmitted.
  
  ```
  switch(config)#no lldp timer 180
  switch(config)#
  ```
12.2.4.11  lldp tlv transmit

The `lldp tlv transmit` command allows the user to specify the type-length-values (TLVs) to include in LLDP packets.

**Command Mode**
Global Configuration

**Command Syntax**

```
lldp tlv transmit TLV_NAME
no lldp tlv transmit TLV_NAME
default lldp tlv transmit TLV_NAME
```

**Parameters**

`TLV_NAME` Options include:

- `link-aggregation` specifies the link aggregation TLV.
- `management-address` specifies the management address TLV.
- `max-frame-size` specifies the Frame size TLV.
- `port-description` specifies the port description TLV.
- `port-vlan` specifies the port VLAN ID TLV.
- `power-via-mdi` specifies the power over Ethernet TLV.
- `system-capabilities` specifies the system capabilities TLV.
- `system-description` specifies the system description TLV.
- `system-name` specifies the system name TLV.

**Examples**

- This command enables the system description TLV:

  ```
  switch(config)#lldp tlv transmit system-description
  switch(config)#
  ```

- This command disables the system description TLV:

  ```
  switch(config)#no lldp tlv transmit system-description
  switch(config)#
  ```

- This command enables the max-frame-size TLV:

  ```
  switch(config)#lldp tlv transmit max-frame-size
  switch(config)#
  ```

- This command disables the max-frame-size TLV:

  ```
  switch(config)#no lldp tlv transmit max-frame-size
  switch(config)#
  ```
12.2.4.12  lldp transmit

The *lldp transmit* command enables the transit of LLDP packets on an interface.

**Command Mode**

Interface-Ethernet configuration

Interface-Management configuration

**Command Syntax**

*lldp transmit*

*no lldp transmit*

*default lldp transmit*

**Examples**

- These commands enable the transmission of LLDP packets.
  
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)#lldp transmit
  switch(config-if-Et4/1)#

- These commands disable the transmission of LLDP packets.
  
  switch(config)#interface ethernet 4/1
  switch(config-if-Et4/1)#no lldp transmit
  switch(config-if-Et4/1)#
12.2.4.13  **poe negotiation lldp disabled**

Power Via MDI TLVs are included by default in LLDP packets sent to power over Ethernet (PoE) powered devices (PDs) to allow dynamic negotiation of power levels. The **poe negotiation lldp disabled** command disables the sending of Power Via MDI TLVs from the configuration-mode interface.

The **no poe negotiation lldp disabled** and **default poe negotiation lldp disabled** commands restore the default behavior (sending Power Via MDI TLVs) by removing the corresponding **poe negotiation lldp disabled** command from **running-config**.

To disable Power Via MDI TLVs globally, use the **no lldp tlv transmit** command and specify the Power Via MDI TLV.

**Command Mode**

Interface-Ethernet configuration

**Command Syntax**

poe negotiation lldp disabled  
no poe negotiation lldp disabled  
default poe negotiation lldp disabled

**Example**

These commands disable the sending of Power Via MDI TLVs on **interface ethernet 5**.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#poe negotiation lldp disabled
switch(config-if-Et5)#
```
show lldp counters

The show lldp counters command displays LLDP traffic information for the switch.

Command Mode
EXEC

Command Syntax
show lldp counters [INTERFACE]

Parameters
INTERFACE Interface type and numbers. Options include:
• no parameter Display information for all interfaces.
• ethernet e_range Ethernet interface range specified by e_range.
• management m_range Management interface range specified by m_range.

Valid e_range and m_range formats include number, number range, or comma-delimited list of numbers and ranges.

Example
This command displays the LLDP counters on the switch.

```
switch#show lldp counters
Port          Tx Frames Tx Length Exceeded
Et20    69485                  0
Et21    69394                  0
Et22    69203                  0
Et23    57546                  0
Et24      0                  0
Ma1    69665                  0

Port          Rx Frames     Rx Errors    Rx Discard  TLVs Discard  TLVs Unknown
Et20    69470             0             0             0             0             0
Et21    69383             0             0             0             0             0
Et22    69143             0             0             0             0             0
Et23    55370             0             0             0             0             0
Et24      0             0             0             0             0             0
Ma1    69078         69078             0         69078             0             0
```
12.2.4.15  show lldp local-info

The `show lldp local-info` command displays LLDP errors and overflows.

**Command Mode**
EXEC

**Command Syntax**
```
show lldp local-info [INTERFACE]
```

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - *no parameter* Display information for all interfaces.
  - *ethernet e_range* Ethernet interface range specified by `e_range`.
  - *management m_range* Management interface range specified by `m_range`.

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**
This command displays the specific LLDP errors and overflows on `management interface 1`.

```plaintext
switch# show lldp local-info management 1
Local System:
  - Chassis ID type: MAC address (4)
    Chassis ID : 001c.730f.11a8qqq
  - System Name: "switch.aristanetworks.com"
  - System Description: "Arista Networks EOS version 4.13.2F running on an Arista Networks DCS-7150S-64-CL"
  - System Capabilities : Bridge, Router
    Enabled Capabilities: Bridge

Interface Management1:
  - Port ID type: Interface name (5)
    Port ID : "Management1"
  - Port Description: ""
  - Management Address Subtype: IPv4 (1)
    Management Address : 172.22.30.154
  - Interface Number Subtype : ifIndex (2)
    Interface Number : 999001
    OID String : 
  - IEEE802.1 Port VLAN ID: 0
  - IEEE802.1/IEEE802.3 Link Aggregation
    Link Aggregation Status: Not Capable (0x00)
    Port ID : 0
  - IEEE802.3 Maximum Frame Size: 1518 bytes
se505.16:01:44#
```

switch#
12.2.4.16 show lldp neighbors

The `show lldp neighbors` command displays information about the switch’s LLDP neighbors.

**Command Mode**

EXEC

**Command Syntax**

`show lldp neighbors [INTERFACE][INFO_LEVEL]`

**Parameters**

- **INTERFACE** Interface type and numbers. Options include:
  - *no parameter* displays information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - *no parameter* Displays information for all interfaces.
  - `detailed` LLDP information for all the adjacent LLDP devices.

**Examples**

- This command displays the neighbor’s information about LLDP.

  ```
  switch(config)#show lldp neighbors
  Last table change time : 0:12:33 ago
  Number of table inserts : 33
  Number of table deletes : 0
  Number of table drops : 0
  Number of table age-outs : 0
  Port      Neighbor Device ID             Neighbor Port ID      TTL
  Et3/1     tg104.sjc.aristanetworks.com   Ethernet3/2           120
  Ma1/1     dc1-rack11-tor1.sjc            1/1                   120
  switch#
  ```

- This command displays LLDP neighbor information for `interface ethernet 3/1`.

  ```
  switch#show lldp neighbors ethernet 3/1
  Last table change time : 0:16:24 ago
  Number of table inserts : 33
  Number of table deletes : 0
  Number of table drops : 0
  Number of table age-outs : 0
  Port      Neighbor Device ID             Neighbor Port ID      TTL
  Et3/1     tg104.sjc.aristanetworks.com   Ethernet3/2           120
  switch#
  ```

- This command displays detailed LLDP neighbor information for `interface ethernet 3/1`.

  ```
  switch# show lldp neighbors 3/1 detail
  Interface Ethernet 3/1 detected 1 LLDP neighbors:

  Neighbor 001c.7300.1506/Ethernet6/25, age 8 seconds
  Discovered 5 days, 3:58:58 ago; Last changed 5 days, 3:56:57 ago
  - Chassis ID type: MAC address (4)
  ```
Chassis ID : 001c.7300.1506
- Port ID type: Interface name (5)
  Port ID : "Ethernet6/25"
- Time To Live: 120 seconds
- Port Description: "Ethernet6/25"
- IEEE802.3 Power Via MDI
  Port Class : PD
  PSE MDI Power Support : Not Supported
  PSE MDI Power State : Disabled
- System Name: "Leaf-Switch1.aristanetworks.com"
- System Description: "Arista Networks EOS version 4.10.1-SSO running on an Arista Networks DCS-7504"
- System Capabilities : Bridge, Router
  Enabled Capabilities: Bridge
- Management Address Subtype: IPv4 (1)
  Management Address : 172.22.30.116
  Interface Number Subtype : ifIndex (2)
  Interface Number : 999999
  OID String :
- IEEE802.1 Port VLAN ID: 1
- IEEE802.1/IEEE802.3 Link Aggregation
  Link Aggregation Status: Capable, Disabled (0x01)
  Port ID : 0
- IEEE802.3 Maximum Frame Size: 9236 bytes
switch#
12.2.4.17 show lldp

The `show lldp` command displays LLDP information.

**Command Mode**
EXEC

**Command Syntax**
`show lldp [INTERFACE]`

**Parameters**

<table>
<thead>
<tr>
<th>INTERFACE</th>
<th>Interface type and numbers. Options include:</th>
</tr>
</thead>
<tbody>
<tr>
<td>no parameter</td>
<td>Display information for all interfaces.</td>
</tr>
<tr>
<td>ethernet e_range</td>
<td>Ethernet interface range specified by <code>e_range</code>.</td>
</tr>
<tr>
<td>management m_range</td>
<td>Management interface range specified by <code>m_range</code>.</td>
</tr>
</tbody>
</table>

Valid `e_range` and `m_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- **This command displays all LLDP information.**

```plaintext
switch#show lldp
LLDP transmit interval : 60 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : test

Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities
  Management Address (Management0)
  IEEE802.1 Port VLAN ID
  IEEE802.3 Link Aggregation
  IEEE802.3 Maximum Frame Size

Port       Tx Enabled  Rx Enabled
Et3/1      Yes         Yes

switch#
```

- **This command displays specific information about LLDP for interface ethernet 3/1.**

```plaintext
switch#show lldp ethernet 3/1
LLDP transmit interval : 30 seconds
LLDP transmit holdtime : 120 seconds
LLDP reinitialization delay : 2 seconds
LLDP Management Address VRF : default

Enabled optional TLVs:
  Port Description
  System Name
  System Description
  System Capabilities

switch#
```

- **This command displays specific information about LLDP for management interface 1/1.**

```plaintext
switch#show lldp management 1/1
```

12.3 Virtual LANs (VLANs)

This chapter describes Arista’s Virtual LANs (VLANs) implementation and MAC address tables. Sections in this chapter include:

- VLAN Introduction
- VLAN Conceptual Overview
- VLAN Configuration Procedures
- VLAN Configuration Commands

12.3.1 VLAN Introduction

Arista switches support industry standard 802.1q VLANs. Arista EOS provides tools to manage and extend VLANs throughout the data center network.

12.3.2 VLAN Conceptual Overview

12.3.2.1 VLAN Definition

A virtual local area network (VLAN) allows a group of devices to communicate as if they were in the same network regardless of their physical location. VLANs are Layer 2 structures based on the 802.1Q standard.

These parameters are associated with a VLAN:

- VLAN number (1-4094): VLAN numbers uniquely identify the VLAN within a network. VLAN 1 exists by default; all other VLANs only exist after they are configured.
- VLAN name (optional): The VLAN name is a text string that describes the VLAN.
- VLAN state (active or suspended): The state specifies the VLAN transmission status within the switch. In the suspended state, VLAN traffic is blocked on all switch ports. The default state is active.

VLANs define Layer 2 broadcast domains in a Layer 2 network, in which each device can receive broadcast frames sent by any other within the domain. Switches accommodating multiple broadcast domains serve as multi-port bridges where each broadcast domain is a distinct virtual bridge. Traffic does not pass directly between different VLANs within a switch or between two switches.

12.3.2.2 VLAN Switching

Ethernet and port channel interfaces are configured as switched ports by default. Switched ports are configurable as members of one or more VLANs. Switched ports ignore all IP-level configuration commands, including IP address assignments.

12.3.2.2.1 VLAN Trunking and Trunk Groups

Trunking extends multiple VLANs beyond the switch through a common interface or port channel. A trunk group is the set of physical interfaces that comprise the trunk and the collection of VLANs whose traffic is carried on the trunk. The traffic of a VLAN that belongs to one or more trunk groups is carried only on ports that are members of trunk groups to which the VLAN belongs, i.e., VLANs configured in a trunk group are pruned of all ports that are not associated with the trunk group. See the Trunk Ports example section for further details.

Note: Be cautious when using allowed VLAN lists or trunk groups to ensure that the VLAN topology is consistent with any Layer-2 control protocol topology, or unpredictable results can occur.
VLAN traffic is carried through Ethernet or LAG ports. A port’s switchport mode defines the number of VLANs for which the port can carry traffic.

- Access ports carry traffic for one VLAN – the access VLAN. Access ports associate untagged frames with the access VLAN. Access ports drop tagged frames that are not tagged with the access VLAN.
- Trunk ports carry traffic for multiple VLANs. Tag frames specify the VLAN for which trunk ports process packets.

### 12.3.2.2 Q-in-Q Trunking

A Q-in-Q network is a multi-tier layer 2 VLAN network. A typical Q-in-Q network is composed of a service provider network (tier 1) where each node connects to a customer network (tier 2).

802.1ad is a networking standard that supports Q-in-Q networks by allowing multiple 802.1Q tags in an Ethernet frame.

Each interface in a customer network is assigned to a customer-VLAN (c-VLAN). Packets in c-VLANs contain 802.1q tags that switch traffic within the network. c-VLANs access the service provider VLAN (s-VLAN) through a provider switch. Customer switch ports connect to an s-VLAN through provider switch edge ports, which are configured as dot1q ports and operate as follows:

- **Inbound traffic (from customer switches)**: adds an s-VLAN tag, then forwards packets to the provider network.
- **Outbound traffic (to customer switches)**: removes the s-VLAN tag, then forwards packets to the customer network.

### 12.3.2.3 TPID (Configurable Ethertypes)

By default, VLAN-tagged packets carry a Tag Protocol Identifier (TPID) of 0x8100. On some Arista platforms, however, the TPID of a switchport can be modified in accordance with IEEE 802.1ad to allow for the use of 802.1q TPIDs other than 0x8100. Well known and standard tags include:

- **0x8100** customer VLAN.
- **0x88a8** service VLAN tag used in provider bridging.
- **0x9100** service VLAN tag used in provider bridging (common, but not standardized).

Other non-standard TPID values may also be configured for interoperability with legacy equipment or non-standard systems. Values range from 0x600 (1536) through 0xFFFF (65535).

Non-default TPID values are most commonly used for provider bridging on a network-to-network interface.

### 12.3.2.3 VLAN Routing

Each VLAN can be associated with a Switch Virtual Interface (SVI), also called a VLAN interface. The VLAN interface functions in a routed network (Layer 3) with an assigned IP subnet address. Connecting different VLANs requires Layer 3 networking.

#### 12.3.2.3.1 VLAN Interfaces

A Switched Virtual Interface (SVI) connects to the VLAN segment on the switch to provide Layer 3 processing for packets from the VLAN. An SVI can be activated only after it is connected to a VLAN. SVIs are typically configured for a VLAN to a default gateway for a subnet to facilitate traffic routing with other subnets.

In a Layer 3 network, each VLAN SVI is associated with an IP subnet, with all stations in the subnet members of the VLAN. Traffic between different VLANs is routed when IP routing is enabled.
12.3.2.3.2 Internal VLANs

A routed port is an Ethernet or port channel interface that functions as a Layer 3 interface. Routed ports do not bridge frames nor switch VLAN traffic. Routed ports have IP addresses assigned to them and packets are routed directly to and from the port.

The switch allocates an internal VLAN for an interface when it is configured as a routed port. The internal VLAN is assigned a previously unused VLAN ID. The switch prohibits the subsequent configuration of VLANs and VLAN interfaces with IDs corresponding to allocated internal VLANs.

12.3.2.3.3 Support for Private VLAN

Private VLAN is a feature that segregates a regular VLAN broadcast domain while maintaining all ports in the same IP subnet. There are three types of VLAN within a private VLAN:

1. **Primary VLAN**: Ports in the primary VLAN can send and or receive traffic from ports in all the corresponding PVLANs. There is only one primary VLAN in a private VLAN.
2. **Community VLAN**: This is a secondary VLAN. Hosts in a community VLAN forward traffic to each other as well as ports in the primary VLAN. There are multiple community VLANs in a private VLAN.
3. **Isolated VLAN**: This is a secondary VLAN. Hosts in an isolated VLAN only forward traffic to ports in the primary VLAN. Hosts within an isolated VLAN can not communicate with each other using bridging. There are multiple isolated VLANs in a private VLAN.

12.3.2.3.3.1 Limitations

**On DCS-7280R, DCS-7280R2, DCS-7500R, DCS-7500R2, DCS-7020R**

- Private VLAN and Algомatch features are mutually exclusive. Disable algомatch with the `hardware access-list mechanism tcam` command. Note that this requires a reload of the system to take effect.
- L2 and L3 multicast traffic is not supported.

**On All Platforms except 7300X3, CCS-720XP, DCS-7050X3**

Private VLAN and IPv4/IPv6 uRPF features are mutually exclusive.

**On All Platforms**

- Tunnel termination on PVLAN ports is not supported.
- Ingress IPv4/IPv6 RACLs on the primary VLAN are not honored for packets ingressing through ports in secondary VLANs.
- Only isolated private VLAN trunks and normal trunk ports are supported. It allows trunk ports to forward and receive traffic for all primary and or secondary VLANs. An isolated trunk translates traffic coming in on a primary VLAN to the lowest valued secondary VLAN on the trunk port.
- Private VLAN is not supported on L2 subinterfaces.
- Hardware accelerated Sflow is not supported on Private VLAN ports.
- VLAN Mapping and or Translation is not supported with Private VLAN.

12.3.2.3.3.2 Show Commands

- Use the `show vlan private-vlan` command to display the primary and secondary defined VLANs:

```
switch#show vlan private-vlan
Primary  Secondary  Type         Ports
-------  -------  -----------  ------------------------
100      101      community    Et1, Et6
```
Layer 2 Configuration

<table>
<thead>
<tr>
<th>VLAN</th>
<th>Name</th>
<th>Status</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>VLAN0100</td>
<td>active</td>
<td>Et1, Et6+, Et7+, Et8+</td>
</tr>
<tr>
<td>101</td>
<td>VLAN0101</td>
<td>active</td>
<td>Et1+, Et6</td>
</tr>
<tr>
<td>102</td>
<td>VLAN0102</td>
<td>active</td>
<td>Et1+, Et7, Et8</td>
</tr>
<tr>
<td>200</td>
<td>VLAN0200</td>
<td>active</td>
<td>Et10</td>
</tr>
<tr>
<td>201</td>
<td>VLAN0201</td>
<td>active</td>
<td>Et10+, Et9</td>
</tr>
</tbody>
</table>

+ indicates a private VLAN promoted port

Promoted ports are displayed to indicate they are part of the same broadcast domain as the indicated VLAN. Interfaces in a primary VLAN are included in the display of all its associated secondary VLANs. Interfaces in secondary VLANs are included in the display of both its primary VLAN and its own domain.

Use the `show platform sand pvlan interfaces` command to display the status of the interfaces to configure a private VLAN.

<table>
<thead>
<tr>
<th>Interface</th>
<th>Secondary VLAN</th>
<th>Primary VLAN</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet6</td>
<td>101</td>
<td>100</td>
<td>enabled</td>
</tr>
<tr>
<td>Ethernet7</td>
<td>102</td>
<td>100</td>
<td>enabled</td>
</tr>
<tr>
<td>Ethernet8</td>
<td>102</td>
<td>100</td>
<td>enabled</td>
</tr>
<tr>
<td>Po1</td>
<td>102</td>
<td>100</td>
<td>enabled</td>
</tr>
<tr>
<td>Ethernet9</td>
<td>201</td>
<td>200</td>
<td>failed</td>
</tr>
<tr>
<td>Po2</td>
<td>202</td>
<td>200</td>
<td>failed</td>
</tr>
</tbody>
</table>

In this output, the Secondary VLAN column indicates the VLAN which is configured on the interface. The Primary VLAN column indicates the primary VLAN to which the secondary VLAN belongs to. The State field has three possible values - enabled, failed, configured. The enabled state indicates that the private VLAN is configured and enabled on that interface. The failed state indicates that the private VLAN configuration has failed for that interface. The configured state indicates that private VLAN is configured on that interface but has not taken effect. When port channels are configured in a private VLAN, it is enabled only if entries for all the member interfaces are successfully programmed in the hardware. If the hardware entries for any one of the member interfaces fails, the entries for other member interfaces are also removed from the hardware and the state is marked as failed.

12.3.2.3.4 VLAN Translation

VLAN translation allows you to map packets from one VLAN to another. This can be carried out only on packets having a dot1q header (tagged frames). The translation rewrites the VID field (VLAN ID) in dot1q headers on packets passing through a switched port without changing any other fields.

VLAN translation also supports the ability to translate packets with a dot1q header to the internal VLAN for a routed port. The VLAN in the incoming packets is mapped to the internal VLAN of the routed port and packets egressing the routed port are encapsulated with a dot1q header for the specified VLAN. For egress packets, no priority information is added to the dot1q header and the priority from the incoming encapsulation will be retained.
When configuring the VLAN translation mode, consider the following:

- VLAN translation is only supported for tagged packets.
- BPDUs from STP, LLDP and other protocols are not affected by this mapping.
- VLAN translation is not applicable for access ports.
- Untagged packets entering the switch on the trunk native VLAN are not mapped.
- TPID and VLAN priority does not get re-written during the translation.

12.3.3  VLAN Configuration Procedures

These sections describe basic VLAN configuration tasks.

- Creating and Configuring VLANs
- Configuring VLAN Switching
- Creating and Configuring VLAN Interfaces
- Allocating Internal VLANs
- Private VLAN Configuration
- Configuring VLAN Translation

12.3.3.1  Creating and Configuring VLANs

The CLI provides two methods of creating VLANs.

- Explicitly through the `vlan` command.
- Implicitly through the `switchport access vlan` command.

The `switchport access vlan` command generates a warning message when it creates a VLAN.

To create a VLAN, use the `vlan` command in global configuration mode. Valid VLAN numbers range between 1 and 4094. To create multiple VLANs, specify a range of VLAN numbers.

To edit an existing VLAN, enter the `vlan` command with the number of the existing VLAN.

**Examples**

- This command creates **VLAN 45** and enters VLAN configuration mode for the new VLAN.

  ```
  switch(config)#vlan 45
  switch(config-vlan-45)#
  ```

- Use the `name (VLAN configuration mode)` command to assign a name to a VLAN.

  These commands assign the name Marketing to VLAN 45.

  ```
  switch(config)#vlan 45
  switch(config-vlan-45)#name Marketing
  switch(config-vlan-45)#show vlan 45
  ```

- To change a VLAN’s state, use the `state` command in VLAN configuration mode.

  These commands suspend **VLAN 45**. VLAN traffic is blocked on all switch ports.

  ```
  switch(config)#vlan 45
  switch(config-vlan-45)#state suspend
  switch(config-vlan-45)#show vlan 45
  ```
Layer 2 Configuration

<table>
<thead>
<tr>
<th>VLAN Name</th>
<th>Status</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>suspended</td>
<td></td>
</tr>
</tbody>
</table>

switch(config-vlan-45)#

- These commands activate **VLAN 45**.

```
switch(config)#vlan 45
switch(config-vlan-45)#state active
switch(config-vlan-45)#show vlan 45
```

<table>
<thead>
<tr>
<th>VLAN Name</th>
<th>Status</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>active</td>
<td>Etl</td>
</tr>
</tbody>
</table>

switch(config-vlan-45)#

12.3.3.1 VLAN Policy

The VLAN policy configuration command enables a switch to configure a VLAN policy when it receives a packet with unknown destination MAC address on a VLAN. The `mac address forwarding` command provides three options to configure a VLAN policy:

- Flood the Layer 2 miss packets on the VLAN
- Drop the Layer 2 miss packets
- Log the Layer 2 miss packets to the CPU (while still flooding them on the VLAN)

The default behavior is to flood the L2 miss packets on all ports of the VLAN.

VLAN policy configuration is supported on the Arista 7010, 7050 (excluding 7050SX3-48YC12, 7050CX3-32S, 7050QX2-32S, 7050SX2-72Q, 7050SX2-128, 7050TX2-128), 7060, 7250, and the 7300 series platforms.

VLAN policy is not supported in the following cases:

- STP, LLDP, and LACP packets
- VLAN policy configurations on VXLAN-enabled VLAN
- On a VLAN if IGMP snooping is configured with Multicast miss action is set to drop, then all multicast packets received on that VLAN are dropped.

Examples

- These commands create a **VLAN 333** and then set the unicast policy to ‘drop’ and the multicast policy to ‘log’ for the specific **VLAN 333**.

```
switch(config)#vlan 333
switch(config-vlan-333)#mac address forwarding unicast miss action drop
switch(config-vlan-333)#mac address forwarding multicast miss action log
```

- These commands display the VLAN policy that was defined when **VLAN 333** is created.

```
switch(config)#show vlan 333 mac address forwarding
VLAN  UcMissAction  McMissAction
      ------  ------------
333    flood     flood
```
• These commands display the VLAN policy type that was defined when VLAN 333 is configured with the ‘drop’ unicast policy and the ‘log’ multicast policy.

```
switch(config)#show vlan 333 mac address forwarding
VLAN  UcMissAction  McMissAction
----  ------------  ------------
333   drop          log
switch(config)#show vlan mac address forwarding
VLAN  UcMissAction  McMissAction
----  ------------  ------------
1     flood         flood
333   drop          log
```

12.3.3.2 Configuring VLAN Switching
The following describe the configuration of VLAN ports.

12.3.3.2.1 Access Ports

Access ports carry traffic for one VLAN, as designated by a `switchport access vlan` command. Access ports associate untagged frames with the access VLAN. Tagged frames received by the interface are dropped unless they are tagged with the access VLAN.

To configure an interface group as an access port, use the `switchport mode` command.

**Examples**

• These commands configure *interface Ethernet 1* as an access port.

```
switch(config)#interface ethernet 1
switch(config-if-Et1)#switchport mode access
switch(config-if-Et1)#
```

• To specify the port’s access VLAN, use the `switchport access vlan` command. These commands configure VLAN 15 as the access VLAN for *interface Ethernet 5*.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport access vlan 15
switch(config-if-Et5)#
```

• These commands configure interface Ethernet 1 through 3 as access ports that process untagged frames as VLAN 5 traffic.

```
switch(config)#interface Ethernet 1-3
switch(config-if-Et1-3)#switchport mode access
switch(config-if-Et1-3)#switchport access vlan 5
switch(config-if-Et1-3)#show interfaces ethernet 1-3 vlans
Port    Untagged  Tagged
Et1     None      23,25
Et2     18        -
Et3     None      14
switch(config-if-Et1-3)#
```

12.3.3.2.2 Trunk Ports

Trunk ports carry traffic for multiple VLANs. Messages use tagged frames to specify the VLAN for which trunk ports process traffic.
• The `vlan trunk list` specifies the VLANs for which the port handles tagged frames. The port drops any packets tagged for VLANs not in the VLAN list.

• The `native vlan` is the VLAN where the port switches untagged frames.

To configure an interface group as a trunk port, use the `switchport mode` command.

**Example**

These commands configure `interface Ethernet 8` as a trunk port.

```plaintext
switch(config)#interface ethernet 8
switch(config-if-Et8)#switchport mode trunk
switch(config-if-Et8)#
```

By default all VLANs are permitted on a port configured with `switchport mode trunk`. To limit the port’s VLAN trunk list, use the `switchport trunk allowed vlan` command. Only VLANs in the allowed list will be permitted.

**Examples**

• These commands configure VLAN `15, 20, 21, 22, 40,` and `75` as the explicitly permitted VLAN trunk list for ethernet interface `12-16`.

```plaintext
switch(config)#interface ethernet 12-16
switch(config-if-Et12-16)#switchport trunk allowed vlan 15,20-22,40,75
switch(config-if-Et12-16)#
```

• These commands explicitly permit VLAN `100` through `120` to the VLAN trunk list for `interface ethernet 14`.

```plaintext
switch(config)#interface ethernet 14
switch(config-if-Et14)#switchport trunk allowed vlan add 100-120
switch(config-if-Et14)#
```

• To specify the port’s native VLAN, use the `switchport trunk native vlan` command. These commands configure `VLAN 12` as the native VLAN trunk for `interface Ethernet 10`.

```plaintext
switch(config)#interface ethernet 10
switch(config-if-Et10)#switchport trunk native vlan 12
switch(config-if-Et10)#
```

• By default, ports send native VLAN traffic with untagged frames. The `switchport trunk native vlan` command can also configure the port to send native VLAN traffic with tag frames. These commands configure `interface ethernet 10` to send native VLAN traffic as tagged.

```plaintext
switch(config)#interface ethernet 10
switch(config-if-Et10)#switchport trunk native vlan tag
switch(config-if-Et10)#
```

• These commands configure `interface Ethernet 12` as a trunk with `VLAN 15` as the native VLAN. The port’s trunk list includes all VLANs except `201-300`.

```plaintext
switch(config)#interface ethernet 12
switch(config-if-Et12)#switchport mode trunk
switch(config-if-Et12)#switchport trunk native vlan 15
switch(config-if-Et12)#switchport trunk allowed vlan except 201-300
switch(config-if-Et12)#
```
• Assume that all ports on the switch are configured with switchport mode trunk similar to Ethernet 1 and 2 shown below:

```plaintext
! interface ethernet 1
   switchport mode trunk
!
interface ethernet 2
   switchport mode trunk
!
```

• Further assume that VLAN 30 is not configured as part of a trunk group.

```plaintext
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- ----------
 1     default                          active    Et1, Et2
 30    vlan30                           active    Et1, Et2
```

• Now configure VLAN 30 as part of trunk group 30:

```plaintext
switch(config)#vlan 30
switch(config-vlan-30)#trunk group 30
```

• This updates the VLAN membership for VLAN 30.

```plaintext
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- ----------
 1     default                          active    Et1, Et2
 30    vlan30                           active
```

- Note: VLAN 30 is no longer on Et1, Et2 i.e. it has been ‘pruned’ due to the trunk group command in the vlan configuration.

• To permit VLAN 30 on Et1, you need to associate the interface with the trunk group as follows:

```plaintext
switch(config-if-Et1)#switchport trunk group 30
```

Now we see Et1 included in the vlan 30 list

```plaintext
switch#show vlan
VLAN  Name                             Status    Ports
----- -------------------------------- --------- ----------
 1     default                          active    Et1, Et2
 30    vlan30                           active    Et1
```

• The trunk group command is not additive to the allowed VLAN command.

```plaintext
interface ethernet 1
   switchport mode trunk
   switchport trunk allowed vlan 10
   switchport trunk group trunk30
```

Vlan 30 will not be permitted on the interface as it is not listed in the allowed vlan list.

12.3.3.2.3 Dot1q Tunnel Ports

**Dot1q (802.1Q)** is a tunneling protocol that encapsulates traffic from multiple customer (c-tag) VLANs in an additional single outer service provider (s-tag) VLAN for transit across a larger network structure
that includes traffic from all customers. Tunneling eliminates the service provider requirement that every VLAN be configured from multiple customers, avoiding overlapping address space issues.

Tunneling preserves the inner VLANs through the tunneled network; these inner VLANs are ignored by intermediate devices that make forwarding decisions based only on the outermost VLAN tag (S-Tag).

A dot1q-tunnel port sits at the edge of the tunneled network. Unlike regular access ports, a dot1q-tunnel port does not drop traffic that arrives with 802.1Q tags in place; it ignores existing 802.1Q information and associates arriving traffic (with or without 802.1Q headers) with a new tunnel VLAN ID.

Packets arriving at a tunnel port are encapsulated with an additional 802.1Q tag that can be trunked between multiple devices like any traditional VLAN. When exiting a dot1-tunnel port, the S-Tag is removed to revert the customer traffic to its original tagged or untagged state.

To configure an interface group as a dot1q tunnel port, use the `switchport mode` command.

**Example**

These commands configure `interface ethernet 12` as a dot1q tunnel port.

```
switch(config)# interface ethernet 12
switch(config-if-Et12)# switchport mode dot1q-tunnel
switch(config-if-Et12)#
```

To specify the dot1q-tunnel port's access VLAN, use the `switchport access vlan` command. The port then handles all inbound traffic as untagged VLAN traffic.

**Example**

These commands configure VLAN 60 as the access VLAN for `interface Ethernet 12`.

```
switch(config)#interface ethernet 12
switch(config-if-Et12)#switchport access vlan 60
switch(config-if-Et12)#
```

### 12.3.3.4 TPID Configuration

The default tag protocol identifier (TPID, also called dot1q ethertype) on all switch ports is 0x8100. To configure a different TPID on a port, use the `switchport dot1q ethertype` command. This feature is available only on 7280E and 7500E platforms.

**Note:** If dot1q tunneling is enabled on the interface, a TPID configured on the interface becomes irrelevant.

**Example**

In this provider bridging example, `interface ethernet 1` is the user network interface and `interface ethernet 2` is the network-to-network interface. These commands configure dot1q tunneling on `interface ethernet 1` and set the TPID of `interface ethernet 2` to 0x9100.

```
switch(config)#interface ethernet 1
switch(config-if-Et1)#switchport mode dot1q-tunnel
switch(config-if-Et1)#interface ethernet 2
switch(config-if-Et2)#switchport mode trunk
switch(config-if-Et2)#switchport dot1q ethertype 0x9100
switch(config-if-Et2)#
```

In the above configuration, packets from **Et1** to **Et2** will undergo dot1q-tunneling (stacking of an additional dot1q tag), with an outer TPID of 0x9100 at egress, while packets with outer TPID 0x9100 going from **Et2** to **Et1** will have the outer tag removed at egress.
12.3.3.2.5 Layer 2 802.1Q Encapsulation

Layer 2 traffic encapsulation is enabled on the configuration mode interface for a specified VLAN through `l2-protocol encapsulation dot1q vlan`.

Example

These commands enable traffic encapsulation for VLAN 200 traffic passing through `interface ethernet 5/2`.

```
switch(config)#interface ethernet 5/2
switch(config-if-Et5/2)#l2-protocol encapsulation dot1q vlan 200
```

12.3.3.2.6 Port VLAN Scaling on DCS-7160

Port VLAN scaling allows the user to configure a subset of ports in the scale mode. The `switchport vlan forwarding` command forwards packets between the ports belonging to VLAN in the interface configuration mode. The Port-VLAN table is used for storing the configuration on a per port/VLAN combination. The scaling configuration is applicable on a per-port basis and supports a maximum of 128 ports.

Note: The configuration is applicable to trunk ports only.

Example

- This command enables VLAN scaling on a port with an `interface Ethernet 2`.
  
  ```
  switch#config terminal
  switch(config)#interface Ethernet 2
  switch(config-if-Et2)#switchport vlan forwarding accept all
  ```

- This command disables VLAN scaling on a port.
  
  ```
  switch(config)#interface Ethernet 2
  switch(config-if-Et2)#no switchport vlan forwarding accept all
  ```

12.3.3.3 Creating and Configuring VLAN Interfaces

The `interface vlan` command places the switch in `VLAN-interface` configuration mode for modifying an SVI. An SVI provides a management address point and Layer 3 processing for packets from all VLAN ports.

Example

This command enters `VLAN-interface` configuration mode for VLAN 12. The command also creates VLAN 12 interface if it was not previously created.

```
switch#config t
switch(config)#interface vlan 12
switch(config-if-Vl12)#
```

12.3.3.4 Allocating Internal VLANs

The `vlan internal order` command specifies the VLANs that the switch allocates as internal VLANs when configuring routed ports and the order of their allocation. By default, the switch allocates VLANs in ascending order. The default allocation range is between VLAN 1006 and VLAN 4094.

The `no switchport` command converts an Ethernet or port channel interface into a routed port, disabling Layer 2 switching for the interface.
Examples

• This command configures the switch to allocate internal VLANs in ascending order starting with 1006.

```
switch(config)#vlan internal order ascending
switch(config)#
```

• This command configures the switch to allocate internal VLANs in descending order starting with 4094.

```
switch(config)#vlan internal order descending
switch(config)#
```

• This command configures the switch to allocate internal VLANs in descending order from 4094 through 4000.

```
switch(config)#vlan internal order descending range 4000 4094
switch(config)#
```

12.3.3.5 Private VLAN Configuration

• On systems with algomatch hardware, the access-list mechanism must explicitly be set to TCAM using the following command. Ignore this step when on non-algomatch hardware based systems.

```
switch(config)#hardware access-list mechanism tcam
```

• To enable the private VLAN feature, you must also enable the forwarding-ID feature.

```
switch(config)#platform sand l2 forwarding-id sharing
```

On All Platforms

• Any regular VLAN can act as a primary without any extra configuration. The only requirement is that the VLAN must be active. Use the following command to configure a VLAN as active or inactive:

```
switch(config)#vlan 100
switch(config)#no vlan 100
switch(config)#default vlan 100
```

• Configure VLANs as secondary inside the VLAN configuration mode. Use the configuration to specify the primary VLAN as isolated and the type of secondary VLAN:

```
switch(config)#vlan 20
switch(config-vlan-20)#private-vlan isolated primary vlan 10
switch(config)#vlan 30
switch(config-vlan-30)#private-vlan community primary vlan 10
```
Figure 27: Support for Private VLAN

- Interfaces are assigned to primary or secondary VLANs in the same way as regular VLANs. It works with both access and trunk ports. The following shows the standard switchport command configuring an access interface to the secondary VLAN configured before:

```
switch(config)#interface Ethernet 1/1
switch(config-if-Et1/1)#switchport access vlan 20
```

- Trunk ports forward any traffic within the allowed VLANs configured on the interface, whether they are primary or secondary VLANs. To configure trunk ports to translate traffic from primary VLAN to secondary (this maps to the lowest secondary VLAN if multiple are allowed) configure the following on the trunk port:

```
switch(config)#interface Ethernet 1/1
switch(config-if-Et1/1)#switchport trunk private-vlan secondary
```

Steps to Unconfigure

On all Platforms

- To unconfigure a private VLAN, use the following command. This reverts the VLAN back to a regular VLAN. At this point, the broadcast domain for this VLAN adjusts and all hosts start to be learned in the regular VLAN, as opposed to the primary VLAN. The MAC table entries previously learned on the primary VLAN are not used anymore for forwarding.

```
switch(config-vlan-20)#no private-vlan
```

- To restore trunk port behavior to allow traffic on all primary and secondary VLANs:

```
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#no switchport trunk private-vlan secondary
```

To unconfigure forwarding-id sharing:

```
switch(config)#no platform sand l2 forwarding-id sharing
```
12.3.3.6 Configuring VLAN Translation

VLAN translation changes the VLAN ID of specified packets entering or leaving a port. The following sections describe the configuration of VLAN translation.

12.3.3.6.1 Per-port VLAN Translation on Switched Ports

The `switchport vlan translation` command allows translation of the VLAN tag of traffic entering or exiting a switched port.

To use VLAN translation on a switched port, the port must be configured as a trunk port using the `switchport mode` command.

Examples

- This command configures `interface ethernet 5` as a trunk port.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport mode trunk
  ```

- By default, the translation is bidirectional: packets ingressing an interface through VLAN A are internally mapped to VLAN B; VLAN B packets egressing the same interface are mapped to VLAN A.

  ```
  • These commands map `interface ethernet 5` traffic with dot1q tag 50 to bridging VLAN 60.
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport vlan translation 50 60
  ```

  ```
  • These commands provides multiple 1:1 VLAN mappings under an interface.
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport vlan translation 50 60
  switch(config-if-Et5)#switchport vlan translation 61 71
  switch(config-if-Et5)#switchport vlan translation 62 72
  ```

- These commands translate only incoming packets.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport vlan translation in 50 60
  ```

- These commands translate only egress packets.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#switchport vlan translation out 60 50
  ```

12.3.3.6.2 Per-port VLAN Translation on Routed Ports

On routed ports, the `encapsulation dot1q vlan` command (permitted only on routed ports) configures the VLAN on the interface to act as the native VLAN. This command will map packets ingressing with the specified VLAN ID to the internal VLAN ID of the routed port. All traffic egressing out of the routed port will be tagged with the VLAN ID specified in the command.
**Example**

These commands translate between *vlan 50* and the internal VLAN for *interface ethernet 5* (a routed port).

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
switch(config-if-Et5)#encapsulation dot1q vlan 50
```

**12.3.6.3 Double VLAN Translation**

Double VLAN translation creates mappings between an inner and outer VLAN ID pair of a double-tagged packet and a single bridging VLAN. On ingress, specified double-tagged packets are mapped to the bridging VLAN, and on egress packets with the ID of the bridging VLAN are double tagged as specified. By default, the translation is bidirectional, but it can be applied only on ingress or egress.

**Example**

These commands causes packets entering *interface ethernet 3/1* with an outer VLAN ID of *1000* and an inner VLAN ID of *100* to be processed in bridging *VLAN 200*.

```bash
switch(config)#interface ethernet 3/1
switch(config-if-Et3/1)#switchport vlan translation in 1000 inner 100 200
switch(config-if-Et3/1)#
```
12.3.4 VLAN Configuration Commands

Global VLAN Configuration Commands
- interface vlan
- vlan
- vlan internal order

VLAN Configuration Mode Commands
- mac address forwarding
- name (VLAN configuration mode)
- state
- trunk group

Layer 2 Interface (Ethernet and Port Channel) Configuration Commands
- switchport access vlan
- switchport dot1q ethertype
- switchport mode
- switchport trunk allowed vlan
- switchport trunk group
- switchport trunk native vlan
- switchport vlan forwarding
- switchport vlan translation

VLAN Interface Configuration Mode Commands
- autostate
- encapsulation dot1q vlan
- l2-protocol encapsulation dot1q vlan
- name (VLAN configuration mode)
- pvlan mapping

Show Commands
- show dot1q-tunnel
- show interfaces switchport
- show interfaces switchport backup-link
- show interfaces switchport vlan mapping
- show interfaces trunk
- show interfaces vlans
- show pvlan mapping interfaces
- show vlan
- show vlan brief count
- show vlan dynamic
- show vlan internal allocation policy
- show vlan internal usage
- show vlan trunk group
12.3.4.1 vlan internal order

The vlan internal order command specifies the range that the switch can allocate as internal VLANs when configuring routed ports and the order of their allocation. By default, the switch allocates VLANs in ascending order from VLAN 1006 to VLAN 4094.

The no vlan internal order and default vlan internal order commands revert the policy to its default.

Command Mode
Global Configuration

Command Syntax

vlan internal order DIRECTION [RANGE_VLAN]
no vlan internal order
default vlan internal order

Parameters
• DIRECTION   VLAN allocation number direction. Options include:
  • ascending allocates internal VLANs from lower VLAN bound to upper VLAN bound.
  • descending allocates internal VLAN from upper VLAN bound to lower VLAN bound.
• RANGE_VLAN   allocation range. Options include:
  • no parameter 1006 (lower bound) to 4094 (upper bound).
  • range, lower, upper specifies lower bound (lower) and upper bound (upper).

Examples
• This command configures the switch to allocate internal VLANS from 3000 through 3999.
  switch(config)#vlan internal order ascending range 3000 3999
  switch(config)#

• This command configures the switch to allocate internal VLANS from 4094 through 1006.
  switch(config)#vlan internal order descending
  switch(config)#

• This command configures the switch to allocate internal VLANS from 4094 down through 4000.
  switch(config)#vlan internal order descending range 4000 4094
  switch(config)#

• This command reverts the allocation policy to its default (ascending, between 1006 and 4094).
  switch(config)#no vlan internal order
  switch(config)#
12.3.4.2 vlan

The `vlan` command places the switch in VLAN configuration mode to configure a set of virtual LANs. The command creates the specified VLANs if they do not exist prior to issuing the command. A VLAN that is in use as an internal VLAN may not be created or configured. The switch rejects any `vlan` command that specifies an internal VLAN ID.

The `default vlan` and `no vlan` commands removes the VLAN statements from `running-config` for the specified VLANs.

The `exit` command returns the switch to global configuration mode.

Command Mode

Global Configuration

Command Syntax

```
vlan vlan_range
no vlan vlan_range
default vlan vlan_range
```

Parameters

`vlan_range` VLAN list.

Formats include a name, number, number range, or comma-delimited list of numbers and ranges.

Commands Available in VLAN Configuration Mode

- `name (VLAN configuration mode)`
- `state`
- `trunk group`

Guidelines

In MLAG configurations, VLANs operate as follows:

- The VLAN must be configured identically on both MLAG peer switches.
- The port-specific bridging configuration originates on the switch where the port is physically located. This configuration includes the switchport access VLAN, switchport mode (trunk or access), trunk-allowed VLANs, the trunk native VLAN, and the switchport trunk groups.

Example

This command creates **VLAN 49** and enters **VLAN** configuration mode for the new VLAN:

```
switch(config)#vlan 49
switch(config-vlan-49)#
```
12.3.4.3 autostate

When autostate is enabled, the VLAN interface will be up when:

- the corresponding VLAN exists and is in the active state.
- one or more Layer 2 ports in the VLAN are up and in spanning-tree forwarding state.
- the VLAN interface exists and is not in a shutdown state.

Autostate is enabled by default. When autostate is disabled, the VLAN interface is forced to be active.

- The no autostate command disables autostate on the configuration mode interface. The no autostate command is stored to running-config.
- The autostate command enables the autostate function on the configuration mode VLAN SVI by removing the corresponding no autostate statement from running-config.
- The default autostate command restores the autostate default state of enabled by removing the corresponding no autostate statement from running-config.

Command Mode

Interface-VLAN Configuration

Command Syntax

autostate

no autostate

default autostate

Guidelines

Autostate should be disabled on SVIs configured as an MLAG local interface.

Examples

- These commands disable autostate on VLAN 100.

switch(config)#interface vlan 100
switch(config-if-Vl100)#no autostate
switch(config-if-Vl100)#

- These commands enable autostate on VLAN 100.

switch(config)#interface vlan 100
switch(config-if-Vl100)#autostate
switch(config-if-Vl100)#
12.3.4.4 encapsulation dot1q vlan

Routed Port VLAN Translation

In the configuration mode for an Ethernet or port channel interface, the `encapsulation dot1q vlan` translates packets with a dot1q header to the internal VLAN for a routed port. The VLAN in the incoming packets is mapped to the internal VLAN of the routed port, and packets egressing the routed port are encapsulated with a dot1q header for the specified VLAN. For egress packets, no priority information is added to the dot1q header and the priority from the incoming encapsulation will be retained.

Subinterface VLAN Assignment

When used in the configuration mode for an Ethernet or port channel subinterface, however, the `encapsulation dot1q vlan` command assigns a dot1q tag to the subinterface. Traffic ingressing on the parent interface with that dot1q tag will then be sent to the configured subinterface. See Subinterfaces and Subinterface Configuration for details.

The `no encapsulation dot1q vlan` and `default encapsulation dot1q vlan` commands restore the default VLAN to the configuration mode interface by removing the corresponding `encapsulation dot1q vlan` command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-port-channel Configuration
Subinterface-Ethernet Configuration
Subinterface-port-channel Configuration

Command Syntax

```
encapsulation dot1q vlan  vlan_id
no encapsulation dot1q vlan
default encapsulation dot1q vlan
```

Parameters

`vlan_id` For VLAN translation, the ID of the external VLAN to be translated; for subinterface configuration, the VLAN of the subinterface. Values range from 1 to 4094.

Examples

- These commands translate between `vlan 50` and the internal VLAN for `interface ethernet 5` (a routed port).

  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no switchport
  switch(config-if-Et5)#encapsulation dot1q vlan 50
  switch(config-if-Et5)#

- These commands assign packets ingressing on `interface ethernet 1/1` with `VLAN ID 100` to subinterface `ethernet 1/1.1`.

  switch(config)#interface ethernet1/1.1
  switch(config-if-Et1/1.1)#no switchport
  switch(config-if-Et1/1.1)#encapsulation dot1q vlan 100
  switch(config-if-Et1/1.1)#
12.3.4.5  interface vlan

The `interface vlan` command places the switch in VLAN-interface configuration mode for modifying parameters of the Switch Virtual Interface (SVI). An SVI provides Layer 3 processing for packets from all ports associated with the VLAN. There is no physical interface for the VLAN.

When entering configuration mode to modify existing SVIs, the command can specify multiple interfaces. The command creates an SVI if the specified interface does not exist prior to issuing the command. When creating an SVI, the command can only specify a single interface.

The `no interface vlan` command deletes the specified SVI interfaces from `running-config`. The `default interface vlan` commands remove all configuration statements for the specified SVI interfaces from `running-config` without deleting the interfaces.

**Command Mode**

Global Configuration

**Command Syntax**

```
interface vlan v_range
no interface vlan v_range
default interface vlan v_range
```

**Parameter**

`v_range`  VLAN interfaces (number, range, or comma-delimited list of numbers and ranges). VLAN number ranges from 1 to 4094.

**Restrictions**

**Internal VLANs:** A VLAN interface cannot be created or configured for internal VLAN IDs. The switch rejects any `interface vlan` command that specifies an internal VLAN ID.

**Example**

This example creates an SVI for **VLAN 12**:

```
switch#config
switch(config)#interface vlan 12
switch(config-if-Vl12)#
```
### 12.3.4.6 l2-protocol encapsulation dot1q vlan

The **l2-protocol encapsulation dot1q vlan** command enables Layer 2 802.1Q traffic encapsulation on the configuration mode interface for a specified VLAN. The default VLAN for all interfaces is VLAN 1.

The **no l2-protocol encapsulation dot1q vlan** and **default l2-protocol encapsulation dot1q vlan** commands disable the specified encapsulation on the configuration mode interface by removing the corresponding **l2-protocol encapsulation dot1q vlan** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

- `l2-protocol encapsulation dot1q vlan vlan_id`
- `no l2-protocol encapsulation dot1q vlan`
- `default l2-protocol encapsulation dot1q vlan`

**Parameters**

- `vlan_id` the ID of the native VLAN. Values range from 1 to 4094.

**Example**

These commands enable 802.1Q encapsulation of traffic on **vlan 200**.

```
switch(config)#interface ethernet 5/2
switch(config-if-Et5/2)#l2-protocol encapsulation dot1q vlan 200
switch(config-if-Et5/2)#show active
interface Ethernet5/2
      l2-protocol encapsulation dot1q vlan 200
switch(config-if-Et5/2)#
```
mac address forwarding

The **mac address forwarding** command enables a switch to configure a VLAN policy when it receives a packet with an unknown destination MAC address on a VLAN. The command provides three options to configure a VLAN policy:

- Flood the Layer 2 miss packets on the VLAN
- Drop the Layer 2 miss packets
- Log the Layer 2 miss packets to the CPU (while still flooding them on the VLAN)

The default state is to flood the L2 miss packets on all ports of the VLAN.

The **show vlan** command displays information about the VLAN policy that is being configured.

The **no** form and the **default** form of the command removes the previously configured VLAN policy on the VLAN.

### Command Mode

**VLAN Configuration**

### Command Syntax

```
mac address forwarding [unicast | multicast] miss action [drop | flood | log]
no mac address forwarding [unicast | multicast] miss action [drop | flood | log]
default mac address forwarding [unicast | multicast] miss action [drop | flood | log]
```

### Parameters

- **unicast** the unicast type of transmission.
- **multicast** the multicast type of transmission.
- **drop** the selected packets are dropped.
- **flood** the selected packets are flooded in the specific VLAN.
- **log** the selected packets are sent to the CPU for logging purpose.

### Guidelines

VLAN policy configuration is supported on the Arista 7010, 7050 (excluding 7050SX3-48Y12, 7050CX3-32S, 7050QX2-32S, 7050SX2-72Q, 7050SX2-128, 7050TX2-128), 7060, 7250, and the 7300 series platforms.

VLAN policy is not supported in the following cases:

- STP, LLDP, and LACP packets
- VLAN policy configurations on VXLAN-enabled VLAN
- On a VLAN if IGMP snooping is configured with Multicast miss action is set to drop, then all multicast packets received on that VLAN are dropped.

### Examples

- These commands create a **VLAN 333** and then set the unicast policy to **drop** and the multicast policy to **log** for the specific **VLAN 333**.

```
switch(config)#vlan 333
switch(config-vlan-333)#mac address forwarding unicast miss action drop
switch(config-vlan-333)#mac address forwarding multicast miss action log
```

- These commands display the VLAN policy that was defined when **VLAN 333** is created.

```
switch(config)#show vlan 333 mac address forwarding
VLAN UcMissAction McMissAction
```
Layer 2 Configuration

- These commands display the VLAN policy type that was defined when VLAN 333 is configured with the drop unicast policy and the log multicast policy.

```bash
switch(config)#show vlan 333 mac address forwarding
VLAN  UcMissAction  McMissAction
----  ------------  ------------
333   drop          log

switch(config)#show vlan mac address forwarding
VLAN  UcMissAction  McMissAction
----  ------------  ------------
 1    flood         flood
333   drop          log
```
12.3.4.8 name (VLAN configuration mode)

The name command configures the VLAN name. The name can have up to 32 characters. The default name for VLAN 1 is default. The default name for all other VLANs is VLANxxxx, where xxxx is the VLAN number. The default name for VLAN 55 is VLAN0055. The show vlan command displays the VLAN name.

The name command accepts all characters except the space.

The no name and default name commands restore the default name by removing the name command from running-config.

Command Mode
VLAN Configuration

Command Syntax
name label_text
no name
default name

Parameters

label_text character string assigned to name attribute. Maximum length is 32 characters. The space character is not permitted in the name string.

Example

These commands assign corporate_100 as the name for VLAN 25, then displays the VLAN name.

```
switch(config)#vlan 25
switch(config-vlan-25)#name corporate_100
switch(config-vlan-25)#show vlan 25
VLAN  Name                 Status  Ports
-----  ----------------------  ------  ------
25     corporate_100         active

switch(config-vlan-25)#
```
12.3.4.9  **pvlan mapping**

The `pvlan mapping` command maps a switch virtual interface (SVI) available in the primary VLAN to the secondary VLAN or VLANS in the VLAN configuration mode. The `show pvlan mapping interfaces` command displays the list of mapped VLANS.

The `no pvlan mapping` and `default pvlan mapping` commands restore the default state of the private VLAN mapping.

**Command Mode**
VLAN Configuration

**Command Syntax**

```
pvlan mapping{add | remove | vlan ID}
no pvlan mapping{add | remove | vlan ID}
default pvlan mapping{add | remove | vlan ID}
```

**Parameters**

- **add** adding VLANs to the PVLAN mapping of the current VLAN interface.
- **remove** removing VLANs from the PVLAN mapping of the current VLAN interface.
- **vlan ID** The secondary VLAN IDs of the private VLAN mapping. The IDs range from 1 to 4094.

**Related Commands**

`show pvlan mapping interfaces`

**Example**

These commands assign a secondary VLAN ID of 50 to the primary VLAN.

```
switch(config)#vlan 25
switch(config-vlan-25)#pvlan mapping 50
switch(config-vlan-25)#
```
12.3.4.10 show dot1q-tunnel

The **show dot1q-tunnel** command displays the ports that are configured in dot1q-tunnel switching mode. The **switchport mode** command configures the switching mode for the configuration mode interface.

**Command Mode**

EXEC

**Command Syntax**

```
show dot1q-tunnel [INTERFACE]
```

**Parameters**

**INTERFACE** Interface type and numbers. Options include:

- **no parameter** Display information for all interfaces.
- **ethernet e_range** Ethernet interface range specified by `e_range`.
- **loopback l_range** Loopback interface specified by `l_range`.
- **management m_range** Management interface range specified by `m_range`.
- **port-channel p_range** Port-Channel Interface range specified by `p_range`.
- **vlan v_range** VLAN interface range specified by `v_range`.
- **vxlan vx_range** VXLAN interface range specified by `vx_range`.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

**Example**

This command displays the ports that are configured in dot1q-tunnel switching mode.

```
switch>show dot1q-tunnel
dot1q-tunnel mode LAN Port (s)
-------------------------------
Po4
Po21
Po22
switch>
```
The `show interfaces switchport backup-link` command displays interfaces that are configured as switchport backup pairs and the operational status of each interface. For each pair, the command displays the names, roles, status, and VLAN traffic of each interface.

**Command Mode**
EXEC

**Command Syntax**
```
show interfaces switchport backup-link
show interfaces switchport backup-link [module{Fabric f_num | Linecard lc_num | Supervisor svr_num | Switchcard | 1-2 | 3-6}]
```

**Parameters**
- **INTERFACE** Interface type and numbers. Options include:
  - `no parameter` Display information for all interfaces.
  - `ethernet e_range` Ethernet interface range specified by `e_range`.
  - `loopback l_range` Loopback interface specified by `l_range`.
  - `management m_range` Management interface range specified by `m_range`.
  - `port-channel p_range` Port-Channel Interface range specified by `p_range`.
  - `vlan v_range` VLAN interface range specified by `v_range`.
  - Valid `e_range`, `l_range`, `m_range`, `p_range`, and `v_range` formats include number, number range, or comma-delimited list of numbers and ranges.
- **module** Displays interfaces of the specified module. Options include:
  - `Fabric f_num` Displays interfaces of the specified fabric module. Value ranges from 1 to 6.
  - `Linecard lc_num` Displays interfaces of the specified linecard module. Value ranges from 3 to 6.
  - `Supervisor svr_num` Displays interfaces of the specified supervisor module. Accepted values are 1 and 2.
  - `Switchcard` Displays interfaces of switchcard modules.
  - `1-2` Displays interfaces of the specified supervisor module.
  - `3-6` Displays interfaces of the specified linecard module.

**Display Values**
- **State** Operational status of the interface. Values include:
  - `Up` Spanning tree mode is `backup`, interface status is `up`.
  - `Down` Spanning tree mode is `backup`, interface status is `down`.
  - `Inactive Configuration` The spanning tree mode is not `backup`.
  - `Forwarding vlans` VLANs forwarded by the interface. Depends on interface operation status and prefer option specified by the `switchport backup` command.

**Examples**
- This command displays the configured switchport primary-backup pairs.

```
switch>show interfaces switchport backup-link
Switch backup interface pair: Ethernet3/17, Ethernet3/8
Primary Interface: Ethernet3/17     State: Inactive Configuration
Backup Interface: Ethernet3/8      State: Inactive Configuration
Preemption delay: 0 milliseconds
Mac move burst size: 0
Mac move burst interval: 20 milliseconds
```
Mac move destination: ff:ff:ff:ff:ff:ff

- This command displays interfaces of the module for **linecard 4**.

```
switch(config)#show int switchport backup-link module Linecard 4
Switch backup interface pair: Ethernet4/19/1, Ethernet4/19/2
Primary Interface: Ethernet4/19/1  State: Inactive Configuration
Backup Interface: Ethernet4/19/2  State: Inactive Configuration
Preemption delay: 0 milliseconds
Mac move burst size: 0
Mac move burst interval: 20 milliseconds
Mac move destination: ff:ff:ff:ff:ff:ff
```
12.3.4.12  show interfaces switchport vlan mapping

The `show interfaces switchport vlan mapping` command displays mapping information of the configured VLANs in an interface mode.

**Command Mode**

EXEC

**Command Syntax**

`show interfaces switchport vlan mapping`

**Examples**

- This command displays mapping information of the configured VLAN IDs.

  ```
  switch#show interfaces switchport vlan mapping
  -----------------  12.3.4.12
  Ethernet3
  Original Vlan  New Vlan  Direction  Direction
  --------------  ---------  --------  --------
  10             100      Active    In/Out
  11             200      Active    In
  300            12       Active    Out
  ```

- This command displays dual tag mapping information of the configured VLAN IDs.

  ```
  switch(config)#show interfaces switchport vlan mapping
  -----------------  12.3.4.12
  Ethernet3/1
  Direction  Outer Tag  Inner Tag  VLAN ID  Status  Configured  Active Dot1   qTunnel
  --------  -------  -------  -------  ------  ----------  ---------  1489
  1000     100      200     200      active  In/Out    In/Out      -
  1001     101      201     201      active  In       In         -
  1002     102      202     202      active  Out      Out        -
  ```

- This command displays dual tag mapping information of the configured VLAN IDs.

  ```
  switch(config)#show interfaces switchport vlan mapping
  -----------------  12.3.4.12
  Ethernet1/1
  Outer Tag  Inner Tag  VLAN ID  Status  Direction  Direction
  ------  -------  -------  ------  --------  --------
  10      50     100     Active  In/Out    In/Out
  20      60     100     Active  In/Out    In/Out
  30      40     200     Active  Out      Out
  ```
12.3.4.13  show interfaces switchport

The `show interfaces switchport` command displays the switching configuration and operational status of the specified ports.

**Command Mode**

EXEC

**Command Syntax**

```
show interfaces [INTERFACE] switchport
```

**Parameters**

**INTERFACE**  Interface type and numbers. Options include:

- `no parameter`  Display the switching status for all interfaces.
- `ethernet e_range`  Ethernet interface range specified by `e_range`.
- `loopback l_range`  Loopback interface specified by `l_range`.
- `management m_range`  Management interface range specified by `m_range`.
- `port-channel p_range`  Port-Channel Interface range specified by `p_range`.
- `vlan v_range`  VLAN interface range specified by `v_range`.

Valid `e_range`, `l_range`, `m_range`, `p_range`, and `v_range` formats include number, number range, or comma-delimited list of numbers and ranges.

**Examples**

- This command displays the switching status for all interfaces.

```
switch(config)#show interface switchport
Default switchport mode: access

Name: Et5/1
Switchport: Enabled
Administrative Mode: static access
Operational Mode: static access
MAC Address Learning: enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Static Trunk Groups:
Dynamic Trunk Groups:

Name: Et5/2
Switchport: Enabled
Administrative Mode: static access
Operational Mode: static access
MAC Address Learning: enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Static Trunk Groups:
Dynamic Trunk Groups:

[...]  
```

- This command displays the switching status of port channel interfaces **21** and **22**.

```
switch>show interface port-channel 21-22 switchport
```
Layer 2 Configuration

Name: Po21
Switchport: Enabled
Administrative Mode: tunnel
Operational Mode: tunnel
Access Mode VLAN: 1 (inactive)
Trunking Native Mode VLAN: 100 (VLAN0100)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Trunk Groups: foo

Name: Po22
Switchport: Enabled
Administrative Mode: tunnel
Operational Mode: tunnel
Access Mode VLAN: 1 (inactive)
Trunking Native Mode VLAN: 1 (inactive)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Trunk Groups:

• This command displays the configured status of VLAN scaling for the interface ethernet 2/1 port.

switch#show interface Ethernet 2/1 switchport
Name: Ethernet 2/1
Switchport: Enabled
Administrative Mode: trunk
Operational Mode: trunk
MAC Address Learning: enabled
Dot1q ethertype/TPID: 0x8100 (active)
Dot1q VLAN Tag: Allowed
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: ALL
Static Trunk Groups:
Dynamic Trunk Groups:
Source interface filtering: enabled
VLAN forwarding mode: allConfiguredVlans

switch>
12.3.4.14  show interfaces trunk

The show interfaces trunk command displays configuration and status information for interfaces configured in switchport trunk mode.

Command Mode

EXEC

Command Syntax

show interfaces [INTERFACE] trunk

Parameters

INTERFACE  Interface type and numbers. Options include:
         •  no parameter  Display information for all interfaces.
         •  ethernet e_range  Ethernet interface range specified by e_range.
         •  management m_range  Management interface range specified by m_range.
         •  port-channel p_range  Port-Channel Interface range specified by p_range.

Valid e_range, m_range, and p_range formats include number, number range, or comma-delimited list of numbers and ranges.

Example

This command displays the trunk status for all interfaces configured in switchport trunk mode.

```
switch>show interfaces trunk
  Port     Mode      Status    Native vlan
Po1       trunk     trunking  1
Po2       trunk     trunking  1

  Port     Vlans allowed
Po1       1-15
Po2       16-30

  Port     Vlans allowed and active in management domain
Po1       1-10
Po2       21-30

  Port     Vlans in spanning tree forwarding state
Po1       1-10
Po2       21-30
switch>
```
12.3.4.15  show interfaces vlans

The *show interfaces vlans* command displays a table that lists the VLANs that are carried by the specified interfaces. Interfaces that do not carry VLANs are not listed in the table. The table lists the untagged (native or access) and tagged VLANs for each interface.

**Command Mode**
EXEC

**Command Syntax**

```
show interfaces [INT_NAME] vlans
```

**Parameters**

- **INT_NAME** Interface type and number. Values include:
  - *ethernet e_num* Ethernet interface specified by *e_num*.
  - *management m_num* Management interface specified by *m_num*.
  - *port-channel p_num* Port-Channel Interface specified by *p_num*.

**Example**

This command displays the VLANs carried by all L2 ports.

```
switch>show interfaces vlans
Port       Untagged Tagged
Et9        3910     -
Et11       3912     -
Et16       500      -
Et17       3908     -
Et18       3908     -
P01        1        101-102,500,721,3000,
P02        101      -
P04        3902     -
P05        3903     -
P06        3992     -
P07        661      -
P08        3911     -
```
show pvlan mapping interfaces

The `show pvlan mapping interfaces` command displays information about the private VLAN mapping interfaces.

**Command Mode**

EXEC

**Command Syntax**

`show pvlan mapping interfaces`

**Example**

This command displays information about the private VLAN mapping interfaces.

```
switch(config)#int vlan 50
switch(config-if-V150)#pvlan mapping 70
switch(config-if-V150)#show pvlan mapping interfaces
Interface       Secondary Vlans
--------------  -------------
Vlan50          70
```
show vlan brief count

The `show vlan brief count` command displays the number of VLANs that are configured on the switch.

**Command Mode**

EXEC

**Command Syntax**

`show vlan brief count`

**Example**

This command displays the number of VLANs on the switch.

```
switch>show vlan brief count
Number of existing VLANs : 18
switch>
```
12.3.4.18  show vlan dynamic

The `show vlan dynamic` command displays the source and quantity of dynamic VLANs on the switch. Dynamic VLANs support VM Tracer monitoring sessions.

Command Mode

EXEC

Command Syntax

`show vlan dynamic`

Example

This command displays the source and quantity of dynamic VLANs on the switch.

```
switch>show vlan dynamic
Dynamic VLAN source       VLANS
vmtracer-poc              88
switch>
```
12.3.4.19  show vlan internal allocation policy

The `show vlan internal allocation policy` command displays the method the switch uses to allocate VLANs to routed ports. The `vlan internal order` command configures the allocation method.

The allocation method consists of two configurable components:

- **range**: the list of VLANs that are allocated to routed ports.
- **direction**: the direction by which VLANs are allocated (ascending or descending).

**Command Mode**

EXEC

**Command Syntax**

`show vlan internal allocation policy`

**Example**

This command displays the internal allocation policy.

```
switch>show vlan internal allocation policy
Internal VLAN Allocation Policy: ascending
Internal VLAN Allocation Range: 1006-4094
switch>
```
12.3.4.20  show vlan internal usage

The `show vlan internal usage` command shows the VLANs that are allocated as internal VLANs for routed ports.

A routed port is an Ethernet or port channel interface that is configured as a layer 3 interface. Routed ports do not bridge frames and are not members of any VLANs. Routed ports can have IP addresses assigned to them and packets are routed directly to and from the port.

When an interface is configured as a routed port, the switch allocates an SVI with a previously unused VLAN ID. The switch prohibits the configuration of VLANs with numbers corresponding to internal VLAN interfaces allocated to a routed port. VLAN interfaces corresponding to SVIs allocated to a routed port cannot be configured by VLAN interface configuration mode commands.

**Command Mode**

EXEC

**Command Syntax**

`show vlan internal usage`

**Example**

This command displays the VLANs that are allocated to routed ports.

```
switch>show vlan internal usage
1006  Ethernet3
1007  Ethernet4
switch>
```
12.3.4.21  show vlan trunk group

The `show vlan trunk group` command displays the trunk group membership of the specified VLANs.

**Command Mode**
EXEC

**Command Syntax**
```
show vlan [VLAN_LIST] trunk group
```

**Parameters**
- **VLAN_LIST**  VLAN list. Options include:
  - `no parameter`  all VLANs.
  - `v_range`  VLANs specified by `v_range`.
  - `id v_range`  VLANs specified by `v_range`.
  - `name v_name`  VLANs specified by the VLAN name `v_name`.

**Display Values**
- **VLAN**  VLAN ID.
- **Trunk Groups**  Trunk groups associated with the listed VLANs.

**Example**
This command displays the trunk group membership of all configured VLANs.

```
switch>show vlan trunk group
VLAN  Trunk Groups
-----  ------------------------------
  5    first_group
 10    second_group
 12    third_group
 101   middle_group
 102
 200

switch>
```
show vlan

The `show vlan` command displays the VLAN ID, name, status, and member ports of all configured VLANs. The command only displays active ports by default; by specifying `configured-ports`, the command displays all ports that are members of a configured VLAN regardless of their activity status, including Ethernet ports that are members of a port channel.

**Command Mode**

EXEC

**Command Syntax**

`show vlan [VLAN_LIST] [PORT_ACTIVITY]`

**Parameters**

- **VLAN_LIST** List of VLANs displayed by command. Options include:
  - `no parameter` all VLANs.
  - `v_range` VLANs specified by `v_range`.
  - `id v_range` VLANs specified by `v_range`.
  - `name v_name` VLANs specified by the VLAN name `v_name`.

  `v_range` formats include number, number range, or comma-delimited list of numbers and ranges.

- **PORT_ACTIVITY** Ports listed in table. Options include:
  - `no parameter` table displays only active ports (same as `active-configuration` option).
  - `active-configuration` table displays only active ports.
  - `configured-ports` table displays all configured ports.

**Display Values**

- **VLAN** The VLAN ID.
- **Name** The name of the VLAN.
- **Status** The status of the VLAN.
- **Ports** The ports that are members of the VLAN.

**Examples**

- This command displays status and ports of VLANs `1-1000`.

```
switch>show vlan 1-1000
VLAN  Name                     Status    Ports
----- ------------------------ --------- --------------
 1     default                  active    Po1
184   fet.arka                 active    Cpu, Po1, Po2
262   mgq.net                  active    PPo2, Po1
512   sant.test                active    Cpu, Et16, Po1
821   ipv6.net                 active    Cpu, Po1, Po7
switch>
```

- This command displays the list of all the member interfaces under each SVI.

```
switch#show vlan
VLAN  Name                     Status    Ports
----- ------------------------ --------- ----------------
 1     default                  active
1248  VLAN2148                 active    Cpu, Et1, Et26
2700  VLAN2700                 active    Cpu, Et18
```
12.3.4.23  state

The state command configures the VLAN transmission state of the configuration mode VLAN.

- **Active state**: Ports forward VLAN traffic.
- **Suspend state**: Ports block VLAN traffic.

The default transmission status is active.

The no state command restores the default VLAN transmission state to the configuration mode VLAN by removing the corresponding state command from running-config.

**Command Mode**

VLAN Configuration

**Command Syntax**

```
state OPERATION_STATE
no state
default state
```

**Parameters**

- **OPERATION_STATE**: VLAN transmission state. Options include:
  - **active**: VLAN traffic is forwarded.
  - **suspend**: VLAN traffic is blocked.

**Example**

These commands suspend VLAN traffic on VLANs 100-102.

```
switch(config)#vlan 100-102
switch(config-vlan-100-102)#state suspend
switch(config-vlan-100-102)#
```
**12.3.4.24  switchport access vlan**

The `switchport access vlan` command specifies the access VLAN of the configuration mode interface. Ethernet or port channel interfaces that are in access mode are members of only the access VLAN. Untagged frames that the interface receives are associated with the access VLAN. Frames tagged with the access VLAN are also associated with the access VLAN. The interface drops all other tagged frames that it receives. By default, VLAN 1 is the access VLAN of all Ethernet and port channel interfaces.

An interface’s access mode is effective only when the interface is in access mode or dot1q-tunnel mode, as specified by the switchport mode command. Interfaces in dot1q-tunnel mode handle inbound traffic as untagged traffic and associate all traffic with the access VLAN. Interfaces configured to switchport trunk mode maintain and ignore existing switchport access commands.

The `no switchport access vlan` and `default switchport access vlan` commands restore VLAN 1 as the access VLAN of the configuration mode interface by removing the corresponding `switchport access vlan` statement from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-channel Configuration

**Command Syntax**

- `switchport access vlan v_num`
- `no switchport access vlan`
- `default switchport access vlan`

**Parameters**

- `v_num` number of access VLAN. Value ranges from 1 to 4094. Default is 1.

**Example**

These commands assign VLAN 100 as the access VLAN to `interface ethernet 5`.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport access vlan 100
switch(config-if-Et5)#
```
12.3.4.25  switchport dot1q ethertype

The `switchport dot1q ethertype` command configures the tag protocol identifier (TPID, also known as a dot1q ethertype), of the configuration mode interface. By default, all switch ports use the standard TPID of `0x8100`.

The `no switchport dot1q ethertype` and `default switchport dot1q ethertype` commands restore the TPID to `0x8100` by removing the corresponding `switchport dot1q ethertype` statement from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
switchport dot1q ethertype ethertype
no switchport dot1q ethertype
default switchport dot1q ethertype
```

**Parameters**

`ethertype`  
ethertype number (TPID). Value ranges from `0x600 (1536)` through `0xFFFF (65535)`, and can be entered in decimal or hexadecimal notation. Value is stored and displayed in hexadecimal form; the default value is `0x8100`.

**Example**

These commands configure `0x9100` as the TPID of `interface ethernet 5`.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport dot1q ethertype 0x9100
switch(config-if-Et5)#
```
The `switchport mode` command specifies the switching mode of the configuration mode interface. The switch supports five switching modes: access, trunk, dot1q-tunnel, tap, and tool.

- **Access switching mode**: The interface is a member of one VLAN, called the access VLAN, as specified by the `switchport access vlan` command. Tagged frames received on the interface are dropped unless they are tagged with the access VLAN. Frames transmitted from the interface are always untagged.
- **Trunk switching mode**: The interface may be a member of multiple VLANs, as configured by the `switchport trunk allowed vlan` command. Untagged traffic is associated with the interface's native VLAN, as configured with the `switchport trunk native vlan` command.
- **Dot1q-tunnel switching mode**: The interface treats all inbound packets as untagged traffic and handles them as traffic of its access VLAN, as specified by the `switchport access vlan` command.
- **Tap mode**: The interface operates as a tap port. Tap ports receive traffic for replication on one or more tool ports. The interface may be a member of multiple VLANs, as configured by the `switchport tap allowed vlan` command. Untagged traffic is associated with the interface's native VLAN, as configured with the `switchport tap native vlan` command.

Tap ports are in STP forwarding state and prohibit egress traffic. MAC learning, control plane interaction and traps for inbound traffic are disabled.

- **Tool mode**: The interface operates as a tool port. Tool ports replicate traffic received by tap ports. The interface may be a member of multiple VLANs, as configured by the `switchport tool allowed vlan` command. MAC learning, control plane interaction and traps for inbound traffic are disabled.

Tool ports are in STP forwarding state and prohibit ingress traffic that uses port settings.

The status of switchport configured ports depends on the switch’s tap aggregation mode (which can be viewed by using the `mode` command):

- tap aggregation mode enabled: tap and tool ports are enabled. Switching ports are errdisabled.
- tap aggregation mode disabled: tap and tool ports are errdisabled. Switching ports are enabled.

The `no switchport mode` and `default switchport mode` commands return the configuration mode interface to its default setting as an access port by deleting the corresponding `switchport mode` command from `running-config`.

**Command Mode**
Interface-Ethernet Configuration  
Interface-Port-channel Configuration

**Command Syntax**

```
switchport mode MODE_TYPE  
no switchport mode  
default switchport mode
```

**Parameters**

- **MODE_TYPE**: switching mode of the configuration mode interfaces. Options include:
  - `access` access switching mode.
  - `dot1q-tunnel` dot1q-tunnel switching mode.
  - `tap` tap switching mode.
  - `tool` tool switching mode.
  - `trunk` trunk switching mode.

**Restrictions**

- **Dot1q-tunnel** switching mode is not available on Petra platform switches.
**Tap** aggregation (tap and tool modes) is available on FM6000 and Arad platform switches.

**Example**

These commands configure *interface ethernet 4* as a trunk port.

```
switch(config)#interface ethernet 4
switch(config-if-Et4)#switchport mode trunk
switch(config-if-Et4)#
```
switchport trunk allowed vlan

The `switchport trunk allowed vlan` command creates or modifies the list of VLANs for which the configuration mode interface, in trunk mode, handles tagged traffic. By default, interfaces handle tagged traffic for all VLANs. Command settings persist in `running-config` without taking effect when the switch is in tap aggregation mode or the interface is not in trunk mode.

The `no switchport trunk allowed vlan` and `default switchport trunk allowed vlan` commands restore the trunk mode default allowed VLAN setting of all by removing the corresponding `switchport trunk allowed vlan` statement from `running-config`.

Command Mode
Interface-Ethernet Configuration
Interface-Port-channel Configuration

Command Syntax

```
switchport trunk allowed vlan EDIT_ACTION
no switchport trunk allowed vlan
default switchport trunk allowed vlan
```

Parameters

**EDIT_ACTION** modifications to the VLAN list.

- `v_range` Creates VLAN list from `v_range`.
- `add v_range` Adds specified VLANs to current list.
- `all VLAN list contains all VLANs.
- `except v_range` VLAN list contains all VLANs except those specified.
- `none VLAN list is empty (no VLANs).
- `remove v_range` Removes specified VLANs from current list.

Valid `v_range` formats include number, range, or comma-delimited list of numbers and ranges.

Example

These commands create the trunk mode allowed VLAN list of 6-10 for `interface ethernet 14`, then verifies the VLAN list.

```
switch(config)#interface ethernet 14
switch(config-if-Et14)#switchport trunk allowed vlan 6-10
switch(config-if-Et14)#show interfaces ethernet 14 switchport
Name: Et14
Switchport: Enabled
Administrative Mode: trunk
Operational Mode: trunk
Access Mode VLAN: 1 (inactive)
Trunking Native Mode VLAN: 1 (inactive)
Administrative Native VLAN tagging: disabled
Trunking VLANs Enabled: 6-10
Trunk Groups:
```

```
12.3.4.28 switchport trunk group

The switchport trunk group command assigns the configuration mode interface to the specified trunk group. Trunk group ports handle traffic of the VLANs assigned to the group.

The no switchport trunk group and default switchport trunk group commands remove the configuration mode interface from the specified trunk group by deleting the corresponding statement from running-config. If the command does not specify a trunk group, the interface is removed from all trunk groups to which it is assigned.

Note: On platforms which support the use of port channels as mirror destinations, a port channel which is being used as a mirror destination must not be assigned to an MLAG.

Command Mode
Interface-Ethernet Configuration
Interface-Port-channel Configuration

Command Syntax
switchport trunk group [group_name]
no switchport trunk group [group_name]
default switchport trunk group [group_name]

Parameters

- **group_name**: trunk group name.

Example
These commands assign port channel 4 to trunk group fe-1.

```
switch(config)#interface port-channel 4
switch(config-if-Po4)#switchport trunk group fe-1
switch(config-if-Po4)#
```
switchport trunk native vlan

The `switchport trunk native vlan` command specifies the trunk mode native VLAN for the configuration mode interface. Interfaces in trunk mode associate untagged frames with the native VLAN. Trunk mode interfaces can also be configured to drop untagged frames. The default native VLAN for all interfaces is VLAN 1.

The `no switchport trunk native vlan` and `default switchport trunk native vlan` commands restore VLAN 1 as the trunk mode native VLAN to the configuration mode interface by removing the corresponding `switchport trunk native vlan` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-channel Configuration

**Command Syntax**

```
switchport trunk native vlan VLAN_ID
no switchport trunk native vlan
default switchport trunk native vlan
```

**Parameters**

- **VLAN_ID** the ID of the native VLAN. Options include:
  - `v_num` VLAN number. Value ranges from 1 to 4094.
  - `tag` interface drops all untagged frames.

**Example**

These commands configure VLAN 100 as the native VLAN for port channel 21.

```
switch(config)#interface port-channel 21
switch(config-if-Po21)#switchport trunk native vlan 100
switch(config-if-Po21)#
```
12.3.4.30  switchport vlan forwarding

The `switchport vlan forwarding` command forwards packets between the ports belonging to VLAN in the interface configuration mode. The scaling configuration is applicable on a per-port basis. In the 7160 platform, the hardware uses a Port-VLAN table for storing the configuration on a per port/VLAN combination and supports a maximum of 128 ports.

Note: The configuration is applicable to trunk ports only.

Command Mode
Interface-Ethernet Configuration

Command Syntax

```
switchport vlan forwarding accept | all
```

Parameters
- accept  accepts packets for VLAN.
- all      all VLANs.

Example
This command forwards and accepts all the packets of VLAN of `interface ethernet 2`.

```
switch(config)#interface ethernet 2
switch(config-if-Et2)#switchport vlan forwarding accept all
switch(config-if-Et2)#
```
12.3.4.31  switchport vlan translation

The `switchport vlan translation` command allows you to map packets from one VLAN to another using VLAN translation. This is carried out on packets having a dot1q header (tagged frames) only. The translation rewrites the VLAN ID (VID) field in dot1q headers on packets passing through a switched port without changing any other fields.

By default, the translation is bidirectional. The packets ingressing an interface through VLAN A are internally mapped to VLAN B; VLAN B packets egressing the same interface are mapped to VLAN A.

To use VLAN translation on a switched port, the port must be configured as a trunk port using the `switchport mode` command.

VLAN translation on routed ports is accomplished through the `encapsulation dot1q vlan` command.

The `no switchport vlan translation` and `default switchport vlan translation` commands remove VLAN mapping by removing the switchport vlan translation command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-channel Configuration

**Command Syntax**

```bash
switchport vlan translation [DIRECTION] incoming_vlanid new_vlanid
no switchport vlan translation incoming_vlanid new_vlanid
no switchport vlan translation DIRECTION incoming_vlanid
default switchport vlan translation incoming_vlanid new_vlanid
default switchport vlan translation DIRECTION incoming_vlanid
```

**Parameters**

- **DIRECTION** direction of traffic to be translated.
  - `no parameter` translates the specified VLAN IDs for transmitted and received traffic.
  - `in` translates the specified VLAN IDs for received traffic only.
  - `out` translates the specified VLAN IDs for transmitted traffic only.
  - `incoming_vlanid` Enter the VLAN ID to be translated. Value ranges from 1 to 4094.
  - `new_vlanid` The new VLAN ID or bridging VLAN ID that will be used internally. Value ranges from 1 to 4094.

**Example**

- These commands translate only incoming packets, changing the VLAN ID to 2008 in the dot1q header of packets ingressing on `vlan 201`.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport vlan translation in 201 2008
switch(config-if-Et5)#
```

- These commands translate multiple VLAN mappings on an `interface ethernet 5`.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#switchport vlan translation 50 60
switch(config-if-Et5)#switchport vlan translation 61 71
switch(config-if-Et5)#switchport vlan translation 62 72
switch(config-if-Et5)#
```
12.3.4.32 trunk group

The `trunk group` command assigns the configuration mode VLAN to a specified trunk group.

A trunk group is the set of physical interfaces that comprise the trunk and the collection of VLANs whose traffic is carried on the trunk. The traffic of a VLAN that belongs to one or more trunk groups is carried only on ports that are members of trunk groups to which the VLAN belongs. Switchport commands specify the physical interfaces that carry trunk group traffic.

The `no trunk group` and `default trunk group` commands remove the configuration mode VLAN from the specified trunk group by removing the corresponding `trunk group` statement from `running-config`. If a trunk group is not specified, the commands remove the configuration mode VLAN from all trunk groups.

**Command Mode**

VLAN Configuration

**Command Syntax**

```
trunk group [name]
no trunk group [name]
default trunk group [name]
```

**Parameters**

`name` a name representing the trunk group.

**Example**

These commands assigns `VLAN 49` to the trunk group `mlagpeer`.

```
switch(config)#vlan 49
switch(config-vlan-49)#trunk group mlagpeer
switch(config-vlan-49)#
```
12.4 DCBX and Flow Control

This section describes Data Center Bridging Capability Exchange (DCBX) configuration tasks. Topics in this section include:

- Introduction
- Overview
- DCBX Configuration and Verification
- Configuring Priority-Flow-Control (PFC)
- Configuring PFC Watchdog
- DCBX and Flow Control Commands

12.4.1 Introduction

EOS implements Link Layer Discovery Protocol (LLDP) and the Data Center Bridging Capability Exchange (DCBX) protocol to help automate the configuration of Data Center Bridging (DCB) parameters, including the Priority-Based Flow Control (PFC) standard, which allows an end-to-end flow-control feature.

This feature enables a switch to recognize when it is connected to an iSCSI device and automatically configure the switch link parameters (such as priority flow control) to provide optimal support for that device. DCBX can be used to prioritize the handling of iSCSI traffic to help ensure that packets are not dropped or delayed. DCBX is off by default.

12.4.2 Overview

12.4.2.1 Data Center Bridging Capability Exchange (DCBX)

DCBX works with LLDP to allow switches to exchange information about their data center bridging (DCB) capabilities and configuration and automatically negotiate common Priority-Based Flow Control (PFC) parameters.

Data is exchanged in Type-Length-Value (TLV) format. For DCBX to function on an interface LLDP must be enabled on that interface as well.

12.4.2.2 Priority-Based Flow Control (PFC)

Priority-Based Flow Control (PFC) uses a new control packet defined in IEEE 802.1Qbb and is not compatible with 802.3x Flow Control (FC). An interface that is configured for PFC will be disabled for FC. When PFC is disabled on an interface, the FC configuration for the interface becomes active. Any FC frames received on a PFC configured interface are ignored.

Each priority is configured as either drop or no-drop. If a priority that is designated as no-drop is congested, the priority is paused. Drop priorities do not participate in pause.

When PFC is disabled, the interface defaults to the IEEE 802.3x flow control setting for the interface. PFC is disabled by default.

12.4.2.3 PFC Watchdog

The PFC watchdog identifies the egress queues that are unable to transmit packets for a long time due to receiving continuous PFC pause frames. On identifying such stuck tx-queue PFC watchdog error-disables the respective port with a error-disable reason of stuck-queue. When there is an error reported on a port the traffic is re-routed through a different port to the destination.

The PFC watchdog supports the following PFC watchdog configurations:

- PFC watchdog forced recovery of queues
• PFC watchdog polling interval configuration
• PFC Watchdog non-disruptive priorities configuration
• Displaying stuck queue and recovery counters

12.4.3 DCBX Configuration and Verification

12.4.3.1 Set the Priority Rank to the Traffic Class

The `dcbx application priority` command assigns a priority rank to the specified traffic class in the application priority table. This table is transmitted on each DCBX-enabled interface.

Examples

• These commands tell the DCBX peer that iSCSI frames (TCP ports 860 and 3260) should be assigned the given priority of 5.

  switch(config)#dcbx application tcp-sctp 860 priority 5
  switch(config)#dcbx application tcp-sctp 3260 priority 5

• These commands specify a different priority for the two iSCSI traffic ports.

  switch(config)# dcbx application tcp-sctp 860 priority 3
  switch(config)# dcbx application tcp-sctp 3260 priority 4

• This command is equivalent to the `dcbx application tcp-sctp` command. The DCBX peer that iSCSI frames are assigned are the given the priority 5.

  switch(config)#dcbx application iscsi priority 5
  switch(config)#

• These commands prevent the peers from sending anything about the iSCSI frames.

  switch(config)#no dcbx application tcp-sctp 860 priority 5
  switch(config)#no dcbx application tcp-sctp 3260 priority 5

12.4.3.2 Configuring CEE DCBX Priority Group

The `priority-flow-control priority` command configures the Enhanced Transmission Selection (ETS) to the specified QoS group, and sets the traffic class priority and the bandwidth percentage for the packets in the traffic class.

Examples

• This command configures the ETS to the QoS group map and assigns the CoS map value as 7 and sets traffic class priority to 5.

  switch(config)#dcbx ets qos map cos 7 traffic-class 5

• This command configures the ETS to the traffic class and sets the traffic class priority as 7 and bandwidth value to 70 percent.

  switch(config)#dcbx ets traffic-class 7 bandwidth 70

12.4.3.3 DCBX Verification

To display the DCBX status and the interfaces on which DCBX is enabled, use the `show dcbx` command.

Example
This command displays the DCBX status for Ethernet 50.

```
switch#show dcbx Ethernet 50
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:06:01 2013
  No priority flow control configuration TLV received
  No application priority configuration TLV received
switch#
```

### 12.4.4 Configuring Priority-Flow-Control (PFC)

#### 12.4.4.1 Enable Priority-Flow-Control (PFC)

The `priority-flow-control` command enables Priority-Flow-Control (PFC) on an individual port.

**Example**

The `priority-flow-control` command in DCBX mode enables PFC on an interface.

```
switch(config)#interface ethernet 2
switch(config-if-Et2)#priority-flow-control on
```

#### 12.4.4.2 Set the Priority Flow Control Priority

The `priority-flow-control priority` command in DCBX mode creates a priority group that pauses priority. Each priority is configured as either drop or no-drop. If a priority that is designated as no-drop is congested, the priority is paused. Drop priorities do not participate in pause.

**Examples**

- The `priority-flow-control priority` command in DCBX mode creates a priority group that pauses priority 5 on `interface ethernet 2`.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control on
  switch(config-if-Et2)#priority-flow-control priority 5 no-drop
  ```

- To enable lossy behavior, use the drop option of the `priority-flow-control priority` command.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control on
  switch(config-if-Et2)#priority-flow-control priority 5 drop
  ```

#### 12.4.4.3 Disable Priority-Flow-Control (PFC)

To disable Priority Flow Control (PFC) on the configuration mode interface and restore the default packet drop setting on the interface, use the `priority-flow-control priority` command.

**Example**

To disable PFC, use the `no priority-flow-control` command.

```
switch (config)#interface ethernet 2
switch(config-if-Et2)#no priority-flow-control
```
12.4.5 Configuring PFC Watchdog

12.4.5.1 Enabling PFC Watchdog

The `priority-flow-control pause watchdog default timeout` command starts monitoring all the egress queues which have guaranteed bandwidth enabled and for the priorities on which PFC is enabled.

**Note:** To enable PFC watchdog, user is required to configure guaranteed bandwidth on the tx-queue to be monitored. Also, PFC must be enabled on the port for the traffic flowing into the queue that is being monitored.

**Example**

These commands enable the PFC watchdog monitoring on tx-queue 3 of Ethernet 1/1, and configures a PFC congestion timeout of 10 seconds which error-disables the port if the queue is stuck.

```
switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1)#exit
switch(config)#priority-flow-control pause watchdog default timeout 10
```

12.4.5.2 Enabling PFC Watchdog Queue Recovery

The `priority-flow-control pause watchdog default recovery-time forced` command recovers a stuck queue after the PFC storm ceases. PFC watchdog supports the following two recovery methods.

- Auto Recovery – recover queue(s) after the PFC storm ceases.
- Forced Recovery – recover queue(s) after a fixed duration, irrespective of PFC storm being received.

**Note:** The default recovery mode is “auto”.

**Example**

This command recovers a stuck queue after a fixed duration of 10 seconds.

```
switch(config)#priority-flow-control pause watchdog default recovery-time 10 forced
```

12.4.5.3 Configuring PFC Watchdog Polling Interval

The `priority-flow-control pause watchdog default polling-interval` command configures the frequency at which queues should be checked for stuck or recovery detection. By default, polling interval is calculated internally or it considers the value configured through the CLI.

**Note:** Configuring a very low polling interval may increase load on the CPU.

**Example**

This command configures a polling interval of 10 seconds on the switch.

```
switch(config)#priority-flow-control pause watchdog default polling-interval 10
```
12.4.5.4 Displaying Stuck Queue and Recovery Counters

The `show priority-flow-control counters watchdog` command displays the value of number of times a queue is identified as stuck and recovered. These counters are maintained only for those queues that have PFC watchdog functionality enabled. These counters are cleared when either PFC or PFC watchdog configuration is disabled. Alternatively, `show interfaces priority-flow-control counters watchdog` command can be used to display the counters.

Examples

- This command displays the value of number of times the queue was stuck and recovered for all the interfaces.

```
switch#show priority-flow-control counters watchdog
Port   TxQ   Total times stuck   Total times recovered
------- ----   -----------   -----------
Et1/1   UC2     2             2
Et1/1   UC3     3             3
Et2/1   UC2    12            12
Et2/1   UC3    31            30
```

- This command displays the value of number of times the queue was stuck and recovered for a specific interface. In this case it is `Et1/1`.

```
switch#show priority-flow-control interfaces Ethernet 1/1 counters watchdog
Port   TxQ   Total times stuck   Total times recovered
------- ----   -----------   -----------
Et1/1   UC2     2             2
Et1/1   UC3     3             3
```

12.4.5.5 PFC Watchdog Non-disruptive Priorities

The PFC Watchdog acts to drop the traffic entering or leaving the port at the stuck PFC priority. Later when the queue recovers, this action is reversed. While applying these actions, some traffic (for all priorities) is dropped on that port. In such case, the `priority-flow-control pause watchdog hardware non-disruptive priority` command can be used to avoid the traffic drop on ports at stuck queues.

This traffic drop can be avoided by configuring specific PFC priorities as non-disruptive. When queues corresponding to these priorities are stuck/recovered, the traffic for other priorities are not impacted.

Examples

- This command configures the specific PFC priorities as non-disruptive, and the priority is set to 3.

```
switch(config)#priority-flow-control pause watchdog hardware non-disruptive priority 3
```

- This command configures all the ports, having a subset of non-disruptive priorities as a part of their no-drop priorities, start in non-disruptive mode.

```
switch(config)#priority-flow-control pause watchdog hardware port non-disruptive-only
```

12.4.5.6 Displaying PFC Watchdog Information

The `show priority-flow-control` command displays the PFC watchdog status information. Note, if the PFC watchdog default timeout value is non-zero then PFC watchdog is active on the switch.
**Example**

This command displays the PFC watchdog default timeout value, in this show example the timeout value is **3.0** which means the PFC watchdog is active.

```
switch#show priority-flow-control
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
The PFC watchdog default timeout is 3.0

<table>
<thead>
<tr>
<th>Port</th>
<th>Enabled</th>
<th>Priorities</th>
<th>Active Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1/1</td>
<td>Yes</td>
<td>34</td>

<td>34</td>
<td>Yes DCBX disabled</td>
</tr>
<tr>
<td>Et1/4</td>
<td>Yes</td>
<td>34</td>
<td>Yes DCBX disabled</td>
</tr>
</tbody>
</table>
```

The **show interface status errdisabled** command displays the port which is error-disabled due to stuck-queue condition.

**Example**

This command displays the interface Ethernet **Eth1/1** status as errdisabled and the reason.

```
switch#show interface Eth1/1 status errdisabled
```

```
<table>
<thead>
<tr>
<th>Port</th>
<th>Name</th>
<th>Status</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1/1</td>
<td>errdisabled</td>
<td></td>
<td>stuck-queue</td>
</tr>
</tbody>
</table>
```

The **show priority-flow-control status** command displays the current PFC watchdog details.

**Example**

This command displays the PFC watchdog configuration details at global and interface level.

```
switch#show priority-flow-control status
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
The PFC watchdog timeout is 1.0 second(s)
The PFC watchdog recovery-time is 2.0 second(s) (auto)
The PFC watchdog polling-interval is 0.1 second(s)
The PFC watchdog non-disruptive priorities are 3 4
The PFC watchdog port non-disruptive-only is False

E: PFC Enabled, D: PFC Disabled, A: PFC Active, W: PFC Watchdog Enabled

..
12.4.6  DCBX and Flow Control Commands

Configuration Commands

- dcbx application priority
- dcbx ets
- dcbx mode
- no priority-flow-control
- platform fm6000 pfc-wm
- priority-flow-control
- priority-flow-control pause watchdog action
- priority-flow-control pause watchdog default
- priority-flow-control pause watchdog hardware
- priority-flow-control priority

Show Commands

- show dcbx
- show dcbx application-priority-configuration
- show dcbx priority-flow-control-configuration
- show dcbx status
- show interfaces priority-flow-control
- show platform fm6000 pfc-wm
- show priority-flow-control
12.4.6.1  dcbx application priority

The `dcbx application priority` command assigns a priority rank to the specified traffic class in the application priority table. This table is transmitted on each DCBX-enabled interface.

The `no dcbx application priority` and `default dcbx application priority` commands remove the specified DCBX traffic class priority assignment by deleting the corresponding `dcbx application priority` command from `running-config`. When the command does not specify a traffic class, all DCBX traffic class priority assignments are removed.

**Command Mode**

Global Configuration

**Command Syntax**

```
dcbx application [APPLICATION_TYPE] priority rank
no dcbx application [APPLICATION_TYPE] priority
default dcbx application [APPLICATION_TYPE] priority
```

**Parameters**

- **APPLICATION_TYPE** traffic class receiving the priority assignment. Options include:
  - `ether ethertype_number` Ethernet traffic. `ethertype_number` varies from 1536 to 65535.
  - `iscsi` iSCSI traffic. Maps to TCP/SCTP ports 860 and 3260.
  - `tcp-sctp port_number` TCP/SCTP traffic. Port number varies from 1 to 65535.
  - `tcp-sctp-udp port_number` TCP/SCTP/UDP traffic. Port number varies from 1 to 65535.
  - `udp port_number` UDP traffic. Port number varies from 1 to 65535.
- **rank** priority assigned to traffic class. Values range from 0 to 7.

**Examples**

- These commands tell the DCBX peer that iSCSI frames (TCP ports 860 and 3260) should be assigned the given priority of 5.

  ```
  switch(config)#dcbx application tcp-sctp 860 priority 5
  switch(config)#dcbx application tcp-sctp 3260 priority 5
  ``

- These commands specify a different priority for the two iSCSI traffic ports.

  ```
  switch(config)#dcbx application tcp-sctp 860 priority 3
  switch(config)#dcbx application tcp-sctp 3260 priority 4
  ``

- This command is equivalent to the `dcbx application tcp-sctp` command. The DCBX peer that iSCSI frames are assigned to is given priority 5.

  ```
  switch(config)#dcbx application iscsi priority 5
  switch(config)#
  ``

- These commands prevent the peers from sending anything about the iSCSI frames.

  ```
  switch(config)#no dcbx application tcp-sctp 860 priority
  switch(config)#no dcbx application tcp-sctp 3260 priority
  ```
12.4.6.2  dcbx ets

The `dcbx ets` command configures the enhanced transmission selection (ETS) to the specified QoS group, and sets the traffic class priority and the bandwidth percentage for the packets in the traffic class.

The `no dcbx ets` and `default dcbx ets` commands remove the specified DCBX traffic class priority assignment by deleting the corresponding `dcbx ets` command from the `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
dcbx ets [qos map cos value traffic-class value [traffic-class value bandwidth value]]
no dcbx ets [qos map cos value traffic-class value [traffic-class value bandwidth value]]
default dcbx ets [qos map cos value traffic-class value [traffic-class value bandwidth value]]
```

**Parameters**

- `qos` QoS to configure. (The sub options include):
  - `map` QoS map to configure.
  - `cos` CoS value assigned to port. Value ranges from 0 to 7. Default value is 0.
  - `traffic-class` Assigns the traffic-class priority to the QoS map. The value ranges from 0 to 7.
  - `traffic-class` Assigns the traffic class priority. The value ranges from 0 to 7. (The sub options include):
    - `bandwidth` The percentage of bandwidth assigned to the packets received from traffic class. The value ranges from 0 to 100 in percentage. The default value is 0.

**Examples**

- This command configures the ETS to the QoS group map and assigns the CoS map value as 7 and sets the traffic class priority to 5.

  ```
  switch(config)#dcbx ets qos map cos 7 traffic-class 5
  ```

- This command configures the ETS to the traffic class and sets the traffic class priority value to 7 and sets the bandwidth value to 70 percent.

  ```
  switch(config)#dcbx ets traffic-class 7 bandwidth 70
  ```
12.4.6.3  `dcbx mode`

The `dcbx mode` command enables DCBX mode on the configuration mode interface. The switch supports **IEEE P802.1Qaz**. When DCBX is enabled, two TLVs are added to outgoing LLDPDUs, which instruct the peer on the interface to configure PFC (priority flow control) and the application priority table in the same way as the switch.

The `no dcbx mode`, `default dcbx mode`, and `dcbx mode none` commands disable DCBX on the configuration mode interface by removing the corresponding `dcbx mode` command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

`dcbx mode MODE_NAME`
`no dcbx mode`
`default dcbx mode`

**Parameters**

**MODE_NAME** Specifies the DCBX version. Options include:

- `ieee` IEEE version.
- `cee` Converged Enhanced Ethernet version.
- `none` DCBX is disabled.

**Examples**

- These commands enable `interface ethernet 2` to use IEEE DCBX.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#dcbx mode ieee
  switch(config-if-Et2)#
  ```

- These commands disable DCBX on `interface ethernet 2`.

  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#dcbx mode none
  switch(config-if-Et2)
  ```
12.4.6.4 no priority-flow-control

The **no priority-flow-control** and **default priority-flow-control** commands disable the priority flow control (PFC) on the configuration mode interface and restore the default packet drop setting on the interface, which takes effect when PFC is re-enabled. The commands delete all corresponding **priority-flow-control** commands from **running-config**.

**Command Mode**
Interface-Ethernet Configuration

**Command Syntax**

- **no priority-flow-control**
- **default priority-flow-control**

**Example**

These commands disable Priority Flow Control (PFC) on **interface Ethernet 3**.

```
switch(config)#interface Ethernet 3
switch(config-if-Et3)#no priority-flow-control
switch(config-if-Et3)#
```
12.4.6.5 platform fm6000 pfc-wm

The platform fm6000 pfc-wm command configures the hardware buffer space allocated to the Priority Flow Control (PFC) RX-Private buffer. The command provides options to configure the buffer size and specify when PFC frames are sent to request that a neighbor stop sending traffic. The default values are as follows:

- RX-Private: 18400 bytes
- on (watermark): 9280 bytes
- off (watermark): 1600 bytes

Values that are entered in the command are rounded up to the closest multiple of 160. The RX-Private value must be greater than the off value, which must be larger than the on value.

The no platform fm6000 pfc-wm and default platform fm6000 pfc-wm commands restore the default settings by removing the platform fm6000 pfc-wm command from running-config.

Command Mode
Global Configuration

Command Syntax
platform fm6000 pfc-wm [RX-PRIVATE_SIZE] [PFC-ON_WM] [PFC-OFF_WM]
no platform fm6000 pfc-wm
default platform fm6000 pfc-wm

The platform fm6000 pfc-wm command must explicitly configure at least one parameter.

Parameters
- RX-PRIVATE_SIZE Specifies size of rx-private buffer. Options include:
  - no parameter rx-private buffer retains previously configured size.
  - rx-private 18268 to 102400 Size of rx-private buffer (bytes).
- PFC-ON_WM Buffer capacity that triggers the switch to send PFC frames. Options include:
  - no parameter Parameter retains previously configured value.
  - on 9134 to 102400 Buffer capacity that triggers PFC frames (bytes).
- PFC-OFF_WM Buffer capacity that triggers the switch to stop PFC frame transmissions. Options include:
  - no parameter Parameter retains previously configured value.
  - off 1536 to 102400 Buffer capacity that turns off PFC frames.

Related Command
show platform fm6000 pfc-wm displays the PFC RX-Private buffer memory allocations.

Example
This command configures the rx-private hardware buffer.

```
switch(config)#platform fm6000 pfc-wm rx-private 24800 on 16000 off 3200
switch(config)#
```
12.4.6.6 priority-flow-control pause watchdog action

The priority-flow-control pause watchdog action command either drops the traffic on a stuck queue, or error disables the port which has a stuck queue, or notifies if there is no action on the stuck queue. The following actions are performed based on the queue status.

The no priority-flow-control pause watchdog action command removes the specified priority-flow-control pause watchdog action configuration by deleting the corresponding priority-flow-control pause watchdog action command from running-config.

Command Mode
Global Configuration

Command Syntax
priority-flow-control pause watchdog action
no priority-flow-control pause watchdog action

Parameters
action PFC watchdog action for stuck transmit queues. Options include.
  • drop Drop traffic on the stuck queue.
  • errdisable Error disable port which has the stuck transmit queue.
  • notify-only No action on the stuck queue.

Guidelines
Before enabling the PFC watchdog configuration, configure the guaranteed bandwidth on the tx-queue to be monitored. Also, enable the PFC on the port for the PFC priorities for the traffic flowing into the queue that is being monitored.

Example
These commands enables the pfc-watchdog monitoring on tx-queue 3 of Ethernet 1/1, and configures a PFC watchdog action drop and drops the traffic if the queue is a stuck queue.

switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1)#exit
switch(config)#priority-flow-control pause watchdog action drop
12.4.6.7  priority-flow-control pause watchdog default

The `priority-flow-control pause watchdog default` command monitors all the egress queues which have guaranteed bandwidth enabled and for the priorities on which PFC is enabled. Guaranteed bandwidth is needed to ensure starvation due to higher priority traffic is not wrongly flagged as a stuck-queue due to congestion. The stuck duration after which the port needs to be error disabled is also configurable.

The `no priority-flow-control pause watchdog default` command removes the specified priority-flow-control pause watchdog configuration by deleting the corresponding `priority-flow-control pause watchdog` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

`priority-flow-control pause watchdog default`

`no priority-flow-control pause watchdog default`

**Parameters**

default Specifies the default value. Options include.

- **polling-interval** Configures the interval at which the watchdog should poll the queues. The polling interval value ranges from **0.005** to **30** seconds.

- **recovery-time** Configures recovery-time after which stuck queue should recover and start forwarding. The recovery-time value ranges from **0.01** to **60** seconds.

  - **forced** Force recover any stuck queue(s) after the recovery-time interval, irrespective of whether PFC frames are being received or not.

  - **timeout** Configures timeout after which port should be errdisabled or should start dropping on congested priorities. The timeout value ranges from **0.01** to **60** seconds.

**Guidelines**

Before enabling the PFC watchdog configuration, configure the guaranteed bandwidth on the tx-queue to be monitored. Also, enable the PFC on the port for the PFC priorities for the traffic flowing into the queue that is being monitored.

- **Polling Interval Discrepancy**

  For user configured polling-interval to be valid, it must satisfy the following conditions

  When the recovery-mode is auto and timeout, recovery-time, and polling-interval are non-default, polling-interval <= min (timeout, recovery-time) / 2,

  When recovery-mode is forced or recovery-time is not configured, polling-interval <= (timeout / 2)

  For better functioning of PFC Watchdog, when user configured polling interval is too large compared to either timeout or recovery time values, Watchdog will use auto calculated value instead of user configured value until the discrepancy is resolved. Also, CLI warning and syslog messages are generated to inform user of the discrepancy.

- **CLI Warnings**

  When there is discrepancy between timeout and polling-interval, the format of the message is as shown below:

  ```
  ! User configured polling interval <user-cfgd polling-interval> second(s) is greater than half of timeout <user-cfgd timeout> second(s). Setting polling-interval to <to-be-used polling-interval> second(s)
  ```
When there is discrepancy between recovery-time and polling-interval, the format of the message is as shown below

```
! User configured polling interval <user-cfgd polling-interval>
 second(s) is greater than half of recovery-time <user-cfgd recovery-time> second(s).
 Setting polling-interval to <to-be-used polling-interval> second(s)
```

Examples

- These commands enable the pfc-watchdog monitoring on tx-queue 3 of **Ethernet 1/1**, and configures a PFC congestion timeout of **10** seconds which error-disables the port if the queue is stuck.

```
switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1-txq-3)#exit
switch(config)#priority-flow-control pause watchdog default timeout 10
```

- These commands enable the pfc-watchdog monitoring on tx-queue 3 of **Ethernet 1/1**, and configures a PFC forced recovery-time interval of **30** seconds after which the stuck queue(s) are recovered, irrespective of whether PFC frames are being received or not.

```
switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1-txq-3)#exit
switch(config)#priority-flow-control pause watchdog default recovery-time 30 forced
```

- These commands enable the pfc-watchdog monitoring on tx-queue 3 of **Ethernet 1/1**, and configures a PFC polling-interval of **20** seconds after which queue is polled.

```
switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1-txq-3)#exit
switch(config)#priority-flow-control pause watchdog default polling-interval 20
```
Layer 2 Configuration

12.4.6.8 priority-flow-control pause watchdog hardware

The `priority-flow-control pause watchdog hardware` command configures specific PFC priorities as non-disruptive. This will avoid traffic drop on queues corresponding to these priorities are stuck/recovered, the traffic for other priorities are not impacted.

The `no priority-flow-control pause watchdog hardware` command removes the specified `priority-flow-control pause watchdog non-disruptive configuration` by deleting the corresponding `priority-flow-control pause watchdog hardware` command from `running-config`.

Command Mode

Global Configuration

Command Syntax

`priority-flow-control pause watchdog hardware`

`no priority-flow-control pause watchdog hardware`

Parameters

`hardware` Configure PFC priority through hardware. Options include:

- `non-disruptive` PFC watchdog non-disruptive configuration. The priority value ranges from 0 to 7.

Guidelines

Before enabling the PFC watchdog configuration, configure the guaranteed bandwidth on the tx-queue to be monitored. Also, enable the PFC on the port for the PFC priorities for the traffic flowing into the queue that is being monitored.

Example

These commands enable the pfc-watchdog monitoring on tx-queue 3 of Ethernet 1/1, and configures PFC priorities as non-disruptive on PFC priorities 3 and 4.

```
switch#config
switch(config)#interface Ethernet1/1
switch(config-if-Et1/1)#priority-flow-control on
switch(config-if-Et1/1)#priority-flow-control priority 3 no-drop
switch(config-if-Et1/1)#tx-queue 3
switch(config-if-Et1/1-txq-3)#bandwidth guaranteed 100
switch(config-if-Et1/1-txq-3)#exit
switch(config-if-Et1/1)#exit
switch(config)#priority-flow-control pause watchdog hardware non-disruptive priority 3 4
```
12.4.6.9  priority-flow-control priority

The `priority-flow-control priority` command configures the packet resolution setting on the configuration mode interface. This setting determines if packets are dropped when priority flow control (PFC) is enabled on the interface. Packets are dropped by default.

The `no priority-flow-control priority` and `default priority-flow-control priority` commands restore the default packet drop setting on the configuration mode interface by deleting the corresponding `priority-flow-control priority` command from `running-config`. The `priority-flow-control priority` command also restores the default setting on the configuration mode interface.

Command Mode
Interface-Ethernet Configuration

Command Syntax
`priority-flow-control priority pack-drop`
`no priority-flow-control priority`
`default priority-flow-control priority`

Parameters
`pack-drop` denotes the interfaces. Options include:
• `drop` Packets are dropped. Default setting.
• `no drop` Packets are not dropped.

Examples
• These commands in DCBX mode create a priority group that pauses dot1p priority 5 on `ethernet 2`.
  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control on
  switch(config-if-Et2)#priority-flow-control priority 5 no-drop
  ```

• These commands enable lossy behavior.
  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control on
  switch(config-if-Et2)#priority-flow-control priority 5 drop
  ```

• These commands remove the priority group that pauses dot1p priority 5 on `ethernet 2`.
  ```
  switch(config)#interface ethernet 2
  switch(config-if-Et2)#priority-flow-control on
  switch(config-if-Et2)#no priority-flow-control priority
  ```
12.4.6.10 priority-flow-control

The `priority-flow-control` command enables Priority Flow Control (PFC) on the configuration mode interface to pause selected traffic classes.

The `no priority-flow-control` and `default priority-flow-control` commands disable PFC on the configuration mode interface by deleting the corresponding `priority-flow-control` command from `running-config`. The `priority-flow-control priority` command also disables PFC on the configuration mode interface.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

- `priority-flow-control on`
- `no priority-flow-control on`
- `default priority-flow-control on`

**Example**

- These commands enable PFC on *interface Ethernet 3*.
  ```
  switch(config)#interface Ethernet 3
  switch(config-if-Et3)#priority-flow-control on
  switch(config-if-Et3)#
  ```

- These commands disable PFC on *interface Ethernet 3*.
  ```
  switch(config)#interface Ethernet 3
  switch(config-if-Et3)#no priority-flow-control
  switch(config-if-Et3)#
  ```
12.4.6.11  show dcbx application-priority-configuration

The `show dcbx application-priority-configuration` command displays the DCBX peer application priority configuration.

Command Mode
EXEC

Command Syntax
`show dcbx [INTERFACE] application-priority-configuration`

Parameters

**INTERFACE** Interface type and number. Options include:

- *no parameter* All configured DCBX interfaces.
- *ethernet e-num* Ethernet interface specified by `e-num`.

Guidelines

This command and the `show priority-flow-control` command function identically.

Example

This command displays the DCBX peer application priority configuration for all DCBX-enabled interfaces.

```
switch# show dcbx application-priority-configuration
Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No application priority configuration TLV received
Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No application priority configuration TLV received
...
Ethernet50:
  Last LLDPDU received on Thu Feb 14 12:08:29 2013
  - Application priority configuration:
    2 application priorities configured:
    tcp-sctp 860 priority 5
tcp-sctp 3260 priority 5
switch#
```
12.4.6.12  show dcbx priority-flow-control-configuration

The show dcbx priority-flow-control-configuration command displays the IEEE DCBX peer priority flow control configurations.

Command Mode
EXEC

Command Syntax
show dcbx [INTERFACE] priority-flow-control-configuration

Parameters
INTERFACE Interface type and number. Options include:
- no parameter all configured DCBX interfaces.
- ethernet e-num Ethernet interface specified by e-num.

Example
This command displays the DCBX peer priority flow control configuration for the DCBX-enabled interfaces on the device.

```
switch#show dcbx priority-flow-control-configuration
Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No priority flow control configuration TLV received
Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
  No priority flow control configuration TLV received
... Ethernet50:
  Last LLDPDU received on Thu Feb 14 12:11:29 2013
    - PFC configuration: willing
      not capable of bypassing MACsec
      supports PFC on up to 4 traffic classes
      PFC enabled on priorities: 5 7
    WARNING: peer PFC configuration does not match the local PFC configuration
switch#
```
12.4.6.13  **show dcbx status**

The **show dcbx status** command displays the DCBX status on the interfaces on which DCBX is enabled.

**Command Mode**

EXEC

**Command Syntax**

`show dcbx [INTERFACE] status`

**Parameters**

**INTERFACE** Interface type and number. Options include:

- *no parameter* all configured DCBX interfaces.
- *ethernet e-num* Ethernet interface specified by *e-num*.

**Example**

This command displays the DCBX status for the DCBX-enabled interfaces.

```
switch# show dcbx status
Ethernet1:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
Ethernet2:
  Last LLDPDU received on Thu Feb 14 10:52:20 2013
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:11:54 2013
switch#
```
12.4.6.14 show dcbx

The `show dcbx` command lists DCBX status and the interfaces on which DCBX is enabled.

**Command Mode**
EXEC

**Command Syntax**

```
show dcbx [INTERFACE]
```

**Parameters**

`INTERFACE` Interface type and number. Options include:

- `no parameter` all configured DCBX interfaces.
- `ethernet e-num` Ethernet interface specified by `e-num`.

**Examples**

- This command displays the DCBX status for **Ethernet 50**.

```
switch#show dcbx Ethernet 50
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:08:01 2013
  No priority flow control configuration TLV received
  No application priority configuration TLV received
switch#
```

- This command displays the DCBX status for **Ethernet 50** when Priority Flow Control (PFC) is not enabled.

```
switch#show dcbx Ethernet 50
Ethernet50:
  IEEE DCBX is enabled and active
  Last LLDPDU received on Thu Feb 14 12:08:29 2013
  - PFC configuration: willing
    - not capable of bypassing MACsec
    - supports PFC on up to 4 traffic classes
    - PFC enabled on priorities: 5 7
    - WARNING: peer PFC configuration does not match the local PFC configuration
  - Application priority configuration:
    - 2 application priorities configured:
      tcp-sctp 860 priority 5
      tcp-sctp 3260 priority 5
switch#
```
12.4.6.15  show interfaces priority-flow-control

The show interfaces priority-flow-control command displays the status of PFC on all interfaces.

Command Mode
EXEC

Command Syntax
show interfaces [INTERFACE] priority-flow-control  [INFO_LEVEL]

Parameters

• INTERFACE Interface type and numbers. Options include:
  • no parameter Display information for all interfaces.
  • ethernet e_range Ethernet interface range specified by e_range.
  • loopback l_range Loopback interface specified by l_range.
  • management m_range Management interface range specified by m_range.
  • port-channel p_range Port-Channel Interface range specified by p_range.
  • vlan v_range VLAN interface range specified by v_range.
  • vxlan vx_range VXLAN interface range specified by vx_range.

Valid range formats include number, number range, or comma-delimited list of numbers and ranges.

• INFO_LEVEL specifies the type of information displayed. Options include:
  • no parameter Displays information about all DCBX neighbor interfaces.
  • status Displays the DCBX status.
  • counters Displays the DCBX counters.

Guidelines
This command and the show priority-flow-control command function identically.

Example
This command displays the PFC for all interfaces.

```
switch#show interfaces priority-flow-control
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7

<table>
<thead>
<tr>
<th>Port</th>
<th>Enabled</th>
<th>Priorities</th>
<th>Active</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>
```

switch#
12.4.6.16  show platform fm6000 pfc-wm

The show platform fm6000 pfc-wm command displays the buffer space allocated to the RX-Private buffer and buffer levels that trigger PFC frame transmission activities.

Command Mode
Privileged EXEC

Command Syntax
show platform fm6000 pfc-wm

Related Command
priority-flow-control priority specifies the PFC RX-Private buffer memory allocation.

Example
This command displays the rx-private hardware buffer memory allocation.

```
switch#show platform fm6000 pfc-wm
Pfc_Rx_Private_WM: 24800 Bytes
Pfc_On_WM: 16000 Bytes
Pfc_Off_WM: 3200 Bytes
switch#`
```
show priority-flow-control

The show priority-flow-control command displays the status and other PFC and PFC watchdog information on all interfaces if no specific interface is specified.

**Command Mode**

EXEC

**Command Syntax**

`show priority-flow-control [status | counters | interfaces]`

**Parameters**

- **interfaces** specifies the interface for which the information is displayed. Options include:
  - Ethernet Hardware Ethernet interface.
  - Loopback Loopback interface.
  - Management Management interface.
  - Port-Channel Lag interface.
  - Recirc-Channel Recirculation interface.
  - Tunnel Tunnel interface.
  - Vlan VLAN interface.
  - Vxlan VXLAN Tunnel Interface.
- **status** displays the interface PFC status.
- **counters** displays the interface PFC counters. Options include:
  - detail displays the DCBX counters for each priority class. This option is available only on Trident switches.
  - watchdog displays the PFC watchdog counters.

**Examples**

- This command displays the PFC status on all interfaces.

```
switch#show priority-flow-control
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
Port    Enabled Priorities Active Note
Et1     No                 No
Et2     No                 No
...    ...                ...
Et50    Yes               5 Yes
...    ...                ...
Port    RxPfc           TxPfc
Et1     0               0
Et2     0               0
...    ...                ...
Et50    0               0
...    ...                ...
```

- This command displays the PFC watchdog status. If PFC watchdog default timeout is non-zero (in this case it is 3.0) then PFC watchdog is actively running on the switch.

```
switch# show priority-flow-control
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
The PFC watchdog default timeout is 3.0
Port    Enabled Priorities Active Note
```
Layer 2 Configuration

<table>
<thead>
<tr>
<th>Layer 2 Configuration</th>

</tbody>
</table>

- This command displays the current value of these counters for all the interfaces being monitored by PFC watchdog. Alternatively, show interfaces priority-flow-control counters watchdog command can be used for the same.

```
switch #show priority-flow-control counters watchdog
Port   TxQ  Total times stuck  Total times recovered
------- ----  ----------- --------  -------------
Et1/1   UC2  2             2
Et1/1   UC3  3             3
Et2/1   UC2  12            12
Et2/1   UC3  31            30
```

- This command displays the current value of these counters for a specific subset of interfaces. Alternatively, show interfaces priority-flow-control counters watchdog command can be used for the same.

```
switch #show priority-flow-control interfaces Ethernet 1/1 counters watchdog
Port   TxQ  Total times stuck  Total times recovered
------- ----  ----------- --------  -------------
Et1/1   UC2  2             2
Et1/1   UC3  3             3
```

- This command displays the configuration details of PFC watchdog at global and interface level.

```
switch #show priority-flow-control status
The hardware supports PFC on priorities 0 1 2 3 4 5 6 7
The PFC watchdog timeout is 1.0 second(s)
The PFC watchdog recovery-time is 2.0 second(s) (auto)
The PFC watchdog polling-interval is 0.1 second(s)
The PFC watchdog non-disruptive priorities are 3 4
The PFC watchdog port non-disruptive-only is False

E: PFC Enabled, D: PFC Disabled, A: PFC Active, W: PFC Watchdog Enabled

12.5 IP Locking

This section describes IP Locking configuration tasks. Topics in this section include:

- Release Updates
- Platform Compatibility
- IPv4 Locking Configuration Commands
- IPv6 Locking
- Show Commands
- Limitations
- IP Locking Commands
12.5.1 IP Locking

IP Locking is an EOS feature configured on an Ethernet Layer 2 port.

When enabled, IP Locking ensures that a port will only permit IP and ARP packets with IP source addresses that have been authorized. As of the **EOS Release 4.25.0F** release update, IP locking can run in two modes - IPv4 Locking (which will be referred to as IP Locking) and IPv6 Locking, which is configured using the commands mentioned in the following sections. IP Locking prevents another host on a different interface from claiming ownership of an IP address through ARP spoofing. IPv6 Locking extends this behavior to IPv6 packets, including ICMPv6 Neighbor Discovery (Router Advertisement, Redirect) and DHCP (server-to-client) packets. Mode specific commands are also discussed.

On an IP Locked Port,
- ARP probes with **0.0.0.0** as Sender Protocol Address (SPA) and is allowed for duplicate address detection (DAD).
- Incoming DHCP server response packets are dropped to avoid rogue device(s) acting as DHCP server(s).
- Incoming DHCP client request packets are allowed for devices to complete DHCP handshake and obtain DHCP leases.

On an IPv6 Locked Port,
- Incoming DHCPv6 server response packets are dropped and incoming DHCPv6 client request packets are allowed.
- Incoming ICMPv6 ND : Router Advertisement packets are dropped as only routers should send these packets.
- Incoming ICMPv6 ND : Router Solicitation packets are allowed.
- Incoming ICMPv6 ND : Redirect packets are dropped as only routers should send these packets.

IP Locking relies on DHCP LeaseQuery (**RFC4388**) and MAC address learning to determine that an IP address has been authorized on a particular port. It is necessary to ensure that DHCP servers used in the network allow LeaseQuery messages.

12.5.1.1 Release Updates

Refer to the release updates for IP Locking.

**EOS Release 4.25.1F:**

Added support for disabling address filtering for IPv6 packets while still keeping all packet type specific drop rules such as ICMPv6 ND:RA, and ICMPv6 ND:Redirect and DHCPv6 (server-to-client) packets, using the `locked-address ipv6 enforcement disabled` command.

**EOS Release 4.24.0F:**

- Added support for expiration modes of locked addresses, using the `locked-address expiration mac disabled` command.
- Added support for counters, using the `show address locking counters` and `clear address locking counters` commands.

**EOS Release 4.23.2F:**
Added support for static lease command, lease <V4ADDR> mac <MACADDR>.

**EOS Release 4.23.1F:**
Added support for clear address locking lease command.

**EOS Release 4.23.0F:**
- Initial release.
- Supports IPv4 address locking.

### 12.5.1.2 Platform Compatibility
Support for IP Locking is found on the following platforms:
- CCS-720XP
- DCS-7050CX3
- DCS-7050SX3

### 12.5.1.3 IPv4 Locking Configuration Commands
Configure IP Locking commands in the *address locking* configuration mode.

```
Example
switch#configure
switch(config)#address locking
switch(config-address-locking)#
```

To enable IP Locking, you must configure
- the DHCP servers from which hosts are expected to acquire leases. IP Locking communicates with these DHCP servers to learn the IP addresses that must be authorized on the switch.

```
switch(config-address-locking)#dhcp server ipv4 10.1.1.1
switch(config-address-locking)#dhcp server ipv4 10.30.1.3
```

- a local L3 interface to communicate with the DHCP server(s). This could be the management interface, a routed interface, or a Switch Virtual Interface (SVI). This interface requires a valid IP address assigned, routable to the configured DHCP server(s), and can reside in non-default VRF. The interface IP is used as the source IP in the switch’s packets to the DHCP server.

```
switch#configure
switch(config)#interface Vlan2160
switch(config-if-Vl2160)#ip address 10.10.1.2/16

switch#configure
switch(config)#interface Vlan2160
switch(config-if-Vl2160)#ip address 10.10.1.2/16
```

To activate IP Locking on ports connected to clients, IP Locking must be enabled in the interface configuration mode. Running this command only activates IPv4 Locking and overrides the previous configuration for the interface.

```
Example
switch(config)#interface Ethernet27/1
```
It is possible to disable IP Locking using the `disabled` command in address-locking mode. This turns off the feature and allows a host to use any IP address, authorized or unauthorized, on any port.

```
switch(config-if-Et27/1)#address locking ipv4
```

### Example

```
switch#configure
switch(config)#address locking
switch(config-address-locking)#disabled
```

#### 12.5.1.3.1 Clear Commands

The `clear address locking lease...` command removes the lease from hardware. This enable mode command removes lease bindings at different granularities.

- The `clear address locking lease ipv4 V4ADDR` command removes a single lease associated with an IPv4 address.
- The `clear address locking lease ipv6 V6ADDR` removes a single lease associated with an IPv6 address.
- The `clear address locking lease intf ethernet slot` removes all leases associated with the specified interface.
- The `clear address locking lease all` removes all leases on the switch.

#### 12.5.1.3.2 Static Lease Commands

The `lease mac` command within address locking configuration mode installs a lease into hardware for the configured IP address on the interface the configured MAC address is associated with. If the MAC address is not in the MAC table or the MAC address is on an interface that is not configured with IP Locking feature, the lease is not installed until the MAC address is added to an interface that is configured with IP Locking.

Note: Any lease from the DHCP server that matches either the same IP or MAC as a statically configured lease is removed from the switch.

```
switch#configure
switch(config)#address locking
switch(config-address-locking)#lease 1.1.1.1 mac a.b.c
```

#### 12.5.1.3.3 Locked Address Expiration Commands

The IP addresses remain authorized and installed even after their corresponding MAC addresses have aged out. IP Locking, by default, deauthorizes leases after their corresponding MAC addresses age out. The `locked-address expiration mac disabled` command configures IP Locking to keep leases installed, even after their corresponding MAC addresses have aged out.

```
switch#configure
switch(config)#address locking
```
12.5.1.3.4 IP Locking Counters

The `show address locking counters` command displays DHCP lease query messages sent, received, and dropped. There are two sets of counters: first, the number of packets sent to and received from each DHCP server; and second, the number of packets sent and received for each locked interface. There are separate counters for the different kinds of messages communicated between the switch and the DHCP server.

Example

```
switch(config-address-locking)#locked-address expiration mac disabled
```

The `show address locking counters` command displays DHCP lease query messages sent, received, and dropped. There are two sets of counters: first, the number of packets sent to and received from each DHCP server; and second, the number of packets sent and received for each locked interface. There are separate counters for the different kinds of messages communicated between the switch and the DHCP server.

Example

```
switch(config-address-locking)#show address locking counters

DHCP Server  Lease Active Lease Unknown Lease Unassigned
------------- ----- ------ ------ -------- ------- -------
80.80.80.80 32860  8002 34  8001 32  13423 134 3234

Interface  Lease Active Lease Unknown Lease Unassigned
---------- -------------- ------------- -------------------
Ethernet2  1747 1234  189  324
```

The `clear address locking counters` command resets all the counters associated with IP Locking to zero.

12.5.4 IPv6 Locking

12.5.4.1 IPv6 Locking Configuration Commands

To enable IPv6 locking, you must:

Disable enforcement of IPv6 address locking.

```
switch(config)#address locking
switch(config-address-locking)#locked-address ipv6 enforcement disabled
```

To activate IPv6 Locking on ports connected to clients, IPv6 Locking must be enabled in the interface configuration mode. Running this command only activates IPv6 Locking and overrides the previous configuration for the interface.

Example

```
switch(config)#interface Ethernet27/1
switch(config-if-Et27/1)#address locking ipv6
```

Both IPv4 and IPv6 locking can be activated on a port by running commands similar to the following:

```
switch(config)#interface Ethernet27/1
switch(config-if-Et27/1)#address locking ipv4 ipv6
```
It is possible to disable IPv6 Locking using the `disabled` command in address-locking mode. This turns off the feature and allows a host to use any IP address, authorized or unauthorized, on any port. Note that this will also disable IP Locking as well.

```
Example
switch#configure
switch(config)#address locking
switch(config-address-locking)#disabled
```

### 12.5.1.4.2 Locked Address IPv6 Enforcement Commands

The `locked-address ipv6 enforcement disabled` command disables address filtering for all ports that have IPv6 Locking enabled. This permits IPv6 packets while still keeping all other drop rules.

```
Example
switch#configure
switch(config)#address locking
switch(config-address-locking)#locked-address ipv6 enforcement disabled
```

### 12.5.1.5 Show Commands

Use the `show address locking` command to display the status of IP and IPv6 locking.

```
Example
switch#show address locking
IP Locking is active
  Interface                  IPv4                   IPv6               
  -------------------------- ----------- -------------------
  Ethernet27/1              yes        no (not configured)
  Ethernet31/1              no (not configured)   no (not a layer 2 interface)
```

The `show address locking` command also displays the reason as to why IP Locking is not enabled for an interface. For an interface, the following priority (highest at top) is imposed on the output when IP Locking is not enabled for an interface:

- not configured
- not a Layer 2 interface
- no local interface
- no dhcp server

The `show address locking table ipv4` command displays all the DHCP leases that IP Locking knows about, whether or not those leases are installed and the interfaces on which these IP addresses are authorized.
Example

```
switch# show address locking table ipv4
IP Address  MAC Address  Interface  Installed  Expiration Time
----------  -----------  ---------  ----------  ---------------
10.30.4.4   ba76.a467.7ff8  Et27/1     installed  in 0:01:57
```

12.5.1.6 Limitations

The IP Locking feature contains the following limitations:

- IP Locking is supported for IPv4 but has limited functionality for IPv6.
- IP Locking works only with DHCP servers that support **RFC 4388** (LeaseQuery) and are configured to allow lease queries. ISC DHCPD and BlueCat are currently known servers that support LeaseQuery.
- IP Locking can only be configured on Ethernet interfaces, excluding sub-interfaces.
- IP Locking and DHCP relay cannot be configured on the same switch. When both are configured, IP Locking is disabled.
- IP Locking and DHCP snooping cannot be configured on the same switch. When both are configured, IP Locking is disabled.
- IP Locking and DHCP server cannot be configured on the same switch. When both are configured, IP Locking is disabled.
- Do not configure IP Locking and the ARP inspection feature on the same switch.
- Do not configure IP Locking and the IP source guard feature on the same switch.
- IP Locking may not immediately invalidate a lease on an access port if the host moves to another port on a different access switch.
- IP Locking supports up to 3400 hosts on the DCS-7050X3 platform, and up to 3800 hosts on the CCS-720XP platform. This scale may reduce further with other features using TCAM resources.
- IPv6 Locking currently only allows disabling address filtering for IPv6 packets while keeping all packet type specific drop rules such as ND:RA, ND:RD, and DHCP Server-to-Client.
- Some DHCP server implementations (such as ISC DHCPD) do not respond to lease query if the **fixed-address** configuration is used. Use reserved leases instead.
- CVP Endpoint Identification is not able to identify hosts connected to an IP Locking enabled switch.
12.5.1.7 IP Locking Commands

IPv4 Clear Commands
• clear address locking lease

IPv4 Static Lease Commands
• lease mac

IPv4 Lock Address Expiration Commands
• locked-address expiration mac disabled

IP Locked Show Commands
• show address locking
• show address locking counters
• show address locking table ipv4
12.5.1.7.1 clear address locking lease

Use the clear address locking lease command to remove lease bindings at different granularities.

Support beginning with EOS Release 4.23.1F:

- The clear address locking lease... command removes the lease from the hardware.
  - The clear address locking lease ipv4 V4ADDR command removes a single lease associated with an IPv4 address.
  - The clear address locking lease ipv6 V6ADDR command removes a single lease associated with an IPv6 address.
  - The clear address locking lease intf ethernet slot command removes all leases associated with the specified interface.
  - The clear address locking lease all command remove all leases on the switch.

Command Mode

Address locking mode

Command Syntax

clear address locking lease [ all | interface [ ethernet slot ] | ipv4 V4ADDR | ipv6 V6ADDR ]

Parameters

- all The entire lease table.
- interface The interface of the lease to be cleared.
  - ethernet slot Ethernet interface slot number.
- ipv4 V4ADDR IPv4 address of the lease to be cleared.
- ipv6 V6ADDR IPv6 address of the lease to be cleared.

Example

switch(config-address-locking)#clear address locking lease all
12.5.1.7.2  lease mac

The lease mac command within the address locking configuration mode installs a lease into hardware for the configured IP address on the interface the configured MAC address is associated with. If the MAC address is not in the MAC table or the MAC address is on an interface that is not configured with IP Locking feature, the lease is not installed until the MAC address is added to an interface that is configured with IP Locking. The no and default forms of the command removes the lease into hardware for the configured IP address on the interface the configured MAC address is associated with.

Command Mode
Address locking configuration mode

Command Syntax

- lease V4ADDR mac MACADDR
- no lease V4ADDR mac MACADDR
- default lease V4ADDR mac MACADDR

Parameters
- lease V4ADDR The lease IP address.
- mac MACADDR The configured mac address for static lease.

Example

Arista#config t
Arista(config)#address locking
Arista(config-address-locking)#lease 1.1.1.1 mac a.b.c
12.5.1.7.3  locked-address expiration mac disabled

IP Locking, by default, deauthorizes leases after their corresponding MAC addresses age out. Use the locked-address expiration mac disabled command to configure IP Locking to keep leases installed, even after their corresponding MAC addresses have aged out.

Command Mode
Address locking configuration mode

Command Syntax
locked-address expiration mac disabled
no locked-address expiration mac disabled
default locked-address expiration mac disabled

Parameters
• expirationConfigs expiration mode for locked addresses.
• mac Configures deauthorizing locked addresses upon MAC aging out.
• disabled Disables deauthorizing locked address upon MAC aging out.

Example

```
switch#configure t
switch(config)#address locking
switch(config-address-locking)#locked-address expiration mac disabled
```
12.5.1.7.4 show address locking

Use the `show address locking` command to display the status of IP and IPv6 locking.

The `show address locking` command also displays the reason as to why IP Locking is not enabled for an interface. For an interface, the following priority (highest at top) is imposed on the output when IP Locking is not enabled for an interface:

- not configured
- not a Layer 2 interface
- no local interface
- no dhcp server

**Command Mode**

EXEC

**Command Syntax**

`show address locking`

**Example**

```
switch#show address locking
IP Locking is active
  Interface              IPv4                     IPv6
  Ethernet27/1  yes                      no (not configured)
  Ethernet31/1  no (not configured)    no (not a layer 2 interface)
```
12.5.1.7.5  show address locking counters

The show address locking counters command displays DHCP lease query messages sent, received, and dropped. There are two sets of counters: first, the number of packets sent to and received from each DHCP server; and second, the number of packets sent and received for each locked interface. There are separate counters for the different kinds of messages communicated between the switch and the DHCP server.

Command Mode
EXEC

Command Syntax
show address locking counters

Related Commands
The clear address locking counters command resets all the counters associated with IP Locking to zero.

Example

```
switch#show address locking counters
DHCP Server Query Lease Active Lease Unknown Lease Unassigned
----------- ----- ------ ------ ------- ------ -------- ------- -------
80.80.80.80 32860 34 8001 32 13423 134 3234

Interface Query Lease Active Lease Unknown Lease Unassigned
--------- ----- -------- ------- ------ ------- -------
Ethernet2 1747 1234 189 324
```
12.5.1.7.6  show address locking table ipv4

Use the `show address locking table ipv4` command to display all the DHCP leases that IP Locking knows about, whether or not those leases are installed and the interfaces on which these IP addresses are authorized.

**Command Mode**
EXEC

**Command Syntax**

```
```

**Parameters**

- **dynamic** Only display the dynamic leases.
  - **installed** Only display the leases that are installed in the hardware.
  - **interface** Only display the leases belonging to a specified interface.
- **static** Only display the static leases.
  - **installed** Only display the leases that are installed in the hardware.
  - **interface** Only display the leases belonging to a specified interface.
  - **Ethernet slot** Specified Ethernet sub-interface.
- **interface** Only display the leases belonging to a specified interface.
  - **Ethernet slot** Specified Ethernet sub-interface.

**Example**

```
switch#show address locking table ipv4
IP Address     MAC Address      Interface  Installed    Expiration Time
-------------- ---------------- ---------- ------------ ---------------
10.30.4.4      ba76.a467.7ff8   Et27/1     installed     in 0:01:57
```

1554
12.6 **L2 Protocol Forwarding**

L2 Protocol Forwarding on Ethernet interfaces is supported, in addition to Type-5 PW. Also, selective forwarding of certain L2 Protocol packets (tagged/untagged/all) as opposed to forwarding all LACP frames (both tagged and untagged) is allowed. The protocol list on which L2 Protocol Forwarding is supported has been extended to PAUSE, LACP, LLDP, MACSEC, STP.

12.6.1 **Configuring L2 Protocol Forwarding**

The following commands allow creation of a profile that allows forwarding tagged/untagged/all types of PAUSE/LACP/LLDP/MACSEC/STP/E-LMI/ISIS/micro-BFD frames.

```plaintext
switch(config-l2-protocol)#forwarding profile abc
switch(config-l2-protocol-abc)#isis forward
switch(config-l2-protocol-abc)#macsec tagged forward
switch(config-l2-protocol-abc)#pause untagged forward
switch(config-l2-protocol-abc)#exit
```

The following commands allow application of a profile on an interface or subinterface:

```plaintext
switch(config)#int Ethernet1/1
switch(config-if-Et1/1)#l2-protocol forwarding profile abc
switch(config-if-Et1/1)#exit
switch(config)#int Ethernet2/1.1
switch(config-if-Et2/1.1)#l2-protocol forwarding profile def
switch(config-if-Et2/1.1)#exit
```

12.6.1.1 **TCAM Profile**

A specific TCAM profile is required to configure L2 Protocol Forwarding profiles except if the L2 Protocol Forwarding profile has only ‘lacp forward’ and is configured on Type-5 PW ports on Type-1 platforms (mentioned above). One such TCAM profile is as follows:

```plaintext
switch(config)#hardware tcam
switch(config-tcam)#profile l2protocolfwd
switch(config-tcam-profile-l2protocolfwd)#feature acl port ip
switch(config-tcam-feature-acl-port-ip)#sequence 45
switch(config-tcam-feature-acl-port-ip)#key size limit 160
switch(config-tcam-feature-acl-port-ip)#key field dscp dst-ip ip-frag ip-protocol 14-dst-port 14-ops 14-src-port src-ip tcp-control ttl
switch(config-tcam-feature-acl-port-ip)#action count drop
switch(config-tcam-feature-acl-port-ip)#packet ipv4 forwarding bridged
switch(config-tcam-feature-acl-port-ip)#packet ipv4 forwarding routed
switch(config-tcam-feature-acl-port-ip)#packet ipv4 forwarding routed multicast
switch(config-tcam-feature-acl-port-ip)#packet ipv4 mpls ipv4 forwarding mpls decap
switch(config-tcam-feature-acl-port-ip)#packet ipv4 mpls ipv6 forwarding mpls decap
switch(config-tcam-feature-acl-port-ip)#packet ipv4 non-vxlan forwarding routed decap
switch(config-tcam-feature-acl-port-ip)#packet ipv4 vxlan eth ipv4 forwarding routed decap
switch(config-tcam-feature-acl-port-ip)#packet ipv4 vxlan forwarding bridged decap
switch(config-tcam-feature-acl-port-ip)#feature acl port ipv6
switch(config-tcam-feature-acl-port-ipv6)#sequence 25
```
switch(config-tcam-feature-acl-port-ipv6)#key field dst-ipv6 ipv6-next-header ipv6-traffic-class l4-dst-port l4-ops-3b l4-src-port src-ipv6-high src-ipv6-low tcp-control
switch(config-tcam-feature-acl-port-ipv6)#action count drop
switch(config-tcam-feature-acl-port-ipv6)#packet ipv6 forwarding bridged
switch(config-tcam-feature-acl-port-ipv6)#packet ipv6 forwarding routed

Once 'l2protocolfwd' or 'l2protocolfwd-bfd-rfc-7130 tcam profile is created, the profile needs to be applied to the switch using the following command under config mode:

switch (config) #hardware tcam
switch (config-tcam) #system profile l2protocolfwd

Consumption of TCAM

The following table describes how TCAM is consumed when the same L2 Protocol Forwarding profile is applied:

<table>
<thead>
<tr>
<th>Level of application</th>
<th>Type-1 platforms</th>
<th>Type-2 platforms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Front panel ports</td>
<td>Separate TCAM entries for each port</td>
<td>Same set of TCAM entries for ports on the same fap and core</td>
</tr>
<tr>
<td>Subinterfaces</td>
<td>Same set of TCAM entries for subinterfaces on the same fap</td>
<td>Same set of TCAM entries for subinterfaces on the same fap and core</td>
</tr>
</tbody>
</table>
12.6.2  L2 Protocol Forwarding Limitations

1. A maximum of \(31\) distinct L2 Protocol Forwarding profiles are applied across multiple subinterfaces on the same FAP.
2. A maximum of \(31\) distinct L2 Protocol Forwarding profiles are applied across multiple subinterfaces, and front panel ports on the same FAP on Type-2 platforms.
3. The feature is not supported for subinterfaces on Type-1 platforms if any of the below features are present in the TCAM Profile:
   - feature pbr subintf ip
   - feature pbr subintf ipv6
   - feature pbr subintf mpls

12.6.3  L2 Protocol Forwarding Show commands

The show l2-protocol forwarding interface displays the L2 protocol forwarding profile configuration corresponding to the interfaces or subinterfaces.

```
switch(config)#show l2-protocol forwarding interface

Interface     Profile
------------- -------
Ethernet1/1    abc
Ethernet2/1.1   def

switch> show l2-protocol forwarding interface Ethernet1/1

Interface     Profile
------------- -------
Ethernet1/1    abc

The following show commands displays all packets forwarding behaviour on an interface or a subinterface:

switch(config)#show l2-protocol forwarding interface detail

Tagging Types: T: tagged U: untagged
Actions: F: forward

<table>
<thead>
<tr>

</table>
12.7 Layer 2 Subinterfaces

A Layer 2 subinterface is a logical bridging endpoint associated with traffic on an interface distinguished by 802.1Q tags, where each `interface, 802.1q tag` tuple is treated as a first-class bridging interface.

Like other types of interfaces, an L2 subinterface is a normal bridging endpoint in the bridging domain.

12.7.1 Configurations

12.7.1.1 Creating a Layer 2 Subinterface

Complete the following steps to configure a layer 2 (L2) subinterface on an Arista switch:

1. Configure the parent interface to be a routed port.

```
switch(config)#interface et1
switch(config-if-Et1)#no switchport
```

2. Create a subinterface on the parent interface (`et1.1`), assign 802.1q encapsulation (`vlan 100`), and assign the forwarding VLAN ID (`vlan 200`).

```
switch(config-if-Et1)#interface et1.1
switch(config-if-Et1.1)#encapsulation dot1q vlan 100
switch(config-if-Et1.1)#vlan id 200
  ! VLAN does not exist. Creating vlan 200
```

3. An alternative to configuring a forwarding VLAN id is to use VLAN name (`office`).

```
switch(config)#vlan 200
switch(config-vlan-200)#name office
switch(config-vlan-200)#int et1.2
switch(config-if-Et1.2)#encapsulation dot1q vlan 101
switch(config-if-Et1.2)#vlan name office
```

4. Now subinterfaces `et1.1` and `et1.2` have been created and added to VLAN 200.

```
switch#show interface et1.1-2 status
Port     Name     Status    Vlan Duplex Speed Type                Flags
Encapsulation
Et1.1           connected    200      full   10G   dot1q-encapsulation       100
Et1.2           connected    200      full   10G   dot1q-encapsulation       101
```
12.7.1.2 MAC Address on Layer 2 Subinterface

MAC addresses can either be statically configured or dynamically assigned behind Layer 2 (L2) subinterfaces.

MAC address learning can be enabled or disabled on an L2 subinterface using the following commands:

In the following example, the `show interface ethernet1.1 switchport` command has this `running-config`:

To enable MAC address learning, use the `no mac address learning disabled` command:

12.7.1.3 QoS Feature

Supported QoS features are:
Shaping

After creating an L2 subinterface, you can configure a shape rate (in Kbps) on the sub-interface. For example, the shape rate is configured to \(50000000\) Kbps.

```console
switch(config-if-Et1.1)# shape rate 50000000
```

The configuration of non-default shape rate results in the allocation of dedicated virtual output queues (VOQ) for the subinterface. Each subinterface allocates four (4) VOQs. Different TC traffic goes to the VOQ according to the following mapping:

- TC6-7 : VOQ3
- TC4-5 : VOQ2
- TC2-3 : VOQ1
- TC0-1 : VOQ0

VOQ3 is in strict-priority mode to the other VOQs.

VOQ2, VOQ1, and VOQ0 are in WRR with a static credit ratio 2:3:6 (higher ratio implies more credits).

The subinterface inherits the trust mode of the parent interface.

Before **EOS Release 4.24.2F**, shaping is supported only on L2 subinterfaces of which the parents are Ethernet interfaces, for example, **Et1.1**. Beginning with **EOS Release 4.24.2F**, shaping on L2 subinterface over a parent interface which is port-channel (for example, **Po1.1**), is supported.

Guaranteed Bandwidth

After configuring shaping on an L2 sub-interface, user can configure a guaranteed bandwidth (in Kbps or percent) on the subinterface using the `bandwidth guaranteed` command.

```console
switch(config-if-Et1.1)# bandwidth guaranteed 10000000
switch(config-if-Et1.1)# bandwidth guaranteed percent 10
```

Policing

For policing to work on the L2 subinterface, you must switch to the QoS profile.

Example

```console
switch(config)# hardware tcam
switch(config-hw-tcam)# system profile qos

Sample Policy-map Configuration:

switch(config)# ip access-list a1
switch(config-acl-a1)# statistics per-entry
switch(config-acl-a1)# 10 permit ip any any

switch(config)# class-map type qos match-any c1
switch(config-cmap-qos-c1)# match ip access-group a1

switch(config)# class-map type qos match-any c2
switch(config-cmap-qos-c2)# match vlan 100 0xffff

switch(config)# ipv6 access-list a1
switch(config-ipv6-acl-a1)# statistics per-entry
switch(config-ipv6-acl-a1)# 10 permit ipv6 any any

switch(config)# class-map type qos match-any c3
```
After you create an L2 subinterface, you can configure a policy-map on the subinterface, similar to the following example.

```plaintext
switch(config-if-Et1.1)#service-policy type qos input pl
```

### Interface Counters

To enable the hardware features for counting packets on L2 subinterfaces ingress and/or egress, use the `hardware counter feature` command, similar to the following example. In the example, subinterface `layer2` is enabled for ingress then enabled for egress.

**Example**

```plaintext
switch(config)#hardware counter feature subinterface in layer2
switch(config)#hardware counter feature subinterface out layer2
```

To display the L2 subinterface counters, use the `show interface counters` command similar to the following example. In the example, subinterface `et1.1` is configured to be displayed.

```plaintext
switch#show interfaces et1.1 counters
```

<table>
<thead>
<tr>
<th>Port</th>
<th>InOctets</th>
<th>InPkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1.1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>OutOctets</th>
<th>OutPkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1.1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

To clear all of the interface counters, use the `clear counters` command similar to the following example:

```plaintext
switch#clear counters
```

To learn counters for a specific L2 interface, use the `clear counters` command, and specify the L2 subinterface to clear, similar to the following example. In the example, L2 subinterface `et1.1` is to be cleared.

```plaintext
switch#clear counters et1.1
```

### 12.7.1.4 Limitations

The following limitations apply to the Layer 2 subinterface feature:

- A total of 256 Layer 2 subinterfaces with shaping are supported across the entire switch and they can be distributed across any number of Ethernet ports.
- When a shape rate is configured on an L2 subinterface over a parent interface which is port-channel (example: `Po1.1`), traffic load-balancing is disabled and is directed to a selected port-channel member. Also, the bandwidth of the port-channel subinterface will be equal to the selected member. However, the `show interface` command continues to show the bandwidth of the port-channel which is incorrect.
Layer 2 Configuration

- After configuring a shape rate on an L2 subinterface, the L2 subinterface must be flapped by using the `shut` and `no shut` commands.
- Shaping of BUM traffic on L2 subinterfaces is supported only with "ingress replication".
- Layer 3 forwarding through SVIs is not supported.
- Routing through the parent interface of a subinterface is not supported.
- Control plane processing, such as IGMP snooping and STP BPDU, is not supported.
- When IGMP protocol packets are expected to be forwarded on L2 subinterfaces, IGMP snooping must be disabled globally on the entire switch using the `no ip igmp snooping` command. When IGMP snooping is configured on any VLAN, then IGMP protocol packets are discarded by L2 subinterfaces.
- Double tagged packets arriving on L2 subinterfaces with a single `encapsulation dot1q vlan <outer_vid>` command configured will match on the outer VLAN tag, and have only the outer VLAN tags terminated.
- Configuration of double tagged L2 subinterfaces through the `encapsulation dot1q vlan <outer_vid> inner <inner_vid>` command is not supported.
- Mixing of shaped and non-shaped subinterfaces under the same parent interface is not supported.
- Traffic classification on ingress traffic to L2 subinterface is disabled by default. To enable this feature, configure using the `qos trust cos` command on the parent interface.
- L2 subinterfaces are not supported in an MLAG environment.

12.7.2 QoS Show Commands

Use the `show interfaces status` command to display the subinterface status.

```
Example

switch#show interfaces status sub-interfaces
Port Name Status Vlan Duplex Speed Type Encapsulation Flags
Encapsulation
Eth1.1 connected 200 full 10G dot1q-encapsulation 100
Eth1.2 connected 200 full 10G dot1q-encapsulation 101
```

Use the `show vlan` command to display the VLAN membership. In the following example, VLAN 200 is configured to be displayed.

```
Example

switch#show vlan 200
VLAN Name Status Ports
----- --------------- --------
200 office active Eth1.1, Eth1.2, Et5
```

Use the `show qos interface` command to display the QoS configuration on an L2 subinterface. In the following example, QoS subinterface `Ethernet 1.1` is configured to be displayed.

```
Example

switch#show qos interface Ethernet 1.1
Ethernet1.1:
    Trust Mode: DSCP
    Default COS: 0
    Default DSCP: 0
```
Use the `show interface counters` with the queue keyword to display the L2 subinterface counters. For example subinterface `Ethernet 1.1` is configured to display the L2 subinterface counters.

**Example**

```
switch# show interface Ethernet 1.1 counters queue
Aggregate VoQ Counters
Egress Traffic Pkts Octets DropPkts DropOctets
Port Class
------------------------------------------------------------
Et1.1 TC0-1 0 0 0 0
Et1.1 TC2-3 0 0 0 0
Et1.1 TC4-5 0 0 0 0
Et1.1 TC6-7 460266 276159600 109316 65589600
```

Use the `show mac address-table` command to display the MAC address on L2 subinterfaces. For example, subinterfaces `Et1.1` and `Et1.2` are configured to be displayed.

**Example**

```
switch# show mac address-table interface et1.1-2
Mac Address Table
------------------
Vlan  Mac Address   Type  Ports  Moves  Last Move
----  -----------    ----  -----  ------  --------
200   0000.000a.000a  STATIC  Et1.1

Layer 3 Configuration

This chapter covers the following Layer 3 sections:

- IPv4
- IPv6
- Ingress and Egress Per-Port for IPv4 and IPv6 Counters
- ACLs and Route Maps
- VARP
- OpenFlow
- DirectFlow
- Decap Groups
- Nexthop Groups
- Global Knob to Set MTU for all Layer 3 Interfaces
- Support for L3 MTU on 7280R3/7500R3/7800R3
- Segment Security
13.1 IPv4

Arista switches support Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) for routing packets across network boundaries. This section describes Arista's implementation of IPv4 and includes these topics:

- IPv4 Addressing
- IPv4 Routing
- IPv4 Multicast Counters
- Route Management
- IPv4 Route Scale
- IP Source Guard
- DHCP Server
- DHCP Relay Global Configuration Mode
- DHCP Relay Across VRF
- DHCP Relay in VXLAN EVPN
- DHCP Snooping with Bridging
- TCP MSS Clamping
- IPv4 GRE Tunneling
- GRE Tunneling Support
- BfRuntime to use non-default VRFs
- IPv4 Commands

13.1.1 IPv4 Addressing

Each IPv4 network device is assigned a 32-bit IP address that identifies its network location. These sections describe IPv4 address formats, data structures, configuration tasks, and display options:

- IPv4 Address Formats
- IPv4 Address Configuration
- Address Resolution Protocol (ARP)
- Displaying ARP Entries

13.1.1.1 IPv4 Address Formats

IPv4 addresses are composed of 32 bits, expressed in dotted decimal notation by four decimal numbers, each ranging from 0 to 255. A subnet is identified by an IP address and an address space defined by a routing prefix. The switch supports the following subnet formats:

- **IP address and subnet mask**: The subnet mask is a 32-bit number (dotted decimal notation) that specifies the subnet address space. The subnet address space is calculated by performing an AND operation between the IP address and subnet mask.

- **IP address and wildcard mask**: The wildcard mask is a 32-bit number (dotted decimal notation) that specifies the subnet address space. Wildcard masks differ from subnet masks in that the bits are inverted. Some commands use wildcard masks instead of subnet masks.

- **CIDR notation**: CIDR notation specifies the scope of the subnet space by using a decimal number to identify the number of leading ones in the routing prefix. When referring to wildcard notation, CIDR notation specifies the number of leading zeros in the routing prefix.

| Examples |
Layer 3 Configuration

- These subnets (subnet mask and CIDR notation) are calculated identically:
  
  | 10.24.154.13 255.255.255.0 |
  | 10.24.154.13/24           |

- The defined space includes all addresses between 10.24.154.0 and 10.24.154.255. These subnets (wildcard mask and CIDR notation) are calculated identically:
  
  | 124.17.3.142 0.0.0.15 |
  | 124.17.3.142/28      |

The defined space includes all addresses between 124.17.3.128 and 124.17.3.143.

13.1.1.2 IPv4 Address Configuration

Assigning an IPv4 Address to an Interface

The `ip address` command specifies the IPv4 address of an interface and the mask for the subnet to which the interface is connected.

**Example**

These commands configure an IPv4 address with subnet mask for VLAN 200:

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ip address 10.0.0.1/24
switch(config-if-Vl200)#
```

Assigning an IPv4 Class E Address to an Interface

The `ipv4 routable 240.0.0.0/4` command assigns a class E addresses to an interface. When configured, the class E address traffic are routed through BGP, OSPF, ISIS, RIP, static routes and programmed to the FIB and kernel. By default, this command is disabled.

**Example**

• These commands configure an IPv4 Class E (240/4) address to an interface.

```
switch(config)#router general
switch(config-router-general)#ipv4 routable 240.0.0.0/4
```

Detecting duplicate IP Addresses on an Interface

The `ip address duplicate detection disabled` command detects any duplicate IP address on the interface. When the duplicate IP address is detected, a syslog message is generated. It helps the network operator to identify IP addresses misconfiguration. By default, this feature is enabled.

**Examples**

• This command disables the feature on the switch.

```
switch(config)#ip address duplicate detection disabled
```

• This command enables the feature.

```
switch(config)#ip address duplicate detection logging
```

Note: Commands are in global configuration mode, and are not per VRF.
This is an example of a Syslog message, when a duplicate IP address is detected.

Mar 24 16:41:57 cd290 Arp: %INTF-4-DUPLICATE_ADDRESS_WITH_HOST: IP address 100.1.1.2 configured on interface Ethernet1/1 is in use by a host with MAC address 00:00:01:01:00:00 on interface Ethernet1/1 in VRF default

13.1.1.3  Address Resolution Protocol (ARP)

Address Resolution Protocol (ARP) is a protocol that maps IP addresses to MAC addresses that local network devices recognize. The ARP cache is a table that stores the correlated addresses of the devices for which the router facilitates data transmissions.

After receiving a packet, routers use ARP to find the MAC address of the device assigned to the packet’s destination IP address. If the ARP cache contains both addresses, the router sends the packet to the specified port. If the ARP cache does not contain the addresses, ARP broadcasts a request packet to all devices in the subnet. The device at the requested IP address responds and provides its MAC address. ARP updates the ARP cache with a dynamic entry and forwards the packet to the responding device. Static ARP entries can also be added to the cache through the CLI.

Proxy ARP is an ARP variant. A network device (proxy) responds to ARP requests for network addresses on a different network with its MAC address. Traffic to the destination is directed to the proxy device which then routes the traffic toward the ultimate destination.

Configuring ARP

The switch uses ARP cache entries to correlate 32-bit IP addresses to 48-bit hardware addresses. The `arp aging timeout` command specifies the duration of dynamic address entries in the Address Resolution Protocol (ARP) cache for addresses learned through the Layer 3 interface. The default duration is 14400 seconds (four hours).

Entries are refreshed and expired at a random time that is in the range of 80%-100% of the cache expiry time. The refresh is tried three times at an interval of 2% of the configured timeout.

Static ARP entries never time out and must be removed from the table manually.

Example

This command specifies an ARP cache duration of 7200 seconds (two hours) for dynamic addresses added to the ARP cache that were learned through VLAN 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#arp aging timeout 7200
switch(config-if-Vl200)#show active
interface Vlan200
    arp aging timeout 7200
switch(config-if-Vl200)#
```

The `arp` command adds a static entry to an Address Resolution Protocol (ARP) cache.

Example

This command adds a static entry to the ARP cache in the default VRF.

```
switch(config)#arp 172.22.30.52 0025.900e.c63c arpa
```
13.1.1.3.1 Gratuitous ARP

Gratuitous ARP packets are broadcast by a device in response to an internal change rather than as a response to an ARP request. The gratuitous ARP packet is a request packet (no reply expected) that supplies an unrequested update of ARP information. In a gratuitous ARP packet, both the source and destination IP addresses are the IP of the sender, and the destination MAC address is the broadcast address (ff:ff:ff:ff:ff).

Gratuitous ARP packets are generated to update ARP tables after an IPv4 address or a MAC address change occurs.

Configuring Gratuitous ARP

By default, Arista switch interfaces reject gratuitous ARP request packets. The `arp gratuitous accept` command configures an L3 interface to accept the gratuitous ARP request packets sent from a different device in the network and add their mappings to the ARP table. Gratuitous ARP can be configured on Ethernet interfaces, VLANs/SVI, or L3 port channels, but has no effect on L2 interfaces.

**Example**

These commands enable gratuitous ARP packet acceptance on `interface Ethernet 2/1`.

```
switch (config)#interface ethernet 2/1
switch (config-if-Et2/1)#arp gratuitous accept
```

13.1.1.4 Displaying ARP Entries

The `show ip arp` command displays ARP cache entries that map an IP address to a corresponding MAC address. The table displays addresses by their host names when the command includes the `resolve` argument.

**Examples**

- This command displays ARP cache entries that map MAC addresses to IPv4 addresses.

```
switch>show ip arp
```

### 13.1.1.4.1 ARP Inspection

Address Resolution Protocol (ARP) inspection command `ip arp inspection vlan` activates a security feature that protects the network from ARP spoofing. ARP requests and responses on untrusted interfaces are intercepted on specified VLANs, and intercepted packets are verified to have valid IP-MAC address bindings. All invalid ARP packets are dropped. On trusted interfaces, all incoming ARP packets are processed and forwarded without verification.

**Enabling and Disabling ARP Inspection**

By default, ARP inspection is disabled on all VLANs.

#### Examples

- This command enables ARP inspection on VLANs 1 through 150.

  ```
  switch(config)#ip arp inspection vlan 1 - 150
  switch(config)#
  ```

- This command disables ARP inspection on VLANs 1 through 150.

  ```
  switch(config)#no ip arp inspection vlan 1 - 150
  switch(config)#
  ```
**Layer 3 Configuration**

- This command sets the ARP inspection default to VLANs 1 through **150**.
  ```
  switch(config)# default ip arp inspection vlan 1 - 150
  switch(config)#
  ```

- These commands enable ARP inspection on multiple VLANs 1 through **150** and **200** through **250**.
  ```
  switch(config)# ip arp inspection vlan 1-150,200-250
  switch(config)#
  ```

**Syslog for Invalid ARP Packets Dropped**

When an invalid ARP packet is dropped, the following syslog message appears. The log severity level can be set higher if required.

```
%SECURITY-4-ARP_PACKET_DROPPED: Dropped ARP packet on interface Ethernet28/1 Vlan 2121 because invalid mac and ip binding. Received: 00:0a:00:bc:00:de/1.1.1.1.
```

**Displaying ARP Inspection States**

The command `show ip arp inspection vlan` displays the configuration and operation state of ARP inspection. For a VLAN range specified by `show ip arp inspection vlan` only VLANs with ARP inspection enabled will be displayed. If no VLAN is specified, all VLANs with ARP inspection enabled are displayed. The operation state turns to **Active** when hardware is ready to trap ARP packets for inspection.

**Example**

This command displays the configuration and operation state of ARP inspection for VLANs 1 through **150**.

```
switch(config)# show ip arp inspection vlan 1 - 150

VLAN 1
------
Configuration : Enabled
Operation State : Active
VLAN 2
------
Configuration : Enabled
Operation State : Active
{...}
VLAN 150
------
Configuration : Enabled
Operation State : Active
switch(config)#
```
Displaying ARP Inspection Statistics

The command `show ip arp inspection statistics` displays the statistics of inspected ARP packets. For a VLAN specified by `show ip arp inspection vlan` only VLANs with ARP inspection enabled will be displayed. If no VLAN is specified, all VLANs with ARP inspection enabled are displayed.

The command `clear arp inspection statistics` clears ARP inspection.

**Examples**

- This command displays ARP inspection statistics for **VLAN 1**.

  ```
  switch(config)#show ip arp inspection statistics vlan 2
  Vlan : 2
  ------------
  ARP Req Forwarded = 20
  ARP Res Forwarded = 20
  ARP Req Dropped = 1
  ARP Res Dropped = 1
  Last invalid ARP:
  Time: 10:20:30 ( 5 minutes ago )
  Reason: Bad IP/Mac match
  Received on: Ethernet 3/1
  Packet:
  Source MAC: 00:01:00:01:00:01
  Dest MAC: 00:02:00:02:00:02
  ARP Type: Request
  ARP Sender MAC: 00:01:00:01:00:01
  ARP Sender IP: 1.1.1
  ```

- This command displays ARP inspection statistics for **Ethernet interface 3/1**.

  ```
  switch(config)#show ip arp inspection statistics ethernet interface 3/1
  Interface : 3/1
  --------
  ARP Req Forwarded = 10
  ARP Res Forwarded = 10
  ARP Req Dropped = 1
  ARP Res Dropped = 1
  Last invalid ARP:
  Time: 10:20:30 ( 5 minutes ago )
  Reason: Bad IP/Mac match
  Received on: VLAN 10
  Packet:
  Source MAC: 00:01:00:01:00:01
  Dest MAC: 00:02:00:02:00:02
  ARP Type: Request
  ARP Sender MAC: 00:01:00:01:00:01
  ARP Sender IP: 1.1.1
  ```

- This command clears ARP inspection statistics.

  ```
  switch(config)#clear arp inspection statistics
  ```
Configure Trust Interface

By default, all interfaces are untrusted. The command `ip arp inspection trust` configures the trust state of an interface.

**Examples**

- This command configures the trust state of an interface.
  
  ```
  switch(config)#ip arp inspection trust
  switch(config)#
  ```

- This command configures the trust state of an interface to untrusted.
  
  ```
  switch(config)#no ip arp inspection trust
  switch(config)#
  ```

- This command configures the trust state of an interface to its default (untrusted).
  
  ```
  switch(config)#default ip arp inspection trust
  switch(config)#
  ```

Configure Rate Limit

When ARP inspection is enabled, ARP packets are trapped to the CPU. Two actions can be taken when the incoming ARP rate exceeds expectation. For notification purpose, the command `ip arp inspection logging` will enable logging of the incoming ARP packets. To prevent a denial-of-service attack, the command `ip arp inspection limit` will error-disable interfaces.

**Examples**

- This command enables logging of incoming ARP packets when its rate exceeds the configured value, and sets the rate to 2048 (which is the upper limit for the number of invalid ARP packets allowed per second), and sets the burst consecutive interval over which the interface is monitored for a high ARP rate to 15 seconds.
  
  ```
  switch(config)#ip arp inspection logging rate 2048 burst interval 15
  switch(config)#
  ```

- This command configures the rate limit of incoming ARP packets to errdisable the interface when the incoming ARP rate exceeds the configured value, sets the rate to 512 (which is the upper limit for the number of invalid ARP packets allowed per second), and sets the burst consecutive interval over which the interface is monitored for a high ARP rate to 11 seconds.
  
  ```
  switch(config)#ip arp inspection limit rate 512 burst interval 11
  switch(config)#
  ```

- This command displays verification of the interface specific configuration.
  
  ```
  switch(config)#interface Ethernet 3 / 1
  ```
Configure Errdisable Caused by ARP Inspection

If the incoming ARP packet rate on an interface exceeds the configured rate limit in burst interval, the interface will be errdisabled (by default). If errdisabled, the interface will stay in this state until you intervene with the command `errdisable detect cause arp-inspection` (e.g., after you perform a `shutdown` or `no shutdown` of the interface) or it automatically recovers after a certain time period. The command `errdisable recovery cause arp-inspection` will enable auto recovery. The command `errdisable recovery interval` will enable sharing the auto recovery interval among all errdisable interfaces. (See the chapter Data Transfer Introduction for information on all `errdisable` commands.

Examples:

- This command enables errdisable caused by an ARP inspection violation.

```
switch(config)#errdisable detect cause arp-inspection
switch(config)#
```

- This command disables errdisable caused by an ARP inspection violation.

```
switch(config)#no errdisable detect cause arp-inspection
switch(config)#
```

- This command enables auto recovery.

```
switch(config)#errdisable recovery cause arp-inspection
switch(config)#
```

- This command disables auto recovery.

```
switch(config)#no errdisable recovery cause arp-inspection
switch(config)#
```

- This command enables sharing the auto recovery interval of 10 seconds among all errdisable interfaces.

```
switch(config)#errdisable recovery interval 10
switch(config)#
```

- This command disables sharing the auto recovery interval of 10 seconds among all errdisable interfaces.

```
switch(config)#no errdisable recovery interval 10
switch(config)#
```
• This command displays the reason for a port entering the errdisab state.

```console
switch(config)# show interfaces status errdisabled
Port   Name     Status      Reason
------- -------- ----------- ---------------
Et3/2   errdisabled    arp-inspection
switch(config)#
```

**Configure Static IP MAC Binding**

The ARP inspection command `ip source binding` allows users to add static IP-MAC binding. If enabled, ARP inspection verifies incoming ARP packets based on the configured IP-MAC bindings. The static IP-MAC binding entry can only be configured on Layer 2 ports. By default, there is no binding entry on the system.

**Examples**

• This command configures static IP-MAC binding for IP address 127.0.0.1, MAC address 0001.0001.0001, VLAN 1, and Ethernet interface slot 4 and port 1.

```console
switch(config)#ip source binding 127.0.0.1 0001.0001.0001 vlan 1 interface ethernet 4/1
switch(config)#
```

• This command configures static IP-MAC binding for IP address 127.0.0.1, MAC address 0001.0001.0001, VLAN 1, and port-channel interface 20.

```console
switch(config)#ip source binding 127.0.0.1 0001.0001.0001 vlan 1 interface port-channel 20
switch(config)#
```

• This command displays the configured IP-MAC binding entries. Note that the Lease column is mainly used for displaying dynamic DHCP snooping binding entries. For static binding entries, lease time is shown as infinite.

```console
switch(config)# show ip source binding 127.0.0.1 0001.0001.0001 static vlan 1 interface port-channel 20
MacAddress  IpAddress  Lease(sec)  Type   VLAN   Interface
------------ ----------- ----------- ------ ----- --------------
0001.0001.0001  127.0.0.1  infinite  static 1  Port-Channel20
switch(config)#
```

### 13.1.2 IPv4 Routing

Internet Protocol version 4 (IPv4) is a communications protocol used for relaying network packets across a set of connected networks using the Internet Protocol suite. Routing transmits network layer data packets over connected independent subnets. Each subnet is assigned an IP address range and each device on the subnet is assigned an IP address from that range. The connected subnets have IP address ranges that do not overlap.

A router is a network device that connects multiple subnets. Routers forward inbound packets to the subnet whose address range includes the packets’ destination address. IPv4 and IPv6 are internet
layer protocols that define packet-switched internetworking, including source-to-destination datagram transmission across multiple networks.

These sections describe IPv4 routing and route creation options:

- Enabling IPv4 Routing
- Static and Default IPv4 Routes
- Dynamic IPv4 Routes
- Viewing IPv4 Routes and Network Components

### 13.1.2.1 Enabling IPv4 Routing

When IPv4 routing is enabled, the switch attempts to deliver inbound packets to destination IPv4 addresses by forwarding them to interfaces or next hop addresses specified by the forwarding table.

The `ip routing` command enables IPv4 routing.

**Example**

This command enables IP routing:

```
switch(config)#ip routing
```

### 13.1.2.2 Static and Default IPv4 Routes

Static routes are entered through the CLI and are typically used when dynamic protocols are unable to establish routes to a specified destination prefix. Static routes are also useful when dynamic routing protocols are not available or appropriate. Creating a static route associates a destination IP address with a local interface. The routing table refers to these routes as connected routes that are available for redistribution into routing domains defined by dynamic routing protocols.

The `ip route` command creates a static route. The destination is a network segment; the nexthop is either an IP address or a routable interface port. When multiple routes exist to a destination prefix, the route with the lowest administrative distance takes precedence.

By default, the administrative distance assigned to static routes is 1. Assigning a higher administrative distance to a static route configures it to be overridden by dynamic routing data. For example, a static route with a distance value of 200 is overridden by OSPF intra-area routes, which have a default distance of 110.

A route tag is a 32-bit number that is attached to a route. Route maps use tags to filter routes. Static routes have a default tag value of 0.

**Example**

This command creates a static route:

```
switch(config)#ip route 172.17.252.0/24 vlan 500
```

### Creating Default IPv4 Routes

The default route denotes the packet forwarding rule that takes effect when no other route is configured for a specified IPv4 address. All packets with destinations that are not established in the routing table are sent to the destination specified by the default route.
The IPv4 destination prefix is \textbf{0.0.0.0} and the next-hop is the default gateway.

\begin{quote}
\textbf{Example}
This command creates a default route and establishes \textbf{192.14.0.4} as the default gateway address:
\begin{verbatim}
switch(config)#ip route 0.0.0.0/0 192.14.0.4
switch(config)#
\end{verbatim}
\end{quote}

\section*{Dynamic IPv4 Routes}
Dynamic routes are established by dynamic routing protocols. These protocols also maintain the routing table and modify routes to adjust for topology or traffic changes. Routing protocols assist the switch in communicating with other devices to exchange network information, maintaining routing tables, and establishing data paths.

The switch supports these dynamic IPv4 routing protocols:
\begin{itemize}
  \item OSPFv2 Introduction
  \item Border Gateway Protocol (BGP)
  \item Routing Information Protocol (RIP)
  \item IS-IS
\end{itemize}

\section*{Viewing IPv4 Routes and Network Components}
\subsection*{Displaying the FIB and Routing Table}
The \texttt{show ip route} command displays routing table entries that are in the forwarding information base (FIB), including static routes, routes to directly connected networks, and dynamically learned routes. Multiple equal-cost paths to the same prefix are displayed contiguously as a block, with the destination prefix displayed only on the first line.

The \texttt{show running-config} command displays configured commands not in the FIB. The \texttt{show ip route summary} command displays the number of routes, categorized by source, in the routing table.

\begin{quote}
\textbf{Examples}
\begin{itemize}
  \item This command displays IP routes learned through BGP.
\end{itemize}
\end{quote}

\begin{verbatim}
switch>show ip route bgp
Codes:  C - connected,  S - static,  K - kernel,

Displaying the IP Route Age

The `show ip route age` command displays the time when the route for the specified network was present in the routing table. It does not account for the changes in parameters like metric, next-hop etc.

Example:

This command displays the amount of time since the last update to ip route 172.17.0.0/20.

```
switch> show ip route 172.17.0.0/20 age

Codes: C - connected, S - static, K - kernel, O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1, E2 - OSPF external type 2, N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP, R - RIP, I - ISIS, A - Aggregate

B E 172.17.0.0/20 via 172.25.0.1, age 3d01h
```

Displaying Gateways

A gateway is a router that provides access to another network. The gateway of last resort, also known as the default route, is the route that a packet uses when the route to its destination address is unknown. The IPv4 default route in is 0.0.0.0.

The `show ip route gateway` command displays IP addresses of all gateways (next hops) used by active routes.
Example

This command displays next hops used by active routes.

```
switch>show ip route gateway
The following gateways are in use:
  172.25.0.1 Vlan101
  172.17.253.2 Vlan2000
  172.17.254.2 Vlan2201
  172.17.254.11 Vlan2302
  172.17.254.13 Vlan2302
  172.17.254.17 Vlan2303
  172.17.254.20 Vlan2303
  172.17.254.66 Vlan2418
  172.17.254.67 Vlan2418
  172.17.254.68 Vlan2768
  172.17.254.29 Vlan3020

switch>
```

Displaying Host Routes

The `show ip route host` command displays all host routes in the host forwarding table. Host routes are those whose destination prefix is the entire address (mask = 255.255.255.255 or prefix = /32). Each displayed host route is labeled with its purpose:

- **F** static routes from the FIB.
- **R** routes defined because the IP address is an interface address.
- **B** broadcast address.
- **A** routes to any neighboring host for which the switch has an ARP entry.

Example

This command displays all host routes in the host forwarding table.

```
switch#show ip route host
R - receive  B - broadcast  F - FIB,  A - attached
F 127.0.0.1 to cpu
B 172.17.252.0 to cpu
A 172.17.253.2 on Vlan2000
R 172.17.253.3 to cpu
A 172.17.253.10 on Vlan2000
R 172.17.254.1 to cpu
A 172.17.254.2 on Vlan2901
B 172.17.254.3 to cpu
B 172.17.254.8 to cpu
A 172.17.254.11 on Vlan2902
R 172.17.254.12 to cpu

F 172.26.0.28 via 172.17.254.20 on Vlan3003
    via 172.17.254.67 on Vlan3008
    via 172.17.254.98 on Vlan3492
via 172.17.254.86 on Vlan3884
    via 172.17.253.2 on Vlan3000
F 172.26.0.29 via 172.25.0.1 on Vlan101
F 172.26.0.30 via 172.17.254.29 on Vlan3910
```
13.1.3 IPv4 Multicast Counters

IPv4 multicast counters allow association of IPv4 multicast routes with a packet or byte counter.

This chapter contains the following sections:

- Multicast Counters Hardware Overview
- Multicast Counters iBGP and eBGP Configuration
- Configuring IPv4 Multicast Counters

13.1.3.1 Multicast Counters Hardware Overview

This section describes a hardware overview for multicast counters, and contains the following sections:

- Platform Independent Requirements for Counters
- Policer Counter Overview
- BGP Functions Supported for Arista Switches
- Additional Requirements

13.1.3.1.1 Platform Independent Requirements for Counters

The following platform independent requirements include:

- Enable/Disable counters
- Clear counters
- Show counters
- Configure counter mode for byte (default) or frame mode

13.1.3.1.2 Policer Counter Overview

The switch hardware has two policer banks, each with 4k entries and each entry has one 32 bit entry1, and one 32 bit entry2, which can be used as either packet counter or byte counter.

In the pipeline, each bank can have one policer index coming from upstream blocks, which means different features cannot update multiple policer entries in the same bank simultaneously. Therefore, different features cannot share entries in the same bank.

In switch hardware routing, each FFU/BST entry points to a corresponding RAM. A policer index is saved in the action ram, so when installing a multicast route into hardware, platform code will get a policer index and saved in the action field. If a policer index is unavailable, a counter is not added to the action field.

Switch hardware can have multiple features competing for the policer banks. It is desirable to have a platform command to reserve policer banks dedicated for a certain feature.

The following command reserves one or two policer banks to be used only by the named feature:

```
[no] platform fm6000 [nat|acl|qos|multicast] policer banks <1|2>
```

Available bank(s) are reserved for the feature. Otherwise the command takes effect at the next reboot or FocalPointV2 agent restart. This reservation guarantees the configured number of bank(s) for this feature. However, the feature can still possibly obtain the other policer bank if it needs more, and the other bank is available.
If a feature has a pending reservation request which is not fulfilled because of availability, and some other feature frees a bank, the bank will be allocated to the pending feature.

13.1.3.3 BGP Functions Supported for Arista Switches

Arista switches support these BGP functions:
- A single BGP instance
- Simultaneous internal (IBGP) and external (EBGP) peering
- Multiprotocol BGP
- BGP Confederations

13.1.3.4 Additional Requirements

On switch hardware, the following additional requirements include:
- Reservation of policer banks
- Notification of policer bank availability when a policer entry is freed by other features

13.1.3.2 Multicast Counters iBGP and eBGP Configuration

This section describes the commands required to configure an iBGP and an eBGP topology, and contains the following sections.
- Policer Usage

13.1.3.2.1 Policer Usage

There are two types of counters – those created by wildcard creation and by specific creation. When a specific counter is required and the hardware runs out of policer entries, a wildcard counter is forced to give up its policer entry.

If the user configures a specific counter and the Starter Group (SG) already has a wildcard-created counter for it, then this counter is upgraded to a specific one, with no change in hardware policer index. If the user configures both a wildcard counter and specific counter for this SG, and subsequently deletes the specific counter, the counter for this SG is downgraded to a wildcard, with no change in hardware policer index. However, if another specific counter is pending for a hardware policer index, then this policer entry will be assigned to that counter due to its higher precedence.

Even if a counter is configured by the user, in order to conserve the use of hardware resources, do not allocate a policer entry until a real route (G, S) is programmed into the Frame Filtering and Forwarding Unit (FFU).

13.1.3.3 Configuring IPv4 Multicast Counters

Perform the following CLI steps to configure IPv4 multicast counters on the FM6000 platform:

1. Execute the global configuration command:
   - no default ip multicast count bytes | packets
     Enables wildcard counters. Also used to change bytes / packets mode. When hardware runs out of resources, specific creation has priority to preempt counters from wildcard creation. The bytes | packets optional keyword enables the counter to be in either bytes mode or packets mode. This mode applies to all counters. When the counter mode changes, all counter values will be reset to zero.
   - no default ip multicast count <G> <S>
     This is only takes affect when ip multicast count is enabled. Either <G> <S> or bytes | packets optional keyword is used. They can not be used concurrently.
No | default Commands: (default is same as no)

- **no ip multicast count** Deletes all multicast counters, including explicit \(<G> <S>\) routes
- **no ip multicast count \(<G> <S>\)** Removes the config. Does not delete the counter because the wildcard is still active.
- If no \(<G, S>\) is specified, all multicast routes will have counters unless the hardware runs out of resources. The creation of counters is referred to as “wildcard creation.”
- If \(<G, S>\) is specified, only \(<G, S>\) will get a counter (and no other route). The creation of counters is referred to as “specific creation.” By default, all mcast routes will have counters allocated. This \(<G, S>\) configuration is applicable when the hardware runs out of resources. Specific \(<G, S>\) creation has priority to preempt counters from wildcard creation.

The **byte** | **frame** optional keyword enables the counter to be in either byte mode or frame mode. This mode applies to all counters. When the counter mode changes, all counter values will be reset to zero.

Either \(<G, S>\), or **byte** | **frame** optional keywords are used but cannot be used together. All counters are **byte** | **frame**. The **byte** | **frame** mode is global, and not applicable on a \(<G, S>\) basis.

2. Execute clear command:

```
clear ip multicast count \(<G> <S>\)
```

3. Execute show command:

```
show multicast fib ipv4 \(<G> count
```

This command currently exists but does not show anything.

This show command is intended to display the following (example):

```
switch>show multicast fib ipv4 count
Activity poll time: 60 seconds
225.1.1.1 100.0.0.2
Byte: 123
Vlan100 (iif)
Vlan200
Activity 0:00:47 ago
```

Total counts is the sum of counts from all sources in that group.

The count value can be **N/A** if a mroute does not have an associated counter.

If the count value for any source in a \(G\) is **N/A**, then the total counts for \(G\) will be shown as **N/A**. However, the count values for other sources are still shown.

### 13.1.4 Route Management

When routing is enabled, the switch discovers the best route to a packet’s destination address by exchanging routing information with other devices. IP routing is disabled by default.

The following sections describes routing features that the switch supports:

- **Route Redistribution**
- **Equal Cost Multipath Routing (ECMP) and Load Sharing**
- **Unicast Reverse Path Forwarding (uRPF)**
- **Routing Tables / Virtual Routing and Forwarding (VRF)**
- **RIB Route Control**
13.1.4.1 Route Redistribution

Route redistribution is the advertisement, into a dynamic routing protocol's routing domain, of connected (static) routes or routes established by other routing protocols. By default, the switch advertises only routes in a routing domain that are established by the protocol that defined the domain.

Route redistribution commands specify the scope of the redistribution action. By default, all routes from a specified protocol (or all static routes) are advertised into the routing domain. Commands can also filter routes by applying a route map, which defines the subset of routes to be advertised.

13.1.4.2 Equal Cost Multipath Routing (ECMP) and Load Sharing

Equal Cost Multi-Path (ECMP) is a routing strategy where traffic is forwarded over multiple paths that have equal routing metric values.

Configuring ECMP (IPv4)

All ECMP paths are assigned the same tag value; commands that change the tag value of a path also change the tag value of all paths in the ECMP route.

In a network topology using ECMP routing, hash polarization may result when all switches perform identical hash calculations. Hash polarization leads to uneven load distribution among the data paths. Hash polarization is avoided when switches use different hash seeds to perform hash calculations.

The `ip load-sharing` command provides the hash seed to an algorithm that the switch uses to distribute data streams among multiple equal-cost routes to a specified subnet.

```
Example

This command sets the IPv4 load sharing hash seed to 20:

switch(config)#ip load-sharing fm6000 20
switch(config)#
```

Multicast Traffic Over ECMP

The switch attempts to spread outbound unicast and multicast traffic to all ECMP route paths equally. To disable the sending of multicast traffic over ECMP, use the `multipath none` command or the no version of the `multipath deterministic` command.

Resilient ECMP

Resilient ECMP is used for those prefixes where it is not desirable for routes to be rehashed due to link flap, typically where ECMP is being used for load balancing. Resilient ECMP configures a fixed number of next-hop entries in the hardware ECMP table for all the routes within a specified IP address prefix. Implementing fixed table entries for a specified next-hop address allows data flows that are hashed to a valid next-hop number to remain intact even when some of the next hops go down or come back online.

Resilient ECMP is enabled for all routes within a specified prefix using the `ip hardware fib ecmp resilience` command. The command specifies the maximum number of next-hop addresses that the hardware ECMP table can contain for the specified IP prefix, and configures a redundancy factor that facilitates the duplication of next-hop addresses in the table. The fixed table space for the address is the maximum number of next hops multiplied by the redundancy factor. When the table contains the maximum number of next-hop addresses, the redundancy factor specifies the number of times each address is listed in the table. When the table contains fewer than the maximum number of next-hop addresses, the table space entries are filled by additional duplication of the nexthop addresses.
Resilient ECMP is also available for IPv6 IP addresses.

**Example**

This command configures a hardware ECMP table space of 24 entries for the IP address 10.14.2.2/24. A maximum of six next-hop addresses can be specified for the IP address. When the table contains six next-hop addresses, each appears in the table four times. When the table contains fewer than six next-hop addresses, each is duplicated until the 24 table entries are filled.

```plaintext
switch(config)#ip hardware fib ecmp resilience 10.14.2.2/24
capacity 6 redundancy 4
switch(config)#
```

### 13.1.4.2.1 Resilient ECMP (RECMP) Deduping

Routes covered by a resilient equal-cost multi-path (RECMP) prefix are types of routes that make use of hardware tables dedicated for equal-cost multi-path (ECMP) routing. Resilient ECMP (RECMP) deduping reduces the number of ECMP hardware table entries allocated by the switch by forcing the routes that share the same set of next hops but point to different hardware table entries to point to the same hardware table entry when hardware resource utilization is high. Forcing RECMP routes to change the hardware table entry that they point to may potentially cause a traffic flow disruption for any existing flows going over that route. The deduping process will attempt to minimize the amount of potential traffic loss caused.

Each route needs to allocate hardware table entries in the ASIC, which contains forwarding information for the route, such as what its next-hops are, what egress links each next-hop uses, etc. The network device uses these hardware table entries when making forwarding decisions for a packet that is meant for a certain route. These ECMP hardware tables are limited in size and can fill up quickly if there are a large number of these hardware table entries allocated. One option to ease the usage of these hardware tables is to force RECMP routes to share hardware table entries.

There is already an existing feature for RECMP routes to get them to point to the same hardware table entry if they share the same set of next hops and the ordering of the next-hops is the same. However, RECMP routes may end up sharing the same set of next-hops, but the next-hop ordering may be different between them, and therefore the routes end up occupying different hardware table entries in the ASIC. RECMP routing has a property wherein the current ordering of next-hops for a given route is influenced by its previous orderings. The ordering between the routes can differ because these routes may have had a different set of next hops at some previous time before they finally converged onto the same set of next-hops.

When the ECMP hardware resource usage crosses the high threshold, the deduping process begins, and it lasts until the ECMP hardware resource usage falls below the low threshold. Use the IP hardware fib next-hop resource optimization thresholds command to modify the thresholds.

### 13.1.4.2.1.1 Configuring Resilient ECMP Deduping

The Resilient ECMP Deduping is enabled by default.

- The following command is used to disable all the hardware resource optimization features:

```plaintext
switch(config)#ip hardware fib next-hop resource optimization disabled
```
Layer 3 Configuration

• The following command is used to re-enable the all hardware resource optimization features after disabling them:

switch(config)#no ip hardware fib next-hop resource optimization disabled

• The following command is used to configure the thresholds for starting and stopping the optimization:

switch(config)#ip hardware fib next-hop resource optimization thresholds low <20> high <80>

Note:
• The value specified for the threshold represents the percentage of resource utilization, and is an integer between 0 and 100.
• Setting the high threshold to 80 indicates that optimization starts when the resource utilization is above 80%. The default value of this threshold is 90.
• Setting the low threshold to 20 indicates that optimization stops when the resource utilization is below 20%. The default value of this threshold is 85.

13.1.4.2.1.2 Show Commands

• The show ip hardware fib summary command is used to display the statistics of this RECMP deduping:

Example

switch#show ip hardware fib summary
Fib summary
--------------
Adjacency sharing: disabled
BFD peer event: enabled
Deletion Delay: 0
Protect default route: disabled
PBR: supported
URPF: supported
ICMP unreachable: enabled
Max Ale ECMP: 600
UCMP weight deviation: 0.0
Maximum number of routes: 0
Fib compression: disabled
Resource optimization for adjacency programming: enabled
Adjacency resource optimization thresholds: low 20, high 80

The last two lines of the output shows whether RECMP deduping is enabled, and what are the corresponding threshold values for starting and stopping the optimization process.

• The show hardware capacity command is used to display the utilization of the hardware resources. The example below shows the multi-level hierarchy ECMP resources:

switch#show hardware capacity
Forwarding Resources Usage
Table Feature Chip Used Used Free Entries (%)
Committed Best Case High Entries
Entries Entries Max Watermark Entries
-------------- ------------------ --------------- ----------
13.1.4.2.1.3 Limitations

- With RECMP deduping, optimization of a sub-optimal ECMP route requires releasing and reallocating hardware resources for the route. Therefore the process may increase overall convergence time for route programming. It may not be desirable to always start the optimization when the hardware resource is sufficient. The threshold value for starting the optimization should be adjusted based on the route scale of the network.
- The deduping of ECMP hardware resources may cause potential traffic flow disruption for traffic flows going over RECMP routes with changing hardware table entries. While the deduping process tries to minimize the amount of traffic flow disruption, it is still sometimes inevitable.
- RECMP hardware table entries can only be deduped to other RECMP hardware table entries that share the same set of nexthops. This puts a limit to the amount of RECMP hardware table entries that can be reduced to the number of RECMP hardware table entries with unique nexthop sets.

13.1.4.3 Unicast Reverse Path Forwarding (uRPF)

Unicast Reverse Path Forwarding (uRPF) verifies the accessibility of source IP addresses in packets that the switch forwards. The switch drops a packet when uRPF determines that the routing table does not contain an entry with a valid path to that packet’s source IP address.

IPv4 and IPv6 uRPF operate independently. uRPF is VRF aware. Commands that do not specify a VRF utilize the default instance. Multicast routing is not affected by uRPF.

uRPF defines two operational modes: strict mode and loose mode.
- **Strict mode**: uRPF also verifies that a packet is received on the interface that its routing table entry will use for its return packet.
- **Loose mode**: uRPF validation does not consider the inbound packet’s ingress interface.

13.1.4.3.1 uRPF Operation

uRPF is configurable on interfaces. For packets arriving on a uRPF-enabled interfaces, the source IP address is verified by examining the source and destination addresses of unicast routing table entries.

uRPF requires a reconfigured routing table to support IP address verification. When uRPF is enabled for the first time, unicast routing is briefly disabled to facilitate the routing table reconfiguration. Multicast routing is not affected by the initial uRPF enabling.

A packet fails uRPF verification if the table does not contain an entry whose source or destination address matches the packet’s source IP address. In strict mode, the uRPF also fails when the matching entry’s outbound interface does not match the packet’s ingress interface.

uRPF verification is not available for the following packets:
- DHCP (Source is **0.0.0.0** – Destination is **255.255.255.255**).
- IPv6 link local (**FE80::/10**).
- Multicast packets.
ECMP uRPF
When verifying ECMP routes, strict mode checks all possible paths to determine that a packet is received on the correct interface. Strict mode is supported for ECMP groups with a maximum of eight routing table entries. The switch reverts to loose mode for ECMP groups that exceed eight entries.

Default Routes
uRPF strict mode provides an allow-default option that accepts default routes. On interfaces that enable allow-default and a default route is defined, uRPF strict mode validates a packet even when the routing table does not contain an entry that matches the packet’s source IP address. When allow-default is not enabled, uRPF does not consider the default route when verifying an inbound packet.

Null Routes
NULL0 routes drop traffic destined to a specified prefix. When uRPF is enabled, traffic originating from a null route prefixes is dropped in strict and loose modes.

13.1.4.3.2 uRPF Configuration
Unicast Reverse Path Forwarding (uRPF) is enabled for IPv4 packets ingressing the configuration mode interface through the ip verify command.

Note: uRPF cannot be enabled on interfaces with ECMP member FECs.

Examples

- This command enables uRPF loose mode on interface vlan 17.
  ```
  switch(config)#interface vlan 17
  switch(config-if-Vl17)#ip verify unicast source reachable-via any
  switch(config-if-Vl17)#show active
  interface Vlan17
  ip verify unicast source reachable-via any
  switch(config-if-Vl17)#
  ```

- This command enables uRPF strict mode on interface vlan 18.
  ```
  switch(config)#interface vlan 18
  switch(config-if-Vl18)#ip verify unicast source reachable-via rx
  switch(config-if-Vl18)#show active
  interface Vlan18
  ip verify unicast source reachable-via rx
  switch(config-if-Vl18)#
  ```

13.1.4.4 Routing Tables / Virtual Routing and Forwarding (VRF)
An IP routing table is a data table that lists the routes to network destinations and metrics (distances) associated with those routes. A routing table is also known as a Routing Information Base (RIB).

Virtual Routing and Forwarding (VRF) allows traffic separation by maintaining multiple routing tables. Arista switches support multiple VRF instances: one global or default VRF called “default” and multiple user-defined VRFs; the number of user-defined VRFs supported varies by platform. VRFs can be used as management or data plane VRFs.

- Management VRFs have routing disabled. They are typically used for management-related traffic.
Dataplane VRFs have routing enabled. They support routing protocols and packet forwarding (hardware and software).

Dataplane VRFs are supported by Trident, FM6000, and Arad platform switches.

VRFs support unicast IPv4 and IPv6 traffic and multicast traffic. Loopback, SVI, and routed ports may be added to VRFs. Management ports may be added without any hardware forwarding.

To allow overlap in the sets of IP addresses used by different VRF instances, a Route Distinguisher (RD) may be prepended to each address. RDs are defined in RFC 4364.

13.1.4.4.1 Default VRF

The default VRF on Arista switches is called “default.” It is created automatically and cannot be renamed or configured. Some configuration options accept “default” as a VRF input.
13.1.4.4.2 User-Defined VRFs

A user-defined VRF is created with the `vrf instance` command. After its creation, a VRF may be assigned a route distinguisher (RD) with the `rd` (VRF configuration mode) command in the VRF submode of Router-BGP Configuration Mode.

**Examples**

- These commands create a VRF named `purple`, place the switch in BGP VRF configuration mode for that VRF, and specify a route distinguisher for the VRF identifying the administrator as **AS 530** and assigning 12 as its local number.

  ```
  switch(config)#vrf instance purple
  switch(config-vrf-purple)#router bgp 50
  switch(config-router-bgp)#vrf purple
  switch(config-router-bgp-vrf-purple)#rd 530:12
  ``

- To add interfaces to a user-defined VRF, enter configuration mode for the interface and use the `vrf` (Interface mode) command. Loopback, SVI, and routed ports can be added to a VRF.

  These commands add **VLAN 20** to the VRF named **purple**.

  ```
  switch(config)#interface VLAN 20
  switch(config-if-Vl20)#vrf purple
  switch(config-if-Vl20)#
  ```

- The `show vrf` command shows information about user-defined VRFs on the switch.

  This command displays information for the VRF named **purple**.

  ```
  switch>show vrf purple
  Vrf    RD         Protocols  State       Interfaces
  ------ ---------- ---------- ----------- ------------
  purple 64496:237 ipv4       no routing  Vlan42, Vlan43
  ```
13.1.4.4.2 rd (VRF configuration mode)

The `rd` command issued in VRF Configuration Mode is a legacy command supported for backward compatibility. To configure a Route Distinguisher (RD) for a VRF, use the `rd (VRF configuration mode)` command.

**Note:** Legacy RDs that were assigned to a VRF in VRF Configuration Mode will still appear in `show vrf` outputs if an RD has not been configured in Router-BGP VRF Configuration Mode, but they no longer have an effect on the system.

13.1.4.4.3 Context-Active VRF

The context-active VRF specifies the default VRF that VRF-context aware commands use when displaying or refreshing routing table data.

VRF-context aware commands include:
- `clear arp-cache`
- `show ip`
- `show ip arp`
- `show ip route`
- `show ip route gateway`
- `show ip route host`

The `cli vrf` command specifies the context-active VRF.

**Example**

This command specifies `magenta` as the context-active VRF.

```
switch# cli vrf magenta
switch# show routing-context vrf
Current VRF routing-context is magenta
```

The `show routing-context vrf` command displays the context-active VRF.

**Example**

This command displays the context-active VRF.

```
switch> show routing-context vrf
Current VRF routing-context is magenta
```

13.1.4.5 RIB Route Control

The Routing Information Base (RIB) is composed of the routing information learned by the routing protocols, including static routes. The Forwarding Information Base (FIB) is composed of the routes actually used to forward traffic through a router.

Forwarding Information Base (FIB) makes IP destination prefix-based switching decisions. The FIB is similar to a routing table or information base. It maintains the forwarding information for the winning routes from the RIB. When routing or topology changes occur in the network, the IP routing table information is updated, and those changes are reflected in the FIB.
13.1.4.5.1 Configuring FIB policy

The RIB calculates the best/winning routes to each destination and place these routes in the forwarding table. Based on the FIB policy configured the best routes are advertised.

For example, a FIB policy can be configured to deny the routes for FIB programming, however, it does not prevent these routes from being advertised by a routing protocol, or to be redistributed into another routing domain, or to be used for recursive resolution in the IP RIB. FIB policies control the size and content of the routing tables, and the best route to take to reach a destination.

The `rib ipv4 | ipv6 fib policy` command is used to enable FIB policy for a particular VRF under router general configuration mode.

The following match statements are supported:

- `match interface`
- `match [ip | ipv6] address prefix-list`
- `match [ip | ipv6] resolved-next-hop prefix-list`
- `match isis level`
- `match metric`
- `match source-protocol`

Example

The following example enables FIB policy for IPv4 in the default VRF, using the route map, `map1`.

```
switch(config)#router general
switch(config-router-general)#vrf default
switch(config-router-general-vrf-default)#rib ipv4 fib policy map1
```

13.1.4.5.2 Displaying FIB Information

Use the `show rib route <ipv4|ipv6> fib policy exclude` command to display the RIB information. The `fib policy excluded` option displays the RIB routes that have been excluded from being programmed into FIB, by FIB policy.

Example

The following example displays the routes filtered by FIB policy using the `fib policy excluded` option of the `show rib route ip|ipv6` command.

```
switch#show rib route ipv6 fib policy excluded
switch#show rib route ip bgp fib policy excluded

VRF name: default, VRF ID: 0xfe, Protocol: bgp
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Ospf, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
       L - Part of a recursive route resolution loop

>B 10.1.0.0/24 [200/0]
   via 10.2.2.1 [115/20] type tunnel
   via 10.3.5.1, Ethernet1
   via 10.3.6.1, Ethernet3

>B 10.1.0.0/24 [200/0]
```
13.1.4.5.3 Displaying RIB Route Information

Use the `show rib route ip` command to view the IPv4 RIB information.

**Example:**

This command displays IPv4 RIB static routes.

```
switch# show rib route ip static
VRF name: default, VRF ID: 0xfe, Protocol: static
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Ospf, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
       L - Part of a recursive route resolution loop
>S 10.80.0.0/12 [1/0]
   via 172.30.149.129 [0/1]
   via Management1, directly connected
>S 172.16.0.0/12 [1/0]
   via 172.30.149.129 [0/1]
   via Management1, directly connected
```

13.1.5 IPv4 Route Scale

IPv4 routes are optimized to achieve route scale when route distribution has a large number of routes of one or two parameters, with each parameter consisting of prefix lengths 12, 16, 20, 24, 28, and 32. If two separate prefix lengths are configured (in any order), one of them must be the prefix length of 32.

**Note:** IPv4 Route Scale cannot be used with AlgoMatch.

The following sections describes IPv4 route scale configuration, show commands, and system log messages:

- Configuring IPv4 Route Scale
- IPv4 Routescale with 2-to-1 Compression
- Show Commands

13.1.5.1 Configuring IPv4 Route Scale

IPv4 route scale is enabled by the `ip hardware fib optimize` command for the configuration mode interface. The platform Layer 3 agent is restarted to ensure IPv4 routes are optimized with the `agent SandL3Unicast terminate` command for the configuration mode interface.

**Example**
This configuration command allows configuring prefix lengths 12 and 32.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 12 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

One of the two prefixes in this command is a prefix-length of 32, which is required in the instance where there are two prefixes. For this command to take effect, you must restart the platform Layer 3 agent.

**Example**

This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.

**Example:**

This configuration command allows configuring prefix lengths 32 and 16.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 32 16
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

One of the two prefixes in this command is a prefix-length of 32, which is required in the instance where there are two prefixes. For this command to take effect, you must restart the platform Layer 3 agent.

**Examples**

- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.
  
  ```
  switch(config)#agent SandL3Unicast terminate
  SandL3Unicast was terminated
  ```

  Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.

- This configuration command allows configuring prefix length 24.
  
  ```
  switch(config)#ip hardware fib optimize exact-match prefix-length 24
  ```
In this instance, there is only one prefix-length, so a prefix-length of 32 is not required. For this command to take effect, you must restart the platform Layer 3 agent.

**Examples**

- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

  ```
  switch(config)#agent SandL3Unicast terminate
  SandL3Unicast was terminated
  ```

  Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.

- This configuration command allows configuring prefix length 32.

  ```
  switch(config)#ip hardware fib optimize exact-match prefix-length 32
  ! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
  ```

  For this command to take effect, you must restart the platform Layer 3 agent.

- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

  ```
  switch(config)#agent SandL3Unicast terminate
  SandL3Unicast was terminated
  ```

  Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.

- This configuration command disables configuring prefix lengths 12 and 32.

  ```
  switch(config)#no ip hardware fib optimize exact-match prefix-length 12 32
  ! Please restart layer 3 forwarding agent to ensure IPv4 routes are not optimized
  ```

One of the two prefixes in this command is a prefix-length of 32, which is required in the instance where there are two prefixes. For this command to take effect, you must restart the platform Layer 3 agent.

**Examples**

- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are not optimized.

  ```
  switch(config)#agent SandL3Unicast terminate
  SandL3Unicast was terminated
  ```

  Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.
Layer 3 Configuration

• This configuration command attempts to configure prefix length 20 and 28 which triggers an error exception. One of the two prefixes in this command must be a prefix-length of 32, which is required in the instance where there are two prefixes.

switch(config)#ip hardware fib optimize exact-match prefix-length 20 28
% One of the prefix lengths must be 32

IPv4 routes of certain prefix lengths can be optimized for enhanced route scale. The following command disable prefix optimization on the specified VRF(s) to provide more flexibility.

Examples

• This configuration command disables prefix optimization on the default VRF.

switch(config)#ip hardware fib optimize disable-vrf default
! Please restart layer 3 forwarding agent to ensure that the disable-vrf option change takes effect

• This configuration command disables prefix optimization on VRFs named vrf1 and vrf2.

switch(config)#ip hardware fib optimize disable-vrf vrf1 vrf2
! Please restart layer 3 forwarding agent to ensure that the disable-vrf option change takes effect

• This configuration command restarts the platform Layer 3 agent to ensure disable-vrf configuration to take effect.

switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated

Starting from the EOS Release 4.26.0F, /32 prefix length optimization command is supported in the R3 series.

Examples

• This configuration command enables prefix optimization on the default VRF.

switch(config)#ip hardware fib optimize vrf default prefix-length 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized

• This configuration command enables prefix optimization on VRFs named vrf1 and vrf2.

switch(config)#ip hardware fib optimize vrf vrf1 vrf2 prefix-length 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized

• This configuration command disables optimization on vrf1 and vrf2 optimization configured in above example.

switch(config)#no ip hardware fib optimize vrf vrf1
The `platform trident forwarding-table partition flexible` command enables ALPM Mode in Flexible UFT mode using a subset of resources, so ALPM and Exact Match can coexist. Prior to this release, ALPM could only be programmed in mode 4 where all the UFT resources were used and in flexible partition mode, configuring ALPM was not supported. This limits the number of IP routes that can be supported.

### Examples

- This configuration command sets up the flexible partition.

  ```
  switch(config)# platform trident forwarding-table partition flexible ?
  alpm         Shared UFT bank entries for the ALPM table
  exact-match  Shared UFT bank entries for the exact-match table
  l2-shared    Shared UFT bank entries for the MAC table
  l3-shared    Shared UFT bank entries for the host table
  ```

- ALPM gives the route prefix in DEFIM (TCAM table for longest prefix matched (LPM) lookup) and ALPM tables.

  ```
  switch(config)# platform trident forwarding-table partition flexible alpm ?
  184320  Upto 180K LPM routes
  368640  Upto 360K LPM routes
  ```

**Note:** The size parameter has following values:

- DCS-7300X3: 180k and 360k are accepted.
- CCS-720XP: 144k and 96k are accepted.
- Other sizes are invalid.

### 13.1.5.2 IPv4 Routescale with 2-to-1 Compression

The IPv4 routescale with 2-to-1 compression optimizes certain prefix lengths and enhances the route scale capabilities on 7500R, 7280R, 7500R2, and 7280R2 platforms. The compression is best suited to achieve route scale when route distribution has a large number of routes of one or two prefix lengths.

#### 13.1.5.2.1 Configuring IPv4 Routescale 2-to-1 Compression

Use the `compress` command to increase the hardware resources available for the specified prefix length. This command allows configuring up to one compressed prefix length, and this command is supported only on 7500R, 7280R, 7500R2, and 7280R2 platforms.

**Note:** The `compress` command takes effect only when you restart the platform Layer3 agent on 7500R, 7280R, 7500R2, and 7280R2 platforms. Use command `agent SandL3Unicast terminate` to restart the platform Layer3 agent.
• In the following example we are configuring prefix length 20 and 24, expanding prefix length 19 and 23, and compressing prefix length 25.

```plaintext
switch(config)#ip hardware fib optimize prefix-length 20 24 expand 19 23 compress 25
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

• In the following example we are configuring prefix length 20 and 23, expanding prefix length 19, compressing prefix length 24.

```plaintext
switch(config)#ip hardware fib optimize prefix-length 20 23 expand 19 compress 24
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

• Optionally, you can also use the internet profile to configure the IPv4 route scale compression.

```plaintext
switch(config)#ip hardware fib optimize prefixes profile internet
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

Configure a new TCAM profile for the compress configuration to work, and disable a few features in the new TCAM profile to make space for the flex-route feature in the hardware. Features like acl vlan ip and the mirror ip have to be disabled, if you need any of these features or any other features to be enabled with flex-route feature, contact the Arista team.

The internet profile works differently based on whether the flex-route feature is enabled in the TCAM profile or not. If the flex-route feature is enabled, the internet profile behaves like ip hardware fib optimize prefix-length 20 23 expand 19 22 compress 24. If the flex-route feature is disabled, the internet profile behaves as ip hardware fib optimize prefix-length 20 24 expand 19 23.

**Example**

```plaintext
switch(config)#hardware tcam
switch(config-hw-tcam)#profile flex-route copy default
switch(config-hw-tcam-profile-flex-route)#feature flex-route copy system-feature-source-profile
switch(config-hw-tcam-profile-flex-route-feature-flex-route)#exit
switch(config-hw-tcam-profile-flex-route)#no feature acl vlan ip
switch(config-hw-tcam-profile-flex-route)#no feature mirror ip
switch(config-hw-tcam-profile-flex-route)#exit
Saving new profile 'flex-route'
switch(config-hw-tcam)#system profile flex-route
```

13.1.5.2.2 Limitations

• A maximum of two prefix lengths can be optimized directly at any point of time, of which only one can be a non-nibble aligned prefix length. Additional prefix lengths can be optimized using the expand or the compress options.

• A maximum of 1-to-4 way expansion and 2-to-1 way compression into any optimized prefix length is supported. Multiple expansion prefix lengths can be programmed at any time, however, there can be just one compression prefix length programmed at any given point in time.

• A maximum of 4096 next-hops can be reliably pointed to by the compressed prefixes using 2-to-1 way compression.

• The 2-to-1 compression cannot be enabled along with unicast RPF. When both features are enabled together, unicast RPF functionality may not be correct.
• The flex-route feature in TCAM profiles based only on the default profile, while disabling the acl vlan ip and the mirror ip features. Contact the Arista team if any other feature, that is not available in the default TCAM profile, is required to be supported along with the flex-route feature, including support for Mirror to GRE tunnel or ACLs on SVI.

• VXLAN is not supported with the compress option of this feature. There is no Syslog or a warning message when VXLAN is configured along with the 2-to-1 way compression feature.

13.1.5.3 Show Commands

The IPv4 route scale summary is displayed by the `show platform arad ip route summary` command for the configuration mode interface. Resources for all IPv4 route scale routes are displayed by the `show platform arad ip route` command for the configuration mode interface.

Examples

• This command shows hardware resource usage of IPv4 routes.

```bash
switch(config)#show platform arad ip route summary
Total number of VRFs: 1
Total number of routes: 25
Total number of route-paths: 21
Total number of lem-routes: 4
```

• This command shows resources for all IPv4 routes in hardware. Routes that use the additional hardware resources appear with an asterisk (*).

```bash
switch(config)#show platform arad ip route
Tunnel Type: M(mpls), G(gre)
* = Routes in LEM

13.1.6 IP Source Guard

IP Source Guard (IPSG) prevents IP spoofing attacks.

IP Source Guard (IPSG) filters inbound IP packets based on their source MAC and IP addresses. IPSG is supported in hardware. IPSG enabled on a Layer 2 port verifies IP packets received on this port. Packets are permitted if each packet source MAC and IP addresses match any of the user-configured IP-MAC binding entries on the receiving VLAN and port. Packets with no match are dropped immediately.

13.1.6.1 Configuring IPSG

IPSG is applicable only to Layer 2 ports, and is enabled by the `ip verify source` command for the configuration mode interface. When configured on Layer 3 ports, IPSG does not take effect until this interface is converted to Layer 2.

IPSG is supported on Layer 2 Port-Channels, not member ports. The IPSG configuration on port channels supersedes the configuration on the physical member ports. Therefore, source IP MAC binding entries should be configured on port channels using the `ip source binding` command. When
configured on a port channel member port, IPSG does not take effect until this port is deleted from the port channel configuration.

**Examples**

- These configuration commands exclude VLAN IDs 1 through 3 from IPSG filtering. When enabled on a trunk port, IPSG filters the inbound IP packets on all allowed VLANs. IP packets received on VLANs 4 through 10 on Ethernet 36 will be filtered by IPSG, while those received on VLANs 1 through 3 are permitted.

```
switch(config)# no ip verify source vlan 1-3
switch(config)# interface ethernet 36
switch(config-if-Et36)# switchport mode trunk
switch(config-if-Et36)# switchport trunk allowed vlan 1-10
switch(config-if-Et36)# ip verify source
```

- This configuration command configures source IP-MAC binding entries to IP address 10.1.1.1, MAC address 0000.aaaa.1111, VLAN ID 4094, and Ethernet interface 36.

```
switch(config)# ip source binding 10.1.1.1 0000.aaaa.1111 vlan 4094 interface ethernet 36
switch(config)#
```

### 13.1.6.2 DHCP Server Show Commands

Use the `show dhcp server` command to display DHCP server information.

- DHCPv4 display example:

```
switch# show dhcp server ipv4
IPv4 DHCP Server is active
Debug log is enabled
DNS server(s): 10.2.2.2
DNS domain name: domainFoo
Lease duration: 1 days 0 hours 0 minutes
TFTP server:
serverFoo (Option 66)
10.0.0.3 (Option 150)
TFTP file: fileFoo
Active Leases: 1
IPv4 DHCP interface status:
  Interface     Status
  -----------------------------------------------
  Ethernet1    Inactive (Could not determine VRF)
  Ethernet2    Inactive (Not in default VRF)
  Ethernet3    Inactive (Kernel interface not created yet)
  Ethernet4    Inactive (Not up)
  Ethernet5    Inactive (No IP address)
  Ethernet6    Active
Vendor information:
Vendor ID: default
  Sub-options     Data
  ---------       -------
  1            192.0.2.0, 192.0.2.1
Vendor ID: vendorFoo
Sub-options     Data
```

For DHCPv6, there are two additional fields in subnet information output, Direct field and the Relay field. These two fields specify if the DHCP Server is accepting broadcast or relayed messages.

The Direct field displays Active when the subnet matches the interface with DHCPv6 configured. This indicates the server is accepting broadcast messages.

The Direct field displays Inactive when there is another existing subnet already matching the interface, or when the subnet matches more than one DHCP configured interface.

Examples of outputs for the DHCPv6 show dhcp server command:

In this example, DHCPv6 is configured with subnet fe80::/10 while being enabled on Ethernet1 with address fe80::1/64 and on Ethernet3 with address fe80::2/64.

```
switch# show dhcp server ipv6
IPv6 DHCP server is active
Debug log is enabled

DNS server(s): fe80::6

DNS domain name: testaristanetworks.com

Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:
```
Layer 3 Configuration

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Active</td>
</tr>
<tr>
<td>Ethernet3</td>
<td>Active</td>
</tr>
</tbody>
</table>

Subnet: fe80::/10

Subnet name: foo

Range: fe80::1 to fe80::3
DNS server(s): fe80::4 fe80::5

Direct: Inactive (Multiple interfaces match this subnet: Ethernet1 Ethernet3)
Relay: Active

Active leases: 0

- This example illustrates when multiple subnets match an interface. In this example, DHCPv6 is configured with subnets fc00::/7 and fe80::/10 while being enabled on **Ethernet1** with address fe80::1/10 and fc00::1/7.

```
switch# show dhcp server ipv6
IPv6 DHCP server is active

DNS server(s): fc00::2

DNS domain name: testaristanetworks.com
```
Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Active</td>
</tr>
</tbody>
</table>

Subnet: fc00::/7

Subnet name: foo

Range: fc00::1 to fc00::5

DNS server(s): fc00::6 fc00::8

Direct: Inactive (This and other subnets match interface Ethernet1)
Relay: Active

Active leases: 0

Subnet: fe80::/10
Subnet name: bar

Direct: Inactive (This and other subnets match interface Ethernet1)  
Relay: Active

Active leases: 0

- When a subnet is disabled, the **show dhcp server** command displays the disable message with a reason. The number of active leases of the disabled subnets will be 0. In this example, there are overlapping subnets.

```plaintext
switch# show dhcp server
IPv4 DHCP Server is active
DNS server(s): 10.2.2.2
Lease duration: 1 days 0 hours 0 minutes
Active Leases: 0
IPv4 DHCP interface status:
  Interface     Status
  -----------------------------
  Ethernet1   Active
Subnet: 10.0.0.0/24 (Subnet is disabled - overlapping subnet 10.0.0.0/8)  
Range: 10.0.0.1 to 10.0.0.10
DNS server(s): 10.3.3.3 10.4.4.4
Default gateway address: 10.0.0.4
Active leases: 0

Subnet: 10.0.0.0/8 (Subnet is disabled - overlapping subnet 10.0.0.0/24)  
DNS server(s):  
Default gateway address: 10.0.0.3
Active leases: 0
```

- In this example, the display output shows overlapping ranges.

```plaintext
switch# show dhcp server
IPv4 DHCP Server is active
DNS server(s): 10.2.2.2
Lease duration: 1 days 0 hours 0 minutes
Active Leases: 0
IPv4 DHCP interface status:
  Interface     Status
  -----------------------------
  Ethernet1   Active
Subnet: 10.0.0.0/8 (Subnet is disabled - range 10.0.0.9-10.0.0.12 overlaps with an existing pool)  
Range: 10.0.0.1 to 10.0.0.10
Range: 10.0.0.9 to 10.0.0.12
DNS server(s): 10.3.3.3 10.4.4.4
Default gateway address: 10.0.0.4
Active leases: 0
```
• This example shows duplicate static IP address reservation.

Subnet: 10.0.0.0/8 (Subnet is disabled – ipv4-address 10.0.0.11 is reserved more than once)
Subnet name:
DNS server(s):
Default gateway address: 10.0.0.3
Active leases: 0
Reservations:
MAC address: 1a1b.1c1d.1e1f
IPv4 address: 10.0.0.11
MAC address: 2a2b.2c2d.2e2f
IPv4 address: 10.0.0.11

• Use the `show dhcp server leases` command to display detailed information about the IP addresses allocated by the DHCP Server (including the IP address, the expected end time for that address, the time when the address is handed out, and the equivalent MAC address).

switch#show dhcp server leases
10.0.0.10
End: 2019/06/20 17:44:34 UTC
Last transaction: 2019/06/19 17:44:34 UTC
MAC address: 5692.4c67.460a

2000::0:0:40::b

End: 2019/06/20 18:06:33 UTC

Last transaction: 2019/06/20 14:36:33 UTC

MAC address: 165a.a86d.ffac

13.1.7  DHCP Server

The router with DHCP Server enabled acts as a server that allocates and delivers network addresses with desired configuration parameters to its hosts.

The DHCP server is based on ISC Kea.

The router with an DHCP Server enabled acts as a server that allocates and delivers network addresses with desired configuration parameters to its hosts.

DHCP Server support includes:

DHCPv4 support includes:

• Configurable on different interfaces: Routed, VLAN, LAG, Sub-interface, and LAG Sub-interface.
• Configurable lease time for allocated network addresses.
• Configurable DNS domain.
• Configurable DNS servers.
• Configurable subnets with parameters:
  • Default gateway
  • DNS servers
  • Ranges
Layer 3 Configuration

- Lease time

Additional features for DHCPv4 include:
- Configurable TFTP server
- Configurable TFTP bootfile

Additional features for DHCPv4 includes:
- Configurable Vendor options with sub options
- Configurable sub option types include: IPv4 address, array of IPv4 addresses, and string
- TFTP bootfile now supports an URI

Additional features for DHCPv4 include a configurable static IP address for exclusive use by a given client, based on the client’s MAC address.

Example deployment:

DHCP Server on an aggregation switch, via VXLAN tunnels.

13.1.7.1 Configuring the DHCP Server

You can enable DHCP Server per interface with the IPv4 or IPv6 address family option.

Example

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#dhcp server ipv4
switch(config)#interface Ethernet2
switch(config-if-Et2)#dhcp server ipv6
```

For DHCPv4 to receive and reply to requests, minimum configurations of a valid subnet corresponding to the enabled interface with at least one valid range are required.

Example

```
switch(config)#interface Ethernet1
```
At least one non link-local address is required for DHCPv6.

**Example**

```
switch(config)#interface Vlan1409
switch(config-if-vlan1409)#dhcp server ipv6
switch(config-dhcp-server)#ipv6 address fe80::1/10

switch(config-if-vlan1409)#dhcp server
  subnet fe80::/10
  range fe80::4 fe80::6
```

To enter DHCP Server global configuration mode (`config-dhcp-server`):

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#
```

To disable DHCP Server:

```
switch(config-dhcp-server)#disabled
switch(config)#
```

To set the lease time for allocated IP addresses. Lease time is configured globally and applied to all subnets. In the example, the lease time is set to 1 day.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#lease time (ipv4|ipv6) 1 days 0 hours 0 minutes
```

To set the domain name for allocated IP addresses. In this example, the domain name is configured to `aristanelworks.com`.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#dns domain name (ipv4|ipv6) aristanetworks.com
```

To set the DNS servers. You can only configure up to two servers. In this example, **10.2.2.2** for **DHCPv4** and **fe80::2** for **DHCPv6**.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#dns server ipv4 10.2.2.2
switch(config-dhcp-server)#dns server ipv6 fe80::2
```
To set TFTP server. The server can be in the form of either an IP address or a fully qualified domain name. This is only available in DHCPv4. In this example, **TFTP server 10.0.0.2**.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#tftp server option 66 ipv4 10.0.0.2
```

To set a list of TFTP servers. The server can only be in the form of an IP address. This is only available in DHCPv4. In this example, **3.0.0.3 and 4.0.0.4** TFTP servers are configured.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#tftp server option 150 ipv4 10.0.0.3 10.0.0.4
```

To set TFTP server boot file (such as DHCP option 67). This is only available in DHCPv4. In this example, **TFTP boot file bootfile.conf** is configured.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#tftp server file ipv4 bootfile.conf
```

Or, a TFTP boot file URL //john.doe@www.example.com:123/example/one

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#tftp server file ipv4 https://john.doe@www.example.com:123/example/one
```

To set a Vendor option, DHCP option 43, with sub options. Most of the time, different clients need different Vendor options. For this reason option 60, vendor class identifier, is used by the client to identify itself in order to request a specific Vendor option. To enter the Vendor option submode **(config-dhcp-vendor)** from **(config-dhcp-server)** config mode, specify a vendor class identifier. This is only available in DHCPv4.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 vendorClassIDA
switch(config-dhcp-vendor)#
```

If **default** is specified, the configured Vendor option is sent to those clients requesting for a Vendor option whose vendor class identifier does not match any configured Vendor option. In this example, the default Vendor option for clients without a configured Vendor option.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 default
```

The Vendor option may contain 0 or more sub options. The resulting Vendor option is sent in hexadecimal format to the desired client. In this example, the Vendor option holding a sub option with IPv4 address **10.0.0.1**, for clients with vendor class identifier **vendorClassIDA**, resulting in Vendor option **1::4:a:0:0:1**. The sub option number is **1**. Length of the Data is **4**. Data is **a:0:0:1**.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 vendorClassIDA
switch(config-dhcp-vendor)#sub-option 1 type ipv4-address data 10.0.0.1
```
In this example, Vendor option holding a sub option with IPv4 addresses 10.0.0.5 and 10.0.0.6, for clients with vendor class identifier vendorClassIDA. Resulting in Vendor option fe:4:a:0:0:5:a:0:0:6.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 vendorClassIDA
switch(config-dhcp-vendor)#sub-option 254 type ipv4-address data 10.0.0.5 10.0.0.6
```

In this example, Vendor option holding a sub option with a string FOO, for all clients whose vendor class identifier does not match any configured Vendor option. Resulting in Vendor option 1e:3:46:4f:4f.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 default
switch(config-dhcp-vendor-option-default)#sub-option 30 type string data "FOO"
```

In this example, Vendor option holding two sub options, where sub option 1 holds the IPv4 address 10.0.0.1, and sub option 2 holds a string FOO, for all clients whose vendor class identifier does not match any configured Vendor option. Resulting in Vendor option 1:4:a:0:0:1:2:3:46:4f:4f.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#vendor-option ipv4 default
switch(config-dhcp-vendor-option-default)#sub-option 1 type ipv4-address data 10.0.0.1
switch(config-dhcp-vendor-option-default)#sub-option 2 type string data "FOO"
```

Configuration options for subnets are configured under IPv4 or IPv6 address family specific subnet submode (config-dhcp-subnet). To enter the submode from (config-dhcp-server) config mode, specify a subnet mask. In this example, 10.0.0.0/8 for DHCPv4 and fe80::/10 for DHCPv6.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server)#subnet fe80::/10
```

There can be multiple subnets configured, but they must not overlap. If this happens, all overlapping subnets are disabled.

For DHCPv6, a subnet may match only one interface and vice versa; otherwise no lease is assigned for that subnet.

In this example, the user enables DHCPv6 on Ethernet1 (with address fe80::1/64) and Ethernet3 (with address fe80::2/64), then configures a subnet fe80::/10 for the DHCPv6:

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#no switchport
switch(config-if-Et1)#ipv6 address fe80::1/64
switch(config-if-Et1)#dhcp server ipv6

switch(config)#interface Ethernet3
switch(config-if-Et3)#no switchport
switch(config-if-Et3)#ipv6 address fe80::1/64
switch(config-if-Et3)#dhcp server ipv6
```
Layer 3 Configuration

```
switch(config-dhcp-server)#subnet fe80::/1
```

To set default-gateway for a subnet. Only one default-gateway is allowed. This is only available in DHCPv4. In this example, **10.0.0.3** is configured as the default gateway for subnet **10.0.0.0/8**:

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server-subnet-ipv4)#default-gateway 10.0.0.3
```

To set the DNS servers for a subnet. In this example, **10.1.1.1** and **10.2.2.2** for DHCPv4 and **fe80::1** and **fe80::2** for DHCPv6. The number of DNS servers cannot exceed two (2):

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server-subnet-ipv4)#dns server 10.1.1.1 10.2.2.2
switch(config-dhcp-server-subnet-ipv4)#subnet fe80::/10
switch(config-dhcp-server-subnet-ipv6)#dns server fe80::1 fe80::2
```

To set the name of the subnet. In this example, the name **foo** for DHCPv4 and name **bar** for DHCPv6 are the selected names.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server-subnet-ipv4)#name foo
switch(config-dhcp-server-subnet-ipv4)#subnet fe80::/10
switch(config-dhcp-server-subnet-ipv6)#name bar
```

To set the range of IP addresses of the subnet. In this example, the IP address range for DHCPv4 is **10.0.0.1** to **10.0.0.10** and for DHCPv6 it is **fe80::1** to **fe80::5**. The range must be within the subnet mask, otherwise the subnet is disabled.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server)#range 10.0.0.1 10.0.0.10
switch(config-dhcp-server)#subnet fe80::/10
switch(config-dhcp-server)#range fe80::1 fe80::5
```

To set TFTP server for a subnet. The server can be in the form of either an IP address or a fully qualified domain name. This is only available in DHCPv4. In this example, **tftpserver.com** is configured.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#subnet 10.0.0.0/8
switch(config-dhcp-server)#tftp server option 66 tftpserver.com
```

To set a list of TFTP servers. The server can only be in the form of an IP address. This is only available in DHCPv4. In this example, TFTP servers **3.0.0.3** and **4.0.0.4** are configured.

```
switch>config
switch(config)#dhcp server
switch(config-dhcp-server)#10.0.0.0/8
switch(config-dhcp-server)#tftp server option 150 3.0.0.3 4.0.0.4
```
To set a TFTP boot file for a subnet. This is only available in DHCPv4. In this example, `subnet-bootfile.conf` is configured.

```
switch> config
switch(config)# dhcp server
switch(config-dhcp-server)# subnet 10.0.0.0/8
switch(config-dhcp-server)# tftp server file subnet-bootfile.conf
```

To set a static IP address for exclusive use by a client, first enter the client’s MAC address reservation submode.

To enter the MAC address reservation submode: `(config-dhcp-mac-address-ipv4)` from the `(config-dhcp-reservations-ipv4)` configuration mode, then specify the client’s MAC address. This is only available in DHCPv4. In this example, we use the static IP address of `10.0.0.1` for a client with MAC address of `1a1b.1c1d.1e1f`.

```
switch> config
switch(config)# dhcp server
switch(config-dhcp-server)# subnet 10.0.0.0/8
switch(config-dhcp-server)# reservations
switch(config-dhcp-server)# mac-address 1a1b.1c1d.1e1f
switch(config-dhcp-server)# ipv4-address 10.0.0.1
```

To enable a debug log and save log to a file (this disables kea syslog messages). In this example, you enable `/tmp/debug-dhcp.log` as the debug log.

```
switch> config
switch(config)# dhcp server
switch(config-dhcp-server)# debug log file:/tmp/debug-dhcp.log
```

### 13.1.7.2 DHCP Server Limitations

The DHCP Server and DHCP Relay cannot be configured on the same router. The DHCP Relay has a higher precedence so the DHCP Server will be disabled when the DHCP Relay is configured.

If DHCPD is enabled on the router, configuring the EOS DHCP Server may cause DHCPD to crash or have unexpected behaviors.

During reload, the DHCP Server is not able to save its leases information. In a modular system, the second supervisor does not have an up-to-date lease database. The clients need to request for new leases. During the synchronizing phase for clients and server, duplicate IP addresses in the network may occur.

The DHCP Server is only supported on default VRF and it currently does not support legacy bootp requests.

All DHCP Server options must be less than 256 bytes in size, otherwise, the DHCP Server will not be able to send the affected option.

On certain platforms VXLAN Recirculation has to be enabled: VXLAN Routing Configuration.

### 13.1.7.3 DHCP Server Show Commands

Use the `show dhcp server` command to display DHCP server information.

- **DHCPv4 display example:**

```
switch# show dhcp server ipv4
IPv4 DHCP Server is active
Debug log is enabled
DNS server(s): 10.2.2.2
```

1616
DNS domain name: domainFoo
Lease duration: 1 days 0 hours 0 minutes
TFTP server:
serverFoo (Option 66)
10.0.0.3 (Option 150)
TFTP file: fileFoo
Active Leases: 1
IPv4 DHCP interface status:
<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Inactive (Could not determine VRF)</td>
</tr>
<tr>
<td>Ethernet2</td>
<td>Inactive (Not in default VRF)</td>
</tr>
<tr>
<td>Ethernet3</td>
<td>Inactive (Kernel interface not created yet)</td>
</tr>
<tr>
<td>Ethernet4</td>
<td>Inactive (Not up)</td>
</tr>
<tr>
<td>Ethernet5</td>
<td>Inactive (No IP address)</td>
</tr>
<tr>
<td>Ethernet6</td>
<td>Active</td>
</tr>
</tbody>
</table>
Vendor information:
Vendor ID: default
<table>
<thead>
<tr>
<th>Sub-options</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>192.0.2.0, 192.0.2.1</td>
</tr>
</tbody>
</table>
Vendor ID: vendorFoo
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>192.0.2.2</td>
</tr>
<tr>
<td>3</td>
<td>&quot;Foo&quot;</td>
</tr>
</tbody>
</table>
Subnet: 10.0.0.0/8
Subnet name: subnetFoo
Range: 10.0.0.1 to 10.0.0.10
DNS server(s): 10.1.1.1 10.2.2.2
Lease duration: 3 days 3 hours 3 minutes
Default gateway address: 10.0.0.3
TFTP server:
subnetServerFoo (Option 66)
10.0.0.4 (Option 150)
TFTP boot file: subnetFileFoo
Active leases: 1
Reservations:
MAC address: 1a1b.1c1d.1e1f
IPv4 address: 10.0.0.1
MAC address: 2a2b.2c2d.2e2f
IPv4 address: 10.0.0.2

• For DHCPv6, there are two additional fields in subnet information output, Direct field and the Relay field. These two fields specify if the DHCP Server is accepting broadcast or relayed messages.

The Direct field displays Active when the subnet matches the interface with DHCPv6 configured. This indicates the server is accepting broadcast messages.

The Direct field displays Inactive when there is another existing subnet already matching the interface, or when the subnet matches more than one DHCP configured interface.

Examples of outputs for the DHCPv6 show dhcp server command:

In this example, DHCPv6 is configured with subnet fe80::/10 while being enabled on Ethernet1 with address fe80::1/64 and on Ethernet3 with address fe80::2/64.

switch#show dhcp server ipv6
IPv6 DHCP server is active
Debug log is enabled

DNS server(s): fe80::6

DNS domain name: testaristanetworks.com

Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Active</td>
</tr>
<tr>
<td>Ethernet3</td>
<td>Active</td>
</tr>
</tbody>
</table>

Subnet: fe80::/10

Subnet name: foo

Range: fe80::1 to fe80::3
DNS server(s): fe80::4 fe80::5
Layer 3 Configuration

Direct: Inactive (Multiple interfaces match this subnet: Ethernet1 Ethernet3)
Relay: Active

Active leases: 0

- This example illustrates when multiple subnets match an interface. In this example, DHCPv6 is configured with subnets fc00::/7 and fe80::/10 while being enabled on Ethernet1 with address fe80::1/10 and fc00::1/7.

switch# show dhcp server ipv6
IPv6 DHCP server is active

DNS server(s): fc00::2

DNS domain name: testaristanetworks.com

Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Active</td>
</tr>
</tbody>
</table>

Subnet: fc00::/7

Subnet name: foo
Range: fc00::1 to fc00::5

DNS server(s): fc00::6 fc00::8

Direct: Inactive (This and other subnets match interface Ethernet1)
Relay: Active

Active leases: 0
Subnet: fe80::/10

Subnet name: bar

Direct: Inactive (This and other subnets match interface Ethernet1)
Relay: Active

Active leases: 0

• When a subnet is disabled, the `show dhcp server` command displays the disable message with a reason. The number of active leases of the disabled subnets will be 0. In this example, there are overlapping subnets.

```
switch# show dhcp server
IPv4 DHCP Server is active
DNS server(s): 10.2.2.2
Lease duration: 1 days 0 hours 0 minutes
Active Leases: 0
IPv4 DHCP interface status:
  Interface    Status
  -------------------------------
  Ethernet1    Active

Subnet: 10.0.0.0/24 (Subnet is disabled - overlapping subnet 10.0.0.0/8)
  Range: 10.0.0.1 to 10.0.0.10
  DNS server(s): 10.3.3.3 10.4.4.4
  Default gateway address: 10.0.0.4
  Active leases: 0

Subnet: 10.0.0.0/8 (Subnet is disabled - overlapping subnet 10.0.0.0/24)
```
Layer 3 Configuration

DNS server(s):
Default gateway address: 10.0.0.3
Active leases: 0

• In this example, the display output shows overlapping ranges.

```
switch#show dhcp server
IPv4 DHCP Server is active
DNS server(s): 10.2.2.2
Lease duration: 1 days 0 hours 0 minutes
Active Leases: 0
IPv4 DHCP interface status:
  Interface   Status
  ----------------------------------------------
  Ethernet1   Active
Subnet: 10.0.0.0/8 (Subnet is disabled - range 10.0.0.9-10.0.0.12 overlaps with an existing pool)
Range: 10.0.0.1 to 10.0.0.10
Range: 10.0.0.9 to 10.0.0.12
DNS server(s): 10.3.3.3 10.4.4.4
Default gateway address: 10.0.0.4
Active leases: 0
```

• This example shows duplicate static IP address reservation.

```
Subnet: 10.0.0.0/8 (Subnet is disabled - ipv4-address 10.0.0.11 is reserved more than once)
Subnet name: 
DNS server(s): 
Default gateway address: 10.0.0.3
Active leases: 0
Reservations: 
MAC address: 1a1b.1c1d.1e1f
IPv4 address: 10.0.0.11
MAC address: 2a2b.2c2d.2e2f
IPv4 address: 10.0.0.11
```

• Use the `show dhcp server leases` command to display detailed information about the IP addresses allocated by the DHCP Server (including the IP address, the expected end time for that address, the time when the address is handed out, and the equivalent MAC address).

```
switch#show dhcp server leases
10.0.0.10
End: 2019/06/20 17:44:34 UTC
Last transaction: 2019/06/19 17:44:34 UTC
MAC address: 5692.4c67.460a
2000:0:0:40::b

End: 2019/06/20 18:06:33 UTC

Last transaction: 2019/06/20 14:36:33 UTC

MAC address: 165a.a86d.ffac
```
13.1.8 DHCP Relay Global Configuration Mode

The `dhcp relay` command is configured under the global configuration mode. When configured, it places the switch on DHCP relay mode and allows the user to configure DHCP relay specific configuration on several interfaces with a single command. Furthermore, configuration entered in the DHCP Relay global configuration mode can be overridden by equivalent interface specific commands.

**Example**

- The `dhcp relay` command places the switch in the DHCP relay configuration mode.

```bash
switch(config)#dhcp relay
switch(config-dhcp-relay)#
```

- It is possible to specify the IP address of the default DHCP or DHCPv6 Server. Multiple IP addresses can be specified and DHCP requests are forwarded to all specified helper addresses. This is equivalent to configuring `ip helper-address <IP_Address>` under each desired routing interface.

- Example to forward DHCP broadcast packets received on interface *Ethernet1* and *Vlan2* to DHCP servers at *10.0.0.1*, *10.0.0.2*, and to hostname *DefaultDHCPHostname*:

```bash
switch(config)#interface Ethernet1
switch(config-if-Et1)#no switchport
switch(config-if-Et1)#ip address 192.168.1.1/16

switch(config)#interface Vlan2
switch(config-if-Et1)#ip address 172.16.1.1/16

switch(config)# dhcp relay
switch(config-dhcp-relay)#server 10.0.0.1
switch(config-dhcp-relay)#server 10.0.0.2
switch(config-dhcp-relay)#server DefaultDHCPHostname
```

- Example to forward DHCPv6 broadcast packet received on interface *Ethernet1* to DHCPv6 Server at *fc00::3*.

```bash
switch(config)#interface Ethernet1
switch(config-if-Et1)#no switchport
switch(config-if-Et1)#ipv6 address fc00::1/10

switch(config)# dhcp relay
switch(config-dhcp-relay)#server fc00::3
```

- This will point a routed interface to the specified DHCP and DHCPv6 server(s), if all the following criteria are met:
  - The routed interface is in the default VRF.
  - The interface has an IP address configured.
  - The interface is not a Management or Loopback.

- Example to remove the default DHCP or DHCPv6 Server.

```bash
switch(config)#dhcp relay
switch(config-dhcp-relay)#no server 10.0.0.1
switch(config-dhcp-relay)#no server 10.0.0.2
switch(config-dhcp-relay)#no server DefaultDHCPHostname
switch(config-dhcp-relay)#no server fc00::3
```

To override the default DHCP Server on an interface, `ip helper-address <IP_Address>` must be used.

•
Example to forward DHCP broadcast packet received on interface Ethernet1 to DHCP Servers at 10.0.0.1, 10.0.0.2 and hostname DefaultDHCPHostname, but VLAN2s broadcast packets to DHCP Server at 10.0.0.3 only.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#no switchport
switch(config-if-Et1)#ip address 192.168.1.1/16

switch(config)#interface Vlan2
switch(config-if-Et1)#ip address 172.16.1.1/16
switch(config-if-Et1)#ip helper-address 11.0.0.3

switch(config)#dhcp relay
switch(config-dhcp-relay)#server 10.0.0.1
switch(config-dhcp-relay)#server 10.0.0.2
switch(config-dhcp-relay)#server DefaultDHCPHostname
```

To override the default DHCPv6 Server on an interface, `ipv6 helper-address <IPv6_Address>` must be used.

Example to forward DHCPv6 broadcast packet received on interface Ethernet1 to DHCPv6 Server at fc00::3, but VLAN2s broadcast packets to DHCPv6 Server at fc00::4 only.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#no switchport
switch(config-if-Et1)#ipv6 address fc00::1/10

switch(config)#interface Vlan2
switch(config-if-Et1)#ipv6 address fc00::2/10
switch(config-if-Et1)#ipv6 helper-address fc00::4

switch(config)#dhcp relay
switch(config-dhcp-relay)#server fc00::3
```

You can disable DHCP or DHCPv6 Relay functionality from a specific interface. This will disable both DHCP Relay global and interface mode configurations.

- Example to disable DHCP Relay functionality only.

```
switch(config)#interface Vlan3
switch(config-if-Et1)#dhcp relay ipv4 disabled
```

- Example to disable DHCPv6 Relay functionality only.

```
switch(config)#interface Vlan3
switch(config-if-Et1)#dhcp relay ipv6 disabled
```

13.1.8.1  DHCP Relay Global Configuration Mode Limitations

The DHCP Relay global configuration mode’s server commands do not apply to:

- Interfaces in non-default VRF.
- Interfaces without an IP address configured.
- Management and Loopback interfaces.

13.1.8.2  DHCP Relay Global Configuration Mode Show Command

Example
This command displays the VRF specifier for the server:

```
switch#show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is enabled
DHCP Smart Relay is disabled
Interface: Ethernet9
Option 82 Circuit ID: Ethernet9
DHCP Smart Relay is disabled
DHCP servers: 10.40.2.3
10.40.2.3:vrf=qchyh-vrf
```

### 13.1.9 DHCP Relay Across VRF

The EOS DHCP relay agent supports forwarding of DHCP requests to DHCP servers located in a different VRF to the DHCP client interface VRF. In order to enable VRF support for the DHCP relay agent, Option 82 (DHCP Relay Agent Information Option) must first be enabled. The DHCP relay agent uses Option 82 to pass client specific information to the DHCP server.

These sections describe DHCP Relay across VRF features:

- **Global Configuration**
- **DHCP Relay Global Configuration Mode Show Command**

The DHCP relay agent inserts Option 82 information into the DHCP forwarded request, which requires the DHCP server belongs to a network on an interface, and that interface belongs to a different VRF than the DHCP client interface. Option 82 information includes the following:

- **VPN identifier**: The VRF name for the ingress interface of the DHCP request, inserted as sub-option 151.

#### Table 68: VPN Identifier

<table>
<thead>
<tr>
<th>SubOpt</th>
<th>Len</th>
<th>ASCII VRF Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>151</td>
<td>7</td>
<td>VRFNAME</td>
</tr>
</tbody>
</table>

- **Link selection**: The subnet address of the interface that receives the DHCP request, inserted as sub-option 5. When the DHCP smart relay is enabled, the link selection is filled with the subnet of the active address. The relay agent will set the Gateway IP address (gIPaddr) to its own IP address so that DHCP messages can be routed over the network to the DHCP server.

#### Table 69: Link Selection

<table>
<thead>
<tr>
<th>SubOpt</th>
<th>Len</th>
<th>Subnet IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>4</td>
<td>A1 A2 A3 A4</td>
</tr>
</tbody>
</table>

- **Server identifier override**: The primary IP address of the interface that receives the DHCP request, inserted as sub-option 11. When the DHCP smart relay is enabled, the server identifier is filled with the active address (one of the primary or secondary addresses chosen by smart relay mechanism).

#### Table 70: Link Selection

<table>
<thead>
<tr>
<th>SubOpt</th>
<th>Len</th>
<th>Overriding Server Identifier Address</th>
</tr>
</thead>
</table>
Layer 3 Configuration

11 4 B1 B2 B3 B4

- VSS control suboption as suboption 152: The DHCP server will strip out this suboption when sending the response to the relay, indicating that the DHCP server used VPN information to allocate IP address.

Note: The DHCP server must be capable of handling VPN identifier information in option 82.

Direct communication between DHCP client and server may not be possible as they are in separate VRFs. The Server identifier override and Link Selection sub-options set the relay agent to act as the DHCP server, and enable all DHCP communication to flow through the relay agent.

The relay agent adds all the appropriate sub-options, and forwards all (including renew and release) request packets to the DHCP server. When the DHCP server response messages are received by the relay, Option 82 information is removed and the response is forwarded to the DHCP client in the client VRF.

13.1.9.1 Global Configuration

The DHCP relay agent information option is inserted in DHCP messages relayed to the DHCP server. The `ip helper-address` command enables DHCP relay on an interface; and relays DHCP messages to the specified IPv4 address.

Example

This command enables DHCP relay on the interface **Ethernet 1/2**, and relays DHCP messages to the server at **1.1.1.1**.

```
switch(config)#interface ethernet 1/2
switch(config-if-Et1/2)#ip helper-address 1.1.1.1
switch(config-if-Et1/2)#
```

The commands provided in examples below will turn on the attachment of VRF-related tags in the relay agent information option. If both the DHCP client interface and server interface are on the same VRF (default or non-default), then no VRF-related DHCP relay agent information option is inserted.

Examples

- This command configures the DHCP relay to add option 82 information.

```
switch(config)#ip dhcp relay information option
```

- These commands configures two new VRF instances and assign them Route Distinguishers (RDs).

```
switch(config)#vrf instance mtxxg-vrf
switch(config-vrf-mtxxg-vrf)#router bgp 50
switch(config-router-bgp)#vrf mtxxg-vrf
switch(config-router-bgp-vrf-mtxxg-vrf)#rd 5546:5546
switch(config)#vrf instance qchyh-vrf
switch(config-vrf-qchyh-vrf)#router bgp 50
switch(config-router-bgp)#vrf qchyh-vrf
switch(config-router-bgp-vrf-qchyh-vrf)#rd 218:218
```
- This command configures an interface connected to DHCP client in vrf `mtxxg-vrf` and assigns an IP address.

  ```
  switch(config)#interface Ethernet 9
  switch(config-if-Et9)#no switchport
  ```

- This command configures the DHCP client interface in VRF `mtxxg-vrf`.

  ```
  switch(config-if-Et9)#vrf mtxxg-vrf
  switch(config-if-Et9)#ip address 10.10.0.1/16
  ```

- This command configures the server interface in VRF `qchyh-vrf`.

  ```
  switch(config-if-Et11)#vrf qchyh-vrf
  switch(config-if-Et11)#ip address 10.40.0.1/16
  ```

- This command configures a helper address for a DHCP server in VRF `qchyh-vrf`.

  ```
  switch(config-if-Et11)#ip helper-address 10.40.2.3 vrf qchyh-vrf
  ```

### 13.1.9.2 DHCP Relay Global Configuration Mode Show Command

**Example**

This command displays the VRF specifier for the server:

```
switch#show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is enabled
DHCP Smart Relay is disabled
Interface: Ethernet9
Option 82 Circuit ID: Ethernet9
DHCP Smart Relay is disabled
DHCP servers: 10.40.2.3
10.40.2.3:vrf=qchyh-vrf
```
The following configures the Loopback interface as the specified source interface for the helper address.

```
switch (config)#interface Vlan100
switch (config-if-Vl100)#ip helper-address 10.1.1.4 source-interface Loopback1
```

The following configures the Loopback interface when the DHCP server is in a different VRF (red). The source interface must be configured in the DHCP server's VRF for the command to take effect.

```
switch (config)#interface Loopback3
switch (config-if-Lo3)#vrf red
switch (config-if-Lo3)#ip address 1.1.1.1/24

switch (config)#interface Vlan100
switch (config-if-Vl100)#ip helper-address 10.1.1.4 vrf red source-interface Loopback3
```

The following disables the use of source interface along with the helper address.

```
switch (config)#interface Vlan100
switch (config-if-Vl100)#no ip helper-address 10.1.1.4 source-interface Loopback1
```

### Configuring DHCP Relay in VXLAN EVPN (IPv6)

The following configures a local interface.

```
switch (config)#interface Loopback2
switch (config-if-Vl100)#ipv6 address 2001::10:20:30:1/128
```

The following configures the Loopback interface as the local interface for the helper address.

```
switch (config)#interface Vlan200
switch (config-if-Vl200)#ipv6 dhcp relay destination 2002::10:20:30:2 local-interface Loopback2
```

The following configures the Loopback interface when the DHCP server is in a different VRF (red). The local interface must be configured in the DHCP server's VRF for the command to take effect.

```
switch (config)#interface Loopback4
switch (config-if-Lo4)#vrf red
switch (config-if-Lo4)#ipv6 address 2001::10:20:30:1/128

switch (config)#interface Vlan200
switch (config-if-Vl200)#ipv6 dhcp relay destination 2002::10:20:30:2 vrf red local-interface Loopback4
```

The following disables the use of local interface along with the helper address.

```
switch (config-if-Vl200)#no ipv6 dhcp relay destination 2002::10:20:30:2 local-interface Loopback4
```

The following displays the status of DHCP relay option (Option 82) and lists the configured DHCP servers.

```
switch#show ip dhcp relay
DHCP Relay is active
```
Limitations

Client requests up to a rate of 130 packets/second are processed.

13.1.11 DHCP Snooping with Bridging

In this configuration, in addition to sending DHCP packets to relay (after adding information option), the packets will also be bridged within the VLAN. In the bridging mode, the switch intercepts DHCP packets, inserts option-82 if not already present, and bridges the packet within the VLAN. This mode of DHCP snooping can be configured without DHCP relay configuration.

13.1.11.1 Configuring DHCP Snooping with Bridging

Following are the steps to configure DHCP snooping with bridging:

1. Enable DHCP snooping feature using the ip dhcp snooping command.

   switch#ip dhcp snooping

2. Enable the insertion of option-82 in DHCP request packets using the ip dhcp snooping information option command. By default, option-82 is not enabled and without this DHCP Snooping is not operational.

   switch#ip dhcp snooping information option

3. Enable DHCP snooping on the corresponding VLANs using the ip dhcp snooping vlan command. By default, DHCP snooping is not enabled on any VLAN.

   switch#ip dhcp snooping vlan

4. Set the circuit-id information that is sent in option-82. By default, Interface name and VLAN ID are sent. Remote circuit-id will always be the MAC address of the relay agent.

   switch#ip dhcp snooping information option circuit-id type 2 format
   %h:%p  Hostname and interface name
   %p:%v  Interface name and VLAN ID

5. Enable bridging capabilities of DHCP snooping using the ip dhcp snooping bridging command. This command will enable DHCP snooping with or without DHCP relay configuration.

   switch#ip dhcp snooping bridging

13.1.11.2 DHCP Snooping with Bridging Limitations

- DHCP snooping with bridging is supported only for IPv4.
- When DHCP snooping is configured without bridging configuration, packets with option-82 already present are dropped.
13.1.11.3 DHCP Snooping with Bridging Show Commands

The `show ip dhcp snooping` displays the DHCP snooping with bridging information.

```
switch# show ip dhcp snooping
DHCP Snooping is enabled
DHCP Snooping is operational
DHCP Snooping is configured on following VLANs:
  650
DHCP Snooping bridging is operational on following VLANs:
  650
Insertion of Option-82 is enabled
Circuit-id sub-option Type: 0
Circuit-id format: Interface name:Vlan ID
Remote-id: 00:1c:73:8d:eb:67 (Switch MAC)
```

13.1.12 TCP MSS Clamping

TCP MSS clamping limits the value of the Maximum Segment Size (MSS) in the TCP header of TCP SYN packets transiting a specified Ethernet or tunnel interface. Setting the MSS ceiling can avoid IP fragmentation in tunnel scenarios by ensuring that the MSS is low enough to account for the extra overhead of GRE and tunnel outer IP headers. TCP MSS clamping can be used when connecting via GRE to cloud providers that require asymmetric routing.

When MSS clamping is configured on an interface, if the TCP MSS value in a SYN packet transiting that interface exceeds the configured ceiling limit it will be overwritten with the configured limit and the TCP checksum will be recomputed and updated.

TCP MSS clamping is handled by default in the software data path, but the process can be supported through hardware configuration to minimize possible packet loss and a reduction in the number of TCP sessions which the switch can establish per second.

13.1.12.1 Cautions

*This feature should be used with caution.* When the TCP MSS clamping feature is enabled by issuing the `tcp mss ceiling` command on any routed interface, all routed IPv4 TCP SYN packets (TCP packets with the “SYN” flag set) are sent by default to the CPU and switched through software, even on interfaces where no TCP MSS ceiling has been configured, as long as TCP MSS clamping is enabled. This limits the number of TCP sessions that can be established through the switch per second, and, because throughput for software forwarding is limited, this feature can also cause packet loss if the rate at which TCP SYN packets are sent to the CPU exceeds the limits configured in the control-plane policy map.

Packet loss and TCP session reductions can be minimized by enabling TCP MSS clamping in hardware, but only SYN packets in which MSS is the first TCP option are clamped in the hardware data path; other TCP SYN packets are still switched through software.

To disable MSS clamping, the MSS ceiling must be removed from every interface on which it has been configured by issuing the `no tcp mss ceiling` command on each configured interface.

13.1.12.2 Enabling TCP MSS Clamping

There is no global configuration to enable TCP MSS clamping. It is enabled as soon as an MSS ceiling is configured on at least one interface.

13.1.12.3 Disabling TCP MSS Clamping

To disable TCP MSS clamping, the MSS ceiling configuration must be removed from every interface by using the `no` or `default` form of the `tcp mss ceiling` command on every interface where a ceiling has been configured.
13.1.12.4 Configuring the TCP MSS Ceiling on an Interface

The TCP MSS ceiling limit is set on an interface using the `tcp mss ceiling` command. This also enables TCP MSS clamping on the switch as a whole.

**Note:** Configuring a TCP MSS ceiling on any interface enables TCP MSS clamping on the switch as a whole. Without hardware support, clamping routes all TCP SYN packets through software, even on interfaces where no TCP MSS ceiling has been configured. This significantly limits the number of TCP sessions the switch can establish per second, and can potentially cause packet loss if the CPU traffic exceeds control plane policy limits.

On Sand platform switches (Qumran-MX, Qumran-AX, Jericho, Jericho+), the following limitations apply:

- This command works only on egress.
- TCP MSS ceiling is supported on IPv4 unicast packets entering the switch; the configuration has no effect on GRE transit packets.
- The feature is supported only on IPv4 routed interfaces. It is not supported on L2 (switchport) interfaces or IPv6 routed interfaces.
- The feature is not supported for IPv6 packets even if they are going to be tunneled over an IPv4 GRE tunnel.
- The feature is not supported on VXLAN, loopback or management interfaces.
- The feature is only supported on IPv4 unicast packets entering the switch. The configuration has no effect on GRE transit packets or GRE decap, even if the egress interface has a TCP MSS ceiling configured.

**Example**

- These commands configure *Ethernet interface 5* as a routed port, then specify a maximum MSS ceiling value of 1458 bytes for TCP SYN packets exiting that port:

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
switch(config-if-Et5)#tcp mss ceiling ipv4 1458 egress
```

- These commands apply TCP MSS clamping at 1436 bytes in the egress direction for IPv6 packets:

```
switch(config)#interface ethernet 26
switch(config)#tcp mss ceiling ipv6 1436 egress
```

- These commands apply TCP MSS clamping at 1476 bytes for IPv4 packets and 1436 bytes for IPv6 packets in egress direction:

```
switch(config)#interface ethernet 27
switch(config)#tcp mss ceiling ipv4 1476 ipv6 1436 egress
```

13.1.12.5 Verifying the TCP MSS Clamping

If TCP MSS ceiling is configured on an interface and if the command `show cpu counters queue | nz` is incrementing in `CoppSystemL3Ttl11IpOptUcast` field for Tcp packet with Syn flag, then TCP MSS clamping is being performed in Software.

```
switch#show cpu counters queue | nz
Fap0.1:
CoPP Class                  Queue Pkts Octets DropPkts DropOctets
Aggregate
---------------------------------------------------------------
CoppSystemL3Ttl11IpOptUcast TC0  1   82    0     0
```
13.1.12.6 Configuring TCP MSS Clamping

Interface Configuration

You can specify the TCP MSS value under the `interface configuration mode`. The command syntax is shown below:

```
tcp mss ceiling [ipv4 | ipv6] 64-65515 egress
```

The keyword `egress` specifies that the MSS clamping is applied on packets transmitted out on the interface in egress direction.

The following example applies TCP MSS clamping at **1436** bytes in the egress direction for IPv4 packets:

```
switch(config)#interface ethernet 25
switch(config)#tcp mss ceiling ipv4 1436 egress
```

the following example applies TCP MSS clamping at **1436** bytes in the egress direction for IPv6 packets:

```
switch(config)#interface ethernet 26
switch(config)#tcp mss ceiling ipv6 1436 egress
```

The following example applies TCP MSS clamping at **1476** bytes for IPv4 packets and **1436** bytes for IPv6 packets in egress direction:

```
switch(config)#interface ethernet 27
switch(config)#tcp mss ceiling ipv4 1476 ipv6 1436 egress
```

Hardware TCP MSS Clamping Configuration

Hardware MSS clamping requires the system TCAM profile to have TCP MSS clamping enabled. You can achieve this by creating a user defined TCAM profile as described below. The User Defined PMF Profiles - TOI provides general guidelines on how to create and configure TCAM profiles.

The system TCAM profile must have the feature `tcp-mss-ceiling ip` in it in order to use hardware MSS clamping. This is applicable regardless of whether the TCAM profile is copied from an existing profile or created from scratch.

**Step 1: Create the user defined TCAM profile**

The following example demonstrates copying any source profile and adding the feature `tcp-mss-ceiling ip`: In this example, the profile name is `Pro1` and the source profile name is `Source1`.

```
(config)#hardware tcam
(config-hw-tcam)#profile Pro1 copy Source1
(config-hw-tcam-profile-Pro1)#feature tcp-mss-ceiling ip copy system-feature-source-profile
```

TCP MSS clamping is supported only for IPv4 routed packets. Set the packet type for the feature as follows. This is optional when using `copy system-feature-source-profile`. In this example, the system profile name is `Pro1` and the feature name is `Source1`.

```
(config-hw-tcam-profile-Pro1-feature-Source1)#packet ipv4 forwarding routed
```
Set the key size limit to 160. This is also optional when the feature is copied from `system-feature-source-profile`. In this example, the system profile name is `Pro1` and the feature name is `Source1`.

```
(config-hw-tcam-profile-Pro1-feature-Source1)#key size limit 160
```

Removing unused features to ensure that the TCP MSS TCAM DB is allocated. In this example, the system profile name is `Pro1` and the feature name is `Source1`.

```
(config-hw-tcam-profile-Pro1-feature-Source1)#exit
(config-hw-tcam-profile-Pro1)#no feature mirror ip
(config-hw-tcam-profile-Pro1)#no feature acl port mac
```

**Step 2: Apply the user defined TCAM profile to the system.**

The following example sets the profile as the system profile under the `hardware tcam` mode. In this example, the system profile name is `red`.

```
(config-hw-tcam)#system profile red
```

When the system TCAM profile is changed, it is expected that some agents will restart. Also it might be necessary to remove some unused features from the TCAM profile to ensure that the TCP MSS feature gets allocated a TCAM DB. For more information about configuring TCAM profiles, refer to User Defined PMF Profiles.

**Note:** The hardware clamping only works for TCP packets with MSS as the first TCP option. Packets where MSS is not the first TCP option are still trapped to CPU for clamping in software even if the `feature tcp-mss-ceiling` is configured in the system TCAM profile.

**Backward Compatibility**

The `tunnel mss ceiling` command which provides the same functionality is deprecated with the introduction of `tcp mss ceiling` command. The configuration option `tunnel mss ceiling` was available only on GRE tunnel interfaces, while `tcp mss ceiling` is supported on other routed IPv4 interfaces as well.

**13.1.12.7 TCP MSS Clamping Limitations**

- The TCP-MSS Clamping is not supported on L2 (switchport) interfaces.
- The TCP-MSS Clamping is NOT supported on VXLAN, Loopback and Management interfaces.
- The TCP-MSS Clamping is supported only in the Egress direction.
- The TCP-MSS Clamping is only supported on unicast routed packets entering the switch. The configuration has no effect on GRE transit packets and GRE decap case, even if the Egress interface has TCP MSS ceiling configured.

**Software TCP MSS Clamping Limitations**

- Once the TCP-MSS Clamping is enabled, all routed TCP-SYN packets will be software switched, even on interfaces where there is no TCP-MSS ceiling configuration.
- TCP SYN packets could get dropped under high CPU usage conditions or due to DOS attack protection mechanisms such as PDP/CoPP. These factors could limit the TCP connection establishment rate, i.e. new TCP sessions established per second through the switch.

**Hardware MSS Clamping Limitations**

- Hardware TCP-MSS clamping is not supported with host routes when the clamping is applied on a non-tunnel interface. This limitation does not apply to GRE tunnel interfaces.
- TCP SYN packets where TCP-MSS is not the first TCP option are trapped to CPU for MSS adjustment even in hardware MSS clamping mode.
• Hardware TCP-MSS clamping is not supported for IPv6 packets.

13.1.12.8 Configuring Hardware Support for TCP MSS Clamping

TCP MSS clamping can be supported in hardware, but some packets are still routed through the software path, and an MSS ceiling value must be configured on each interface where clamping is to be applied.

Hardware support for clamping is accomplished through the use of a user-defined TCAM profile. The TCAM profile can be created from scratch or copied from an existing profile, but in either case it must include the `tcp-mss-ceiling ip` feature.

Guidelines

• When the system TCAM profile is changed, some agents will restart.
• To ensure that the TCP MSS feature is allocated a TCAM DB, it may be necessary to remove some unused features from the TCAM profile.
• Hardware TCP MSS clamping only works for TCP packets with MSS as the first TCP option. Other TCP SYN packets are still trapped to the CPU for clamping in software.
• Hardware TCP MSS clamping is not supported with host routes when the clamping is applied on a non-tunnel interface. This limitation does not apply to GRE tunnel interfaces.
• The maximum MSS ceiling limit with hardware MSS clamping is 32727 even though the CLI allows configuration of much larger values.
• For more information on the creation of user-defined TCAM profiles, see https://eos.arista.com/eos-4-20-5f/user-defined-pmf-profile/.

To configure hardware support for TCP MSS clamping, create a TCAM profile that includes the `tcp mss ceiling` feature, then apply it to the system.

13.1.12.8.1 Creating the TCAM Profile

A TCAM profile that supports TCP MSS clamping can be created from scratch, or the feature can be added to a copy of the default TCAM profile. When creating a profile from scratch, care must be taken to ensure that all needed TCAM features are included in the profile.

Modifying a Copy of the Default TCAM Profile

The following commands create a copy of the default TCAM profile, name it `tcp-mss-clamping`, and configure it to enable MSS clamping in hardware, then remove some unused features included in the default profile to ensure that there are sufficient TCAM resources for the clamping feature.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#profile tcp-mss-clamping copy default
switch(config-hw-tcam-profile-tcp-mss-clampingl)#feature tcp-mss-ceiling
switch(config-hw-tcam-profile-tcp-mss-clampingfeature-tcp-mss-ceiling)#copy
switch(config-hw-tcam-profile-tcp-mss-clampingfeature-tcp-mss-ceiling)#system-feature-source-profile
switch(config-hw-tcam-profile-tcp-mss-clampingfeature-tcp-mss-ceiling)#size limit 160
switch(config-hw-tcam-profile-tcp-mss-clampingfeature-tcp-mss-ceiling)#packet ipv4 forwarding routed
switch(config-hw-tcam-profile-tcp-mss-clampingfeature-tcp-mss-ceiling)#exit
switch(config-hw-tcam-profile-tcp-mss-clamping)#no feature mirror ip
switch(config-hw-tcam-profile-tcp-mss-clamping)#no feature acl port mac
switch(config-hw-tcam-profile-tcp-mss-clampingl)#exit
```
13.1.12.8.2 Applying the TCAM Profile to the System

The following commands enter Hardware TCAM Configuration Mode and set the tcp-mss-clamping profile as the system profile.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#system profile tcp-mss-clamping
switch(config-hw-tcam)#
```

13.1.12.8.3 Verifying the TCAM Profile Configuration

The following command displays hardware TCAM profile information to verify that the user-defined TCAM profile has been applied correctly.

```
switch(config)#show hardware tcam profile
Configuration        Status
FixedSystem          tcp-mss-clamping         tcp-mss-clamping
switch(config)#
```

13.1.13 IPv4 GRE Tunneling

GRE tunneling supports the forwarding over IPv4 GRE tunnel interfaces. The GRE tunnel interfaces act as a logical interface that performs GRE encapsulation or decapsulation.

**Note:** The forwarding over GRE tunnel interface on DCS-7500R is supported only if all the line cards on the system have Jericho family chip-set.

13.1.13.1 Configuring GRE Tunneling Interface

**On a Local Arista Switch**

```
switch(config)#ip routing
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel mode gre
switch(config-if-Tu10)#ip address 192.168.1.1/24
switch(config-if-Tu10)#tunnel source 10.1.1.1
switch(config-if-Tu10)#tunnel destination 10.1.1.2
switch(config-if-Tu10)#tunnel path-mtu-discovery
switch(config-if-Tu10)#tunnel tos 10
switch(config-if-Tu10)#tunnel ttl 10
```

**On a Remote Arista Switch**

```
switch(config)#ip routing
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel mode gre
switch(config-if-Tu10)#ip address 192.168.1.2/24
switch(config-if-Tu10)#tunnel source 10.1.1.2
switch(config-if-Tu10)#tunnel destination 10.1.1.1
switch(config-if-Tu10)#tunnel path-mtu-discovery
```
Layer 3 Configuration

switch(config-if-Tu10)#tunnel tos 10
switch(config-if-Tu10)#tunnel ttl 10

Alternative Configuration for Tunnel Source IPv4 Address

switch(config)#interface Loopback 10
switch(config-if-Lo10)#ip add 10.1.1.1/32
switch(config-if-Lo10)#exit
switch(config)#conf terminal
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel source interface Loopback 10

Configuration for Adding an IPv4 Route over the GRE Tunnel Interface

switch(config)#ip route 192.168.100.0/24 Tunnel 10

Tunnel Mode
Tunnel Mode needs to be configured as gre, for GRE tunnel interface. Default value is tunnel mode gre.

IP Address
Configures the IP address for the GRE tunnel interface. The IP address can be used for routing over the GRE tunnel interface. The configured subnet is reachable over the GRE tunnel interface and the packets to the subnet are encapsulated in the GRE header.

Tunnel Source
Specifies the source IP address for the outer IPv4 encapsulation header for packets going over the GRE tunnel interface. The tunnel source IPv4 address should be a valid local IPv4 address configured on the Arista Switch. The tunnel source can also be specified as any routed interface on the Arista Switch. The routed interface’s IPv4 address is assigned as the tunnel source IPv4 address.

Tunnel Destination
Specifies the destination IPv4 address for the outer IPv4 encapsulation header for packets going over the GRE tunnel interface. The tunnel destination IPv4 should be reachable from the Arista Switch.

Tunnel Path Mtu Discovery
Specifies if the “Do not Fragment” flag needs to set in the outer IPv4 encapsulation header for packets going over the GRE tunnel interface.

Tunnel TOS
Specifies the Tunnel Type of Service (ToS) value to be assigned to the outer IPv4 encapsulation header for packets going over the GRE tunnel interface. Default TOS value of 0 will be assigned if tunnel TOS is not configured.

Tunnel TTL
Specifies the TTL value to the assigned to the outer IPv4 encapsulation header for packet going over the GRE tunnel interface. The TTL value is copied from the inner IPv4 header if tunnel TTL is not configured. The tunnel TTL configuration requires the tunnel Path MTU Discovery to be configured.
13.1.13.2  Displaying GRE tunnel Information

- The following commands display the tunnel configuration.

```plaintext
switch#show interfaces Tunnel 10
Tunnel10 is up, line protocol is up (connected)
Hardware is Tunnel, address is 0a01.0101.0800
Internet address is 192.168.1.1/24
Broadcast address is 255.255.255.255
Tunnel source 10.1.1.1, destination 10.1.1.2
Tunnel protocol/transport GRE/IP
  Key disabled, sequencing disabled
  Checksumming of packets disabled
Tunnel TTL 10, Hardware forwarding enabled
Tunnel TOS 10
Path MTU Discovery
Tunnel transport MTU 1476 bytes
Up 3 seconds
```

```plaintext
switch#show gre tunnel static
Name    Index  Source   Destination  Nexthop  Interface
-------- ------ -------- ------------ -------- -----------
Tunnel10 10     10.1.1.1 10.1.1.2     10.6.1.2 Ethernet6/1
```

switch#show tunnel fib static interface gre 10
Type 'Static Interface', index 10, forwarding Primary
  via 10.6.1.2, 'Ethernet6/1'
  GRE, destination 10.1.1.2, source 10.1.1.1, ttl 10, tos 0xa

- Use the `show platform fap tcam summary` command to verify if the TCAM bank is allocated for GRE packet termination lookup.

```plaintext
switch#show platform fap tcam summary
Tcam Allocation (Jericho0)
Bank    Used By     Reserved By
---------- ------------ -----------
0        dbGreTunnel -
```

- Use the `show ip route` command to verify if the routes over tunnel is setup properly.

```plaintext
switch#show ip route
VRF: default
Codes: C - connected, S - static, K - kernel,
  O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
  E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
  N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
  R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,

```

13.1.14 GRE Tunneling Support

GRE tunneling supports the forwarding over IPv4 GRE tunnel interfaces. The GRE tunnel interfaces act as a logical interface that performs GRE encapsulation or decapsulation. A maximum of 256 GRE-tunnel interfaces are supported.

Note: GRE keepalives are not supported.

To configure a local Arista switch on a GRE-tunnel interface, consider the following an example.

```bash
switch(config)#ip routing
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel mode gre
switch(config-if-Tu10)#ip address 192.168.1.1/24
switch(config-if-Tu10)#tunnel source 10.1.1.1
switch(config-if-Tu10)#tunnel destination 10.1.1.2
switch(config-if-Tu10)#tunnel path-mtu-discovery
switch(config-if-Tu10)#tunnel tos 10
switch(config-if-Tu10)#tunnel ttl 10
```

To configure a remote Arista switch on a GRE-tunnel interface, consider the following an example.

```bash
switch(config)#ip routing
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel mode gre
switch(config-if-Tu10)#ip address 192.168.1.2/24
switch(config-if-Tu10)#tunnel source 10.1.1.2
switch(config-if-Tu10)#tunnel destination 10.1.1.1.underlayVrf
switch(config-if-Tu10)#tunnel path-mtu-discovery
switch(config-if-Tu10)#tunnel tos 10
switch(config-if-Tu10)#tunnel ttl 10
```
To add an IPv4 route over the GRE-tunnel interface, configure similar to the following.

```
switch(config)#ip route 192.168.100.0/24 Tunnel 10
```

**Note:** IPv6 GRE-Tunnels are not supported. This is only a data-plane limitation whereas IS-IS IPv6 (such as control-plane) can still work.

Use the `show interfaces Tunnel` command to display the interface tunnel.

```
switch(config)#show interfaces Tunnel 10
Tunnel10 is up, line protocol is up (connected)
    Hardware is Tunnel, address is 0a01.0101.0800
    Internet address is 192.168.1.1/24
    Broadcast address is 255.255.255.255
    Tunnel source 10.1.1.1, destination 10.1.1.2
    Tunnel protocol/transport GRE/IP
    Key disabled, sequencing disabled
    Checksumming of packets disabled
    Tunnel TTL 10, Hardware forwarding enabled
    Tunnel TOS 10
    Path MTU Discovery
    Tunnel transport MTU 1476 bytes
    Tunnel underlay VRF "underlayVrf"
    Up 3 seconds
```

Use the `show gre tunnel static` command to display a static interface tunnel.

```
switch(config)#show gre tunnel static
Name     Index     Source         Destination       Nexthop
Interface ------- -------    -----------    -------------     ----------
---------- -------    -----------    -------------     ----------
Tunnel10  10         10.1.1.1       10.1.1.2          10.6.1.2
Ethernet6/1
```

Use the `show tunnel fib static interface` command to display a fib static interface tunnel.

```
switch(config)#show tunnel fib static interface gre 10
Type 'Static Interface', index 10, forwarding Primary
    via 10.6.1.2, 'Ethernet6/1'
    GRE, destination 10.1.1.2, source 10.1.1.1, ttl 10, tos 0xa
```

**Tunnel Mode**

Tunnel mode is **GRE** for a GRE-tunnel interface which is also the default tunnel mode.

**IP address**

Use this IP address for routing over the GRE-tunnel interface. The configuration subnet is reachable over the GRE-tunnel interface, and the packets to the subnet is encapsulated with the GRE header.

**Tunnel Source**

Specifies the source IP address for the encapsulating IPv4 header of a packet going over the GRE-tunnel interface. The tunnel source IPv4 address is a valid local IPv4 address configured on the Arista switch. It uses any route interface on the Arista switch. The routed interfaces IPv4 address assigns the tunnel source IPv4 address. Maximum of 16 unique tunnel source IPv4 addresses are supported across all GRE-tunnel interfaces.
The following is an example of an interface as a Tunnel source.

```plaintext
switch(config)#interface Loopback 10
switch(config-if-Lo10)#ip add 10.1.1.1/32
switch(config-if-Lo10)#exit
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel source interface Loopback 10
```

- **Note:** Coexistence of GRE-tunnel interfaces and Decap-Groups is not supported.
- **Note:** Coexistence of GRE-tunnel interfaces and VxLan is not supported.
- **Note:** GRE-tunnel is not supported with MLAG configuration.

**Tunnel Destination**

Specifies the destination IPv4 address for the encapsulating IPv4 header of a packet going over the GRE-tunnel interface. The tunnel destination IPv4 is reachable from the Arista switch.

- **Note:** Multicast traffic over GRE-Tunnels is not supported.

**Tunnel Path MTU Discovery**

The tunnel path Maximum Transmission Unit (MTU) Discovery specifies if the Don't Fragment (DF) flag needs to be set in the encapsulating IPv4 header of a packet going over the GRE-Tunnel interface. MTU configuration on the GRE-tunnel interface is used by control plane protocols and not enforced in hardware for packets forwarded in data-plane. The MTU change on the tunnel interface does not take effect until the tunnel interface is flapped.

**Tunnel TOS**

The Tunnel TOS specifies the TOS value to be set in the encapsulating IPv4 header of a packet going over the GRE-Tunnel interface. The default value of 0 is assigned if tunnel TOS is not configured. Maximum of seven unique tunnel TOS values are supported across all GRE-tunnel interfaces.

**Tunnel TTL**

The Tunnel TTL specifies the TTL value to be set in the encapsulating IPv4 header of a packet going over the GRE-tunnel interface. The TTL value is copied from the inner IPv4 header if tunnel TTL is not configured. The tunnel TTL configuration requires the tunnel path MTU discovery to be configured. Maximum of four unique tunnel TTL values are supported across all GRE-tunnel interfaces.

**VRF Forwarding (Overlay VRF)**

The following configuration is an example of overlay VRF, for a GRE tunnel interface.

```plaintext
switch(config)#vrf instance overlayVrf
switch(config)#ip routing vrf overlayVrf
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#vrf overlayVrf
```

- **Note:** Both the tunnels source and destination address must be in the underlay VRF. GRE key forwarding is not supported.

The following is an example of a static route configuration, with an overlay VRF.

```plaintext
switch(config)#ip route vrf overlayVrf 7.7.0.0/24 192.168.1.2
```
VRF Forwarding (Underlay VRF)

The following is an configuration example of a underlay VRF for a GRE tunnel interface.

```
switch(config)#vrf instance underlayVrf
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel underlay vrf underlayVrf
```

13.1.14.1 TCAM Bank Allocation

**Note:** Command to check if Ternary Content-Addressable Memory (TCAM) bank is allocated for GRE packet termination lookup.

```
switch(config)#show platform fap tcam summary
```

```
<table>
<thead>
<tr>
<th>Bank</th>
<th>Used By</th>
<th>Reserved By</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>dbGreTunnel</td>
<td>-</td>
</tr>
</tbody>
</table>
```

PBR is not supported on GRE terminated packets.

Verifying Tunnel Routes

Use the `show ip route` command to check if the routes over tunnel is setup correctly.

```
switch(config)#show ip route
```

Gateway of last resort is not set

```
C      192.168.1.0/24 is directly connected, Tunnel10, Static Interface
GRE-Tunnel index 10, dst 10.1.1.2, src 10.1.1.1, TTL 10, TOS 10
S      192.168.100.0/24 is directly connected, Tunnel10, Static Interface GRE-Tunnel index 10, dst 10.1.1.2, src 10.1.1.1, TTL 10, TOS 10
```

Verifying Tunnel Encap

Use the `show platform fap eedb ip-tunnel gre interface Tunnel` command to check the tunnel encap programming on the GRE interface.

```
switch(config)#show platform fap eedb ip-tunnel gre interface Tunnel 10
```

```
<table>
<thead>
<tr>
<th>Bank/Offset</th>
<th>OutLIF</th>
<th>NextLIF</th>
<th>VSI</th>
<th>Encap</th>
<th>TTL</th>
<th>Source</th>
<th>Destination</th>
<th>CamLIF</th>
<th>OutLIF</th>
<th>Drop</th>
</tr>
</thead>
<tbody>
<tr>
<td>3/0</td>
<td>0x6000</td>
<td>0x4010</td>
<td>0</td>
<td>2</td>
<td>10</td>
<td>10</td>
<td>10.1.1.1</td>
<td>0</td>
<td>0</td>
<td>No</td>
</tr>
</tbody>
</table>
```
Use the `show platform fap eedb ip-tunnel` command to check the tunnel encap programming on the IP-tunnel interface.

```
switch(config)#show platform fap eedb ip-tunnel
 Jericho0
<table>
<thead>
<tr>
<th>IP Tunnel Egress Encapsulation DB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offset</td>
</tr>
<tr>
<td>--------</td>
</tr>
<tr>
<td>3/0</td>
</tr>
</tbody>
</table>
```

Verifying Tunnel VRF

Use the `show ip interface tunnel` command to check the overlay VRF.

```
switch(config)#show ip interface tunnel 10
Tunnel10 is up, line protocol is up (connected)
 IPv4 Interface Forwarding : None
 Proxy-ARP is disabled
 Local Proxy-ARP is disabled
 Gratuitous ARP is ignored
 IP MTU 1476 bytes
 VPN Routing/Forwarding "overlayVrf"
```

```
switch(config)#show ip route vrf overlayVrf
 VRF: overlayVrf
 Codes: C - connected, S - static, K - kernel,
 O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
 E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
 N2 - OSPF NSSA external type2, B I - IBGP, B E - eBGP,
 R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
 O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
 NG - Nexthop Group Static Route, V - VXLAN Control Service,
 DH - DHCP client installed default route, M - Martian,
 DP - Dynamic Policy Route, L - VRF Leaked
 Gateway of last resort is not set
 C 1.1.1.0/24 is directly connected, Ethernet1
 S 7.7.7.0/24 [1/0] via 192.168.1.2, Tunnel10, Static Interface
 GRE-Tunnel index 10, dst 10.1.1.2, src 10.1.1.1
 C 192.168.1.0/24 is directly connected, Tunnel10, Static Interface
 GRE-Tunnel index 10, dst 10.1.1.2, src 10.1.1.1
```

Tunnel underlay VRF Configuration

Use the `show interfaces Tunnel` command to check the underlay VRF.

```
switch(config)#show interfaces Tunnel 10
Tunnel10 is up, line protocol is up (connected)
 Hardware is Tunnel, address is 0a01.0101.0800
 Internet address is 192.168.1.1/24
 Broadcast address is 255.255.255.255
 Tunnel source 10.1.1.1, destination 10.1.1.2
 Tunnel protocol/transport GRE/IP
 Key disabled, sequencing disabled
 Checksumming of packets disabled
 Tunnel TTL 10, Hardware forwarding enabled
 Tunnel TOS 10
 Path MTU Discovery
 Tunnel transport MTU 1476 bytes
```
Use the `show ip route vrf underlayVrf` command to check the IP route VFR underlayVRF.

```
switch(config)#show ip route vrf underlayVrf
VRF: underlayVrf
Codes: C - connected, S - static, K - kernel,
      O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
      E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
      N2 - OSPF NSSA external type 2, B - BGP, B I - iBGP, B E - eBGP,
      R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
      O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
      NG - Nexthop Group Static Route, V - VXLAN Control Service,
      DH - DHCP client installed default route, M - Martian,
      DP - Dynamic Policy Route, L - VRF Leaked,

Gateway of last resort is not set
C        10.1.1.0/24 is directly connected, Ethernet1
```

### 13.1.15 BfRuntime to use non-default VRFs

Use the following to configure the VRF for the BfRuntime connection for the management interface on the switches that support it. The management interface may be configured on a different VRF from the default one.

#### Configuring BfRuntime to use Non-default VRFs

The `platform barefoot bfrt vrf` command configures the forwarding plane agent to restart and listen on the configured VRFs for connections.

```
(config)#platform barefoot bfrt vrf <VRF name>
```

If left unconfigured, the default VRF is used for the IP and port for the the BfRuntime server.

The following shows a typical configuration.

```
(config)#vrf instance management
(config-vrf-management)#exit
(config)#platform barefoot bfrt 0.0.0.0 50052
(config)#platform barefoot bfrt vrf <VRF name>
(config)#int management1
(config-if-Ma1)#vrf management
```

#### Displaying BfRuntime Configuration

The `show platform barefoot bfrt` command displays the existing configuration for the BfRuntime server.

```
(switch)#show platform barefoot bfrt
Namespace: management
FixedSystem:0.0.0.0:50052
```
### 13.1.16 IPv4 Commands

#### IP Routing and Address Commands

- agent SandL3Unicast terminate
- clear arp inspection statistics
- compress
- ip arp inspection limit
- ip arp inspection logging
- ip arp inspection trust
- ip arp inspection vlan
- ip hardware fib ecmp resilience
- ip hardware fib optimize
- ip hardware fib next-hop resource optimization
- ip icmp redirect
- ip load-sharing
- ip route
- ip routing
- ip source binding
- ip verify
- ip verify source
- ipv4 routable 240.0.0.0/4
- rib fib policy
- show dhcp server
- show hardware capacity
- show ip
- show ip arp inspection vlan
- show ip arp inspection statistics
- show ip hardware fib summary
- show ip interface
- show ip interface brief
- show ip route
- show ip route age
- show ip route gateway
- show ip route host
- show ip route match tag
- show ip route summary
- show rib route ip
- show rib route [ipv4 | ipv6>] fib policy excluded
- show rib route summary
- show routing-context vrf
- show vrf
- show ip verify source
- show platform arad ip route
- show platform arad ip route summary
- tcp mss ceiling

#### IPv4 DHCP Relay

- clear ip dhcp relay counters
- dhcp relay
Layer 3 Configuration

- `ip dhcp relay all-subnets`
- `ip dhcp relay all-subnets default`
- `ip dhcp relay always-on`
- `ip dhcp snooping information option`
- `ip dhcp relay information option circuit-id`
- `ip helper-address`
- `show ip dhcp relay`
- `show ip dhcp relay counters`

### IPv4 DHCP Snooping

- `clear ip dhcp snooping counters`
- `ip dhcp snooping`
- `ip dhcp snooping bridging`
- `ip dhcp snooping information option`
- `ip dhcp snooping vlan`
- `show ip dhcp snooping`
- `show ip dhcp snooping counters`
- `show ip dhcp snooping hardware`

### IPv4 Multicast Counters

- `clear ip multicast count`
- `ip multicast count`

### ARP Table

- `arp`
- `arp aging timeout`
- `arp cache persistent`
- `arp gratuitous accept`
- `clear arp-cache`
- `clear arp`
- `ip local-proxy-arp`
- `ip proxy-arp`
- `show arp`
- `show ip arp`

### VRF Commands

- `compress`
- `cli vrf`
- `description (VRF)`
- `platform barefoot bfrt vrf`
- `show platform barefoot bfrt`
- `show routing-context vrf`
- `show vrf`
- `vrf (Interface mode)`
- `vrf instance`

### Trident Forwarding Table Commands

- `platform trident forwarding-table partition`
• platform trident routing-table partition
• show platform trident forwarding-table partition

IPv4 GRE Tunneling Commands
• interface tunnel
• tunnel
• show interface tunnel
• show platform fap eedb ip-tunnel gre interface tunnel
• show tunnel fib static interface gre
• show platform fap tcam summary
13.1.16.1 agent SandL3Unicast terminate

The `agent SandL3Unicast terminate` command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

**Command Mode**
Global Configuration

**Command Syntax**

agent SandL3Unicast terminate

**Related Commands**

- `ip hardware fib optimize` enables IPv4 route scale.
- `show platform arad ip route` shows resources for all IPv4 routes in hardware. Routes that use the additional hardware resources will appear with an asterisk.
- `show platform arad ip route summary` shows hardware resource usage of IPv4 routes.

**Example**

This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.
13.1.16.2  **arp aging timeout**

The **arp aging timeout** command specifies the duration of dynamic address entries in the Address Resolution Protocol (ARP) cache for addresses learned through the configuration mode interface. The default duration is 14400 seconds (four hours).

The **arp aging timeout** and **default arp aging timeout** commands restores the default ARP aging timeout for addresses learned on the configuration mode interface by deleting the corresponding **arp aging timeout** command from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
arp aging timeout  *arp_time*
no arp aging timeout
default arp aging timeout
```

**Parameters**

*arp_time*  ARP aging timeout period (seconds). Values range from 60 to 65535. Default value is **14400**.

**Example**

This command specifies an ARP cache duration of **7200** seconds (two hours) for dynamic addresses added to the ARP cache that were learned through **VLAN 200**.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#arp aging timeout 7200
switch(config-if-Vl200)#show active
  interface Vlan200
    arp aging timeout 7200
switch(config-if-Vl200)#
```
13.1.16.3  arp cache persistent

The `arp cache persistent` command restores the dynamic entries in the Address Resolution Protocol (ARP) cache after reboot.

The `no arp cache persistent` and `default arp cache persistent` commands remove the ARP cache persistent configuration from the running-config.

Command Mode
Global Configuration

Command Syntax
- `arp cache persistent`
- `no arp cache persistent`
- `default arp cache persistent`

Example
This command restores the ARP cache after reboot.

```
switch(config)#arp cache persistent
switch(config)#
```
13.1.16.4  arp gratuitous accept

The `arp gratuitous accept` command configures the configuration mode interface to accept gratuitous ARP request packets received on that interface. Accepted gratuitous ARP requests are then learned by the ARP table.

The `no` and `default` forms of the command prevent the interface from accepting gratuitous ARP requests. Configuring gratuitous ARP acceptance on an L2 interface has no effect.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-VLAN Configuration
- Interface Port-channel Configuration

**Command Syntax**

`arp gratuitous accept`

`no arp gratuitous accept`

`default arp gratuitous accept`

**Example**

These commands configure *Ethernet interface 2/1* to accept gratuitous ARP request packets.

```
switch (config)#interface ethernet 2/1
switch (config-if-Et2/1)#arp gratuitous accept
switch (config-if-Et2/1)#
```
13.1.16.5  arp

The `arp` command adds a static entry to an Address Resolution Protocol (ARP) cache. The switch uses ARP cache entries to correlate 32-bit IP addresses to 48-bit hardware addresses.

The `no arp` and `default arp` commands remove the ARP cache entry with the specified IP address. When multiple VRFs contain ARP cache entries for identical IP addresses, each entry can only be removed individually.

**Command Mode**
Global Configuration

**Command Syntax**

```
arp [VRF_INSTANCE] ipv4_addr mac_addr arpa
no arp [VRF_INSTANCE] ipv4_addr
default arp [VRF_INSTANCE] ipv4_addr
```

**Parameters**

- **VRF_INSTANCE**  Specifies the VRF instance being modified.
- **no parameter**   Changes are made to the default VRF.
- **vrf vrf_name**   Changes are made to the specified user-defined VRF.
- **ipv4_addr**      IPv4 address of ARP entry.
- **mac_addr**       Local data-link (hardware) address (48-bit dotted hex notation – H.H.H).

**Examples**

- This command adds a static entry to the ARP cache in the default VRF.

```
switch(config)#arp 172.22.30.52 0025.900e.c63c arpa
```

- This command adds the same static entry to the ARP cache in the VRF named `purple`.

```
switch(config)#arp vrf purple 172.22.30.52 0025.900e.c63c arpa
```
13.1.16.6 clear arp inspection statistics

The clear arp inspection statistics command clears ARP inspection statistics.

Command Mode
EXEC

Command Syntax
clear arp inspection statistics

Related Commands
• ip arp inspection limit
• ip arp inspection logging
• ip arp inspection trust
• ip arp inspection vlan
• show ip arp inspection vlan
• show ip arp inspection statistics

Example
This command clears ARP inspection statistics.

```
switch(config)#clear arp inspection statistics
switch(config)#
```
13.1.16.7 clear arp

The clear arp command removes the specified dynamic ARP entry for the specified IP address from the Address Resolution Protocol (ARP) table.

Command Mode
Privileged EXEC

Command Syntax

clear arp [VRF_INSTANCE] ipv4_addr Parameters

- VRF_INSTANCE Specifies the VRF instance for which arp data is removed.
  - no parameter Specifies the context-active VRF.
  - vrf vrf_name Specifies name of VRF instance. System default VRF is specified by default.
- ipv4_addr IPv4 address of dynamic ARP entry.

Example

These commands display the ARP table before and after the removal of dynamic ARP entry for IP address 172.22.30.52.

```
switch#show arp
Address         Age (min)  Hardware Addr   Interface
172.22.30.1             0  001c.730b.1d15  Management1
172.22.30.52            0  0025.900e.c468  Management1
172.22.30.53            0  0025.900e.c63c  Management1
172.22.30.133           0  001c.7304.3906  Management1

switch#clear arp 172.22.30.52

switch#show arp
Address         Age (min)  Hardware Addr   Interface
172.22.30.1             0  001c.730b.1d15  Management1
172.22.30.53            0  0025.900e.c63c  Management1
172.22.30.133           0  001c.7304.3906  Management1

switch#
```
clear arp-cache

The clear arp-cache command refreshes dynamic entries in the Address Resolution Protocol (ARP) cache. Refreshing the ARP cache updates current ARP table entries and removes expired ARP entries not yet deleted by an internal, timer-driven process.

The command, without arguments, refreshes ARP cache entries for all enabled interfaces. With arguments, the command refreshes cache entries for the specified interface. Executing clear arp-cache for all interfaces can result in extremely high CPU usage while the tables are resolving.

Command Mode
Privileged EXEC

Command Syntax

clear arp-cache [VRF_INSTANCE][INTERFACE_NAME]

Parameters

- **VRF_INSTANCE** Specifies the VRF instance for which arp data is refreshed.
  - no parameter Specifies the context-active VRF.
  - vrf vrf_name Specifies name of VRF instance. System default VRF is specified by default.
- **INTERFACE_NAME** Interface upon which ARP cache entries are refreshed. Options include:
  - no parameter All ARP cache entries.
  - interface ethernet e_num ARP cache entries of specified Ethernet interface.
  - interface loopback l_num ARP cache entries of specified loopback interface.
  - interface management m_num ARP cache entries of specified management interface.
  - interface port-channel p_num ARP cache entries of specified port-channel Interface.
  - interface vlan v_num ARP cache entries of specified VLAN interface.
  - interface vxlan vx_num VXLAN interface specified by vx_num.

Related Commands

The cli vrf command specifies the context-active VRF.

Example

These commands display the ARP cache before and after ARP cache entries are refreshed.

```
switch#show arp
Address    Age (min)  Hardware Addr   Interface
172.22.30.1   0       001c.7301.1d15  Management1
172.22.30.118  0       001c.7301.6015  Management1

switch#clear arp-cache
switch#show arp
Address    Age (min)  Hardware Addr   Interface
172.22.30.1   0       001c.7301.1d15  Management1
```

1654
13.1.16.9 clear ip dhcp relay counters

The clear ip dhcp relay counters command resets the DHCP relay counters. The configuration mode determines which counters are reset:

**Interface configuration:** command clears the counter for the configuration mode interface.

**Command Mode**
Privileged EXEC

**Command Syntax**
clear ip dhcp relay counters [INTERFACE_NAME]

**Parameters**

- **INTERFACE_NAME** Entity for which counters are cleared. Options include:
  - no parameter Clears counters for the switch and for all interfaces.
  - interface ethernet e_num Clears counters for the specified Ethernet interface.
  - interface loopback l_num Clears counters for the specified loopback interface.
  - interface port-channel p_num Clears counters for the specified port-channel Interface.
  - interface vlan v_num Clears counters for the specified VLAN interface.

**Examples**

- These commands clear the DHCP relay counters for VLAN 1045 and shows the counters before and after the clear command.

```
switch#show ip dhcp relay counters

<table>
<thead>
<tr>
<th>Interface</th>
<th>Dhcp Packets</th>
<th>Rcvd Fwdd Drop</th>
<th>Last Cleared</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Req</td>
<td>376</td>
<td>376</td>
<td>0</td>
</tr>
<tr>
<td>All Resp</td>
<td>277</td>
<td>277</td>
<td>0</td>
</tr>
<tr>
<td>Vlan1001</td>
<td>207</td>
<td>148</td>
<td>0</td>
</tr>
<tr>
<td>Vlan1045</td>
<td>376</td>
<td>277</td>
<td>0</td>
</tr>
</tbody>
</table>

switch#clear ip dhcp relay counters interface vlan 1045

<table>
<thead>
<tr>
<th>Interface</th>
<th>Dhcp Packets</th>
<th>Rcvd Fwdd Drop</th>
<th>Last Cleared</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Req</td>
<td>380</td>
<td>380</td>
<td>0</td>
</tr>
<tr>

13.1.16.10 clear ip dhcp snooping counters

The `clear ip dhcp snooping counters` command resets the DHCP snooping packet counters.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear ip dhcp snooping counters [COUNTER_TYPE]`

**Parameters**
- **COUNTER_TYPE** The type of counter that the command resets. Options include:
  - `no parameter` Counters for each VLAN.
  - `debug` Aggregate counters and drop cause counters.

**Examples**
- This command clears the DHCP snooping counters for each VLAN.

```text
switch# clear ip dhcp snooping counters
switch# show ip dhcp snooping counters
<table>
<thead>

switch#
```
13.1.16.11 clear ip multicast count

The `clear ip multicast count` command clears all counters associated with the multicast traffic.

**Command Mode**
Global Configuration

**Command Syntax**
`clear ip multicast count [group_address [source_address]]`

**Parameters**
- `no parameters` Clears all counts of the multicast route traffic.
- `group_address` Clears the multicast traffic count of the specified group address.
  - `source_address` Clears the multicast traffic count of the specified group and source addresses.

**Guidelines**
This command functions only when the `ip multicast count` command is enabled.

**Examples**
- This command clears all counters associated with the multicast traffic.
  ```
  switch(config)#clear ip multicast count
  ```
- This command clears the multicast traffic count of the specified group address.
  ```
  switch(config)#clear ip multicast count 16.39.24.233
  ```
The `cli vrf` command specifies the context-active VRF. The context-active VRF determines the default VRF that VRF-context aware commands use when displaying routing table data.

**Command Mode**
Privileged EXEC

**Command Syntax**
`cli vrf [VRF_ID]`

**Parameters**

**VRF_ID**  Name of VRF assigned as the current VRF scope. Options include:
- `vrf_name`  Name of user-defined VRF.
- `default`  System-default VRF.

**Guidelines**
VRF-context aware commands include:

- `clear arp-cache`
- `show ip`
- `show ip arp`
- `show ip route`
- `show ip route gateway`
- `show ip route host`

**Related Commands**
The `show routing-context vrf` command displays the context-active VRF.

**Example**
These commands specify `magenta` as the context-active VRF, then display the context-active VRF.

```
switch#cli vrf magenta
switch#show routing-context vrf
Current VRF routing-context is magenta
switch#
```
The *compress* command increases the hardware resources available for the specified prefix lengths. The *no compress* command removes the 2-to-1 compression configuration from the *running-config*.

**Note:** The *compress* command is supported only on 7500R, 7280R, 7500R2 and 7280R2 platforms.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip hardware fib optimize prefix-length <prefix-length> expand <prefix-length> compress
no ip hardware fib optimize prefix-length <prefix-length> expand <prefix-length> compress
```

**Parameters**

*compress*  Allows configuring up to one compressed prefix length.

**Example**

In the following example we are configuring prefix length **20** and **24**, expanding prefix length **19** and **23**, and compressing prefix length **25**.

```
switch(config)#ip hardware fib optimize prefix-length 20 24
expand 19 23 compress 25
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```
13.1.16.14 description (VRF)

The `description` command adds a text string to the configuration mode VRF. The string has no functional impact on the VRF.

The `no description` and `default description` commands remove the text string from the configuration mode VRF by deleting the corresponding `description` command from `running-config`.

**Command Mode**

VRF Configuration

**Command Syntax**

description `label_text`

no description

default description

**Parameters**

`label_text`  Character string assigned to the VRF configuration.

**Related Commands**

The `vrf instance` command places the switch in VRF configuration mode.

**Example**

These commands add description text to the `magenta` VRF.

```
switch(config)#vrf instance magenta
switch(config-vrf-magenta)#description This is the first vrf
switch(config-vrf-magenta)#show active
vrf instance magenta
    description This is the first vrf

switch(config-vrf-magenta)#
```
13.1.16.15 dhcp relay

The `dhcp relay` command places the switch in the DHCP relay mode. This command is executed under *global configuration mode*.

The `no dhcp relay` command removes DHCP relay configuration from the *running-config*.

**Command Mode**

Global Configuration Mode

**Command Syntax**

`dhcp relay`

`no dhcp relay`

**Example**

The `dhcp relay` command places the switch in the DHCP relay configuration mode.

```
switch(config)#dhcp relay
switch(config-dhcp-relay)#
```
13.1.16.16  interface tunnel

The `interface tunnel` command places the switch in interface-tunnel configuration mode. Interface-tunnel configuration mode is not a group change mode; `running-config` is changed immediately after commands are executed.

The `no interface tunnel` command deletes the specified interface tunnel configuration. The `exit` command returns the switch to the global configuration mode.

**Command Mode**
Global Configuration

**Command Syntax**
`interface tunnel number`

`no interface tunnel number`

**Parameter**
`number`  Tunnel interface number. Values range from 0 to 255.

**Example**
This command places the switch in interface-tunnel configuration mode for tunnel interface 10.

```
switch(config)#interface tunnel 10
switch(config-if-Tu10)#
```
13.1.16.17  ip arp inspection limit

The *ip arp inspection limit* command err-disables the interface if the incoming ARP rate exceeds the configured value rate limit the incoming ARP packets on an interface.

**Command Mode**

EXEC

**Command Syntax**

```
ip arp inspection limit [RATE pps] [BURST_INTERVAL sec | none]
no ip arp inspection limit [RATE pps] [BURST_INTERVAL sec | none]
default ip arp inspection limit [RATE pps] [BURST_INTERVAL sec | none]
```

**Parameters**

- **RATE**  
  Specifies the ARP inspection limit rate in packets per second.
- **pps**  
  ARP inspection limit rate packets per second.
- **BURST_INTERVAL**  
  Specifies the ARP inspection limit burst interval.
- **sec**  
  Burst interval second.

**Related Commands**

- ip arp inspection limit
- ip arp inspection trust
- ip arp inspection vlan
- show ip arp inspection vlan

**Examples**

- This command configures the rate limit of incoming ARP packets to errdisable the interface when the incoming ARP rate exceeds the configured value, sets the rate to *512* (which is the upper limit for the number of invalid ARP packets allowed per second), and sets the burst consecutive interval over which the interface is monitored for a high ARP rate to *11* seconds.

```
switch(config)#ip arp inspection limit rate 512 burst interval 11
switch(config)#
```

- This command displays verification of the interface specific configuration.

```
switch(config)#interface Ethernet 3/1
switch(config)#ip arp inspection limit rate 20 burst interval 5
switch(config)#interface Ethernet 3/3
switch(config)#ip arp inspection trust
switch(config)#show ip arp inspection interfaces

<table>
<thead>
<tr>
<th>Interface</th>
<th>Trust State</th>
<th>Rate (pps)</th>
<th>Burst Interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et3/1</td>
<td>Untrusted</td>
<td>20</td>
<td>5</td>
</tr>
<tr>
<td>Et3/3</td>
<td>Trusted</td>
<td>None</td>
<td>N/A</td>
</tr>
</tbody>
</table>

switch(config)#
```
13.1.16.18  ip arp inspection logging

The `ip arp inspection logging` command enables logging of incoming ARP packets on the interface if the rate exceeds the configured value.

**Command Mode**
EXEC

**Command Syntax**

```
ip arp inspection logging [RATE pps] [BURST_INTERVAL sec | none]
no ip arp inspection logging [RATE pps] [BURST_INTERVAL sec | none]
default ip arp inspection logging [RATE pps] [BURST_INTERVAL sec | none]
```

**Parameters**
- **RATE**  Specifies the ARP inspection limit rate in packets per second.
  - `<pps>` ARP inspection limit rate packets per second.
- **BURST_INTERVAL**  Specifies the ARP inspection limit burst interval.
  - `sec` Burst interval second.

**Related Commands**
- `ip arp inspection limit`
- `ip arp inspection trust`
- `ip arp inspection vlan`
- `show ip arp inspection vlan`

**Example**

This command enables logging of incoming ARP packets when the incoming ARP rate exceeds the configured value on the interface, sets the rate to 2048 (which is the upper limit for the number of invalid ARP packets allowed per second), and sets the burst consecutive interval over which the interface is monitored for a high ARP rate to 15 seconds.

```
switch(config)#ip arp inspection logging rate 2048 burst interval 15
switch(config)#
```
13.1.16.19 ip arp inspection trust

The ip arp inspection trust command configures the trust state of an interface. By default, all interfaces are untrusted.

Command Mode
EXEC

Command Syntax
ip arp inspection trust
no ip arp inspection trust
default ip arp inspection trust

Related Commands
• ip arp inspection limit
• ip arp inspection logging
• show ip arp inspection vlan
• ip arp inspection vlan

Examples
• This command configures the trust state of an interface.

```
switch(config)#ip arp inspection trust
switch(config)#
```

• This command configures the trust state of an interface to untrusted.

```
switch(config)#no ip arp inspection trust
switch(config)#
```

• This command configures the trust state of an interface to its default (untrusted).

```
switch(config)#default ip arp inspection trust
switch(config)#
```
13.16.20 ip arp inspection vlan

The **ip arp inspection vlan** command enables ARP inspection. ARP requests and responses on untrusted interfaces are intercepted on specified VLANs, and intercepted packets are verified to have valid IP-MAC address bindings. All invalid ARP packets are dropped. On trusted interfaces, all incoming ARP packets are processed and forwarded without verification. By default, ARP inspection is disabled on all VLANs.

**Command Mode**
EXEC

**Command Syntax**

```
ip arp inspection vlan [LIST]
```

**Parameters**

**LIST** Specifies the VLAN interface number.

**Related Commands**

- **ip arp inspection limit**
- **ip arp inspection trust**
- **ip arp inspection vlan**

**Example**

- This command enables ARP inspection on VLANs 1 through 150.

  ```
  switch(config)#ip arp inspection vlan 1 - 150
  switch(config)#
  ```

- This command disables ARP inspection on VLANs 1 through 150.

  ```
  switch(config)#no ip arp inspection vlan 1 - 150
  switch(config)#
  ```

- This command sets the ARP inspection default to VLANs 1 through 150.

  ```
  switch(config)#default ip arp inspection vlan 1 - 150
  switch(config)#
  ```

- These commands enable ARP inspection on multiple VLANs 1 through 150 and 200 through 250.

  ```
  switch(config)#ip arp inspection vlan 1-150,200-250
  switch(config)#
  ```
13.1.16.21  ip dhcp relay all-subnets default

The **ip dhcp relay all-subnets default** command configures the global DHCP smart relay setting. DHCP smart relay supports forwarding DHCP requests with a client’s secondary IP addresses in the gateway address field. The default global DHCP smart relay setting is disabled.

The global DHCP smart relay setting is applied to all interfaces for which an **ip dhcp relay all-subnets** statement is not configured. Enabling DHCP smart relay on an interface requires that DHCP relay is also enabled on that interface.

The **no ip dhcp relay all-subnets default** and **default ip dhcp relay all-subnets default** commands restore the global DHCP smart relay default setting of disabled by removing the **ip dhcp relay all-subnets default** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip dhcp relay all-subnets default
no ip dhcp relay all-subnets default
default ip dhcp relay all-subnets default
```

**Related Commands**

- **ip helper-address** Enables the DHCP relay agent on a configuration mode interface.
- **ip dhcp relay all-subnets** Enables the DHCP smart relay agent on a configuration mode interface.

**Example**

This command configures the global DHCP smart relay setting to **enabled**.

```
switch(config)#ip dhcp relay all-subnets default
switch(config)#
```
13.16.22 ip dhcp relay all-subnets

The **ip dhcp relay all-subnets** command configures the DHCP smart relay status on the configuration mode interface. DHCP smart relay supports forwarding DHCP requests with a client’s secondary IP addresses in the gateway address field. Enabling DHCP smart relay on an interface requires that DHCP relay is also enabled on that interface.

By default, an interface assumes the global DHCP smart relay setting as configured by the **ip dhcp relay all-subnets default** command. The **ip dhcp relay all-subnets** command, when configured, takes precedence over the global smart relay setting.

The **no ip dhcp relay all-subnets** command disables DHCP smart relay on the configuration mode interface. The **default ip dhcp relay all-subnets** command restores the interface’s to the default DHCP smart relay setting, as configured by the **ip dhcp relay all-subnets default** command, by removing the corresponding **ip dhcp relay all-subnets** or **no ip dhcp relay all-subnets** statement from **running-config**.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- ip dhcp relay all-subnets
- no ip dhcp relay all-subnets
- default ip dhcp relay all-subnets

**Examples**

- This command enables DHCP smart relay on VLAN interface 100.

  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#ip helper-address 10.4.4.4
  switch(config-if-Vl100)#ip dhcp relay all-subnets
  switch(config-if-Vl100)#show ip dhcp relay
  DHCP Relay is active
  DHCP Relay Option 82 is disabled
  DHCP Smart Relay is enabled
  Interface: Vlan100
  DHCP Smart Relay is enabled
  DHCP servers: 10.4.4.4
  switch(config-if-Vl100)#
  ```

- This command disables DHCP smart relay on VLAN interface 100.

  ```
  switch(config-if-Vl100)#no ip dhcp relay all-subnets
  switch(config-if-Vl100)#show active
  interface Vlan100
  no ip dhcp relay all-subnets
  ip helper-address 10.4.4.4
  switch(config-if-Vl100)#show ip dhcp relay
  DHCP Relay is active
  DHCP Relay Option 82 is disabled
  DHCP Smart Relay is enabled
  Interface: Vlan100
  DHCP Smart Relay is disabled
  DHCP servers: 10.4.4.4
  switch(config-if-Vl100)#
  ```
This command enables DHCP smart relay globally, configures VLAN interface 100 to use the global setting, then displays the DHCP relay status.

```
switch(config)#ip dhcp relay all-subnets default
switch(config)#interface vlan 100
switch(config-if-Vl100)#ip helper-address 10.4.4.4
switch(config-if-Vl100)#default ip dhcp relay
switch(config-if-Vl100)#show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is disabled
DHCP Smart Relay is enabled
Interface: Vlan100
    Option 82 Circuit ID: 333
    DHCP Smart Relay is enabled
    DHCP servers: 10.4.4.4
switch(config-if-Vl100)#
```
The ip dhcp relay always-on command enables the switch DHCP relay agent on the switch regardless of the DHCP relay agent status on any interface. By default, the DHCP relay agent is enabled only if at least one routable interface is configured with an ip helper-address statement.

The no ip dhcp relay always-on and default ip dhcp relay always-on commands remove the ip dhcp relay always-on command from running-config.

Command Mode
Global Configuration

Command Syntax

ip dhcp relay always-on
no ip dhcp relay always-on
default ip dhcp relay always-on

Related Commands
These commands implement DHCP relay agent.

• ip helper-address
• ip dhcp relay information option (Global)
• ip dhcp relay information option circuit-id

Example
This command enables the DHCP relay agent.

```
switch(config)#ip dhcp relay always-on
switch(config)#
```
13.1.16.24 ip dhcp relay information option (Global)

The `ip dhcp relay information option` command configures the switch to attach tags to DHCP requests before forwarding them to the DHCP servers designated by `ip helper-address` commands. The command specifies the tag contents for packets forwarded by the interface that it configures.

The `no ip dhcp relay information option` and `default ip dhcp relay information option` commands restore the switch’s default setting of not attaching tags to DHCP requests by removing the `ip dhcp relay information option` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip dhcp relay information option
no ip dhcp relay information option
default ip dhcp relay information option
```

**Related Commands**
These commands implement DHCP relay agent.
- `ip helper-address`
- `ip dhcp relay always-on`
- `ip dhcp relay information option circuit-id`

**Example**
This command enables the attachment of tags to DHCP requests that are forwarded to DHCP server addresses.

```
switch(config)#ip dhcp relay information option
switch(config)#
```
13.1.16.25 ip dhcp relay information option circuit-id

The `ip dhcp relay information option circuit-id` command specifies the content of tags that the switch attaches to DHCP requests before they are forwarded from the configuration mode interface to DHCP server addresses specified by `ip helper-address` commands. Tags are attached to outbound DHCP requests only if the information option is enabled on the switch (`ip dhcp relay information option circuit-id`). The default value for each interface is the name and number of the interface.

The `no ip dhcp relay information option circuit-id` and `default ip dhcp relay information option circuit-id` commands restore the default content setting for the configuration mode interface by removing the corresponding command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ip dhcp relay information option circuit-id id_label
no ip dhcp relay information option circuit-id
default ip dhcp relay information option circuit-id
```

**Parameters**

`id_label`  Tag content. Format is alphanumeric characters (maximum 15 characters).

**Related Commands**

- `ip helper-address`
- `ip dhcp relay always-on`
- `ip dhcp relay information option (Global)`

**Example**

This command configures `x-1234` as the tag content for packets send from VLAN 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ip dhcp relay information option circuit-id x-1234
switch(config-if-Vl200)#
```
13.1.16.26 ip dhcp snooping

The `ip dhcp snooping` command enables DHCP snooping globally on the switch. DHCP snooping is a set of Layer 2 processes that can be configured on LAN switches and used with DHCP servers to control network access to clients with specific IP/MAC addresses. The switch supports Option-82 insertion, which is a DHCP snooping process that allows relay agents to provide remote-ID and circuit-ID information to DHCP reply and request packets. DHCP servers use this information to determine the originating port of DHCP requests and associate a corresponding IP address to that port. DHCP servers use port information to track host location and IP address usage by authorized physical ports.

DHCP snooping uses the information option (Option-82) to include the switch MAC address (router-ID) along with the physical interface name and VLAN number (circuit-ID) in DHCP packets. After adding the information to the packet, the DHCP relay agent forwards the packet to the DHCP server as specified by the DHCP protocol.

DHCP snooping on a specified VLAN requires all of these conditions to be met:

• DHCP snooping is globally enabled.
• Insertion of option-82 information in DHCP packets is enabled.
• DHCP snooping is enabled on the specified VLAN.
• DHCP relay is enabled on the corresponding VLAN interface.

The `no ip dhcp snooping` and `default ip dhcp snooping` commands disables global DHCP snooping by removing the `ip dhcp snooping` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

`ip dhcp snooping`

`no ip dhcp snooping`

`default ip dhcp snooping`

**Related Commands**

• `ip dhcp snooping information option` enables insertion of option-82 snooping data.
• `ip helper-address` enables the DHCP relay agent on a configuration mode interface.

**Example**

This command globally enables snooping on the switch, displaying DHCP snooping status prior and after invoking the command.

```
switch(config)#show ip dhcp snooping
DHCP Snooping is disabled
switch(config)#ip dhcp snooping
switch(config)#show ip dhcp snooping
DHCP Snooping is enabled
DHCP Snooping is not operational
DHCP Snooping is configured on following VLANs:
  None
DHCP Snooping is operational on following VLANs:
  None
Insertion of Option-82 is disabled
switch(config)#
```
13.1.16.27 ip dhcp snooping bridging

The `ip dhcp snooping bridging` command enables the DHCP snooping bridging configuration. The `no ip dhcp snooping bridging` command removes the DHCP snooping bridging configuration from the `running-config`.

**Command Mode**
Global Configuration Mode

**Command Syntax**

- `ip dhcp snooping bridging`
- `no ip dhcp snooping bridging`

**Example**
This command configures the DHCP snooping bridging.

```
switch#configure
switch(config)#ip dhcp snooping bridging
```
The `ip dhcp snooping information option` command enables the insertion of option-82 DHCP snooping information in DHCP packets on VLANs where DHCP snooping is enabled. DHCP snooping is a layer 2 switch process that allows relay agents to provide remote-ID and circuit-ID information to DHCP reply and request packets. DHCP servers use this information to determine the originating port of DHCP requests and associate a corresponding IP address to that port.

DHCP snooping uses information option (Option-82) to include the switch MAC address (router-ID) along with the physical interface name and VLAN number (circuit-ID) in DHCP packets. After adding the information to the packet, the DHCP relay agent forwards the packet to the DHCP server through DHCP protocol processes.

DHCP snooping on a specified VLAN requires all of these conditions to be met:

- DHCP snooping is globally enabled.
- Insertion of option-82 information in DHCP packets is enabled.
- DHCP snooping is enabled on the specified VLAN.
- DHCP relay is enabled on the corresponding VLAN interface.

When global DHCP snooping is not enabled, the `ip dhcp snooping information option` command persists in `running-config` without any operational effect.

The `no ip dhcp snooping information option` and `default ip dhcp snooping information option` commands disable the insertion of option-82 DHCP snooping information in DHCP packets by removing the `ip dhcp snooping information option` statement from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip dhcp snooping information option
no ip dhcp snooping information option
default ip dhcp snooping information option
```

**Related Commands**

- `ip dhcp snooping` globally enables DHCP snooping.
- `ip helper-address` enables the DHCP relay agent on a configuration mode interface.

**Example**
These commands enable DHCP snooping on DHCP packets from ports on snooping-enabled VLANs. DHCP snooping was previously enabled on the switch.

```
switch(config)#ip dhcp snooping information option
switch(config)#show ip dhcp snooping
DHCP Snooping is enabled
DHCP Snooping is operational
DHCP Snooping is configured on following VLANs:
  100
DHCP Snooping is operational on following VLANs:
  100
Insertion of Option-82 is enabled
Circuit-id format: Interface name:Vlan ID
Remote-id: 00:1c:73:1f:b4:38 (Switch MAC)
```
switch(config)#
The **ip dhcp snooping vlan** command enables DHCP snooping on specified VLANs. DHCP snooping is a Layer 2 process that allows relay agents to provide remote-ID and circuit-ID information in DHCP packets. DHCP servers use this data to determine the originating port of DHCP requests and associate a corresponding IP address to that port. DHCP snooping is configured on a global and VLAN basis.

VLAN snooping on a specified VLAN requires each of these conditions:

- DHCP snooping is globally enabled.
- Insertion of option-82 information in DHCP packets is enabled.
- DHCP snooping is enabled on the specified VLAN.
- DHCP relay is enabled on the corresponding VLAN interface.

When global DHCP snooping is not enabled, the **ip dhcp snooping vlan** command persists in **running-config** without any operational affect.

The **no ip dhcp snooping information option** and **default ip dhcp snooping information option** commands disable DHCP snooping operability by removing the **ip dhcp snooping information option** statement from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip dhcp snooping vlan v_range
no ip dhcp snooping vlan v_range
default ip dhcp snooping vlan v_range
```

**Parameters**

- **v_range** VLANs upon which snooping is enabled. Formats include a number, a number range, or a comma-delimited list of numbers and ranges. Numbers range from 1 to 4094.
- The **ip dhcp snooping** command globally enables DHCP snooping.
- The **ip dhcp snooping vlan** command enables insertion of option-82 snooping data.
- The **ip helper-address** command enables the DHCP relay agent on a configuration mode interface.

**Example**

These commands enable DHCP snooping globally, DHCP on VLAN interface **100**, and DHCP snooping on **VLAN 100**.

```
switch(config)#ip dhcp snooping
switch(config)#ip dhcp snooping information option
switch(config)#ip dhcp snooping vlan 100
switch(config)#interface vlan 100
switch(config-if-Vl100)#ip helper-address 10.4.4.4
switch(config-if-Vl100)#show ip dhcp snooping
DHCP Snooping is enabled
DHCP Snooping is operational
DHCP Snooping is configured on following VLANs:
  100
DHCP Snooping is operational on following VLANs:
  100
Insertion of Option-82 is enabled
Circuit-id format: Interface name:Vlan ID
Remote-id: 00:1c:73:1f:b4:38 (Switch MAC)
```
<table>
<thead>
<tr>
<th>switch(config)#</th>
</tr>
</thead>
</table>
The **ip hardware fib ecmp resilience** command enables resilient ECMP for the specified IP address prefix and configures a fixed number of next hop entries in the hardware ECMP table for that prefix. In addition to specifying the maximum number of next hop addresses that the table can contain for the prefix, the command includes a redundancy factor that allows duplication of each next hop address. The fixed table space for the address is the maximum number of next hops multiplied by the redundancy factor.

Resilient ECMP is useful when it is not desirable for routes to be rehashed due to link flap, as when ECMP is being used for load balancing.

The **no ip hardware fib ecmp resilience** and **default ip hardware fib ecmp resilience** commands restore the default hardware ECMP table management by removing the **ip hardware fib ecmp resilience** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip hardware fib ecmp resilience net_addr capacity nhop_max redundancy duplicates
no ip hardware fib ecmp resilience net_addr
default ip hardware fib ecmp resilience net_addr
```

**Parameters**

- **net_addr** IP address prefix managed by command. (CIDR or address-mask).
- **nhop_max** Maximum number of nexthop addresses for specified IP address prefix. Value range varies by platform:
  - Helix: <2 to 64>
  - Trident: <2 to 32>
  - Trident II: <2 to 64>
- **duplicates** Specifies the redundancy factor. Value ranges from 1 to 128.

**Example**

This command configures a hardware ECMP table space of 24 entries for the IP address **10.14.2.2/24**. A maximum of six next-hop addresses can be specified for the IP address. When the table contains six next-hop addresses, each appears in the table four times. When the table contains fewer than six next-hop addresses, each is duplicated until the 24 table entries are filled.

```
switch(config)#ip hardware fib ecmp resilience 10.14.2.2/24
capacity 6 redundancy 4
switch(config)#
```
13.1.16.31 ip hardware fib next-hop resource optimization

The `ip hardware fib next-hop resource optimization` command is used to enable or disable the resource optimization features on the switch. By default, RECMP is enabled on the switch.

The `no hardware fib next-hop resource optimization` command removes all the resource optimization features running on the switch.

**Command Mode**

Global Configuration Mode

**Command Syntax**

```plaintext
ip hardware fib next-hop resource optimization OPTIONS
no ip hardware fib next-hop resource optimization OPTIONS
```

**Parameters**

- The following two options are allowed to configure with this command:
  - `disabled` Disable hardware resource optimization for adjacency programming.
  - `thresholds` Utilization percentage for starting or stopping optimization. The resource utilization percentage value ranges from 0 to 100. It can be set to low and high.

**Examples**

- The following command is used to disable all hardware resource optimization features on the switch:

  ```plaintext
  switch#conf
  switch(config)#ip hardware fib next-hop resource optimization disabled
  ```

- The following command is used to configure the thresholds for starting and stopping the optimization:

  ```plaintext
  switch(config)#ip hardware fib next-hop resource optimization
  thresholds low 20 high 80
  ```
13.1.16.32  ip hardware fib optimize

The `ip hardware fib optimize` command enables IPv4 route scale. The platform layer 3 agent is restarted to ensure IPv4 routes are optimized with the `agent SandL3Unicast terminate` command for the configuration mode interface.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip hardware fib optimize exact-match prefix-length
```

**Parameters**

`prefix-length` The length of the prefix equal to `12`, `16`, `20`, `24`, `28`, or `32`. One additional prefix-length limited to the prefix-length of `32` is optional.

**Related Commands**

- The `agent SandL3Unicast terminate` command enables restarting the layer 3 agent to ensure IPv4 routes are optimized.
- The `show platform arad ip route` command shows resources for all IPv4 routes in hardware. Routes that use the additional hardware resources will appear with an asterisk.
- The `show platform arad ip route summary` command shows hardware resource usage of IPv4 routes.

**Examples**

- This configuration command allows configuring prefix lengths `12` and `32`.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 12 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

- One of the two prefixes in this command is a prefix-length of `32`, which is required in the instance where there are two prefixes. For this command to take effect, the platform Layer 3 agent must be restarted.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

- Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.

- This configuration command allows configuring prefix lengths `32` and `16`.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 32 16
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

- One of the two prefixes in this command is a prefix-length of `32`, which is required in the instance where there are two prefixes. For this command to take effect, the platform Layer 3 agent must be restarted.
Layer 3 Configuration

- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

- Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.
- This configuration command allows configuring prefix length 24.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 24
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

- In this instance, there is only one prefix-length, so a prefix-length of 32 is not required. For this command to take effect, the platform Layer 3 agent must be restarted.
- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

- Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.
- This configuration command allows configuring prefix length 32.

```
switch(config)#ip hardware fib optimize exact-match prefix-length 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are optimized
```

- For this command to take effect, the platform Layer 3 agent must be restarted.
- This configuration command restarts the platform Layer 3 agent to ensure IPv4 routes are optimized.

```
switch(config)#agent SandL3Unicast terminate
SandL3Unicast was terminated
```

- Restarting the platform Layer 3 agent results in deletion of all IPv4 routes, which are re-added to the hardware.
- This configuration command disables configuring prefix lengths 12 and 32.

```
switch(config)#no ip hardware fib optimize exact-match prefix-length 12 32
! Please restart layer 3 forwarding agent to ensure IPv4 routes are not optimized
```

- One of the two prefixes in this command is a prefix-length of 32, which is required in the instance where there are two prefixes. For this command to take effect, the platform Layer 3 agent must be restarted.
13.1.16.33 ip helper-address

The **ip helper-address** command enables the DHCP relay agent on the configuration mode
interface and specifies a forwarding address for DHCP requests. An interface that is configured with
multiple helper-addresses forwards DHCP requests to all specified addresses.

The **no ip helper-address** and **default ip helper-address** commands remove the
 corresponding **ip helper-address** command from **running-config**. Commands that do not specify
an IP helper-address remove all helper-addresses from the interface.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```plaintext
ip helper-address ipv4_addr [vrf vrf_name] [source-address ipv4_addr | source-interface INTERFACES]
no ip helper-address [ipv4_addr]
default ip helper-address [ipv4_addr]
```

**Parameters**

- **vrf vrf_name**  Specifies the user-defined VRF for DHCP server.
- **ipv4_addr**  Specifies the DHCP server address accessed by interface.
- **source-address ipv4_addr**  Specifies the source IPv4 address to communicate with DHCP
  server.
- **source-interface INTERFACES**  Specifies the source interface to communicate with DHCP
  server. Options include:
  - **Ethernet eth_num**  Specifies the Ethernet interface number.
  - **Loopback lpbck_num**  Specifies the loopback interface number. Value ranges from 0 to 1000.
  - **Management mgmt_num**  Specifies the management interface number. Accepted values are
    1 and 2.
  - **Port-Channel {int_num | sub_int_num}**  Specifies the port-channel interface or subinterface
    number. Value of interface ranges from 1 to 2000. Value of sub-interface ranges from 1 to 4094.
  - **Tunnel tnl_num**  Specifies the tunnel interface number. Value ranges from 0 to 255.
  - **VLAN vlan_num**  Specifies the Ethernet interface number. Value ranges from 1 to 4094.

**Related Commands**

- **ip dhcp relay always-on**
- **ip dhcp relay information option (Global)**
- **ip dhcp relay information option circuit-id**

**Guidelines**

If the source-address parameter is specified, then the DHCP client receives an IPv4 address from the
subnet of source IP address. The source-address must be one of the configured addresses on the
interface.

| Examples |
Layer 3 Configuration

- This command enables DHCP relay on the VLAN interface 200; and configure the switch to forward DHCP requests received on this interface to the server at 10.10.41.15.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ip helper-address 10.10.41.15
switch(config-if-Vl200)#show active
interface Vlan200
  ip helper-address 10.10.41.15
switch(config-if-Vl200)#
```

- This command enables DHCP relay on the interface Ethernet 1/2; and configures the switch to use 2.2.2.2 as the source IP address when relaying IPv4 DHCP messages to the server at 1.1.1.1.

```
switch(config)#interface ethernet 1/2
switch(config-if-Et1/2)#ip helper-address 1.1.1.1 source-address 2.2.2.2
switch(config-if-Et1/2)#
```
13.1.16.34  ip icmp redirect

The **ip icmp redirect** command enables the transmission of ICMP redirect messages. Routers send ICMP redirect messages to notify data link hosts of the availability of a better route for a specific destination.

The **no ip icmp redirect** disables the switch from sending ICMP redirect messages.

**Command Mode**
Global Configuration

**Command Syntax**

- **ip icmp redirect**
- **no ip icmp redirect**
- **default ip icmp redirect**

**Example**

This command disables the redirect messages.

```
switch(config)#no ip icmp redirect
switch(config)#show running-config
<-------OUTPUT OMITTED FROM EXAMPLE-------->
!
no ip icmp redirect
ip routing
!
<-------OUTPUT OMITTED FROM EXAMPLE-------->
switch(config)#
```
The `ip load-sharing` command provides the hash seed to an algorithm that the switch uses to distribute data streams among multiple equal-cost routes to an individual IPv4 subnet.

In a network topology using Equal-Cost Multipath routing, all switches performing identical hash calculations may result in hash polarization, leading to uneven load distribution among the data paths. Hash polarization is avoided when switches use different hash seeds to perform different hash calculations.

The `no ip load-sharing` and `default ip load-sharing` commands return the hash seed to the default value of zero by removing the `ip load-sharing` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip load-sharing HARDWARE seed
no ip load-sharing HARDWARE
default ip load-sharing HARDWARE
```

**Parameters**

- **HARDWARE** The ASIC switching device. The available option depend on the switch platform. Verify available options with the CLI `?` command.
  - `arad`
  - `fm6000`
  - `petraA`
  - `trident`
- **seed** The hash seed. Value range varies by switch platform. The default value on all platforms is 0.
  - when `HARDWARE=arad` `seed` ranges from 0 to 2.
  - when `HARDWARE=fm6000` `seed` ranges from 0 to 39.
  - when `HARDWARE=petraA` `seed` ranges from 0 to 2.
  - when `HARDWARE=trident` `seed` ranges from 0 to 5.

**Example**
This command sets the IPv4 load sharing hash seed to one on FM6000 platform switches.

```
switch(config)#ip load-sharing fm6000 1
switch(config)#
```
13.1.16.36 ip local-proxy-arp

The `ip local-proxy-arp` command enables local proxy ARP (Address Resolution Protocol) on the configuration mode interface. When local proxy ARP is enabled, ARP requests received on the configuration mode interface will return an IP address even when the request comes from within the same subnet.

The `no ip local-proxy-arp` and `default ip local-proxy-arp` commands disable local proxy ARP on the configuration mode interface by removing the corresponding `ip local-proxy-arp` command from `running-config`.

**Command Mode**
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

**Command Syntax**
- `ip local-proxy-arp`
- `no ip local-proxy-arp`
- `default ip local-proxy-arp`

**Example**

These commands enable local proxy ARP on VLAN interface **140**.

```
switch(config)#interface vlan 140
switch(config-if-Vl140)#ip local-proxy-arp
switch(config-if-Vl140)#show active
interface Vlan140
  ip local-proxy-arp
switch(config-if-Vl140)#
```
13.1.16.37  ip multicast count

The `ip multicast count` command enables the IPv4 multicast route traffic counter of group and source addresses in either bytes or packets.

The `no ip multicast count` command deletes all multicast counters including the routes of group and source addresses.

The `no ip multicast count group_address source_address` command removes the current configuration of the specified group and source addresses. It does not delete the counter because the wildcard is still active.

The `default ip multicast count` command reverts the current counter configuration of multicast route to the default state.

Command Mode
Global Configuration

Command Syntax

```
ip multicast count [group_address [source_address] | bytes | packets]
do ip multicast count [group_address [source_address] | bytes | packets]
default ip multicast count [group_address [source_address] | bytes | packets]
```

Parameters

- `group_address`  Configures the multicast route traffic count of the specified group address.
- `source_address` Configures the multicast route traffic count of the specified group and source addresses.
- `bytes` Configures the multicast route traffic count to bytes.
- `packets` Configures the multicast route traffic count to packets.

Guidelines

This command is supported on the FM6000 platform only.

Examples

- This command configures the multicast route traffic count to bytes.
  ```
  switch(config)#ip multicast count bytes
  ```

- This command configures the multicast route traffic count of the specified group and source addresses.
  ```
  switch(config)#ip multicast count 10.50.30.23 45.67.89.100
  ```

- This command deletes all multicast counters including the routes of group and source addresses.
  ```
  switch(config)#no ip multicast count
  ```

- This command reverts the current multicast route configuration to the default state.
  ```
  switch(config)#default ip multicast count
  ```
13.1.16.38  ip proxy-arp

The \texttt{ip proxy-arp} command enables proxy ARP on the configuration mode interface. Proxy ARP is disabled by default.

The \texttt{no ip proxy-arp} and \texttt{default ip proxy-arp} commands disable proxy ARP on the configuration mode interface by removing the corresponding \texttt{ip proxy-arp} command from \textit{running-config}.

\textbf{Command Mode}

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

\textbf{Command Syntax}

\texttt{ip proxy-arp}

\texttt{no ip proxy-arp}

\texttt{default ip proxy-arp}

\begin{verbatim}
Example
This command enables proxy ARP on Ethernet interface 4.

switch(config)#interface ethernet 4
switch(config-if-Et4)#ip proxy-arp
switch(config-if-Et4)#
\end{verbatim}
13.1.16.39 ip route

The *ip route* command creates a static route. The destination is a network segment; the nexthop address is either an IPv4 address or a routable port. When multiple routes exist to a destination prefix, the route with the lowest administrative distance takes precedence.

By default, the administrative distance assigned to static routes is 1. Assigning a higher administrative distance to a static route configures it to be overridden by dynamic routing data. For example, a static route with an administrative distance value of 200 is overridden by OSPF intra-area routes, which have a default administrative distance of 110.

Tags are used by route maps to filter routes. The default tag value on static routes is 0.

Multiple routes with the same destination and the same administrative distance comprise an Equal Cost Multi-Path (ECMP) route. The switch attempts to spread outbound traffic equally through all ECMP route paths. All paths comprising an ECMP are assigned identical tag values; commands that change the tag value of a path change the tag value of all paths in the ECMP.

The *no ip route* and *default ip route* commands delete the specified static route by removing the corresponding *ip route* command from *running-config*. Commands that do not list a nexthop address remove all *ip route* statements with the specified destination from *running-config*. If an *ip route* statement exists for the same IP address in multiple VRFs, each must be removed separately. All static routes in a user-defined VRF are deleted when the VRF is deleted.

**Command Mode**

**Global Configuration**

**Command Syntax**

```plaintext
ip route [VRF_INSTANCE] dest_net NEXTHOP [DISTANCE][TAG_OPTION][RT_NAME]
no ip route [VRF_INSTANCE] dest_net [NEXTHOP][DISTANCE]
default ip route [VRF_INSTANCE] dest_net [NEXTHOP][DISTANCE]
```

**Parameters**

- **VRF_INSTANCE**  Specifies the VRF instance being modified.
  - *no parameter*  Changes are made to the default VRF.
  - vrf *vrf_name*  Changes are made to the specified VRF.
- **dest_net**  Destination IPv4 subnet (CIDR or address-mask notation).
- **NEXTHOP**  Location or access method of next hop device. Options include:
  - *ipv4_addr*  An IPv4 address.
  - *null0*  Null0 interface.
  - *ethernet* *e_num*  Ethernet interface specified by *e_num*.
  - *loopback* *l_num*  Loopback interface specified by *l_num*.
  - *management* *m_num*  Management interface specified by *m_num*.
  - *port-channel* *p_num*  Port-channel interface specified by *p_num*.
  - *vlan* *v_num*  VLAN interface specified by *v_num*.
  - *vxlan* *vx_num*  VXLAN interface specified by *vx_num*.
- **DISTANCE**  Administrative distance assigned to route. Options include:
  - *no parameter*  Route assigned default administrative distance of one.
  - 1–255  The administrative distance assigned to route.
- **TAG_OPTION**  Static route tag. Options include:
  - *no parameter*  Assigns default static route tag of 0.
  - *tag* *t_value*  Static route tag value. *t_value* ranges from 0 to 4294967295.
- **RT_NAME**  Associates descriptive text to the route. Options include:
• **no parameter**  No text is associated with the route.
• **name descriptive_text**  The specified text is assigned to the route.

Related Command

The **ip route nexthop-group** command creates a static route that specifies a Nexthop Group to determine the Nexthop address.

---

**Example**

This command creates a static route in the default VRF.

```
switch(config)#ip route 172.17.252.0/24 vlan 2000
switch(config)#
```
Layer 3 Configuration

13.1.16.40  ip routing

The `ip routing` command enables IPv4 routing. When IPv4 routing is enabled, the switch attempts to deliver inbound packets to destination IPv4 addresses by forwarding them to interfaces or next hop addresses specified by the forwarding table.

The `no ip routing` and `default ip routing` commands disable IPv4 routing by removing the `ip routing` command from `running-config`. When IPv4 routing is disabled, the switch attempts to deliver inbound packets to their destination MAC addresses. When this address matches the switch’s MAC address, the packet is delivered to the CPU. IP packets with IPv4 destinations that differ from the switch’s address are typically discarded. The `delete-static-routes` option removes static entries from the routing table.

IPv4 routing is disabled by default.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
ip routing [VRF_INSTANCE]
no ip routing [DELETE_ROUTES][VRF_INSTANCE]
default ip routing [DELETE_ROUTES][VRF_INSTANCE]
```

**Parameters**

- **DELETE_ROUTES** Resolves routing table static entries when routing is disabled.
  - `no parameter` Routing table retains static entries.
  - `delete-static-routes` Static entries are removed from the routing table.
- **VRF_INSTANCE** Specifies the VRF instance being modified.
  - `no parameter` Changes are made to the default VRF.
  - `vrf vrf_name` Changes are made to the specified user-defined VRF.

**Example**

This command enables IPv4 routing.

```
switch(config)#ip routing
switch(config)#
```
13.1.16.41 ip source binding

IP source guard (IPSG) is supported on Layer 2 Port-Channels, not member ports. The IPSG configuration on port channels supersedes the configuration on the physical member ports. Hence, source IP MAC binding entries should be configured on port channels. When configured on a port channel member port, IPSG does not take effect until this port is deleted from the port channel configuration.

Note: IP source bindings are also used by static ARP inspection.

The no ip source binding and default ip source binding commands exclude parameters from IPSG filtering, and set the default for ip source binding.

Command Mode
Interface-Ethernet Configuration

Command Syntax

```
ip source binding [IP_ADDRESS][MAC_ADDRESS] vlan [VLAN_RANGE] interface [INTERFACE]
no ip source binding [IP_ADDRESS][MAC_ADDRESS] vlan [VLAN_RANGE] interface [INTERFACE]
default ip source binding [IP_ADDRESS][MAC_ADDRESS] vlan [VLAN_RANGE] interface [INTERFACE]
```

Parameters

- **IP_ADDRESS** Specifies the IP ADDRESS.
- **MAC_ADDRESS** Specifies the MAC ADDRESS.
- **VLAN_RANGE** Specifies the VLAN ID range.
- **INTERFACE** Specifies the Ethernet interface.

Related Commands

- ip verify source
- show ip verify source

Example

This command configures source IP-MAC binding entries to IP address 10.1.1.1, MAC address 0000.aaaa.1111, VLAN ID 4094, and Ethernet interface 36.

```
switch(config)#ip source binding 10.1.1.1 0000.aaaa.1111 vlan 4094 interface ethernet 36
switch(config)#
```
13.1.16.42  ip verify source

The `ip verify source` command configures IP source guard (IPSG) applicable only to Layer 2 ports. When configured on Layer 3 ports, IPSG does not take effect until this interface is converted to Layer 2.

IPSG is supported on Layer 2 Port-Channels, not member ports. The IPSG configuration on port channels supersedes the configuration on the physical member ports. Therefore, source IP MAC binding entries should be configured on port channels. When configured on a port channel member port, IPSG does not take effect until this port is deleted from the port channel configuration.

The `no ip verify source` and `default ip verify source` commands exclude VLAN IDs from IPSG filtering, and set the default for `ip verify source`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
ip verify source vlan [VLAN_RANGE]
no ip verify source [VLAN_RANGE]
default ip verify source
```

**Parameters**

`VLAN_RANGE`  Specifies the VLAN ID range.

**Related Commands**

- `ip source binding`
- `show ip verify source`

**Example**

This command excludes VLAN IDs 1 through 3 from IPSG filtering. When enabled on a trunk port, IPSG filters the inbound IP packets on all allowed VLANs. IP packets received on VLANs 4 through 10 on `Ethernet 36` will be filtered by IPSG, while those received on VLANs 1 through 3 are permitted.

```
switch(config)#no ip verify source vlan 1-3
switch(config)#interface ethernet 36
switch(config-if-Et36)#switchport mode trunk
switch(config-if-Et36)#switchport trunk allowed vlan 1-10
switch(config-if-Et36)#ip verify source
```

The **ip verify** command configures Unicast Reverse Path Forwarding (uRPF) for inbound IPv4 packets on the configuration mode interface. uRPF verifies the accessibility of source IP addresses in packets that the switch forwards.

uRPF defines two operational modes: strict mode and loose mode.

- **Strict mode**: uRPF verifies that a packet is received on the interface that its routing table entry specifies for its return packet.
- **Loose mode**: uRPF validation does not consider the inbound packet’s ingress interface only that there is a valid return path.

The **no ip verify** and **default ip verify** commands disable uRPF on the configuration mode interface by deleting the corresponding **ip verify** command from **running-config**.

### Command Mode

| Interface-Ethernet Configuration |
| Interface-Loopback Configuration |
| Interface-Management Configuration |
| Interface-Port-Channel Configuration |
| Interface-VLAN Configuration |

### Command Syntax

- **ip verify unicast source reachable-via RPF_MODE**
- **no ip verify unicast**
- **default ip verify unicast**

### Parameters

- **RPF_MODE**  
  Specifies the uRPF mode. Options include:
  - **any**: Loose mode.
  - **rx**: Strict mode.
  - **rx allow-default**: Strict mode. All inbound packets are forwarded if a default route is defined.

### Guidelines

The first IPv4 uRPF implementation briefly disrupts IPv4 unicast routing. Subsequent **ip verify** commands on any interface do not disrupt IPv4 routing.

### Examples

- This command enables uRPF loose mode on **VLAN interface 17**.

  ```
  switch(config)#interface vlan 17
  switch(config-if-Vl17)#ip verify unicast source reachable-via any
  switch(config-if-Vl17)#show active
  interface Vlan17   
  ip verify unicast source reachable-via any
  switch(config-if-Vl17)#
  ```

- This command enables uRPF strict mode on **VLAN interface 18**.

  ```
  switch(config)#interface vlan 18
  switch(config-if-Vl18)#ip verify unicast source reachable-via rx
  ```
switch(config-if-V118)#show active
  interface Vlan18
  ip verify unicast source reachable-via rx
switch(config-if-V118)#
13.1.16.44 ipv4 routable 240.0.0.0/4

The `ipv4 routable 240.0.0.0/4` command assigns class E addresses to an interface. When configured, the class E address traffic are routed through BGP, OSPF, ISIS, RIP, static routes and programmed to the FIB and kernel. By default, this command is disabled.

The `no ipv4 routable 240.0.0.0/4` and `default ipv4 routable 240.0.0.0/4` commands disable IPv4 Class E routing by removing the `ipv4 routable 240.0.0.0/4` command from `running-config`.

IPv4 routable `240.0.0.0/4` routing is disabled by default.

**Command Mode**

Router General Configuration

**Command Syntax**

`ipv4 routable 240.0.0.0/4`

`no ipv4 routable 240.0.0.0/4`

`default ipv4 routable 240.0.0.0/4`

**Example**

These commands configure an IPv4 Class E (240/4) address to an interface.

```
switch(config)#router general
switch(config-router-general)#ipv4 routable 240.0.0.0/4
```
13.1.16.45  platform barefoot bfrt vrf

The **platform barefoot bfrt vrf** command configures the forwarding plane agent on supported platforms to restart and listen on the configured VRF for connections. If left unconfigured, the default VRF is used for the IP and port for the BfRuntime server.

**Command Mode**
Global Configuration

**Command Syntax**

`platform barefoot bfrt vrf VRF name`

**Parameters**

**VRF name** configured VRF for connections.

**Example**

These commands configure the forwarding plane agent to restart and listen on the configured VRF for connections.

```
switch(config)#vrf instance management
switch(config-vrf-management)#exit
switch(config)#platform barefoot bfrt 0.0.0.0 50052
switch(config)#platform barefoot bfrt vrf <VRF name>
switch(config)#int management1
switch(config-if-Ma1)#vrf management
```
13.1.16.46 platform trident forwarding-table partition

The **platform trident forwarding-table partition** command provides a shared table memory for L2, L3 and algorithmic LPM entries that can be partitioned in different ways.

Instead of having fixed-size tables for L2 MAC entry tables, L3 IP forwarding tables, and Longest Prefix Match (LPM) routes, the tables can be unified into a single shareable forwarding table.

**Note:** Changing the Unified Forwarding Table mode causes the forwarding agent to restart, briefly disrupting traffic forwarding on all ports.

The **no platform trident forwarding-table partition** and **default platform trident forwarding-table partition** commands remove the **platform trident forwarding-table partition** command from *running-config*.

**Command Mode**
Global Configuration

**Command Syntax**

```
platform trident forwarding-table partition SIZE
```

```
no platform trident forwarding-table partition
```

```
default platform trident forwarding-table partition
```

**Parameters**

**SIZE**  Size of partition. Options include:

- **0**: 288k L2 entries, 16k host entries, 16k lpm entries.
- **1**: 224k L2 entries, 80k host entries, 16k lpm entries.
- **2**: 160k L2 entries, 144k host entries, 16k lpm entries.
- **3**: 96k L2 entries, 208k host entries, 16k lpm entries.

The default value is **2** (160k L2 entries, 144k host entries, 16k lpm entries).

**Examples**

- This command sets the single shareable forwarding table to option 2 that supports 160k L2 entries, 144k host entries, and 16k LPM entries.

  ```
  switch(config)#platform trident forwarding-table partition 2
  switch(config)
  ```

- This command sets the single shareable forwarding table to option 3 that supports 96k L2 entries, 208k host entries, and 16k LPM entries. Since the switch was previously configured to option 2, you'll see a warning notice before the changes are implemented.

  ```
  #switch(config)#platform trident forwarding-table partition 3
  Warning: StrataAgent will restart immediately
  ```
### 13.1.16.47 platform trident routing-table partition

The **platform trident routing-table partition** command manages the partition sizes for the hardware LPM table that stores IPv6 routes of varying sizes.

An IPv6 route of length /64 (or shorter) requires half the hardware resources of an IPv6 route that is longer than /64. The switch installs routes of varying lengths in different table partitions. This command specifies the size of these partitions to optimize table usage.

**Note:** Changing the routing table partition mode causes the forwarding agent to restart, briefly disrupting traffic forwarding on all ports.

The **no platform trident routing-table partition** and **default platform trident routing-table partition** commands restore the default partitions sizes by removing the **platform trident routing-table partition** command from **running-config**.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
platform trident routing-table partition SIZE
no platform trident routing-table partition
default platform trident routing-table partition
```

**Parameters**

- **SIZE**  
  Size of partition. Options include:
  - **1** 16k IPv4 entries, 6k IPv6 (/64 and smaller) entries, 1k IPv6 (any prefix length).
  - **2** 16k IPv4 entries, 4k IPv6 (/64 and smaller) entries, 2k IPv6 (any prefix length).
  - **3** 16k IPv4 entries, 2k IPv6 (/64 and smaller) entries, 3k IPv6 (any prefix length).

  The default value is **2** (16k IPv4 entries, 4k IPv6 (/64 and smaller) entries, 2k IPv6 (any prefix length).

**Restrictions**

Partition allocation cannot be changed from the default setting when uRPF is enabled for IPv6 traffic.

**Example**

This command sets the shareable routing table to option **1** that supports **6K** prefixes equal to or shorter than **/64** and **1K** prefixes longer than **/64**.

```plaintext
switch(config)#platform trident routing-table partition 1
switch(config)
```
13.16.48 rib fib policy

The `rib fib policy` command enables FIB policy for a particular VRF under router general configuration mode. The FIB policy can be configured to advertise only specific RIB routes and exclude all other routes.

For example, a FIB policy can be configured that will not place routes associated with a specific origin in the routing table. These routes will not be used to forward data packets and these routes are not advertised by the routing protocol to neighbors.

The `no rib fib policy` and `default rib fib policy` commands restore the switch to its default state by removing the corresponding rib fib policy command from `running-config`.

**Command Mode**

Router General Configuration

**Command Syntax**

```
rib [ipv4 | ipv6] fib policy name
no rib [ipv4 | ipv6] fib policy name
default rib [ipv4 | ipv6] fib policy name
```

**Parameters**

- `ipv4` IPv4 configuration commands.
- `ipv6` IPv6 configuration commands.
- `name` Route map name.

**Example**

The following example enables FIB policy for IPv4 in the default VRF, using the route map, `map1`.

```
Switch(config)#router general
Switch(config-router-general)#vrf default
Switch(config-router-general-vrf-default)#rib ipv4 fib policy map1
```
Layer 3 Configuration

13.1.16.49 show arp

The `show arp` command displays all ARP tables. This command differs from the `show ip arp` command in that it shows MAC bindings for all protocols, whereas `show ip arp` only displays MAC address – IP address bindings. Addresses are displayed as their host name by including the `resolve` argument.

Command Mode

EXEC

```
show arp [VRF_INST][FORMAT][HOST_ADD][HOST_NAME][INTF][MAC_ADDR][DATA]
```

Parameters

The `VRF_INST` and `FORMAT` parameters are always listed first and second. The `DATA` parameter is always listed last. All other parameters can be placed in any order.

- **VRF_INST**  
  Specifies the VRF instance for which data is displayed.
  - no parameter  
    Context-active VRF.
  - `vrf` `vrf_name`  
    Specifies name of VRF instance. System default VRF is specified by `default`.

- **FORMAT**  
  Displays format of host address. Options include:
  - no parameter  
    Entries associate hardware address with an IPv4 address.
  - `resolve`  
    Enter associate hardware address with a host name (if it exists).

- **HOST_ADD**  
  IPv4 address by which routing table entries are filtered. Options include:
  - no parameter  
    Routing table entries are not filtered by host address.
  - `ipv4_addr`  
    Table entries matching specified IPv4 address.

- **HOST_NAME**  
  Host name by which routing table entries are filtered. Options include:
  - no parameter  
    Routing table entries are not filtered by host name.
  - `host` `hostname`  
    Entries matching `hostname` (text).

- **INTF**  
  Interfaces for which command displays status.
  - no parameter  
    Routing table entries are not filtered by interface.
  - `interface ethernet` `e_num`  
    Routed Ethernet interface specified by `e_num`.
  - `interface loopback` `l_num`  
    Routed loopback interface specified by `l_num`.
  - `interface management` `m_num`  
    Routed management interface specified by `m_num`.
  - `interface port-channel` `p_num`  
    Routed port channel Interface specified by `p_num`.
  - `interface vlan` `v_num`  
    VLAN interface specified by `v_num`.
  - `interface vxlan` `vx_num`  
    VXLAN interface specified by `vx_num`.

- **MAC_ADDR**  
  MAC address by which routing table entries are filtered. Options include:
  - no parameter  
    Routing table entries are not filtered by interface MAC address.
  - `mac_address` `mac_address`  
    Entries matching `mac_address` (dotted hex notation – H.H.H).

- **DATA**  
  Detail of information provided by command. Options include:
  - no parameter  
    Routing table entries.
  - `summary`  
    Summary of ARP table entries.
  - `summary total`  
    Number of ARP table entries.

Related Commands

The `cli vrf` command specifies the context-active VRF.

---

Example
This command displays the ARP table.

```
switch> show arp
Address   Age (min)   Hardware Addr   Interface
172.22.30.1  0       001c.730b.1d15  Management1
172.22.30.133  0       001c.7304.3906  Management1
```

```
13.1.16.50  show dhcp server

Use the show dhcp server command to display DHCP server information.

Command Mode
EXEC

Command Syntax

```
show dhcp server [ ipv4 | ipv6 [ leases [ A.B.C.D/E | NAME ]]] | [ leases [ ipv4 | ipv6 | NAME ]]`
```

Parameters

- **ipv4** Displays details related to IPv4.
- **ipv6** Displays details related to IPv6.
- **leases** Displays active leases.
  - **A.B.C.D/E** IPv4 subnet.
  - **NAME** Subnet name.

Examples

- DHCPv4 display example.

```
switch#show dhcp server ipv4
IPv4 DHCP Server is active
Debug log is enabled
DNS server(s): 10.2.2.2
DNS domain name: domainFoo
Lease duration: 1 days 0 hours 0 minutes
TFTP server:
serverFoo (Option 66)
10.0.0.3 (Option 150)
TFTP file: fileFoo
Active Leases: 1
IPv4 DHCP interface status:
  Interface  Status
  ----------------------------------------
  Ethernet1 Inactive (Could not determine VRF)
  Ethernet2 Inactive (Not in default VRF)
  Ethernet3 Inactive (Kernel interface not created yet)
  Ethernet4 Inactive (Not up)
  Ethernet5 Inactive (No IP address)
  Ethernet6 Active

Vendor information:
Vendor ID: default
  Sub-options   Data
  ---------------------
  1  192.0.2.0, 192.0.2.1

Vendor ID: vendorFoo
  Sub-options   Data
  ---------------------
  2  192.0.2.2
  3 "Foo"

Subnet: 10.0.0.0/8
Subnet name: subnetFoo
Range: 10.0.0.1 to 10.0.0.10
DNS server(s): 10.1.1.1 10.2.2.2
Lease duration: 3 days 3 hours 3 minutes
Default gateway address: 10.0.0.3
TFTP server:
```
```
In this example, DHCPv6 is configured with subnet fe80::/10 while being enabled on Ethernet1 with address fe80::1/64 and on Ethernet3 with address fe80::2/64.

switch# show dhcp server ipv6
IPv6 DHCP server is active
Debug log is enabled

DNS server(s): fe80::6

DNS domain name: testaristanetworks.com

Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Active</td>
</tr>
<tr>
<td>Ethernet3</td>
<td>Active</td>
</tr>
</tbody>
</table>

Subnet: fe80::/10
Subnet name: foo

Range: fe80::1 to fe80::3
DNS server(s): fe80::4 fe80::5

Direct: Inactive (Multiple interfaces match this subnet: Ethernet1 Ethernet3)
Relay: Active

Active leases: 0

- This example illustrates when multiple subnets match an interface. In this example, DHCPv6 is configured with subnets fc00:/7 and fe80::/10 while being enabled on Ethernet1 with address fe80::1/10 and fc00::1/7.

```
switch# show dhcp server ipv6
IPv6 DHCP server is active

DNS server(s): fc00::2

DNS domain name: testaristanetworks.com

Lease duration: 1 days 3 hours 30 minutes

Active leases: 0

IPv6 DHCP interface status:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Ethernet1    Active

Subnet: fc00::/7

Subnet name: foo

Range: fc00::1 to fc00::5

DNS server(s): fc00::6 fc00::8

Direct: Inactive (This and other subnets match interface Ethernet1)
Relay: Active

Active leases: 0

Subnet: fe80::/10

Subnet name: bar

Direct: Inactive (This and other subnets match interface Ethernet1)
Relay: Active

Active leases: 0

- When a subnet is disabled, the `show dhcp server` command displays the disable message with a reason. The number of active leases of the disabled subnets will be 0. In this example, there are overlapping subnets.

```
switch#show dhcp server
IPv4 DHCP Server is active
```
Layer 3 Configuration

- **In this example, the display output shows overlapping ranges.**

```plaintext
switch# show dhcp server
IPv4 DHCP Server is active
DNS server(s): 10.2.2.2
Lease duration: 1 days 0 hours 0 minutes
Active Leases: 0
IPv4 DHCP interface status:
   Interface   Status
   -----------------------------------------------
   Ethernet1   Active
Subnet: 10.0.0.0/24 (Subnet is disabled - overlapping subnet 10.0.0.0/8)
Range: 10.0.0.1 to 10.0.0.10
DNS server(s): 10.3.3.3 10.4.4.4
Default gateway address: 10.0.0.4
Active leases: 0
Subnet: 10.0.0.0/8 (Subnet is disabled - overlapping subnet 10.0.0.0/24)
DNS server(s):
Default gateway address: 10.0.0.3
Active leases: 0
```

- **This example shows duplicate static IP address reservation.**

```plaintext
Subnet: 10.0.0.0/8 (Subnet is disabled - ipv4-address 10.0.0.11 is reserved more than once)
Subnet name:
DNS server(s):
Default gateway address: 10.0.0.3
Active leases: 0
Reservations:
   MAC address: 1a1b.1c1d.1e1f
   IPv4 address: 10.0.0.11
   MAC address: 2a2b.2c2d.2e2f
   IPv4 address: 10.0.0.11
```

- **Use the `show dhcp server leases` command to display detailed information about the IP addresses allocated by the DHCP Server (including the IP address, the expected end time for that address, the time when the address is handed out, and the equivalent MAC address).**

```plaintext
switch# show dhcp server leases
10.0.0.10
End: 2019/06/20 17:44:34 UTC
```
Last transaction: 2019/06/19 17:44:34 UTC
MAC address: 5692.4c67.460a

2000:0:0:40::b

End: 2019/06/20 18:06:33 UTC

Last transaction: 2019/06/20 14:36:33 UTC

MAC address: 165a.a86d.ffac
13.1.16.51 show hardware capacity

The `show hardware capacity` command displays the utilization of the hardware resources:

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show hardware capacity
```

**Example**

- The following command is used to show the utilization of the hardware resources:

  ```
  switch#show hardware capacity
  Forwarding Resources Usage
  Table  Feature          Chip     Used     Used     Free
         Committed Best Case High Entries (%) Entries
  -------- ---------- --------------- ---------- ---------
  ECMP     ECMP         0 4095 0 4095 0
  ECMP     Mpls         0 4095 0 4095 0
  ECMP     Routing      0 4095 0 4095 0
  ECMP     VxlanOverlay 0 4095 0 4095 0
  ECMP     VxlanTunnel 0 3891 0 3891 0
  ```
13.1.16.52 show interface tunnel

The `show interface tunnel` command displays the interface tunnel information.

**Command Mode**

EXEC

**Command Syntax**

`show interface tunnel number`

**Parameter**

`number` Specifies the tunnel interface number.

**Example**

This command displays tunnel interface configuration information for tunnel interface **10**.

```
switch#show interface tunnel 10

Tunnel10 is up, line protocol is up (connected)
Hardware is Tunnel, address is 0a01.0101.0800
Internet address is 192.168.1.1/24
Broadcast address is 255.255.255.255
Tunnel source 10.1.1.1, destination 10.1.1.2
Tunnel protocol/transport GRE/IP
  Key disabled, sequencing disabled
  Checksumming of packets disabled
Tunnel TTL 10, Hardware forwarding enabled
Tunnel TOS 10
Path MTU Discovery
Tunnel transport MTU 1476 bytes
Up 3 seconds
```
show ip arp inspection statistics

The `show ip arp inspection statistics` command displays the statistics of inspected ARP packets. For a VLAN specified, only VLANs with ARP inspection enabled will be displayed. If no VLAN is specified, all VLANs with ARP inspection enabled are displayed.

**Command Mode**
EXEC

**Command Syntax**
```
show ip arp inspection statistics [vlan [VID]][INTERFACE] interface intf_slot | intf_port
```

**Parameters**
- **VID** Specifies the VLAN interface ID.
- **INTERFACE** Specifies the interface (e.g., Ethernet).
  - **intf_slot** Interface slot.
  - **intf_port** Interface port.
- **INTF** Specifies the VLAN interface slot and port.

**Related Commands**
- ip arp inspection limit
- ip arp inspection trust
- ip arp inspection vlan

**Examples**

- This command display statistics of inspected ARP packets for VLAN 10.
  ```
  switch(config)#show ip arp inspection statistics vlan 10
  Vlan : 10
  ------------
  ARP
  Req Forwarded = 20
  ARP Res Forwarded = 20
  ARP Req Dropped = 1
  ARP Res Dropped = 1
  Last invalid ARP:
  Time: 10:20:30 ( 5 minutes ago )
  Reason: Bad IP/Mac match
  Received on: Ethernet 3/1
  Packet:
    Source MAC: 00:01:00:01:00:01
    Dest MAC: 00:02:00:02:00:02
    ARP Type: Request
    ARP Sender MAC: 00:01:00:01:00:01
    ARP Sender IP: 1.1.1
  ```

- This command displays ARP inspection statistics for Ethernet interface 3/1.
  ```
  switch(config)#show ip arp inspection statistics ethernet interface 3/1
  Interface : 3/1
  --------
  ARP
  Req Forwarded = 10
  ARP Res Forwarded = 10
  ARP Req Dropped = 1
  ```
ARP Res Dropped = 1

Last invalid ARP:
Time: 10:20:30 ( 5 minutes ago )
Reason: Bad IP/Mac match
Received on: VLAN 10
Packet:
   Source MAC: 00:01:00:01:00:01
   Dest MAC: 00:02:00:02:00:02
   ARP Type: Request
   ARP Sender MAC: 00:01:00:01:00:01
   ARP Sender IP: 1.1.1

switch(config)#
13.1.16.54  show ip arp inspection vlan

The **show ip arp inspection vlan** command displays the configuration and operation state of ARP inspection. For a VLAN range specified, only VLANs with ARP inspection enabled will be displayed. If no VLAN is specified, all VLANs with ARP inspection enabled are displayed. The operation state turns to **Active** when hardware is ready to trap ARP packets for inspection.

**Command Mode**

EXEC

**Command Syntax**

```
show ip arp inspection vlan [LIST]
```

**Parameters**

**LIST** Specifies the VLAN interface number.

**Related Commands**

- `ip arp inspection limit`
- `ip arp inspection trust`
- `show ip arp inspection statistics`

**Example**

This command displays the configuration and operation state of ARP inspection for VLANs 1 through **150**.

```
switch(config)#show ip arp inspection vlan 1 - 150

VLAN 1  
-------
Configuration : Enabled  
Operation State : Active

VLAN 2  
-------
Configuration : Enabled  
Operation State : Active

(...) 

VLAN 150  
--------
Configuration : Enabled  
Operation State : Active

switch(config)#
```
13.16.55  show ip arp

The `show ip arp` command displays ARP cache entries that map an IPv4 address to a corresponding MAC address. The table displays addresses by their host names when the command includes the `resolve` argument.

Command Mode
EXEC

Command Syntax
`show ip arp [VRF_INST][FORMAT][HOST_ADD][HOST_NAME][INTF][MAC_ADDR][DATA]`

Parameters
The `VRF_INST` and `FORMAT` parameters are always listed first and second. The `DATA` parameter is always listed last. All other parameters can be placed in any order.

- **VRF_INST**  Specifies the VRF instance for which data is displayed.
  - no parameter  Context-active VRF.
  - vrf vrf_name  Specifies name of VRF instance. System default VRF is specified by `default`.
- **FORMAT**  Displays format of host address. Options include:
  - no parameter  Entries associate hardware address with an IPv4 address.
  - resolve  Enter associate hardware address with a host name (if it exists).
- **HOST_ADDR**  IPv4 address by which routing table entries are filtered. Options include:
  - no parameter  Routing table entries are not filtered by host address.
  - ipv4_addr  Table entries matching specified IPv4 address.
- **HOST_NAME**  Host name by which routing table entries are filtered. Options include:
  - no parameter  Routing table entries are not filtered by host name.
  - host hostname  Entries matching `hostname` (text).
- **INTERFACE_NAME**  Interfaces for which command displays status.
  - no parameter  Routing table entries are not filtered by interface.
  - interface ethernet e_num  Routed Ethernet interface specified by `e_num`.
  - interface loopback l_num  Routed loopback interface specified by `l_num`.
  - interface management m_num  Routed management interface specified by `m_num`.
  - interface port-channel p_num  Routed port channel Interface specified by `p_num`.
  - interface vlan v_num  VLAN interface specified by `v_num`.
  - interface vxlan vx_num  VXLAN interface specified by `vx_num`.
- **MAC_ADDR**  MAC address by which routing table entries are filtered. Options include:
  - no parameter  Routing table entries are not filtered by interface MAC address.
  - mac_address mac_address  entries matching `mac_address` (dotted hex notation – H.H.H).
- **DATA**  Detail of information provided by command. Options include:
  - no parameter  Routing table entries.
  - summary  Summary of ARP table entries.
  - summary total  Number of ARP table entries.

Related Commands
The `cli vrf` command specifies the context-active VRF.

| Examples |
• This command displays ARP cache entries that map MAC addresses to IPv4 addresses.

switch>
```
13.1.16.57  show ip dhcp relay

The show ip dhcp relay command displays the DHCP relay agent configuration status on the switch.

**Command Mode**

EXEC

**Command Syntax**

show ip dhcp relay

**Example**

This command displays the DHCP relay agent configuration status.

```
switch>show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is disabled
DHCP Smart Relay is enabled
Interface: Vlan100
    DHCP Smart Relay is disabled
    DHCP servers: 10.4.4.4
switch>
```
show ip dhcp snooping counters

The `show ip dhcp snooping counters` command displays counters that track the quantity of DHCP request and reply packets that the switch receives. Data is either presented for each VLAN or aggregated for all VLANs with counters for packets dropped.

**Command Mode**

EXEC

**Command Syntax**

`show ip dhcp snooping counters [COUNTER_TYPE]`

**Parameters**

**COUNTER_TYPE** The type of counter that the command resets. Formats include:

- **no parameter** Command displays counters for each VLAN.
- **debug** Command displays aggregate counters and drop cause counters.

**Examples**

- This command displays the number of DHCP packets sent and received on each VLAN.

  ```
  switch> show ip dhcp snooping counters
  |
  Vlan     Dhcp Request Pkts | Dhcp Reply Pkts |
  Rcvd Fwdd Drop     Rcvd Fwdd Drop     Last Cleared
  ----|------------|------------|----------------|
  100 |     0     0     0 |    0    0     0 | 0:35:39 ago
  ```

- This command displays the number of DHCP packets sent on the switch.

  ```
  switch> show ip dhcp snooping counters debug
  Counter Snooping                Snooping to Relay Relay to
  ----------------------------- ----------------- ------------|
  Received            0 0 0 0 | 0 0 0 | 0:37:08 ago
  Forwarded           0 0 0 0 | 0 0 0 |
  Dropped - Invalid VlanId     0 0 0 0 | 0 0 0 |
  Dropped - Parse error      0 0 0 0 | 0 0 0 |
  Dropped - Invalid Dhcp Optype 0 0 0 0 | 0 0 0 |
  Dropped - Invalid Info Option 0 0 0 0 | 0 0 0 |
  Dropped - Snooping disabled 0 0 0 0 | 0 0 0 |
  Last Cleared: 3:37:18 ago
  ```
**Layer 3 Configuration**

13.1.16.59 show ip dhcp snooping hardware

The `show ip dhcp snooping hardware` command displays internal hardware DHCP snooping status on the switch.

**Command Mode**

EXEC

**Command Syntax**

`show ip dhcp snooping hardware`

**Example**

This command displays DHCP snooping hardware status.

```
switch>show ip dhcp snooping hardware
DHCP Snooping is enabled
DHCP Snooping is enabled on following VLANs:
  None
Vlans enabled per Slice
  Slice: FixedSystem
    None
switch>
```
13.1.16.60  show ip dhcp snooping

The `show ip dhcp snooping` command displays the DHCP snooping configuration.

**Command Mode**
EXEC

**Command Syntax**

```
show ip dhcp snooping
```

**Related Commands**
- `ip dhcp snooping` globally enables DHCP snooping.
- `ip dhcp snooping vlan` enables DHCP snooping on specified VLANs.
- `ip dhcp relay information option (Global)` enables insertion of option-82 snooping data.
- `ip helper-address` enables the DHCP relay agent on a configuration mode interface.

**Example**

This command displays the switch’s DHCP snooping configuration.

```
switch>show ip dhcp snooping
DHCP Snooping is enabled
DHCP Snooping is operational
DHCP Snooping is configured on following VLANs:
  100
DHCP Snooping is operational on following VLANs:
  100
Insertion of Option-82 is enabled
  Circuit-id format: Interface name:Vlan ID
  Remote-id: 00:1c:73:1f:b4:38 (Switch MAC)
switch>
```
13.1.16.61  show ip hardware fib summary

The `show ip hardware fib summary` command displays the statistics of the RECMP.

**Command Mode**

Privileged EXEC

**Command Syntax**

`show ip hardware fib summary`

**Example**

- The following command is used to show the statistics of RECMP:

```
switch#show ip hardware fib summary
Fib summary
----------
Adjacency sharing: disabled
BFD peer event: enabled
Deletion Delay: 0
Protect default route: disabled
PBR: supported
URPF: supported
ICMP unreachable: enabled
Max Ale ECMP: 600
UCMP weight deviation: 0.0
Maximum number of routes: 0
Fib compression: disabled
Resource optimization for adjacency programming: enabled
Adjacency resource optimization thresholds: low 20, high 80
```

**About Output**

- The last two lines of the output shows whether the feature is enabled and what are the corresponding threshold values for starting and stopping the optimization process.
13.1.16.62  show ip interface brief

Use the `show ip interface brief` command output to display the status summary of the specified interfaces that are configured as routed ports. The command provides the following information for each specified interface:

- IP address
- Operational status
- Line protocol status
- MTU size

**Command Mode**

EXEC

**Command Syntax**

`show ip interface [INTERFACE_NAME][VRF_INST] brief`

**Parameters**

- **INTERFACE_NAME** Interfaces for which command displays status.
  - `no parameter` All routed interfaces.
  - `ipv4_addr` Neighbor IPv4 address.
  - `ethernet e_range` Routed Ethernet interfaces specified by `e_range`.
  - `loopback l_range` Routed loopback interfaces specified by `l_range`.
  - `management m_range` Routed management interfaces specified by `m_range`.
  - `port-channel p_range` Routed port channel Interfaces specified by `p_range`.
  - `vlan v_range` VLAN interfaces specified by `v_range`.
  - `vxlan vx_range` VXLAN interface range specified by `vx_range`.
- **VRF_INST** Specifies the VRF instance for which data is displayed.
  - `no parameter` Context-active VRF.
  - `vrf vrf_name` Specifies name of VRF instance. System default VRF is specified by `default`.

**Example**

This command displays the summary status of VLAN interfaces **900-910**.

```
switch>show ip interface vlan 900-910 brief
! Some interfaces do not exist
<table>
<thead>
<tr>
<th>Interface</th>
<th>IP Address</th>
<th>Status</th>

</table>
```
Layer 3 Configuration

13.1.16.63 show ip interface

The `show ip interface` command displays the status of specified interfaces that are configured as routed ports. The command provides the following information:

- Interface description
- Internet address
- Broadcast address
- Address configuration method
- Proxy-ARP status
- MTU size

**Command Mode**

EXEC

**Command Syntax**

`show ip interface [INTERFACE_NAME][VRF_INST]`

**Parameters**

- **INTERFACE_NAME** Interfaces for which command displays status.
  - `no parameter` All routed interfaces.
  - `ipv4_addr` Neighbor IPv4 address.
  - `ethernet e_range` Routed Ethernet interfaces specified by `e_range`.
  - `loopback l_range` Routed loopback interfaces specified by `l_range`.
  - `management m_range` Routed management interfaces specified by `m_range`.
  - `port-channel p_range` Routed port channel Interfaces specified by `p_range`.
  - `vlan v_range` VLAN interfaces specified by `v_range`.
  - `vxlan vx_range` VXLAN interfaces specified by `vx_range`.
- **VRF_INST** Specifies the VRF instance for which data is displayed.
  - `no parameter` Context-active VRF.
  - `vrf vrf_name` Specifies name of VRF instance. System default VRF is specified by `default`.

**Example**

- This command displays IP status of configured VLAN interfaces numbered between 900 and 910.

```
switch>show ip interface vlan 900-910
! Some interfaces do not exist
Vlan901 is up, line protocol is up (connected)
   Description: ar.pqt.mlag.peer
   Internet address is 170.23.254.1/30
   Broadcast address is 255.255.255.255
   Address determined by manual configuration
   Proxy-ARP is disabled
   MTU 9212 bytes
Vlan903 is up, line protocol is up (connected)
   Description: ar.pqt.rn.170.23.254.16/29
   Internet address is 170.23.254.19/29
   Broadcast address is 255.255.255.255
   Address determined by manual configuration
   Proxy-ARP is disabled
   MTU 9212 bytes
```
• This command displays the configured TCP Maximum Segment Size (MSS) ceiling value of **1436** bytes for an Ethernet interface **25**.

```plaintext
switch>show ip interface ethernet 25
Ethernet25 is up, line protocol is up (connected)
   Internet address is 10.1.1.1/24
   Broadcast address is 255.255.255.255
   IPv6 Interface Forwarding : None
   Proxy-ARP is disabled
   Local Proxy-ARP is disabled
   Gratuitous ARP is ignored
   IP MTU 1500 bytes
   IPv4 TCP MSS egress ceiling is 1436 bytes
```
13.1.16.64  show ip route age

The show ip route age command displays the time when the route for the specified network was present in the routing table. It does not account for the changes in parameters like metric, next-hop etc.

Command Mode
EXEC

Command Syntax
show ip route ADDRESS age

Parameters
ADDRESS   Filters routes by IPv4 address or subnet.
           •  ipv4_addr     Routing table entries matching specified address.
           •  ipv4_subnet   Routing table entries matching specified subnet (CIDR or address-mask).

Example
This command shows the amount of time since the last update to ip route 172.17.0.0/20.

switch>show ip route 172.17.0.0/20 age
Codes: C - connected, S - static, K - kernel, O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1, E2 - OSPF external type 2, N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP, R - RIP, I - ISIS, A - Aggregate
B E  172.17.0.0/20 via 172.25.0.1, age 3d01h
switch>
show ip route gateway

The `show ip route gateway` command displays IP addresses of all gateways (next hops) used by active routes.

**Command Mode**
EXEC

**Command Syntax**
`show ip route [VRF_INSTANCE] gateway`

**Parameters**

- **VRF_INSTANCE** Specifies the VRF instance for which data is displayed.
  - *no parameter* Context-active VRF.
  - *vrf vrf_name* Specifies name of VRF instance. System default VRF is specified by `default`.

**Related Commands**
The `cli vrf` command specifies the context-active VRF.

### Example

This command displays next hops used by active routes.

```
switch>show ip route gateway
The following gateways are in use:
  172.25.0.1 Vlan101
  172.17.253.2 Vlan3000
  172.17.254.2 Vlan3901
  172.17.254.11 Vlan3902
  172.17.254.13 Vlan3902
  172.17.254.17 Vlan3903
  172.17.254.20 Vlan3903
  172.17.254.66 Vlan3908
  172.17.254.67 Vlan3908
  172.17.254.68 Vlan3908
  172.17.254.29 Vlan3910
  172.17.254.33 Vlan3911
  172.17.254.35 Vlan3911
  172.17.254.105 Vlan3912
  172.17.254.86 Vlan3984
  172.17.254.98 Vlan3992
  172.17.254.99 Vlan3992
switch>
```
13.1.16.66  show ip route host

The `show ip route host` command displays all host routes in the host forwarding table. Host routes are those whose destination prefix is the entire address (mask = 255.255.255.255 or prefix = /32). Each entry includes a code of the route's purpose:

- **F** static routes from the FIB.
- **R** routes defined because the IP address is an interface address.
- **B** broadcast address.
- **A** routes to any neighboring host for which the switch has an ARP entry.

**Command Mode**
EXEC

**Command Syntax**

`show ip route [VRF_INSTANCE] host`

**Parameters**

- **VRF_INSTANCE** Specifies the VRF instance for which data is displayed.
  - _no parameter_ Context-active VRF.
  - _vrf vrf_name_ Specifies name of VRF instance. System default VRF is specified by `default`.

**Related Commands**
The `cli vrf` command specifies the context-active VRF.

**Example**

This command displays all host routes in the host forwarding table.

```
switch>show ip route host
R - receive B - broadcast F - FIB, A - attached
F  127.0.0.1 to cpu
B  172.17.252.0 to cpu
A  172.17.253.2 on Vlan2000
R  172.17.253.3 to cpu
A  172.17.253.10 on Vlan2000
B  172.17.253.255 to cpu
B  172.17.254.0 to cpu
R  172.17.254.1 to cpu
B  172.17.254.3 to cpu
B  172.17.254.8 to cpu
A  172.17.254.11 on Vlan2902
R  172.17.254.12 to cpu
F  172.26.0.28 via 172.17.254.20 on Vlan3003
    via 172.17.254.67 on Vlan3008
    via 172.17.254.98 on Vlan3492
    via 172.17.254.2 on Vlan3601
    via 172.17.254.13 on Vlan3602
    via 172.17.253.2 on Vlan3000
F  172.26.0.29 via 172.25.0.1 on Vlan101
F  172.26.0.30 via 172.17.254.29 on Vlan3910
F  172.26.0.32 via 172.17.254.105 on Vlan3912
switch>
```
The `show ip route match tag` command displays the route tag assigned to the specified IPv4 address or subnet. Route tags are added to static routes for use by route maps.

**Command Mode**
EXEC

**Command Syntax**
```bash
show ip route [VRF_INSTANCE] ADDRESS match tag
```

**Parameters**
- **VRF_INSTANCE** Specifies the VRF instance for which data is displayed.
  - **no parameter** Context-active VRF.
  - **vrf vrf_name** Specifies name of VRF instance. System default VRF is specified by `default`.
- **ADDRESS** Displays routes of specified IPv4 address or subnet.
  - **ipv4_addr** Routing table entries matching specified IPv4 address.
  - **ipv4_subnet** Routing table entries matching specified IPv4 subnet (CIDR or address-mask).

**Example**
This command displays the route tag for the specified subnet.

```
switch>show ip route 172.17.50.0/23 match tag
Codes: C - connected, S - static, K - kernel,
      O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
      E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
      N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
      R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
      O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
      NG - Nexthop Group Static Route, V - VXLAN Control
      Service,
      DH - DHCP client installed default route, M - Martian

O E2  172.17.50.0/23 tag 0
switch>
```
13.1.16.68  show ip route summary

The `show ip route summary` command displays the number of routes, categorized by destination prefix, in the routing table.

**Command Mode**

EXEC

**Command Syntax**

```bash
show ip route [VRF_INSTANCE] summary
```

**Parameters**

- **VRF_INSTANCE** Specifies the VRF instance for which data is displayed.
  - `no parameter` Context-active VRF.
  - `vrf vrf_name` Specifies name of VRF instance. System default VRF is specified by `default`.

**Example**

This command displays a summary of the routing table contents.

```bash
switch>show ip route summary
Route Source         Number Of Routes
-------------------------------------
connected                   15
static                       0
ospf                        74
   Intra-area: 32 Inter-area:33 External-1:0 External-2:9
   NSSA External-1:0 NSSA External-2:0
bgp                          7
   External: 6 Internal: 1
internal                    45
attached                    18
aggregate                   0
switch>
```
13.1.16.69 show ip route

The `show ip route` command displays routing table entries that are in the Forwarding Information Base (FIB), including static routes, routes to directly connected networks, and dynamically learned routes. Multiple equal-cost paths to the same prefix are displayed contiguously as a block, with the destination prefix displayed only on the first line.

The `show running-config` command displays configured commands not in the FIB.

Command Mode
EXEC

Command Syntax
show ip route [VRF_INSTANCE][ADDRESS][ROUTE_TYPE][INFO_LEVEL][PREFIX]

Parameters
The VRF_INSTANCE and ADDRESS parameters are always listed first and second, respectively. All other parameters can be placed in any order.

- **VRF_INSTANCE** Specifies the VRF instance for which data is displayed.
  - *no parameter* Context-active VRF.
  - *vrf vrf_name* Specifies name of VRF instance. System default VRF is specified by `default`.
- **ADDRESS** Filters routes by IPv4 address or subnet.
  - *no parameter* All routing table entries.
  - *ipv4_addr* Routing table entries matching specified address.
  - *ipv4_subnet* Routing table entries matching specified subnet (CIDR or address-mask).
- **ROUTE_TYPE** Filters routes by specified protocol or origin. Options include:
  - *no parameter* All routing table entries.
  - *aggregate* Entries for BGP aggregate routes.
  - *bgp* Entries added through BGP protocol.
  - *connected* Entries for routes to networks directly connected to the switch.
  - *isis* Entries added through ISIS protocol.
  - *kernel* Entries appearing in Linux kernel but not added by EOS software.
  - *ospf* Entries added through OSPF protocol.
  - *rip* Entries added through RIP protocol.
  - *static* Entries added through CLI commands.
  - *vrf* Displays routes in a VRF.
- **INFO_LEVEL** Filters entries by next hop connection. Options include:
  - *no parameter* Filters routes whose next hops are directly connected.
  - *detail* Displays all routes.
- **PREFIX** Filters routes by prefix.
  - *no parameter* Specific route entry that matches the ADDRESS parameter.
  - *longer-prefixes* All subnet route entries in range specified by ADDRESS parameter.

Related Commands
The `cli vrf` command specifies the context-active VRF.

**Examples**
- This command displays IPv4 routes learned through BGP.

```
switch>show ip route bgp
Codes: C - connected, S - static, K - kernel,
```

- This command displays the leaked routes from a source VRF.

```shell
switch# show ip route vrf VRF2 20.0.0.0/8
```

...  
S L 20.0.0.0/8 [1/0] (source VRF VRF1) via 10.1.2.10, Ethernet1
13.1.16.70  show ip verify source

The `show ip verify source` command displays the IP source guard (IPSG) configuration, operational states, and IP-MAC binding entries for the configuration mode interface.

**Command Mode**
EXEC

**Command Syntax**
```
show ip verify source [VLAN | DETAIL]
```

**Parameters**
- `VLAN` Displays all VLANs configured in `no ip verify source vlan`.
- `DETAIL` Displays all source IP-MAC binding entries configured for IPSG.

**Related Commands**
- `ip source binding`
- `ip verify source`

**Examples**
- This command verifies the IPSG configuration and operational states.

```
switch(config)#show ip verify source
Interface                      Operational State
----------------------------- ------------------------
Ethernet1                     IP source guard enabled
Ethernet2                     IP source guard disabled
```

- This command displays all VLANs configured in `no ip verify source vlan`. Hardware programming errors, e.g., VLAN classification failed, are indicated in the operational state. If an error occurs, this VLAN will be considered as enabled for IPSG. Traffic on this VLAN will still be filtered by IPSG.

```
switch(config)#show ip verify source vlan
IPSG disabled on VLANS: 1-2
VLAN Operational State
----------------------------- ------------------------
1                           IP source guard disabled
2                           Error: vlan classification failed
```

- This command displays all source IP-MAC binding entries configured for IPSG. A source binding entry is considered active if it is programmed in hardware. IP traffic matching any active binding entry will be permitted. If a source binding entry is configured on an interface or a VLAN whose operational state is IPSG disabled, this entry will not be installed in the hardware, in which case an "IP source guard disabled" state will be shown. If a port channel has no member port configured, binding entries configured for this port channel will not be installed in hardware, and a "Port-Channel down" state will be shown.

```
switch(config)#show ip verify source detail
Interface      IP Address  MAC Address     VLAN  State
-------------- ----------- --------------- ----- ------------------------
Ethernet1      10.1.1.1    0000.aaaa.1111   5     active
Ethernet1      10.1.1.5    0000.aaaa.5555   1     IP source guard disabled
Port-Channel1  20.1.1.1    0000.bbbb.1111   4     Port-Channel down
```
The `show ip` command displays IPv4 routing, IPv6 routing, IPv4 multicast routing, and VRRP status on the switch.

**Command Mode**

EXEC

**Command Syntax**

`show ip`

**Example**

This command displays IPv4 routing status.

```
switch>show ip

IP Routing : Enabled
IP Multicast Routing : Disabled
VRRP: Configured on 0 interfaces

IPv6 Unicast Routing : Enabled
IPv6 ECMP Route support : False
IPv6 ECMP Route nexthop index: 5
IPv6 ECMP Route num prefix bits for nexthop index: 10

switch>
```
13.1.16.72  show platform arad ip route summary

The show platform arad ip route summary command shows hardware resource usage of IPv4 routes.

Command Mode
EXEC

Command Syntax
show platform arad ip route summary

Related Commands
- The agent SandL3Unicast terminate command enables restarting the layer 3 agent to ensure IPv4 routes are optimized.
- The ip hardware fib optimize command enables IPv4 route scale.
- The show platform arad ip route command shows resources for all IPv4 routes in hardware. Routes that use the additional hardware resources will appear with an asterisk.

Example
This command shows hardware resource usage of IPv4 routes.

```
switch(config)#show platform arad ip route summary
Total number of VRPs: 1
Total number of routes: 25
Total number of route-paths: 21
Total number of lem-routes: 4

switch(config)#
```
13.1.16.73  show platform arad ip route

The `show platform arad ip route` command shows resources for all IPv4 routes in hardware. Routes that use the additional hardware resources will appear with an asterisk.

**Command Mode**

EXEC

**Command Syntax**

`show platform arad ip route`

**Examples**

- This command displays the platform unicast forwarding routes. In this example, the ACL label field in the following table is **4094** by default for all routes. If an IPv4 egress RACL is applied to an SVI, all routes corresponding to that VLAN will have an ACL label value. In this case, the ACL Label field value is 2.

```
switch#show platform arad ip route
Tunnel Type: M(mpls), G(gre)

switch(config)#
13.1.16.74 show platform barefoot bfrt

The `show platform barefoot bfrt` command displays information about the current BfRuntime server configuration.

**Command Mode**

EXEC

**Command Syntax**

`show platform barefoot bfrt`

**Parameters**

`no parameter` state of the system.

**Example**

The following output is for a system where the BfRuntime server has been configured.

```
(switch)# show platform barefoot bfrt
Namespace: management
FixedSystem: 0.0.0.0:50052
```
13.1.16.75 show platform fap eedb ip-tunnel gre interface tunnel

The *show platform fap eedb ip-tunnel gre interface tunnel* command verifies the tunnel encapsulation programming for the tunnel interface.

**Command Mode**

EXEC

**Command Syntax**

*show platform fap eedb ip-tunnel gre interface tunnel number*

**Parameter**

*number* Specifies the tunnel interface number.

**Example**

These commands verify the tunnel encapsulation programming for the *tunnel interface 10*.

```
switch# show platform fap eedb ip-tunnel gre interface tunnel 10
-------------------------------------------------------------
|          |          | GRE Tunnel Egress Encapsulation DB |
|          |          |
|-----------|---------|-----------------------------------|
| Bank/     | OutLIF  | Next    | VSI  | Encap | TOS | TTL | Source   | Destination |
| OamLIF/   | OutLIF  | Drop|     | Offset| | OutLIF | LSB | Mode | IP | IP | Set |
| Profile|     |     | | 3/0 | 0x6000 | 0x4010 | 0 | 2 | 10 | 10 | 10.1.1.1 | 10.1.1.2 | No |
| 0 | No |

switch# show platform fap eedb ip-tunnel
-------------------------------------------------------------
|          | Jericho0 | IP Tunnel Egress Encapsulation DB |
|          |          |

| Profile|     |     | | 3/0 | 0x6000 | 0x4010 | 0 | 2 | 9 | 0 | 0 | 10.1.1.2 | No |
| 0 | No |
```
13.16.76 show platform fap tcam summary

The `show platform fap tcam summary` command displays information about the TCAM bank that is allocated for GRE packet termination lookup.

**Command Mode**

EXEC

**Command Syntax**

`show platform fap tcam summary`

**Example**

This command verifies if the TCAM bank is allocated for GRE packet termination lookup.

```
switch#show platform fap tcam summary
Tcam Allocation (Jericho0)
Bank    Used By             Reserved By
-------- ------------------- -----------
0        dbGreTunnel        -
```
13.1.16.77 show platform trident forwarding-table partition

The `show platform trident forwarding-table partition` command displays the size of the L2 MAC entry tables, L3 IP forwarding tables, and Longest Prefix Match (LPM) routes.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show platform trident forwarding-table partition
show platform trident forwarding-table partition flexible
```

**Example**

The `show platform trident forwarding-table partition` command shows the Trident forwarding table information.

```
switch(config)#show platform trident forwarding-table partition
L2 Table Size: 96k
L3 Host Table Size: 208k
LPM Table Size: 16k
switch(config)#
```

The `show platform trident forwarding-table partition flexible` shows the banks allocated for ALPM as well.

```
switch(config)#show platform trident forwarding-table partition flexible
--------------------------------------------------
Minimum L2 entries             = 32768
Minimum L3 entries             = 16384
Maximum L2 entries             = 262144
Maximum L3 entries             = 262144
Maximum Exact Match entries    = 131072
L2 entries per bucket          = 4
L3 entries per bucket          = 4
Exact Match entries per bucket = 2
Maximum entries per bucket     = 4
Maximum shared buckets         = 65536
Maximum entries per bank       = 32768
Maximum shared banks           = 8
ALPM entries per bank          = 46080
ALPM                            = Enabled

13.1.16.78  show rib route ip

The `show rib route ip` command displays a list of IPv4 Routing Information Base (RIB) routes.

**Command Mode**
EXEC

**Command Syntax**
`show rib route ip [vrf vrf_name][PREFIX][ROUTE TYPE]`

**Parameters**
- `vrf vrf_name` Displays RIB routes from the specified VRF.
- `PREFIX` Displays routes filtered by the specified IPv4 information. Options include:
  - `ip_address` Displays RIB routes filtered by the specified IPv4 address.
  - `ip_subnet_mask` Displays RIB routes filtered by the specified IPv4 address and subnet mask.
  - `ip_prefix` Displays RIB routes filtered by the specified IPv4 prefix.
- `ROUTE TYPE` Displays routes filtered by the specified route type. Options include:
  - `bgp` Displays RIB routes filtered by BGP.
  - `connected` Displays RIB routes filtered by connected routes.
  - `dynamicPolicy` Displays RIB routes filtered by dynamic policy routes.
  - `host` Displays RIB routes filtered by host routes.
  - `isis` Displays RIB routes filtered by ISIS routes.
  - `ospf` Displays RIB routes filtered by OSPF routes.
  - `ospf3` Displays RIB routes filtered by OSPF3 routes.
  - `reserved` Displays RIB routes filtered by reserved routes.
  - `route-input` Displays RIB routes filtered by route-input routes.
  - `static` Displays RIB routes filtered by static routes.
  - `vrf` Displays routes in a VRF.
  - `vrf-leak` Displays leaked routes in a VRF.

**Examples**
- This command displays IPv4 RIB static routes.

```
switch#show rib route ip static
VRF name: default, VRF ID: 0xfe, Protocol: static
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Ospf, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
       L - Part of a recursive route resolution loop
> S 10.80.0.0/12 [1/0]
    via 172.30.149.129 [0/1]
      via Management1, directly connected
> S 172.16.0.0/12 [1/0]
    via 172.30.149.129 [0/1]
      via Management1, directly connected
switch#
```
- This command displays IPv4 RIB connected routes.

```
switch#show rib route ip connected
VRF name: default, VRF ID: 0xfe, Protocol: connected
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Ospf, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
```
### Layer 3 Configuration

**switch#**

- This command displays routes leaked through VRF leak agent.

**switch#**

```
show rib route ip vrf VRF2 vrf-leak
VRF: VRF2, Protocol: vrf-leak
...
>VL 20.0.0.0/8 [1/0] source VRF: VRF1
    via 10.1.2.10 [0/0] type ipv4
    via 10.1.2.10, Ethernet1
```
13.1.16.79  `show rib route [ipv4 | ipv6] fib policy excluded`

The `show rib route <ipv4 | ipv6> fib policy excluded` command displays the RIB routes filtered by FIB policy. The `fib policy exclude` option displays the RIB routes that have been excluded from being programmed into FIB, by FIB policy.

**Command Mode**

EXEC

**Command Syntax**

`show rib route [ipv4 | ipv6] fib policy excluded`

**Example**

The following example displays the RIB routes excluded by the FIB policy using the `fib policy excluded` option of the `show rib route` command.

```
Switch# show rib route ipv6 fib policy excluded
switch# show rib route ip bgp fib policy excluded

VRF name: default, VRF ID: 0xfe, Protocol: bgp
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Ospf, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
       L - Part of a recursive route resolution loop
>B  10.1.0.0/24 [200/0]
   via 10.2.2.1 [115/20] type tunnel
   via 10.3.5.1, Ethernet1
   via 10.2.0.1 [115/20] type tunnel
   via 10.3.4.1, Ethernet2
   via 10.3.6.1, Ethernet3
>B  10.1.0.0/24 [200/0]
   via 10.2.2.1 [115/20] type tunnel
   via 10.3.5.1, Ethernet1
   via 10.2.0.1 [115/20] type tunnel
   via 10.3.4.1, Ethernet2
   via 10.3.6.1, Ethernet3
```
13.1.16.80 show rib route summary

The `show rib route summary` command displays information about the routes present in the Routing Information Base.

**Command Mode**
EXEC

**Command Syntax**
```
show rib route summary [INFO_LEVEL]
```

**Parameters**
- **no parameter** variable displays data in one table with the summary of all routes in the RIB for default VRF.
- **brief** keyword displays one table with the summary of all routes across all configured VRFs.
- **ip** keyword displays one table with the summary of all IPv4 in the RIB for default VRF.
- **ipv6** keyword displays one table with the summary of all IPv4 in the RIB for default VRF.
- **vrf vrf_Name** keyword displays one table with the summary of all routes in the Routing Information Base for the specified VRF.
- **vrf all** keyword displays one table with the summary of all routes in the Routing Information Base for each configured VRF.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - **Display Values**
    - **VRF** VRF RIB displayed.
    - **Route Source** Source for the route.
    - **Number of Routes** Number of routes for each source.

**Examples**
- The following displays data in one table with the summary of all routes in the RIB for default VRF.

  ```
  switch>show rib route summary
  VRF: default
  Route Source Number Of Routes
  ------------------------ ------------
  BGP                        1
  Connected                  4
  Dynamic policy             0
  IS-IS                      0
  OSPF                       0
  OSPFv3                     0
  RIP                         0
  Route input                2
  Static                     0
  VRF leak                   0
  ```

- The following displays data in one table with the summary of all routes across all configured VRFs.

  ```
  switch>show rib route summary brief
  Route Source Number Of Routes
  -----------------------------
  BGP                           2
  Connected                    8
  Dynamic policy               0
  IS-IS                        0
  ```
**OSPF** | 0  
**OSPFv3** | 0  
**RIP** | 0  
**Route input** | 0  
**Static** | 0  
**VRF leak** | 0

- The following displays data in one table with the summary of all IPv4 routes in the RIB for default VRF.

```
switch>show rib route summary ip
VRF: default
Route Source         Number Of Routes
-------------------- ----------------
BGP                                 1
Connected                           4
Dynamic policy                      0
IS-IS                               0
OSPF                                0
OSPFv3                              0
RIP                                 0
Route input                         2
Static                              0
VRF leak                            0
```

- The following displays data in one table with the summary of all IPv6 routes in the RIB for default VRF.

```
switch>show rib route summary ipv6
VRF: default
Route Source         Number Of Routes
-------------------- ----------------
BGP                                 0
Connected                           0
Dynamic policy                      0
IS-IS                               0
OSPF                                0
OSPFv3                              0
RIP                                 0
Route input                         0
Static                              0
VRF leak                            0
```

- The following displays data in one table with the summary of all routes in the RIB for the VRF named `red`.

```
switch>show rib route summary vrf red
VRF: red
Route Source         Number Of Routes
-------------------- ----------------
BGP                                 1
Connected                           4
Dynamic policy                      0
IS-IS                               0
OSPF                                0
OSPFv3                              0
RIP                                 0
Route input                         2
Static                              0
VRF leak                            0
```
- The following displays data in one table with the summary of all routes in the RIB for each configured VRF.

```plaintext
switch>show rib route summary vrf all
VRF: red
Route Source         Number Of Routes
-------------------- ----------------
BGP                   1

Static                0
VRF leak              0
```
13.1.16.81  show routing-context vrf

The `show routing-context vrf` command displays the context-active VRF. The context-active VRF determines the default VRF that VRF-context aware commands use when displaying routing table data from a specified VRF.

**Command Mode**
EXEC

**Command Syntax**
show routing-context vrf

**Related Commands**
The `cli vrf` command specifies the context-active VRF.

**Example**
This command displays the context-active VRF.

```
switch>show routing-context vrf
Current VRF routing-context is PURPLE
switch>
```
13.1.16.82  show tunnel fib static interface gre

The `show tunnel fib static interface gre` command displays the Forwarding Information Base (FIB) information for a static interface GRE tunnel.

**Command Mode**

EXEC

**Command Syntax**

`show tunnel fib static interface gre number`

**Parameter**

*number*   Specifies the tunnel index number.

**Example**

This command display the interface tunnel configuration with GRE configured.

```
switch#show tunnel fib static interface gre 10
Type 'Static Interface', index 10, forwarding Primary via 10.6.1.2, 'Ethernet6/1'
    GRE, destination 10.1.1.2, source 10.1.1.1, ttl 10, tos 0xa
```
The `show vrf` command displays the VRF name, RD, supported protocols, state and included interfaces for the specified VRF or for all VRFs on the switch.

**Command Mode**
EXEC

**Command Syntax**
`show vrf` [VRF_INSTANCE]

**Parameters**

- **VRF_INSTANCE** Specifies the VRF instance to display.
  - *no parameter* Information is displayed for all VRFs.
  - *vrf vrf_name* Information is displayed for the specified user-defined VRF.

**Example**
This command displays information for the VRF named *purple*.

```
switch>show vrf purple
Vrf      RD          Protocols  State       Interfaces
-------- ----------- ---------- ----------- --------------
purple   64496:237   ipv4       no routing  Vlan42, Vlan43
switch>
```
13.1.16.84 tcp mss ceiling

The tcp mss ceiling command configures the Maximum Segment Size (MSS) limit in the TCP header on the configuration mode interface and enables TCP MSS clamping.

The no tcp mss ceiling and the default tcp mss ceiling commands remove any MSS ceiling limit previously configured on the interface.

Note: Configuring a TCP MSS ceiling on any Ethernet or tunnel interface enables TCP MSS clamping on the switch as a whole. Without hardware support, clamping routes all TCP SYN packets through software, even on interfaces where no TCP MSS ceiling has been configured. This significantly limits the number of TCP sessions the switch can establish per second, and can potentially cause packet loss if the CPU traffic exceeds control plane policy limits.

Command Mode
Interface-Ethernet Configuration
Subinterface-Ethernet Configuration
Interface-Port-channel Configuration
Subinterface-Port-channel Configuration
Interface-Tunnel Configuration
Interface-VLAN Configuration

Command Syntax

```
tcp mss ceiling { ipv4 segment size | ipv6 segment size}{ egress | ingress }
no tcp mss ceiling
default tcp mss ceiling
```

Parameters

- **ipv4 segment size** The IPv4 segment size value in bytes. Values range from 64 to 65515.
- **ipv6 segment size** The IPv6 segment size value in bytes. Values range from 64 to 65495. This option is not supported on Sand platform switches (Qumran-MX, Qumran-AX, Jericho, Jericho+).
- **egress** The TCP SYN packets that are forwarded from the interface to the network.
- **ingress** The TCP SYN packets that are received from the network to the interface. Not supported on Sand platform switches.

Guidelines

- On Sand platform switches (Qumran-MX, Qumran-AX, Jericho, Jericho+), this command works only for egress, and is supported only on IPv4 unicast packets entering the switch.
- Clamping can only be configured in one direction per interface and works only on egress on Sand platform switches.
- To configure ceilings for both IPv4 and IPv6 packets, both configurations must be included in a single command; re-issuing the command overwrites any previous settings.
- Clamping configuration has no effect on GRE transit packets.

Example

These commands configure interface ethernet 5 as a routed port, then specify a maximum MSS ceiling value of 1458 bytes in TCP SYN packets exiting that port. This enables TCP MSS clamping on the switch.

```
switch(config)#interface ethernet 5
switch(config-if-Et5)#no switchport
switch(config-if-Et5)#tcp mss ceiling ipv4 1458 egress
```
switch(config-if-Et5)#
13.1.16.85  tunnel

The `tunnel` command configures options for protocol-over-protocol tunneling. Because interface-tunnel configuration mode is not a group change mode, `running-config` is changed immediately after commands are executed. The `exit` command does not affect the configuration.

The `no tunnel` command deletes the specified tunnel configuration.

**Command Mode**

Interface-tunnel Configuration

**Command Syntax**

`tunnel options`

`no tunnel options`

**Parameters**

- **options**  Specifies the various tunneling options as listed below.
  - destination  Destination address of the tunnel.
  - ipsec  Secures the tunnel with the IPsec address.
  - key  Sets the tunnel key.
  - mode  Tunnel encapsulation method.
  - path-mtu-discovery  Enables the Path MTU discovery on tunnel.
  - source  Source of the tunnel packets.
  - tos  Sets the IP type of service value.
  - ttl  Sets time to live value.
  - underlay  Tunnel underlay.

**Example**

These commands place the switch in interface-tunnel configuration mode for *interface Tunnel 10* and with GRE tunnel configured on the interfaces specified.

```
switch(config)#ip routing
switch(config)#interface Tunnel 10
switch(config-if-Tu10)#tunnel mode gre
switch(config-if-Tu10)#ip address 192.168.1.1/24
switch(config-if-Tu10)#tunnel source 10.1.1.1
switch(config-if-Tu10)#tunnel destination 10.1.1.2
switch(config-if-Tu10)#tunnel path-mtu-discovery
switch(config-if-Tu10)#tunnel tos 10
switch(config-if-Tu10)#tunnel ttl 10
```
The `vrf` command adds the configuration mode interface to the specified VRF. You must create the VRF first, using the `vrf instance` command.

The `no vrf` and `default vrf` commands remove the configuration mode interface from the specified VRF by deleting the corresponding `vrf` command from *running-config*.

All forms of the `vrf` command remove all IP addresses associated with the configuration mode interface.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `vrf [vrf_name]`
- `no vrf [vrf_name]`
- `default vrf [vrf_name]`

**Parameters**

- `vrf_name` Name of configured VRF.

**Examples**

- These commands add the configuration mode interface (`vlan 20`) to the VRF named `purple`.

```
switch(config)#interface vlan 20
switch(config-if-Vl20)#vrf purple
switch(config-if-Vl20)#
```

- These commands remove the configuration mode interface from VRF `purple`.

```
switch(config)#interface vlan 20
switch(config-if-Vl20)#no vrf purple
switch(config-if-Vl20)#ab
```
13.1.16.87  vrf instance

The vrf instance command places the switch in VRF configuration mode for the specified VRF. If the named VRF does not exist, this command creates it. The number of user-defined VRFs supported varies by platform.

To add an interface to the VRF once it is created, use the vrf (Interface mode) command.

The no vrf instance and default vrf instance commands delete the specified VRF instance by removing the corresponding vrf instance command from running-config. This also removes all IP addresses associated with interfaces that belong to the deleted VRF.

The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax
vrf instance [vrf_name]
no vrf instance [vrf_name]
default vrf instance [vrf_name]

Parameters
vrf_name Name of VRF being created, deleted or configured. The names main and default are reserved.

Example
This command creates a VRF named purple and places the switch in VRF configuration mode for that VRF.

```
switch(config)#vrf instance purple
switch(config-vrf-purple)#
```
13.2 IPv6

Arista switches support Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) for routing packets across network boundaries. This section describes Arista’s implementation of IPv6 and includes these topics:

- Introduction
- IPv6 Description
- Configuring IPv6
- IPv6 Commands

13.2.1 Introduction

Routing transmits network layer data packets over connected independent subnets. Each subnet is assigned an IP address range and each device on the subnet is assigned an IP address from that range.

Connected subnets have IP address ranges that do not overlap. A router is a network device connecting multiple subnets. Routers forward inbound packets to the subnet whose address range includes the packets’ destination address.

IPv4 and IPv6 are Internet layer protocols that define packet-switched inter-networking, including source-to-destination datagram transmission across multiple networks. The switch supports IP version 4 (IPv4) and IP version 6 (IPv6).

13.2.2 IPv6 Description

Internet Protocol version 6 is a communications protocol used for relaying network packets across a set of connected networks using the Internet Protocol suite. Each network device is assigned a 128 bit IP address that identifies its network location.

IPv6 specifies a packet format that minimizes router processing of packet headers. Since the IPv4 and IPv6 packet headers differ significantly, the protocols are not interoperable. Many transport and application-layer protocols require little or no change to operate over IPv6.

- IPv6 Address Format
- IPv6 DHCP Snooping
- Neighbor Discovery Protocol

13.2.2.1 IPv6 Address Format

IPv6 addresses have 128 bits, represented by eight 16-bit hexadecimal numbers separated by colons. IPv6 addresses are abbreviated as follows:

- Leading zeros in each 16-bit number may be omitted.
- One set of consecutive 16-bit numbers that equal zero may be replaced by a double colon.

Example

The following three IPv6 hexadecimal number representations refer to the same address:

- d28e:0:0:0:234:812f:61ed:4419
- d28e::234:812f:61ed:4419

IPv6 addresses typically denote a 64-bit network prefix and a 64-bit host address.
Unicast and Anycast Addressing

Unicast addressing defines a one-to-one association between the destination address and a network endpoint. Each destination address uniquely identifies a single receiver endpoint. Anycast addressing defines a one-to-one-of-many association: packets to a single member of a group of potential receivers identified by the same destination address.

Unicast and anycast addresses are typically composed as follows:

- A 64-bit network prefix that identifies the network segment.
- A 64-bit interface identifier that is based on interface MAC address.

The format of a network address identifies the scope of the address:

- Global address: valid in all networks and connect with other addresses with global scope anywhere or to addresses with link-local scope on the directly attached network.
- Link-local address: scope extends only to the link to which the interface is directly connected. Link-local addresses are not routable off the link.

Link-local addresses are created by the switch and are not configurable. The following figure depicts the switch’s link local address derivation method.

Figure 28: Link Local Address Derivation

Multicast Addressing

Multicast addressing defines a one-to-many association: packets are simultaneously routed from a single sender to multiple endpoints in a single transmission. The network replicates packets as required by network links that contain a recipient endpoint. One multicast address is assigned to an interface for each multicast group to which the interface belongs.

Figure 29: Link Local Address Derivation

A solicited-node multicast address is an IPv6 multicast address whose scope extends only to the link to which the interface is directly connected. All IPv6 hosts have at least one such address per interface. Solicited-node multicast addresses are used by the Neighbor Discovery Protocol to obtain Layer 2 link-layer addresses of other nodes.
13.2.2 IPv6 DHCP Snooping

Dynamic Host Configuration Protocol (DHCP) snooping is a Layer 2 feature that is configured on LAN switches. The Arista EOS switch supports Option-37 insertion that allows relay agents to provide remote-id information in DHCP request packets. DHCP servers use this information to determine the originating port of DHCP requests and associate a corresponding IP address to that port. DHCP servers use port information to track host location and IP address usage by authorized physical ports.

DHCP snooping uses the information option (Option-37) to include the switch MAC address (router-id) along with the physical interface name and VLAN number (remote-id) in DHCP packets. After adding the information to the packet, the DHCP relay agent forwards the packet to the DHCP server as specified by the DHCP protocol.

13.2.2.3 Neighbor Discovery Protocol

The Neighbor Discovery Protocol (RFC 4861) operates with IPv6 to facilitate the following tasks for nodes within a specified prefix space:

- autoconfiguring a node's IPv6 address
- sensing other nodes on the link
- discovering the link-local addresses of other nodes on the link
- detecting duplicate addresses
- discovering available routers
- discovering DNS servers
- discovering the link's address prefix
- maintaining path reachability data to other active neighbor nodes

The Neighbor Discovery Protocol protocol defines five different ICMPv6 packet types:

- Router Solicitation
- Router Advertisement
- Neighbor Solicitation
- Neighbor Advertisement
- Redirect

13.2.3 Configuring IPv6

These sections describe IPv6 configuration tasks:

- Configuring IPv6 on the Switch
- Configuring IPv6 on an Interface
- Configuring IPv6 DHCP Snooping
- Viewing IPv6 Network Components
- DHCP Relay Agent for IPv6
- TCP MSS Clamping for IPv6

13.2.3.1 Configuring IPv6 on the Switch

13.2.3.1.1 Enabling IPv6 Unicast Routing on the Switch

The `ipv6 unicast-routing` command enables the forwarding of IPv6 unicast packets. When routing is enabled, the switch attempts to deliver inbound packets to destination addresses by forwarding them to interfaces or next hop addresses specified by the IPv6 routing table.

Example
This command enables IPv6 unicast-routing.

```
switch(config)#ipv6 unicast-routing
switch(config)#
```

### 13.2.3.1.2 Configuring Default and Static IPv6 Routes

The `ipv6 route` command creates an IPv6 static route. The destination is an IPv6 prefix; the source is an IPv6 address or a routable interface port. When multiple routes exist to a destination prefix, the route with the lowest administrative distance takes precedence.

By default, the administrative distance assigned to static routes is 1. Assigning a higher administrative distance to a static route configures it to be overridden by dynamic routing data. For example, a static route with a distance value of 200 is overridden by OSPF intra-area routes, which have a default distance of 110.

**Example**

This command creates an IPv6 static route.

```
switch(config)#ipv6 route 10:23:31:00:01:32:93/24 vlan 300
switch(config)#
```

The default route denotes the packet forwarding rule that takes effect when no other route is configured for a specified IPv6 address. All packets with destinations that are not established in the routing table are sent to the destination specified by the default route.

The IPv6 default route source is `::/0`. The default route destination is referred to as the default gateway.

**Example**

This command creates a default route and establishes `fd7a:629f:52a4:fe61::2` as the default gateway address.

```
switch(config)#ipv6 route ::/0 fd7a:629f:52a4:fe61::2
switch(config)#
```

### 13.2.3.1.3 IPv6 ECMP

Multiple routes that are configured to the same destination with the same administrative distance comprise an Equal Cost Multi-Path (ECMP) route. The switch attempts to spread outbound traffic across all ECMP route paths equally. All ECMP paths are assigned the same tag value; commands that change the tag value of any ECMP path change the tag value of all paths in the ECMP.

Resilient ECMP is available for IPv6 routes. *Equal Cost Multipath Routing (ECMP) and Load Sharing* describes resilient ECMP. The `ipv6 hardware fib ecmp resilience` command implements IPv6 resilient ECMP.

**Example**

This command implements IPv6 resilient ECMP by configuring a hardware ECMP table space of 15 entries for IPv6 address `2001:db8:0::/64`. A maximum of five nexthop addresses can be specified for the address. When the table contains five addresses, each appears in the table three times. When the table contains fewer than five addresses, each is duplicated until the 15 table entries are filled.

```
switch(config)#ipv6 hardware fib ecmp resilience 2001:db8:0::/64 capacity 5
   redundancy 3
switch(config)#
```
13.2.3.2 Configuring IPv6 on an Interface

13.2.3.2.1 Enabling IPv6 on an Interface

The `ipv6 enable` command enables IPv6 on the configuration mode interface if it does not have a configured IPv6 address. It also configures the interface with an IPv6 address.

The `no ipv6 enable` command disables IPv6 on a configuration mode interface not configured with an IPv6 address. Interfaces configured with an IPv6 address are not disabled by this command.

**Example**

This command enables IPv6 on **VLAN interface 200**.

```
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 enable
switch(config-vl200)#
```

13.2.3.2.2 Assigning an IPv6 Address to an Interface

The `ipv6 address` command enables IPv6 on the configuration mode interface, assigns a global IPv6 address to the interface, and defines the prefix length. This command is supported on routable interfaces. Multiple global IPv6 addresses can be assigned to an interface.

**Example**

These commands configure an IPv6 address with subnet mask for **VLAN 200**:

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 address 10:23:31::1:32:93/64
switch(config-if-Vl200)#
```

13.2.3.2.3 IPv6 Neighbor Discovery

The IPv6 Neighbor Discovery protocol defines a method for nodes to perform the following network maintenance tasks:

- determine Layer 2 addresses for neighbors known to reside on attached links.
- detect changed Layer 2 addresses.
- purge invalid values from the neighbor cache table.
- (hosts) find neighboring routers to forward packets.
- track neighbor reachability status.

IPv6 Neighbor Discovery is defined by RFC 2461. IPv6 Stateless Address Autoconfiguration is described by RFC 2462.

The following sections describe Neighbor Discovery configuration tasks.

13.2.3.2.3.1 Reachable Time

The `ipv6 nd reachable-time` command specifies the time period that the switch includes in the reachable time field of Router Advertisements (RAs) sent from the configuration mode interface. The reachable time defines the period that a remote IPv6 node is considered reachable after a reachability confirmation event.

**Example**
These commands configure the entry of 25000 (25 seconds) in the reachable time field of RAs sent from **VLAN 200**.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd reachable-time 25000
switch(config-if-Vl200)#show active
    interface Vlan200
        ipv6 address fd7a:4321::1/64
        ipv6 nd reachable-time 25000
switch(config-if-Vl200)#
```

### 13.2.3.2.3.2 Router Advertisement Interval

The **ipv6 nd ra interval** command configures the interval between IPv6 RA transmissions from the configuration mode interface.

**Example**

These commands configure a RA transmission interval of 60 seconds on **VLAN interface 200**, then displays the interface status.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra interval 60
switch(config-if-Vl200)#show active
    interface Vlan200
        ipv6 nd ra interval 60
switch(config-if-Vl200)#
```

### 13.2.3.2.3.3 Router Lifetime

The **ipv6 nd ra lifetime** command specifies the value that the switch places in the router lifetime field of IPv6 RAs sent from the configuration mode interface.

If the value is set to **0**, IPv6 peers connected to the specified interface will remove the switch from their lists of default routers. Values greater than **0** indicate the time in seconds that peers should keep the router on their default router lists without receiving further RAs from the switch. Unless the value is **0**, the router lifetime value should be equal to or greater than the interval between unsolicited RAs sent on the interface.

**Example**

This command configures the switch to enter 2700 in the router lifetime field of RAs transmitted from **vlan 200**.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra lifetime 2700
switch(config-if-Vl200)#show active
    interface Vlan200
        ipv6 nd ra lifetime 2700
switch(config-if-Vl200)#
```

### 13.2.3.2.3.4 Router Advertisement Prefix

The **ipv6 nd prefix** command configures neighbor discovery router advertisement prefix inclusion for RAs sent from the configuration mode interface.

By default, all prefixes configured as IPv6 addresses are advertised in the interface’s RAs. The **ipv6 nd prefix** command with the **no-advertise** option prevents advertising of the specified prefix without affecting the advertising of other prefixes specified as IPv6 addresses. When an interface configuration...
Layer 3 Configuration

includes at least one `ipv6 nd prefix` command that enables prefix advertising, RAs advertise only prefixes specified through `ipv6 nd prefix` commands.

Commands enabling prefix advertising also specify the advertised valid and preferred lifetime periods. Default periods are **2,592,000** (valid) and **604,800** (preferred) seconds.

**Example**

These commands enable neighbor discovery advertising for IPv6 address *3012:D678::/64*, specifying a valid lifetime of **1,296,000** seconds and the default preferred lifetime.

```plaintext
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd prefix 3012:D678::/64 1296000
```

13.2.3.2.3.5 Router Advertisement Suppression

The `ipv6 nd ra disabled` command suppress IPv6 RA transmissions on the configuration mode interface. By default, only unsolicited RAs that are transmitted periodically are suppressed. The `all` option configures the switch to suppress all RAs, including those responding to a router solicitation.

**Example**

This command suppresses all RAs on *interface vlan 200*.

```plaintext
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 nd ra disabled all
```

13.2.3.2.3.6 Router Advertisement MTU Suppression

The `ipv6 nd ra mtu suppress` command suppresses the router advertisement MTU option on the configuration mode interface. The MTU option causes an identical MTU value to be advertised by all nodes on a link. By default, the router advertisement MTU option is not suppressed.

**Example**

This command suppresses the MTU option on *interface vlan 200*.

```plaintext
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 nd ra mtu suppress
```

13.2.3.2.3.7 Router Advertisement Flag Configuration

The following commands sets the specified configuration flag in IPv6 RAs transmitted from the configuration mode interface:

- The `ipv6 nd managed-config-flag` command sets the `managed address configuration` flag. This bit instructs hosts to use stateful address autoconfiguration.
- The `ipv6 nd managed-config-flag` command sets the other `stateful configuration` flag. This bit indicates availability of autoconfiguration information, other than addresses. Hosts should use stateful autoconfiguration when available. The setting of this flag has no effect if the `managed address configuration` flag is set.
- These commands configure the switch to set the `managed address configuration` flag in advertisements sent from *interface vlan 200*.

```plaintext
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd managed-config-flag
```
13.2.3.2.4 IPv6 Router Preference

The IPv6 Router Preference protocol supports an extension to RA messages for communicating default router preferences and more specific routes from routers to hosts. This provides assistance to hosts when selecting a router. RFC 4191 describes the IPv6 Router Preference Protocol.

The `ipv6 nd router-preference` command specifies the value that the switch enters in the Default Router Preference (DRP) field of RAs that it sends from the configuration mode interface. The default field entry value is `medium`.

**Example**

This command configures the switch as a medium preference router on RAs sent from `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd router-preference medium
```

13.2.3.2.5 uRPF Configuration

Unicast Reverse Path Forwarding (uRPF) verifies the accessibility of source IP addresses in packets that the switch forwards. *Unicast Reverse Path Forwarding (uRPF)* describes uRPF. uRPF is enabled for IPv6 packets entering the configuration mode interface through the `ipv6 verify` command.

uRPF defines two operational modes: strict mode and loose mode.

- **Strict mode:** uRPF verifies that a packet is received on the interface that its routing table entry specifies for its return packet.
- **Loose mode:** uRPF validation does not consider the inbound packet’s ingress interface only that there is a valid return path.

**Example**

This command enables uRPF strict mode on `interface vlan 100`. If a default route is configured on the interface, all inbound packets will pass the uRPF check as valid.

```
switch(config)#interface vlan 100
switch(config-if-Vl100)#ipv6 verify unicast source reachable-via rx allow-default
switch(config-if-Vl100)#show active
  interface Vlan100
    ipv6 verify unicast source reachable-via rx allow-default
```

```
13.2.3 Configuring IPv6 DHCP Snooping

13.2.3.1 Enabling IPv6 DHCP Snooping on the Switch

The `ipv6 dhcp snooping` command enables DHCP snooping globally on the switch. DHCP snooping is a Layer 2 feature that can be configured on LAN switches. The Arista switch supports Option-37 insertion that allows relay agents to provide remote-ID information in DHCP request packets.

**Note:** DHCPv6 VLAN classification and DHCPv4 VLAN classification share same hardware resource.

**Examples**

- The following configuration enables IPv6 DHCP snooping feature at the global level.

```
switch(config)#ipv6 dhcp snooping
switch(config)#ipv6 dhcp snooping remote-id option
switch(config)#ipv6 dhcp snooping vlan <vlan|vlan-range>
```

- The following command display IPv6 DHCP snooping state.

```
switch(config)#ipv6 dhcp snooping
switch(config)#show ipv6 dhcp snooping
DHCPv6 Snooping is enabled
DHCPv6 Snooping is operational
DHCPv6 Snooping is configured on following VLANs:
  2789-2790
DHCPv6 Snooping is operational on following VLANs:
  2789
Insertion of Option-37 is enabled
```

13.2.4 Viewing IPv6 Network Components

13.2.3.4.1 Displaying RIB Route Information

Use the `show rib route ipv6` command view the IPv6 Routing Information Base (RIB) information.

**Example**

This command displays IPv6 RIB BGP routes.

```
switch#show rib route ipv6 bgp
VRF name: default, VRF ID: 0xfe, Protocol: bgp
Codes: C - Connected, S - Static, P - Route Input
       B - BGP, O - Osfp, O3 - Ospf3, I - Isis
       > - Best Route, * - Unresolved Nexthop
       L - Part of a recursive route resolution loop
B  2001:10:1::/64 [200/42]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
>B  2001:10:100::/64 [200/200]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
>B  2001:10:100:1::/64 [200/0]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
>B  2001:10:100:2::/64 [200/42]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
switch#
```
13.2.3.4.2 Displaying the FIB and Routing Table

The `show ipv6 route` command displays routing table entries that are in the Forwarding Information Base (FIB), including static routes, routes to directly connected networks, and dynamically learned routes. Multiple equal cost paths to the same prefix are displayed contiguously as a block, with the destination prefix displayed only on the first line.

**Example**

This command displays a route table entry for a specific IPv6 route.

```
switch>show ipv6 route fd7a:3418:52a4:fe18::/64
IPv6 Routing Table - 77 entries
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP, R - RIP, A - Aggregate
O fd7a:3418:52a4:fe18::/64 [10/20]
   via f180::21c:73ff:fe00:1319, Vlan3601
   via f180::21c:73ff:fe00:1319, Vlan3602
   via f180::21c:73ff:fe00:1319, Vlan3608
   via f180::21c:73ff:fe0f:6a80, Vlan3610
   via f180::21c:73ff:fe00:1319, Vlan3611
switch>
```

13.2.3.4.3 Displaying the Route Age

The `show ipv6 route age` command displays the IPv6 route age to the specified IPv6 address or prefix.

**Example**

This command displays the route age for the specified prefix.

```
switch>show ipv6 route 2001::3:0/11 age
IPv6 Routing Table - 74 entries
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP, R - RIP, A - Aggregate
C 2001::3:0/11 age 00:02:34
switch>
```

13.2.3.4.4 Displaying Host Routes

The `show ipv6 route host` command displays all host routes in the IPv6 host forwarding table. Host routes are those whose destination prefix is the entire address (prefix = /128). Each displayed host route is labeled with its purpose:

- **F** static routes from the FIB.
- **R** routes defined because the IP address is an interface address.
- **A** routes to any neighboring host for which the switch has an ARP entry.

**Example**

This command displays all IPv6 host routes in the host forwarding table.

```
switch#show ipv6 route host
R - receive F - FIB, A - attached
F ::1 to cpu
```

13.2.3.4.5 Displaying Route Summaries

The `show ipv6 route summary` command displays the current number of routes of the IPv6 routing table in summary format.

**Example**

This command displays the route source and the corresponding number of routes in the IPv6 routing table.

```
switch>show ipv6 route summary
Route Source          Number Of Routes
--------------------- ----------------
connected             2
static                0
ospf                  5
bgp                   7
isis                  0
internal              1
attached              0
aggregate             2
                      Total Routes 17
switch>
```

13.2.3.5 DHCP Relay Agent for IPv6

13.2.3.5.1 Configuring IPv6 DHCP Relay

13.2.3.5.1.1 Configuring the IPv6 DHCP Relay Agent (Global)

The `ipv6 dhcp relay always-on` command enables the switch DHCP relay agent globally regardless of the DHCP relay agent status on any interface. The DHCP relay agent is enabled by default if at least one routable interface is configured with an `ipv6 dhcp relay destination` statement.

**Example**

This command enables the DHCP relay agent.

```
switch(config)#ipv6 dhcp relay always-on
switch(config)#
```

13.2.3.5.1.2 Configuring DHCP for IPv6 Relay Agent

The `ipv6 dhcp relay destination` command enables the DHCPv6 relay agent function and specifies the client message destination address on an interface.

**Example**
This command enables the DHCPv6 relay agent function and sets the client message destination address to `2001:0db8:0:1::1` on Ethernet interface 4.

```
switch(config)#interface ethernet 4
switch(config-if-Et4)#ipv6 dhcp relay destination 2001:0db8:0:1::1
switch(config-if-Et4)
```

### 13.2.3.5.1.3 Configuring the Client Link Layer Address for the IPv6 DHCP Relay Agent

The `ipv6 dhcp relay option link-layer address` command enables the DHCPv6 relay agent to configure the client link layer address option to solicit and request messages. In other words, the command enables the link layer address option (79) in the global configuration mode. The `no ipv6 dhcp relay option link-layer address` command disables the link layer address option (79) in the global configuration mode.

**Example**

This command enables the insertion of link layer address option (79) in the global configuration mode.

```
switch(config)#ipv6 dhcp relay option link-layer address
```

### 13.2.3.5.1.4 Clearing IPv6 DHCP Relay Counters

The `clear ipv6 dhcp relay counters` command resets the DHCP relay counters. The configuration mode determines which counters are reset:

- **Global configuration**: command clears the counters for the switch and for all interfaces.
- **Interface configuration**: command clears the counter for the configuration mode interface.

**Examples**

- These commands clear all DHCP relay counters on the switch.
  
  ```
  switch(config-if-Et4)#exit
  switch(config)#clear ipv6 dhcp relay counters
  switch(config)#
  ```

- These commands clear the DHCP relay counters for `interface ethernet 4`.
  
  ```
  switch(config)#interface ethernet 4
  switch(config-if-Et4)#clear ipv6 dhcp relay counters
  switch(config)#
  ```

### 13.2.3.5.2 Viewing IPv6 DHCP Relay Information

#### 13.2.3.5.2.1 IPv6 DHCP Status

The `show ip dhcp relay` command displays the status of DHCP relay agent parameters on the switch and each interface where at least one feature parameter is listed. The command displays the status for both global and interface configurations.

**Example**

This command displays the DHCP Agent Relay parameter status.

```
switch(config)#interface ethernet 1/2
switch(config-if-Et1/2)#show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is disabled
```
Layer 3 Configuration

DHCPv6 Relay Link-layer Address Option (79) is disabled
DHCP Smart Relay is disabled
Interface: Ethernet1/2
  DHCP Smart Relay is disabled
DHCP servers: 1::1
  2001:db8:0:1::1
switch(config-if-Et1/2)#

13.2.3.5.2 IPv6 DHCP Relay Counters

The `show ipv6 dhcp relay counters` command displays the number of DHCP packets received, forwarded, or dropped on the switch and on all interfaces enabled as DHCP relay agents.

Example

This command displays the IP DHCP relay counter table.

```
switch> show ipv6 dhcp relay counters

<table>
<thead>
<tr>
<th>Interface</th>
<th>Dhcp Packets</th>
<th>Rcvd Fwdd Drop</th>
<th>Last Cleared</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Req</td>
<td>376</td>
<td>376</td>
<td>0</td>
</tr>
<tr>
<td>All Resp</td>
<td>277</td>
<td>277</td>
<td>0</td>
</tr>
<tr>
<td>Ethernet4</td>
<td>207</td>
<td>148</td>
<td>0</td>
</tr>
</tbody>
</table>

switch>
```

13.2.3.6 TCP MSS Clamping for IPv6

TCP MSS clamping limits the value of the Maximum Segment Size (MSS) in the TCP header of TCP SYN packets transiting a specified Ethernet or tunnel interface. Setting the MSS ceiling can avoid IP fragmentation in tunnel scenarios by ensuring that the MSS is low enough to account for the extra overhead of GRE and tunnel outer IP headers. TCP MSS clamping can be used when connecting via GRE to cloud providers that require asymmetric routing.

When MSS clamping is configured on an interface, if the TCP MSS value in a SYN packet transiting that interface exceeds the configured ceiling limit it will be overwritten with the configured limit and the TCP checksum will be recomputed and updated.

TCP MSS clamping is handled by default in the software data path, but the process can be supported through hardware configuration to minimize possible packet loss and a reduction in the number of TCP sessions which the switch can establish per second.

13.2.3.6.1 Configuring the TCP MSS Ceiling on an IPv6 Interface

The TCP MSS ceiling limit is set on an interface using command `tcp mss ceiling ipv6`. This also enables TCP MSS clamping on the switch.

Note: Clamping routes all TCP SYN packets through software, even on interfaces where no TCP MSS ceiling has been configured without any hardware support. This significantly limits the number of TCP sessions the switch can establish per second, and can potentially cause packet loss if the CPU traffic exceeds control plane policy limits.

On platform switches **DCS-7280R3, DCS-7500R3 Line Cards and DCS-7800R3 Line Cards**, the following limitations apply:

- This command works only on egress.
- TCP MSS ceiling is supported on unicast packets entering the switch; the configuration has no effect on GRE transit packets.
- It is not supported on L2 (switchport) interfaces.
- This is not supported on VXLAN, Loopback or management interfaces.
- This is only supported on unicast packets entering the switch. The configuration has no effect on GRE transit packets or GRE decap, even if the egress interface has a TCP MSS ceiling configured.
- This cannot co-exist with Policy Based Routing (PBR) on switches running releases EOS-4.21.5F or older.
- Only hardware TCP MSS clamping is supported from release EOS-4.26.1F.

**Example**

These commands configure interface ethernet 26 as a routed port, then specify a maximum MSS ceiling value of 1436 bytes for TCP SYN packets exiting that port.

```
switch(config)#interface ethernet 26
switch(config-if-Et5)#no switchport
switch(config-if-Et5)#tcp mss ceiling ipv6 1436 egress
switch(config-if-Et5)#
```
13.2.4 IPv6 Commands

Global Configuration Commands

- ipv6 dhcp relay always-on
- ipv6 dhcp relay option link-layer address
- ipv6 hardware fib aggregate-address
- ipv6 hardware fib ecmp resilience
- ipv6 hardware fib nexthop-index
- ipv6 neighbor
- ipv6 neighbor cache persistent
- ipv6 route
- ipv6 unicast-routing

Interface Configuration Commands

- ipv6 address
- ipv6 dhcp relay destination
- ipv6 dhcp snooping
- ipv6 enable
- ipv6 nd managed-config-flag
- ipv6 nd ns-interval
- ipv6 nd other-config-flag
- ipv6 nd prefix
- ipv6 nd ra dns-server
- ipv6 nd ra dns-servers lifetime
- ipv6 nd ra dns-suffix
- ipv6 nd ra dns-suffixes lifetime
- ipv6 nd ra hop-limit
- ipv6 nd ra interval
- ipv6 nd ra lifetime
- ipv6 nd ra mtu suppress
- ipv6 nd ra disabled
- ipv6 nd reachable-time
- ipv6 nd router-preference
- ipv6 verify
- pim ipv6 sparse-mode

Privileged EXEC Commands

- clear ipv6 dhcp relay counters
- clear ipv6 dhcp snooping counters
- clear ipv6 neighbors

EXEC Commands

- show ipv6 dhcp relay counters
- show ipv6 dhcp snooping
- show ipv6 dhcp snooping counters
- show ipv6 dhcp snooping hardware
- show ipv6 hardware fib aggregate-address
- show ipv6 interface
Layer 3 Configuration

- show ipv6 nd ra internal state
- show ipv6 neighbors
- show ipv6 route
- show ipv6 route age
- show ipv6 route host
- show ipv6 route interface
- show ipv6 route match tag
- show ipv6 route summary
- show rib route ipv6
13.2.4.1  clear ipv6 dhcp relay counters

The clear ipv6 dhcp relay counters command resets the DHCP relay counters. When no port is specified, the command clears the counters for the switch and for all interfaces. Otherwise, the command clears the counter for the specified interface.

Command Mode
Privileged EXEC

Command Syntax

clear ipv6 dhcp relay counters[PORT]

Parameters

PORT Interface through which neighbor is accessed. Options include:

- **no parameter**  all dynamic entries are removed.
- **interface ethernet e_num**  Ethernet interface specified by **e_num**.
- **interface loopback l_num**  Loopback interface specified by **l_num**.
- **interface port-channel p_num**  Port-channel interface specified by **p_num**.
- **interface vlan v_num**  VLAN interface specified by **v_num**.

Example

These commands clear the DHCP relay counters for **interface ethernet 4** and shows the counters before and after the clear command.

```
switch(config)#show ipv6 dhcp relay counters
<table>
<thead>
<tr>
<th>Dhcp Packets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
</tr>
<tr>
<td>All Req</td>
</tr>
<tr>
<td>All Resp</td>
</tr>
<tr>
<td>Ethernet4</td>
</tr>
</tbody>
</table>

switch(config)#interface ethernet 4
switch(config-if-Et4)#clear ipv6 dhcp relay counters

switch(config-if-Et4)#show ipv6 dhcp relay counters
<table>
<thead>
<tr>
<th>Dhcp Packets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
</tr>
<tr>
<td>All Req</td>
</tr>
<tr>
<td>All Resp</td>
</tr>
<tr>
<td>Ethernet4</td>
</tr>
</tbody>
</table>

These commands clear all DHCP relay counters on the switch.
switch(config-if-Et4)#exit

switch(config)#clear ipv6 dhcp relay counters

switch(config)#show ipv6 dhcp relay counters
<table>
<thead>
<tr>
<th>Dhcp Packets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
</tr>
<tr>
<td>All Req</td>
</tr>
<tr>
<td>All Resp</td>
</tr>
<tr>
<td>Ethernet4</td>
</tr>
</tbody>
</table>
```

switch(config)#
13.2.4.2 clear ipv6 dhcp snooping counters

The clear ipv6 dhcp snooping counters command resets the DHCP snooping packet counters.

Command Mode
Privileged EXEC

Command Syntax

clear ipv6 dhcp snooping counters [COUNTER_TYPE]

Parameters

- COUNTER_TYPE  The type of counter that the command resets.
- no parameter command clears the counters for each VLAN.
- debug command clears aggregate counters and drop cause counters.

Examples

- This command clears the number of DHCP packets sent and received on each VLAN.

```plaintext
switch# clear ipv6 dhcp snooping counters
switch# show ipv6 dhcp snooping counters

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Dhcpv6 Request Pkts</th>
<th>Dhcpv6 Reply Pkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2789</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Last Cleared: 0:03:09 ago
```

- This command clears the number of DHCP packets sent on the switch.

```plaintext
switch# clear ipv6 dhcp snooping counters debug
switch# show ipv6 dhcp snooping counters debug

Counter

<table>
<thead>
<tr>
<th>Counter</th>
<th>Snooping to Relay</th>
<th>Relay to Snooping</th>
</tr>
</thead>
<tbody>
<tr>
<td>Received</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Forwarded</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Dropped - Invalid VlanId</td>
<td>0</td>
<td>0</td>
</tr>
<tr>

<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Dropped - Invalid Remote-ID Option</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Dropped - Snooping disabled</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Last Cleared: 0:04:29 ago
```
13.2.4.3  clear ipv6 neighbors

The `clear ipv6 neighbors` command removes the specified dynamic IPv6 neighbor discovery cache entries. Commands that do not specify an IPv6 address remove all dynamic entries for the listed interface. Commands that do not specify an interface remove all dynamic entries.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear ipv6 neighbors [PORT][DYNAMIC_IPV6]`

**Parameters**

- **PORT** Interface through which neighbor is accessed. Options include:
  - *no parameter* all dynamic entries are removed.
  - *ethernet e_num* Ethernet interface specified by `e_num`.
  - *loopback l_num* Loopback interface specified by `l_num`.
  - *management m_num* Management interface specified by `m_num`.
  - *port-channel p_num* Port-channel interface specified by `p_num`.
  - *vlan v_num* VLAN interface specified by `v_num`.
  - *vxlan vx_num* VXLAN interface specified by `vx_num`.

- **DYNAMIC_IPV6** Address of entry removed by the command. Options include:
  - *no parameter* All dynamic entries for specified interface are removed.
  - *ipv6_addr* IPv6 address of entry.

**Example**

This command removes all dynamic neighbor entries for *vlan 200*.

```
switch#clear ipv6 neighbors vlan 200
switch#
```
13.2.4.4  ipv6 address

The ipv6 address command assigns a global IPv6 address to the IPv6 interface, and defines the prefix length. This command is supported on routable interfaces. Multiple global IPv6 addresses can be assigned to an interface.

The no ipv6 address and default ipv6 address commands remove the IPv6 address assignment from the configuration mode interface by deleting the corresponding ipv6 address command from running-config. If the command does not include an address, all address assignments are removed from the interface. IPv6 remains enabled on the interface after the removal of all IPv6 addresses only if an ipv6 enable command is configured on the interface.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax
ipv6 address [ipv6_prefix]
no ipv6 address [ipv6_prefix]
default ipv6 address [ipv6_prefix]

Parameter
ipv6_prefix  address assigned to the interface (CIDR notation).

Guidelines
This command is supported on routable interfaces.

Example
These commands configure an IPv6 address and prefix length for vlan 200:

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 address 10:23:31:00:01:32:93/64
switch(config-if-Vl200)#
```
13.2.4.5  ipv6 dhcp relay always-on

The `ipv6 dhcp relay always-on` command enables the switch DHCP relay agent on the switch regardless of the DHCP relay agent status on any interface. By default, the DHCP relay agent is enabled only if at least one routable interface is configured with an `ipv6 dhcp relay destination` statement.

The `no ipv6 dhcp relay always-on` and `default ipv6 dhcp relay always-on` commands remove the `ipv6 dhcp relay always-on` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

- `ipv6 dhcp relay always-on`
- `no ipv6 dhcp relay always-on`
- `default ipv6 dhcp relay always-on`

**Example**
This command enables the DHCP relay agent.

```
switch(config)#ipv6 dhcp relay always-on
switch(config)#
```
13.2.4.6 ipv6 dhcp relay destination

The ipv6 dhcp relay destination command enables the DHCPv6 relay agent and sets the destination address on the configuration mode interface.

The no ipv6 dhcp relay destination and default ipv6 dhcp relay destination commands remove the corresponding ipv6 dhcp relay destination command from running-config. When the commands do not list an IPv6 address, all ipv6 dhcp relay destination commands are removed from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax

ipv6 dhcp relay destination [ipv6_addr][source-address ipv6_addr]
no ipv6 dhcp relay destination [ipv6_addr]
default ipv6 dhcp relay destination [ipv6_addr]

Parameters

• ipv6_addr    DCHP Server's IPv6 address.
• source-address ipv6_addr specify the source IPv6 address to communicate with DHCP server.

Guidelines

If the source-address parameter is specified, then the DHCP client receives an IPv6 address from the subnet of source IP address. The source-address must be one of the configured addresses on the interface.

Example

This command enables the DHCPv6 relay agent and sets the destination address to 2001:0db8:0:1::1 on interface ethernet 4.

```
switch(config)#interface ethernet 4
switch(config-if-Et4)#ipv6 dhcp relay destination 2001:0db8:0:1::1
switch(config-if-Et4)#show ip dhcp relay
DHCP Relay is active
DHCP Relay Option 82 is disabled
DHCPv6 Relay Link-layer Address Option (79) is disabled
DHCP Smart Relay is disabled
Interface: Ethernet4
    DHCP Smart Relay is disabled
    DHCP servers: 1::1
    2001:db8:0:1::1
switch(config-if-Et4)#
```
13.2.4.7 ipv6 dhcp relay option link-layer address

The `ipv6 dhcp relay option link-layer address` command enables the DHCPv6 relay agent to configure the client link layer address option to solicit and request messages. In other words, the command enables the link layer address option (79) in the global configuration mode.

The `no ipv6 dhcp relay option link-layer address` command disables the link layer address option (79) in the global configuration mode.

**Command Mode**
Global Configuration

**Command Syntax**

```
ipv6 dhcp relay option link-layer address
no ipv6 dhcp relay option link-layer address
default ipv6 dhcp relay option link-layer address
```

**Example**

This command enables the insertion of link layer address option (79) in the global configuration mode.

```
switch(config)#ipv6 dhcp relay option link-layer address
```
13.2.4.8  ipv6 enable

The **ipv6 enable** command enables IPv6 on the configuration mode interface. Assigning an IPv6 address to an interface also enables IPv6 on the interface.

The **no ipv6 enable** and **default ipv6 enable** command remove the corresponding **ipv6 enable** command from **running-config**. This action disables IPv6 on interfaces that are not configured with an IPv6 address.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- **ipv6 enable**
- **no ipv6 enable**
- **default ipv6 enable**

**Example**

This command enables IPv6 on **interface vlan 200**.

```
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 enable
switch(config-vl200)#
```
13.2.4.9  ipv6 hardware fib aggregate-address

The `ipv6 hardware fib aggregate-address` command specifies the routing table repository of specified IPv6 route.

By default, routes that are created statically through the CLI or dynamically through routing protocols are initially stored in software routing tables, then entered in the hardware routing table by the routing agent. This command prevents the entry of the specified route into the hardware routing table. Specified routes that are in the hardware routing table are removed by this command. Specific routes that are encompassed within the specified route prefix are affected by this command.

The `no ipv6 hardware fib aggregate-address` and `default ipv6 hardware fib aggregate-address` commands remove the restriction from the hardware routing table for the specified routes by removing the corresponding `ipv6 hardware fib aggregate-address` command from `running-config`.

Command Mode
Global Configuration

Command Syntax

```
ipv6 hardware fib aggregate-address ipv6_prefix summary-only software-forward
no ipv6 hardware fib aggregate-address ipv6_prefix
default ipv6 hardware fib aggregate-address ipv6_prefix
```

Parameters

- `ipv6_prefix` IPv6 prefix that is restricted from the hardware routing table (CIDR notation).

Example

These commands configure a hardware routing restriction for an IPv6 prefix, then displays that restriction.

```
switch(config)#ipv6 hardware fib aggregate-address fd77:4890:5313:ffed::/64
summary-only software-forward
switch(config)#show ipv6 hardware fib aggregate-address
Codes: S - Software Forwarded
S  fd77:4890:5313:ffed::/64

switch(config)#
```
13.2.4.10 ipv6 hardware fib ecmp resilience

The `ipv6 hardware fib ecmp resilience` command configures a fixed number of next hop entries in the hardware ECMP table for the specified IPv6 address prefix. In addition to specifying the maximum number of next hop addresses that the table can contain for the prefix, the command introduces a redundancy factor that allows duplication of each next hop address. The fixed table space for the address is the maximum number of next hops multiplied by the redundancy factor.

The default method of adding or removing next hop entries when required by the active hashing algorithm leads to inefficient management of the ECMP table, which can result in the rerouting of packets to different next hops that breaks TCP packet flows. Implementing fixed table entries for a specified IP address allows data flows that are hashed to a valid next hop number to remain intact. Additionally, traffic is evenly distributed over a new set of next hops.

The `no ipv6 hardware fib ecmp resilience` and `default ipv6 hardware fib ecmp resilience` commands restore the default hardware ECMP table management by removing the `ipv6 hardware fib ecmp resilience` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ipv6 hardware fib ecmp resilience net_prfx capacity nhop_max redundancy duplicates
no ipv6 hardware fib ecmp resilience net_addr
default ipv6 hardware fib ecmp resilience net_addr
```

**Parameters**
- `net_prfx` IPv6 address prefix managed by command.
- `nhop_max` Specifies maximum number of nexthop entries for specified IP address prefix. Value range varies by platform:
  - Helix: `<2 to 64>`
  - Trident: `<2 to 32>`
  - Trident II: `<2 to 64>`
- `duplicates` Specifies the redundancy factor. Value ranges from 1 to 128.

**Example**

This command configures a hardware ECMP table space of 15 entries for the IPv6 address `2001:db8:0::/64`. A maximum of five nexthop addresses can be specified for the address. When the table contains five nexthop addresses, each appears in the table three times. When the table contains fewer than five nexthop addresses, each is duplicated until the 15 table entries are filled.

```
switch(config)#ipv6 hardware fib ecmp resilience 2001:db8:0::/64 capacity 5 redundancy 3
```
13.2.4.11  ipv6 hardware fib nexthop-index

The `ipv6 hardware fib nexthop-index` command deterministically selects the next hop used for ECMP routes. By default, routes that are created statically through the CLI or dynamically through routing protocols are initially stored in software routing tables, then entered in the hardware routing table by the routing agent. This command specifies the method of creating an index-offset number that points to the next hop from the list of the route’s ECMP next hops.

The index-offset is calculated by adding the next hop index to a prefix offset.

- **Next hop index**: specified in the command.
- **Prefix offset**: the least significant bits of the route’s prefix.

The command specifies the number of bits that comprise the prefix offset. The prefix offset is set to the prefix when the command specifies a prefix size larger than the prefix. If the command specifies an prefix size of zero, the prefix-offset is also zero and the index-offset is set to the next hop index.

When the index-offset is greater than the number of next hops in the table, the position of the next hop is the remainder of the division of the index-offset by the number of next hop entries.

The `no ipv6 hardware fib nexthop-index` and `default ipv6 hardware fib nexthop-index` commands remove the specified nexthop used for ECMP routes by removing the `ipv6 hardware fib nexthop-index` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

`ipv6 hardware fib nexthop nxthop_index[PREFIX]`

`no ipv6 hardware fib nexthop`

`default ipv6 hardware fib nexthop`

**Parameters**

- **nxthop_index** specifies the next hop index. Value ranges from 0 to 32.
- **PREFIX** Number of bits of the route’s prefix to use as the prefix-offset. Value ranges from 0 to 64.
  - **no parameter** The prefix offset is set to zero.
  - **prefix-bits 0 to 64** Specifies the number bits to use as the prefix-offset.

**Example**

This command specifies the next hop from the list of ECMP next hops for the route.

```
switch(config)#ipv6 hardware fib nexthop-index 5 prefix-bits 10
switch>show ip
IP Routing : Enabled
IP Multicast Routing : Disabled
VRRP: Configured on 0 interfaces

IPv6 Unicast Routing : Enabled
IPv6 ECMP Route support : False
IPv6 ECMP Route nexthop index: 5
IPv6 ECMP Route num prefix bits for nexthop index: 10
switch>
```
13.2.4.12  ipv6 nd managed-config-flag

The `ipv6 nd managed-config-flag` command causes the managed address configuration flag to be set in IPv6 RA packets transmitted from the configuration mode interface.

The `no ipv6 nd managed-config-flag` and `default ipv6 nd managed-config-flag` commands restore the default setting where the managed address configuration flag is not set in IPv6 RA packets transmitted by the interface by removing the corresponding `ipv6 nd managed-config-flag` command from `running-config`.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax
`ipv6 nd managed-config-flag`
`no ipv6 nd managed-config-flag`
`default ipv6 nd managed-config-flag`

Example
These commands cause the managed address configuration flag to be set in IPv6 RA packets sent from `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-V1200)#ipv6 nd managed-config-flag
switch(config-if-V1200)#
```
13.2.4.13  ipv6 nd ns-interval

The ipv6 nd ns-interval command configures the interval between IPv6 Neighbor Solicitation (NS) transmissions from the configuration mode interface.

The no ipv6 nd ns-interval and default ipv6 nd ns-interval commands return the IPv6 NS transmission interval for the configuration mode interface to the default value of 1000 milliseconds by removing the corresponding ipv6 nd ns-interval command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax
ipv6 nd ns-interval period
no ipv6 nd ns-interval
default ipv6 nd ns-interval

Parameter
period  interval in milliseconds between successive IPv6 neighbor solicitation transmissions. Values range from 1000 to 4294967295. The default period is 1000 milliseconds.

Example
This command configures a neighbor solicitation transmission interval of 30 seconds on interface vlan 200.

switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ns-interval 30000
switch(config-if-Vl200)#
13.2.4.14  ipv6 nd other-config-flag

The `ipv6 nd other-config-flag` command configures the configuration mode interface to send IPv6 RAs with the *other stateful configuration* flag set.

The `no ipv6 nd other-config-flag` and `default ipv6 nd other-config-flag` commands restore the default setting by removing the corresponding `ipv6 nd other-config-flag` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `ipv6 nd other-config-flag`
- `no ipv6 nd other-config-flag`
- `default ipv6 nd other-config-flag`

**Example**

These commands configure the switch to set the other stateful configuration flag in advertisements sent from `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd other-config-flag
switch(config-if-Vl200)#
```

13.2.4.15  ipv6 nd prefix

The `ipv6 nd prefix` command configures neighbor discovery Router Advertisements (RAs) prefix inclusion for RAs sent from the configuration mode interface.

By default, all prefixes configured as IPv6 addresses are advertised in the interface's RAs. The `ipv6 nd prefix` command with the `no-advertise` option prevents advertising of the specified prefix without affecting the advertising of other prefixes specified as IPv6 addresses. When an interface configuration includes at least one `ipv6 nd prefix` command that enables prefix advertising, RAs advertise only prefixes specified through `ipv6 nd prefix` commands.

Commands enabling prefix advertising also specify the advertised valid and preferred lifetime periods. Default periods are 2,592,000 (valid) and 604,800 (preferred) seconds.

The `no ipv6 nd prefix` and `default ipv6 nd prefix` commands remove the corresponding `ipv6 nd prefix` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ipv6 nd prefix ipv6_prefix LIFETIME [FLAGS]
nipv6 nd prefix ipv6_prefix no-advertise
no ipv6 nd prefix ipv6_prefix
default ipv6 nd prefix ipv6_prefix
```

**Parameters**

- `ipv6_prefix` IPv6 prefix (CIDR notation).
- `no-advertise` Prevents advertising of the specified prefix.
- `LIFETIME` Period that the specified IPv6 prefix is advertised (seconds). Options include:
  - `valid preferred` Two values that set the `valid` and `preferred` lifetime periods.
  - `valid` One value that sets the `valid` lifetime. The `preferred` lifetime is set to the default value.
  - `no parameter` The `valid` and `preferred` lifetime periods are set to their default values.

Options for `valid`: 0 to 4294967295 and `infinite`. Default value is 2592000. Options for `preferred`: 0 to 4294967295 and `infinite`. The default value is 604800. The maximum value (4294967295) and `infinite` are equivalent settings.

- `FLAGS` `on-link` and `autonomous address-configuration` flag values in RAs.
  - `no parameter` both flags are set.
  - `no-autoconfig` `autonomous address-configuration` flag is reset.
  - `no-onlink` `on-link` flag is reset.
  - `no-autoconfig no-onlink` both flags are reset.
  - `no-onlink no-autoconfig` both flags are reset.

**Example**
These commands enable neighbor discovery advertising for IPv6 address \texttt{3012:D678::/64}, on \texttt{interface vlan 200}, specifying a valid lifetime of \texttt{1,296,000} seconds and the default preferred lifetime.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd prefix 3012:D678::/64 1296000
```
13.2.4.16  ipv6 nd ra disabled

The *ipv6 nd ra disabled* command suppress IPv6 Router Advertisement (RA) transmissions on the configuration mode interface. By default, only unsolicited RAs that are transmitted periodically are suppressed. The **all** option configures the switch to suppress all RAs, including those responding to a router solicitation.

The *no ipv6 nd ra disabled* and *default ipv6 nd ra disabled* commands restore the transmission of RAs on the configuration mode interface by deleting the corresponding *ipv6 nd ra disabled* command from *running-config*.

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```
ipv6 nd ra disabled [SCOPE]
no ipv6 nd ra disabled
default ipv6 nd ra disabled
```

**Parameters**

- **SCOPE** specifies the RAs that are suppressed.
  - **no parameter** Periodic unsolicited RAs are suppressed.
  - **all** All RAs are suppressed.

**Example**

This command suppresses all RAs on *interface vlan 200*.

```
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 nd ra disabled all
switch(config-vl200)#
```
13.2.4.17 ipv6 nd ra dns-server

The `ipv6 nd ra dns-server` command configures the IPv6 address of a preferred Recursive DNS Server (RDNSS) for the command mode interface to include in its neighbor-discovery Router Advertisements (RAs). Including RDNSS information in RAs provides DNS server configuration for connected IPv6 hosts without requiring DHCPv6.

Multiple servers can be configured on the interface by using the command repeatedly. A lifetime value for the RDNSS can optionally be specified with this command, and overrides any default value configured for the interface using the `ipv6 nd ra dns-servers lifetime` command.

The `no ipv6 nd ra dns-server` and `default ipv6 nd ra dns-server` commands remove the corresponding `ipv6 nd ra dns-server` command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax

`ipv6 nd ra dns-server ipv6_addr SERVER_LIFE`

`no ipv6 nd ra dns-server ipv6_addr`

`default ipv6 nd ra dns-server ipv6_addr`

Parameters

- `ipv6_addr` RDNSS address to be included in RAs from the command mode interface.
- `SERVER_LIFE` maximum lifetime value for the specified RDNSS entry. This value overrides any default lifetime value. Value should be between the RA interval configured on the interface and two times that interval. Options include:
  - `no parameter` lifetime period is the default lifetime period configured on the interface. If no lifetime period is configured on the interface, the default value is 1.5 times the maximum RA interval set by the `ipv6 nd ra interval` command.
  - `lifetime 0` the configured RDNSS is not to be used.
  - `lifetime 1 to 4294967295` specifies the lifetime period for this RDNSS in seconds.

Example

This command configures the RDNSS at `2001:0db8:0:1::1` as a preferred RDNSS for `interface vlan 200` to include in its neighbor-discovery route advertisements, and sets its lifetime value to 300 seconds.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra dns-server 2001:0db8:0:1::1 lifetime 300
switch(config-if-Vl200)#
```
Layer 3 Configuration

13.2.4.18  ipv6 nd ra dns-servers lifetime

The **ipv6 nd ra dns-servers lifetime** command sets the default value that the configuration mode interface uses for the lifetime of any Recursive DNS Server (RDNSS) configured on the interface. A lifetime value set for an individual RDNSS overrides this value. The lifetime value is the maximum amount of time after a route advertisement packet is sent that the RDNSS referenced in the packet may be used for name resolution.

The **no ipv6 nd ra dns-servers lifetime** and **default ipv6 nd ra dns-servers lifetime** commands remove the default lifetime value from the interface by removing the corresponding **ipv6 nd ra dns-servers lifetime** command from **running-config**. When there is no default RDNSS lifetime value configured on the interface, an RDNSS without a custom lifetime value will default to 1.5 times the RA interval configured on the interface. A lifetime of zero seconds means that the RDNSS must not be used for name resolution.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- **ipv6 nd ra dns-servers lifetime** *period*
- **no ipv6 nd ra dns-servers lifetime**
- **default ipv6 nd ra dns-servers lifetime**

**Parameters**

- **period** the RDNSS lifetime value for the configuration mode interface. Options include:
  - **0** any RDNSS configured on the command mode interface without a custom lifetime value must not be used.
  - **1 to 4294967295** maximum RDNSS lifetime value for the configuration mode interface. This value is overridden by any lifetime value set with the **ipv6 nd ra dns-server** command. Should be between the router advertisement interval configured on the interface and two times that interval.

**Example**

This command sets the default RDNSS maximum lifetime value for **vlan 200** to **350** seconds.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra dns-servers lifetime 350
switch(config-if-Vl200)#
```
13.2.4.19  ipv6 nd ra dns-suffix

The `ipv6 nd ra dns-suffix` command creates a DNS Search List (DNSSL) for the command mode interface to include in its neighbor-discovery Router Advertisements as defined in RFC 6106. The DNSSL contains the domain names of DNS suffixes for IPv6 hosts to append to short, unqualified domain names for DNS queries.

Multiple DNS domain names can be added to the DNSSL by using the command repeatedly. A lifetime value for the DNSSL can optionally be specified with this command, and overrides any default value configured for the interface using the `ipv6 nd ra dns-suffixes lifetime` command.

The `no ipv6 nd ra dns-suffix` and `default ipv6 nd ra dns-suffix` commands remove the corresponding `ipv6 nd ra dns-suffix` command from `running-config`.

Command Mode

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

Command Syntax

```
ipv6 nd ra dns-suffix domain SUFFIX_LIFE
no ipv6 nd ra dns-suffix ipv6_addr
default ipv6 nd ra dns-suffix ipv6_addr
```

Parameters

- `domain`  domain suffix for IPv6 hosts to append to short, unqualified domain names for DNS queries. Suffix must contain only alphanumeric characters, "." and "-", and must begin and end with an alphanumeric character.
- `SUFFIX_LIFE`  maximum lifetime value for the specified domain suffix. This value overrides any default lifetime value. Value should be between the RA interval configured on the interface and two times that interval. Options include:
  - `no parameter`  lifetime period is the default lifetime period configured on the interface. If no lifetime period is configured on the interface, the default value is 1.5 times the maximum RA interval set by the ipv6 nd ra interval command.
  - `lifetime 0`  the configured domain suffix is not to be used.
  - `lifetime 1 to 4294967295`  specifies the lifetime period for this domain suffix in seconds.

Example

These commands create a DNSSL for `interface vlan 200` to include in its neighbor-discovery route advertisements, and set its lifetime value to 300 seconds.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra dns-suffix test.com lifetime 300
switch(config-if-Vl200)#
```
13.2.4.20 ipv6 nd ra dns-suffixes lifetime

The **ipv6 nd ra dns-suffixes lifetime** command sets the default value that the configuration mode interface uses for the lifetime of any DNS Search List (DNSSL) configured on the interface. A lifetime value set for an individual DNSSL overrides this value. The lifetime value is the maximum amount of time after a route advertisement packet is sent that the DNSSL included in the packet may be used for name resolution.

The **no ipv6 nd ra dns-suffixes lifetime** and **default ipv6 nd ra dns-suffixes lifetime** commands remove the default lifetime value from the interface by removing the corresponding **ipv6 nd ra dns-suffixes lifetime** command from **running-config**. When there is no default DNSSL lifetime value configured on the interface, a DNSSL without a custom lifetime value will default to 1.5 times the RA interval configured on the interface. A lifetime of zero seconds means that the DNSSL must not be used for name resolution.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ipv6 nd ra dns-suffixes lifetime <period>
no ipv6 nd ra dns-suffixes lifetime
default ipv6 nd ra dns-suffixes lifetime
```

**Parameters**

- **period** the DNSSL lifetime value for the configuration mode interface. Options include:
  - **0** any DNSSL configured on the command mode interface without a custom lifetime value must not be used.
  - **1 to 4294967295** maximum DNSSL lifetime value for the configuration mode interface. This value is overridden by any lifetime value set with the **ipv6 nd ra dns-suffix** command. Should be between the RA interval configured on the interface and two times that interval.

**Example**

This command sets the default DNSSL maximum lifetime value for **interface vlan 200** to **350** seconds.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra dns-suffixes lifetime 350
switch(config-if-Vl200)#
```
13.2.4.21  ipv6 nd ra hop-limit

The ipv6 nd ra hop-limit command sets a suggested hop-limit value to be included in Router Advertisement (RA) packets. The hop-limit value is to be used by attached hosts in outgoing packets.

The no ipv6 nd ra hop-limit and default ipv6 nd ra hop-limit commands remove the corresponding ipv6 nd ra hop-limit command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax

ipv6 nd ra hop-limit quantity

no ipv6 nd ra hop-limit lifetime

default ipv6 nd ra hop-limit lifetime

Parameters

quantity  the hop-limit value to be included in RA packets sent by the configuration mode interface. Options include:

• 0  indicates that outgoing packets from attached hosts are to be immediately discarded.

• 1 to 255  number of hops. The default value is 64.

Example

These commands include a hop-limit value of 100 in RA packets sent by interface vlan 200.

switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra hop-limit
switch(config-if-Vl200)#
13.2.4.22  ipv6 nd ra interval

The `ipv6 nd ra interval` command configures the interval between IPv6 Router Advertisement transmissions from the configuration mode interface.

The `no ipv6 nd ra interval` and `default ipv6 nd ra interval` commands return the IPv6 RA transmission interval for the configuration mode interface to the default value of 200 seconds by removing the corresponding `ipv6 nd ra interval` command from `running-config`.

Command Mode

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

Command Syntax

```
ipv6 nd ra interval [SCALE] ra_period [minimum_period]
no ipv6 nd ra interval
default ipv6 nd ra interval
```

Parameters

- **SCALE**  timescale in which command parameter values are expressed.
  - `no parameter`  seconds.
  - `msec`  milliseconds.
  - `ra_period`  maximum interval between successive IPv6 RA transmissions. The default period is 200 seconds.
    - `4 - 1800`  valid range when `SCALE` is set to default value (seconds).
    - `500 - 1800000`  valid range when `SCALE` is set to `msec`.
  - `minimum_period`  minimum interval between successive IPv6 RA transmissions. Must be smaller than `ra_period`. By default, a minimum period is not defined.
    - `no parameter`  Command does not specify a minimum period.
    - `3 - 1799`  valid range when `scale` is set to default value (seconds).
    - `375 - 1799999`  valid range when `scale` is set to `msec`.

Example

These commands configure a RA transmission interval of 60 seconds on VLAN interface `interface vlan 200`, then displays the interface status.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra interval 60
switch(config-if-Vl200)#show active
interface Vlan200
  ipv6 nd ra interval 60
switch(config-if-Vl200)#
```
13.2.4.23  ipv6 nd ra lifetime

The `ipv6 nd ra lifetime` command specifies the value that the switch places in the `router lifetime` field of IPv6 Router Advertisements sent from the configuration mode interface.

If the value is set to 0, IPv6 peers connected to the specified interface will remove the switch from their lists of default routers. Values greater than 0 indicate the time in seconds that peers should keep the router on their default router lists without receiving further RAs from the switch. Unless the value is 0, the router lifetime value should be equal to or greater than the interval between unsolicited RAs sent on the interface.

The `no ipv6 nd ra lifetime` and `default ipv6 nd ra lifetime` commands return the IPv6 RA lifetime data entry field to the default value of 1800 seconds by removing the corresponding `ipv6 nd ra lifetime` command from `running-config`.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Management Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax

```
ipv6 nd ra lifetime ra_lifetime
no ipv6 nd ra lifetime
default ipv6 nd ra lifetime
```

Parameters

`ra_lifetime`  router lifetime period (seconds). Default value is 1800. Options include:

- 0  Router should not be considered as a default router.
- 1 - 65535  Lifetime period advertised in RAs. Should be greater than or equal to the interval between IPv6 RA transmissions from the configuration mode interface as set by the `ipv6 nd ra interval` command.

Example

This command configures the switch to enter 2700 in the router lifetime field of RAs transmitted from `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd ra lifetime 2700
switch(config-if-Vl200)#show active
interface Vlan20
  ipv6 nd ra lifetime 2700
switch(config-if-Vl200)#
```
13.2.4.24  ipv6 nd ra mtu suppress

The `ipv6 nd ra mtu suppress` command suppresses the Router Advertisement (RA) MTU option on the configuration mode interface. The MTU option causes an identical MTU value to be advertised by all nodes on a link. By default, the RA MTU option is not suppressed.

The `no ipv6 nd ra mtu suppress` and `default ipv6 nd ra mtu suppress` commands restores the MTU option setting to enabled by for the configuration mode interface by removing the corresponding `ipv6 nd ra mtu suppress` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `ipv6 nd ra mtu suppress`
- `no ipv6 nd ra mtu suppress`
- `default ipv6 nd ra mtu suppress`

**Example**

This command suppresses the MTU option on `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-vl200)#ipv6 nd ra mtu suppress
switch(config-vl200)#
```
13.2.4.25 ipv6 nd reachable-time

The `ipv6 nd reachable-time` command specifies the time period that the switch includes in the reachable time field of RAs sent from the configuration mode interface. The reachable time defines the period that a remote IPv6 node is considered reachable after a reachability confirmation event.

RAs that advertise zero seconds indicate that the router does not specify a reachable time. The default advertisement value is 0 seconds. The switch reachability default period is 30 seconds.

The `no ipv6 nd reachable-time` and `default ipv6 nd reachable-time` commands restore the entry of the default value (0) in RAs sent from the configuration mode interface by deleting the corresponding `ipv6 nd reachable-time` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
- `ipv6 nd reachable-time period`
- `no ipv6 nd reachable-time`
- `default ipv6 nd reachable-time`

**Parameter**
- `period` Reachable time value (milliseconds). Value ranges from 0 to 4294967295. Default is 0.

**Example**
These commands configure the entry of 25000 (25 seconds) in the reachable time field of RAs sent from `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd reachable-time 25000
interface Vlan200
    ipv6 address fd7a:4321::1/64
    ipv6 nd reachable-time 25000
switch(config-if-Vl200)#
```
13.2.4.26  ipv6 nd router-preference

The `ipv6 nd router-preference` command specifies the value that the switch enters in the Default Router Preference (DRP) field of Router Advertisements (RAs) that it sends from the configuration mode interface. The default field entry value is `medium`.

The `no ipv6 nd router-preference` and `default ipv6 nd router-preference` commands restore the switch to enter the default DRP field value of `medium` in RAs sent from the configuration mode interface by deleting the corresponding `ipv6 nd router-preference` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Management Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ipv6 nd router-preference RANK
no ipv6 nd router-preference
default ipv6 nd router-preference
```

**Parameters**

- **RANK**  
  Router preference value. Options include:
  - `high`
  - `low`
  - `medium`

**Example**

This command configures the switch as a medium preference router on RAs sent from `interface vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 nd router-preference medium
switch(config-if-Vl200)#
```
13.2.4.27  ipv6 neighbor cache persistent

The `ipv6 neighbor cache persistent` command restores the IPv6 neighbor cache after reboot. The `no ipv6 neighbor cache persistent` and `default ipv6 neighbor cache persistent` commands remove the ARP cache persistent configuration from the `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

- `ipv6 neighbor cache persistent`
- `no ipv6 neighbor cache persistent`
- `default ipv6 neighbor cache persistent`

**Example**
This command restores the ipv6 neighbor cache after reboot.

```
switch(config)#ipv6 neighbor cache persistent
switch(config)#
```
13.2.4.28  ipv6 neighbor

The `ipv6 neighbor` command creates an IPv6 neighbor discovery cache static entry. The command converts pre-existing dynamic cache entries for the specified address to static entries.

The `no ipv6 neighbor` and `default ipv6 neighbor` commands remove the specified static entry from the IPv6 neighbor discovery cache and delete the corresponding `ipv6 neighbor` command from `running-config`. These commands do not affect any dynamic entries in the cache.

Command Mode
Global Configuration

Command Syntax

```
ipv6 neighbor ipv6_addr PORT mac_addr
no ipv6 neighbor ipv6_address PORT
default ipv6 neighbor ipv6_addr PORT
```

Parameters

- `ipv6_addr` Neighbor’s IPv6 address.
- `PORT` Interface through which the neighbor is accessed. Options include:
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.
  - `vxlan vx_num` VXLAN interface specified by `vx_num`.
- `mac_addr` Neighbor’s data-link (hardware) address. (48-bit dotted hex notation – H.H.H).

Example

This command will add a static entry to the neighbor discovery cache for the neighbor located at `3100:4219::3EF2` with hardware address `0100.4EA1.B100` and accessible through `vlan 200`.

```
switch(config)#ipv6 neighbor 3100:4219::3EF2 vlan 200 0100.4EA1.B100
switch(config)#
```
13.2.4.29  ipv6 route

The ipv6 route command creates an IPv6 static route. The destination is a IPv6 prefix; the source is an IPv6 address or a routable interface port. When multiple routes exist to a destination prefix, the route with the lowest administrative distance takes precedence.

By default, the administrative distance assigned to static routes is 1. Assigning a higher administrative distance to a static route configures it to be overridden by dynamic routing data. For example, a static route with a distance value of 200 is overridden by OSPF intra-area routes, which have a default distance of 110.

The command provides these methods of designating the nexthop location:

- null0: Traffic to the specified destination is dropped.
- IPv6 gateway: Switch identifies egress interface by recursively resolving the next-hop.
- Egress interface: Switch assumes destination subnet is directly connected to interface; when routing to any subnet address, the switch sends an ARP request to find the MAC address for the first packet.
- Combination Egress interface and IPv6 gateway: Switch does not assume subnet is directly connected to interface; the only ARP traffic is for the nexthop address for the first packet on the subnet. Combination routes are not recursively resolved.

Multiple routes that are configured to the same destination with the same administrative distance comprise an Equal Cost Multi-Path (ECMP) route. The switch attempts to spread outbound traffic across all ECMP route paths equally. All ECMP paths are assigned the same tag value; commands that change the tag value of any ECMP path change the tag value of all paths in the ECMP.

The no ipv6 route and default ipv6 route commands delete static routes by removing the corresponding ipv6 route statements from running-config. Commands not including a source delete all statements to the destination. Only statements with parameters that match specified command arguments are deleted. Parameters that are not in the command line are not evaluated.

Command Mode
Global Configuration

Command Syntax
ipv6 route dest_prefix NEXTHOP [DISTANCE][TAG_OPT][RT_NAME]
no ipv6 route dest_prefix [nexthop_addr][DISTANCE]
default ipv6 route dest_prefix [nexthop_addr][DISTANCE]

Parameters
- dest_prefix Destination IPv6 prefix (CIDR notation).
- NEXTHOP Access method of next hop device. Options include:
  - null0 Null0 interface – route is dropped.
  - nexthop_addr IPv6 address of nexthop device.
  - ethernet e_num Ethernet interface specified by e_num.
  - loopback l_num Loopback interface specified by l_num.
  - management m_num Management interface specified by m_num.
  - port-channel p_num Port-channel interface specified by p_num.
  - vlan v_num VLAN interface specified by v_num.
  - vxlan vx_num VXLAN interface specified by vx_num.
  - ethernet e_num nexthop_addr Combination route (Ethernet interface and gateway).
  - loopback l_num nexthop_addr Combination route (loopback interface and gateway).
  - management m_num nexthop_addr Combination route (management interface and gateway).
• **port-channel p_num nexthop_addr** Combination route (port channel interface and gateway).
• **vlan v_num nexthop_addr** Combination route (VLAN interface and gateway).
• **vxlan vx_num nexthop_addr** Combination route (VXLAN interface and gateway).
• **DISTANCE** administrative distance assigned to route. Options include:
  • **no parameter** route assigned default administrative distance of one.
  • **1 to 255** The administrative distance assigned to route.
• **TAG_OPT** static route tag. Options include:
  • **no parameter** assigns default static route tag of 0.
  • **tag 0 to 4294967295** Static route tag value.
• **RT_NAME** Associates descriptive text to the route. Options include:
  • **no parameter** No text is associated with the route.
  • **name descriptive_text** The specified text is assigned to the route.

**Example**

This command creates an IPv6 static route.

```
switch(config)#ipv6 route 10:23:31:00:01:32:93/24 vlan 300
```
13.2.4.30 **ipv6 unicast-routing**

The `ipv6 unicast-routing` command enables the forwarding of IPv6 unicast packets. When routing is enabled, the switch attempts to deliver inbound packets to destination addresses by forwarding them to interfaces or next hop addresses specified by the IPv6 routing table.

The `no ipv6 unicast-routing` and `default ip ipv6 unicast-routing` commands disable IPv6 unicast routing by removing the `ipv6 unicast-routing` command from `running-config`. Dynamic routes added by routing protocols are removed from the routing table. Static routes are preserved by default; the `delete-static-routes` option removes static entries from the routing table.

IPv6 unicast routing is disabled by default.

**Command Mode**

Global Configuration

**Command Syntax**

- `ipv6 unicast-routing`
- `no ipv6 unicast-routing [DELETE_ROUTES]`
- `default ipv6 unicast-routing [DELETE_ROUTES]`

**Parameters**

- **DELETE_ROUTES**  Resolves routing table static entries when routing is disabled.
- **no parameter**  Routing table retains static entries.
- **delete-static-routes**  Static entries are removed from the routing table.

**Example**

This command enables IPv6 unicast-routing.

```
switch(config)#ipv6 unicast-routing
switch(config)#
```
### 13.2.4.31 ipv6 verify

The `ipv6 verify` command configures Unicast Reverse Path Forwarding (uRPF) for inbound IPv6 packets on the configuration mode interface. uRPF verifies the accessibility of source IP addresses in packets that the switch forwards.

uRPF defines two operational modes: strict mode and loose mode.

- **Strict mode**: uRPF also verifies that a packet is received on the interface that its routing table entry specifies for its return packet.
- **Loose mode**: uRPF validation does not consider the inbound packet’s ingress interface.

The `no ipv6 verify` and `default ipv6 verify` commands disable uRPF on the configuration mode interface by deleting the corresponding `ipv6 verify` command from `running-config`.

#### Command Mode

<table>
<thead>
<tr>
<th>Interface-Ethernet Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface-Loopback Configuration</td>
</tr>
<tr>
<td>Interface-Management Configuration</td>
</tr>
<tr>
<td>Interface-Port-Channel Configuration</td>
</tr>
<tr>
<td>Interface-VLAN Configuration</td>
</tr>
</tbody>
</table>

#### Command Syntax

- `ipv6 verify unicast source reachable-via RPF_MODE`
- `no ipv6 verify unicast`
- `default ipv6 verify unicast`

#### Parameters

- **RPF_MODE**  Specifies the uRPF mode. Options include:
  - `any`  Loose mode.
  - `rx`  Strict mode.
  - `rx allow-default`  Strict mode. All inbound packets are forwarded if a default route is defined.

#### Guidelines

The first IPv6 uRPF implementation briefly disables IPv6 unicast routing. Subsequent `ip verify` commands on any interface do not disable IPv6 routing.

#### Example

This command enables uRPF strict mode on `interface vlan 100`. When a default route is configured on the interface, all inbound packets are checked as valid.

```
switch(config)#interface vlan 100
switch(config-if-Vl100)#ipv6 verify unicast source reachable-via rx allow-default
switch(config-if-Vl100)#show active
interface Vlan100
     ipv6 verify unicast source reachable-via rx allow-default
switch(config-if-Vl100)#
```
13.2.4.32  ipv6 dhcp snooping

The `ipv6 dhcp snooping` command enables DHCP snooping globally on the switch.

The `no ipv6 dhcp snooping` and `default ipv6 dhcp snooping` commands disable global DHCP snooping by removing the ipv6 dhcp snooping command from `running-config`.

Command Mode
Global Configuration

Command Syntax

`ipv6 dhcp snooping [remote-id option | vlan [$ | vlan-range]]`
`no ipv6 dhcp snooping [remote-id option | vlan [$ | vlan-range]]`
`default ipv6 dhcp snooping [remote-id option | vlan [$ | vlan-range]]`

Parameters

- `remote-id option` configures the remote ID option.
- `vlan` enables IPv6 DHCP snooping for a specific VLAN. Numbers range from 1 to 4094.
- `$` end of range.
- `vlan-range` VLANs based on the snooping enabled. Formats include a number, a number range, or a comma-delimited list of numbers and ranges. Numbers range from 1 to 4094.

Examples

- The following configuration enables IPv6 DHCP snooping feature at the global level.

```
switch(config)#ipv6 dhcp snooping
switch(config)#ipv6 dhcp snooping remote-id option
switch(config)#ipv6 dhcp snooping vlan <vlan|vlan-range>
```

- The following command display IPv6 DHCP snooping state.

```
switch(config)#ipv6 dhcp snooping
DHCPv6 Snooping is enabled
DHCPv6 Snooping is operational
DHCPv6 Snooping is configured on following VLANs:
   2789-2790
DHCPv6 Snooping is operational on following VLANs:
   2789
Insertion of Option-37 is enabled
```
13.2.4.33  pim ipv6 sparse-mode

The `pim ipv6 sparse-mode` command enables PIM Sparse Mode (PIM-SM) and IGMP (router mode) on the configuration mode interface.

**Note:** PIM and multicast border router (MBR) must be mutually exclusive on an interface. If the interface is configured as an MBR, do not enable PIM on the interface.

The `no pim ipv6 sparse-mode` and `default pim ipv6 sparse-mode` commands restore the default PIM and IGMP (router mode) settings of `disabled` on the configuration mode interface by removing the `pim ipv6 sparse-mode` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel
Configuration Interface-VLAN Configuration

**Command Syntax**

- `pim ipv6 sparse-mode`
- `no pim ipv6`
- `no pim ipv6 sparse-mode`
- `default pim ipv6`
- `default pim ipv6 sparse-mode`

**Example**

This command enables `pim ipv6 sparse-mode` on `interface vlan 4` interface.

```
switch(config)#interface vlan 4
switch(config-if-Vl4)#pim ipv6 sparse-mode
switch(config-if-Vl4)#
```
13.2.4.34 show ipv6 dhcp relay counters

The `show ipv6 dhcp relay counters` command displays the number of DHCP packets received, forwarded, or dropped on the switch and on all interfaces enabled as DHCP relay agents.

**Command Mode**
EXEC

**Command Syntax**
`show ipv6 dhcp relay counters`

**Example**
This command displays the IP DHCP relay counter table.

```
switch>show ipv6 dhcp relay counters
Dhcp Packets
Interface | Rcvd | Fwdd | Drop | Last Cleared
----------|------|------|------|---------------------
All Req   | 376  | 376  | 0    | 4 days, 19:55:12 ago
All Resp  | 277  | 277  | 0    |
Ethernet4 | 207  | 148  | 0    | 4 days, 19:54:24 ago
switch>
```
13.2.4.35  show ipv6 dhcp snooping counters

The `show ipv6 dhcp snooping counters` command displays counters that track the quantity of DHCP request and reply packets that the switch receives. Data is either presented for each VLAN or aggregated for all VLANs with counters for packets dropped.

**Command Mode**
EXEC

**Command Syntax**
`show ipv6 dhcp snooping counters [COUNTER_TYPE]`

**Parameters**
- **COUNTER_TYPE**  The type of counter that the command displays.
- **no parameter**  command displays counters for each VLAN.
- **debug**  command displays aggregate counters and drop cause counters.

**Examples**
- This command displays the number of DHCP packets sent and received on each VLAN.

```
switch#show ipv6 dhcp snooping counters
<table>
<thead>
<tr>
<th>Dhcpv6 Request Pkts</th>
<th>Dhcpv6 Reply Pkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vlan</td>
<td>Rcvd</td>
</tr>
<tr>
<td>-------</td>
<td>------</td>
</tr>
<tr>
<td>2789</td>
<td>1</td>
</tr>
</tbody>
</table>
```

- This command displays the number of DHCP packets sent on the switch.

```
switch#show ipv6 dhcp snooping counters debug

Counter | Snooping to Relay | Relay to Snooping |
----------|------------------|------------------|
Received  | 1                | 1                |
Forwarded | 1                | 1                |
Dropped  - Invalid VlanId | 0 | 0 |
Dropped  - Parse error | 0 | 0 |
Dropped  - Invalid Dhcp Optype | 0 | 0 |
Dropped  - Invalid Remote-ID Option | 0 | 0 |
Dropped  - Snooping disabled | 0 | 0 |

Last Cleared: 0:04:29 ago
```
13.2.4.36  show ipv6 dhcp snooping hardware

The `show ipv6 dhcp snooping hardware` command displays internal hardware DHCP snooping status on the switch.

Command Mode
EXEC

Command Syntax
`show ipv6 dhcp snooping hardware`

Example
This command displays DHCP snooping hardware status.

```bash
switch#show ipv6 dhcp snooping hardware
DHCPv6 Snooping is enabled
DHCPv6 Snooping is enabled on following VLANs:
  2789
  Vlans enabled per Slice
  Slice:  Linecard0-0
  2789
  Slice:  Linecard0-1
  2789
  Slice:  Linecard0-2
  2789
  Slice:  Linecard0-3
  2789
```
13.2.4.37  show ipv6 dhcp snooping

The show ipv6 dhcp snooping command displays information about the DHCP snooping configuration.

Command Mode
EXEC

Command Syntax
show ipv6 dhcp snooping

Related Commands
• ipv6 dhcp snooping
• show ipv6 dhcp snooping counters
• show ipv6 dhcp snooping hardware
• clear ipv6 dhcp snooping counters

Example
This command displays the switch’s DHCP snooping configuration.

```
switch#show ipv6 dhcp snooping
DHCPv6 Snooping is enabled
DHCPv6 Snooping is operational
DHCPv6 Snooping is configured on following VLANs:
  2789-2790
DHCPv6 Snooping is operational on following VLANs:
  2789
Insertion of Option-37 is enabled
```
13.2.4.38  show ipv6 hardware fib aggregate-address

The `show ipv6 hardware fib aggregate-address` command displays the IPv6 prefixes that are restricted from entry into the hardware routing table. The `ipv6 hardware fib aggregate-address` command configures IPv6 prefix restrictions.

Command Mode
EXEC

Command Syntax
`show ipv6 address fib aggregate-address [ADDRESS] [RESTRICTION]`

Parameters
- **ROUTE_FILTER** filters by IPv6 address. Options include:
  - `no parameter` Displays all routes.
  - `ipv6_addr` Command displays only specified address.
  - `ipv6_prefix` Command displays addresses filtered by specified prefix (CIDR notation).
- **RESTRICTION** filters by route restriction.
  - `no parameter` displays routes restricted from the hardware routing table.
  - `software-forward` displays routes restricted from the hardware routing table.

Example
This command displays the routes that are restricted from the hardware routing table.

```
switch> show ipv6 hardware fib aggregate-address
Codes: S - Software Forwarded
S  fd77:4890:5313:aaed::/64
S  fd77:4890:5313:ffed::/64
switch>
```
show ipv6 interface

The `ipv6 interface` command displays the status of specified routed interfaces that are configured for IPv6.

Command Mode
EXEC

Command Syntax
`show ipv6 interface [INTERFACE_NAME][INFO_LEVEL]`

Parameters
- **INTERFACE_NAME** interfaces for which command displays status.
  - no parameter all routed interfaces.
  - ethernet e_num Ethernet interface specified by e_num.
  - loopback l_num Loopback interface specified by l_num.
  - management m_num Management interface specified by m_num.
  - port-channel p_num Port-Channel Interface specified by p_num.
  - vlan v_num VLAN interface specified by v_num.
  - vxlan vx_num VXLAN interface specified by vx_num.
- **INFO_LEVEL** amount of information that is displayed. Options include:
  - no parameter command displays data block for each specified interface.
  - brief command displays table that summarizes IPv6 interface data.

Example
This command displays the status of `interface vlan 903`.

```
switch>show ipv6 interface vlan 903
Vlan903 is up, line protocol is up (connected)
  IPv6 is enabled, link-local is fe80::21c:73ff:fe01:21e/64
  Global unicast address(es):
    fd7a:629f:52a4:fe10::3, subnet is fd7a:629f:52a4:fe10::/64
  Joined group address(es):
    ff02::1
    ff02::1:ff01:21e
    ff02::1:ff00:3
    ff01::2
switch>
```
13.2.4.40  show ipv6 nd ra internal state

The `ipv6 nd ra internal state` command displays the state of the IPv6 Router Advertisement (RA) daemon for the specified routable interface.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 nd ra internal state [INTERFACE_NAME]`

**Parameters**

**INTERFACE_NAME**  interfaces for which command displays status.

- `no parameter`  all routed interfaces.
- `ethernet e_num`  Ethernet interface specified by `e_num`.
- `loopback l_num`  Loopback interface specified by `l_num`.
- `management m_num`  Management interface specified by `m_num`.
- `port-channel p_num`  Port-Channel Interface specified by `p_num`.
- `vlan v_num`  VLAN interface specified by `v_num`.
- `vxlan vx_num`  VXLAN interface specified by `vx_num`.

**Example**

This command displays the IPv6 RA daemon for `vlan 1243`.

```
switch>show ipv6 nd ra internal state vlan 1243
INTERFACE: Vlan3908
   ifindex : 0x00000021
   mtu : 9212
   numIcmpV6Addr : 2
   numPrefixToAdvertise : 0
   numPrefixToSuppress : 0
   RaSuppress : 0
   RsRepSuppress : 0
   raIntervalMaxMsec : 200000
   raIntervalMinMsec : 0
   managedConfigFlag : 0
   otherConfigFlag : 0
   raMtuSuppress : 0
   raLifetime : 1800
   reacheableTime : 0
   routerPreference : 0

   notSentIntfNotReady : 0
   numRaSent : 219
   numRaRcvd : 0
   numRaSuppressed : 0
   numRsRspSent : 0
   numRsRspSuppressed : 0
   numRsRspSuppressed : 0
   initialized : 1
switch>
```
13.2.4.41  show ipv6 neighbors

The `show ipv6 neighbors` command displays the IPv6 neighbor discovery cache. The command provides filters to restrict the list to a specified IPv6 address or routable interface.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 neighbors [PORT][SOURCE][INFO_LEVEL]
```

**Parameters**

- **PORT** Filters by interface through which neighbor is accessed. Options include:
  - `no parameter` all routed interfaces.
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-channel interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.
  - `vxlan vx_num` VXLAN interface specified by `vx_num`.

- **SOURCE** Filters by neighbor IPv6 address. Options include:
  - `<no parameter>` all IPv6 neighbors.
  - `ipv6_addr` IPv6 address of individual neighbor.

- **INFO_LEVEL** amount of information that is displayed. Options include:
  - `no parameter` command displays the discovery cache for the specified interfaces.
  - `summary` command displays summary information only.

**Example**

This command displays the IPv6 neighbor discovery cache for IPv6 address `fe80::21c:73ff:fe01:5fe1`.

```
switch>show ipv6 neighbors fe80::21c:73ff:fe01:5fe1
IPv6 Address                              Age Hardware Addr   State Interface
fe80::21c:73ff:fe01:5fe1                    0 001c.d147.8214   REACH E12
fe80::21c:73ff:fe01:5fe1                    0 001c.d147.8214   REACH Po999

fe80::21c:73ff:fe01:5fe1                    0 001c.d147.8214   REACH V1304
fe80::21c:73ff:fe01:5fe1                    0 001c.d147.8214   REACH V1305
fe80::21c:73ff:fe01:5fe1                    0 001c.d147.8214   REACH V1306
```
13.2.42  show ipv6 route age

The `show ipv6 route age` command displays the IPv6 route age to the specified IPv6 address or prefix.

**Command Mode**
EXEC

**Command Syntax**
`show ipv6 route ADDRESS age`

**Parameters**
ADDRESS filters routes by IPv6 address or prefix.

**Example**
This command displays the route age for the specified prefix.

```
switch>show ipv6 route 2001::3:0/11 age
IPv6 Routing Table - 74 entries
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP, R - RIP, A - Aggregate
C 2001::3:0/11 age 00:02:34
switch>
```
13.2.4.43  show ipv6 route host

The `show ipv6 route host` command displays all host routes in the IPv6 host forwarding table. Host routes are those whose destination prefix is the entire address (prefix = /128). Each displayed host route is labeled with its purpose:

- **F** static routes from the FIB.
- **A** routes to any neighboring host for which the switch has an ARP entry.
- **R** routes defined because the IP address is an interface address.

**Command Mode**
EXEC

**Command Syntax**

`show ipv6 route host`

**Example**

This command displays all IPv6 host routes in the host forwarding table.

```
switch> show ipv6 route host
R - receive  F - FIB,  A - attached
  F  ::1 to cpu
  A  fee7:48a2:0c11:1900:400::1 on Vlan102
  R  fee7:48a2:0c11:1900:400::2 to cpu
  F  fee7:48a2:0c11:1a00::b via fe80::21c:73ff:fe0b:a80e on Vlan3902
  R  fee7:48a2:0c11:1a00::17 to cpu
  F  fee7:48a2:0c11:1a00::20 via fe80::21c:73ff:fe0b:33e on Vlan3913
  F  fee7:48a2:0c11:1a00::22 via fe80::21c:73ff:fe01:5fe1 on Vlan3908
                          via fe80::21c:73ff:fe01:5fe1 on Vlan3902
switch>
```
13.2.4.44  show ipv6 route interface

The `show ipv6 route interface` command displays routing table entries on a specified routed port.

**Command Mode**
EXEC

**Command Syntax**
```
show ipv6 route [ADDRESS] interface PORT_NAME [INFO_LEVEL]
```

**Parameters**
ADDRESS, when present, is always listed first. All other parameters can be placed in any order.

- **ADDRESS** filters routes by IPv6 address or prefix.
  - `no parameter` all routing table entries.
  - `ipv6_address` routing table entries matching specified IPv6 address.
  - `ipv6_prefix` routing table entries matching specified IPv6 prefix (CIDR notation).
- **PORT_NAME** interfaces for which command displays status.
  - `ethernet e_num` Ethernet interface specified by `e_num`.
  - `loopback l_num` Loopback interface specified by `l_num`.
  - `management m_num` Management interface specified by `m_num`.
  - `port-channel p_num` Port-Channel Interface specified by `p_num`.
  - `vlan v_num` VLAN interface specified by `v_num`.
  - `vxlan vx_num` VXLAN interface specified by `vx_num`.
- **INFO_LEVEL** filters entries by next hop connection.
  - `no parameter` filters routes whose next hops are directly connected.
  - `detail` displays all routes.

**Example**

This command displays the IPv6 routes in *interface ethernet 8*.

```
switch>show ipv6 route interface ethernet 8
IPv6 Routing Table - 77 entries

```
13.2.4.45  show ipv6 route match tag

The `show ipv6 route match tag` command displays the route tag assigned to the specified IPv6 address or prefix. Route tags are added to static routes for use by route maps.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 route ADDRESS match tag`

**Parameters**

`ADDRESS` filters routes by IPv6 address or prefix.

**Example**

This command displays the route tag for the specified prefix.

```
switch>show ipv6 route 2001:0DB8::/64 match tag
IPv6 Routing Table - 74 entries
Codes: C - connected, S - static, K - kernel, O3 - OSPFv3, B - BGP, R - RIP, A B - BGP Aggregate, I L1 - IS-IS level 1, I L2 - IS-IS level 2, DH - DHCP, NG - Nexthop Group Static Route, M - Martian, DP - Dynamic Policy Route, L - VRF Leaked
C  2001:0DB8::/64 tag 0
switch>
```
13.2.4.46  show ipv6 route summary

The show ipv6 route summary command displays the information about the IPv6 routing table.

Command Mode
EXEC

Command Syntax
show ipv6 route summary

Example
This command displays the route source and the corresponding number of routes in the IPv6 routing table.

```
switch>show ipv6 route summary
Route Source    Number Of Routes
------------------ ----------------
    connected                      2
       static                        0
       ospf                            5
       bgp                                7
       isis                              0
       internal                         1
       attached                        0
       aggregate                       2
       Total Routes                    17
switch>
```
13.2.4.47  show ipv6 route

The `show ipv6 route` command displays IPv6 routing table entries that are in the Forwarding Information Base (FIB), including static routes, routes to directly connected networks, and dynamically learned routes. Multiple equal cost paths to the same prefix are displayed contiguously as a block, with the destination prefix displayed only on the first line.

The `show running-config` command displays all configured routes.

Command Mode

EXEC

Command Syntax

`show ipv6 route [ADDRESS][ROUTE_TYPE][INFO_LEVEL]`

Parameters

- **ADDRESS**, when present, is always listed first. All other parameters can be placed in any order.
  - **ADDRESS** filters routes by IPv6 address or prefix.
    - *no parameter* all routing table entries.
    - *ipv6_address* routing table entries matching specified IPv6 address.
    - *ipv6_prefix* routing table entries matching specified IPv6 prefix (CIDR notation).
  - **ROUTE_TYPE** filters routes by specified protocol or origin.
    - *no parameter* all routing table entries.
    - *aggregate* entries for BGP aggregate routes.
    - *bgp* entries added through BGP protocol.
    - *connected* entries for routes to networks directly connected to the switch.
    - *kernel* entries appearing in Linux kernel but not added by EOS software.
    - *isis* entries added through IS-IS protocol.
    - *ospf* entries added through OSPF protocol.
    - *static* entries added through CLI commands.
  - **INFO_LEVEL** Filters entries by next hop connection.
    - *no parameter* filters routes whose next hops are directly connected.
    - *detail* displays all routes.

Example

This command displays a route table entry for a specific IPv6 route.

```
switch>show ipv6 route fd7a:3418:52a4:fe18::/64
IPv6 Routing Table - 77 entries
Codes:  C - connected,  S - static,  K - kernel,  O - OSPF,  B - BGP,  R - RIP,  A - Aggregate

O  fd7a:3418:52a4:fe18::/64 [10/20]
   via fe80::21c:73ff:fe00:1319, Vlan3601
   via fe80::21c:73ff:fe00:1319, Vlan3602
   via fe80::21c:73ff:fe00:1319, Vlan3608
   via fe80::21c:73ff:fe0f:6a80, Vlan3610
   via fe80::21c:73ff:fe00:1319, Vlan3611

switch>
```
13.2.4.48  show platform fap mroute ipv6

The `show platform fap mroute ipv6` command enables PIM Sparse Mode (PIM-SM) and IGMP (router mode) on the configuration mode interface.

**Command Mode**

EXEC

**Command Syntax**

`show platform`

**Example**

This command enables PIM sparse mode on VLAN 4 interface.

```
switch# show platform fap mroute ipv6
Jericho0 Multicast Routes:

Layer 3 Configuration

13.2.4.49  show rib route ipv6

The `show rib route ipv6` command displays a list of IPv6 Routing Information Base (RIB) routes.

**Command Mode**

EXEC

**Command Syntax**

`show rib route ipv6 [vrf vrf_name] [PREFIX][ROUTE TYPE]`

**Parameters**

- `vrf vrf_name`  displays RIB routes from the specified VRF.
- `PREFIX`  displays routes filtered by the specified IPv6 information. Options include:
  - `ipv6_address`  displays RIB routes filtered by the specified IPv6 address.
  - `ipv6_subnet_mask`  displays RIB routes filtered by the specified IPv6 address and subnet mask.
  - `ipv6_prefix`  displays RIB routes filtered by the specified IPv6 prefix.
- `ROUTE TYPE`  displays routes filtered by the specified route type. Options include:
  - `bgp`  displays RIB routes filtered by BGP.
  - `connected`  displays RIB routes filtered by connected routes.
  - `dynamicPolicy`  displays RIB routes filtered by dynamic policy routes.
  - `host`  displays RIB routes filtered by host routes.
  - `isis`  displays RIB routes filtered by ISIS routes.
  - `ospf`  displays RIB routes filtered by OSPF routes.
  - `ospf3`  displays RIB routes filtered by OSPF3 routes.
  - `reserved`  displays RIB routes filtered by reserved routes.
  - `route-input`  displays RIB routes filtered by route-input routes.
  - `static`  displays RIB routes filtered by static routes.

**Examples**

- This command displays IPv6 RIB BGP routes.

```
switch# show rib route ipv6 bgp
VRF name: default, VRF ID: 0xfe, Protocol: bgp
Codes: C - Connected, S - Static, P - Route Input
B - BGP, 0 - Ospf, 03 - Ospf3, I - Isis
> - Best Route, * - Unresolved Nexthop
L - Part of a recursive route resolution loop
B  2001:10:1::/64 [200/42]
   via 2001:10:1::100 [0/1]

   via Ethernet1, directly connected
>B  2001:10:100:1::/64 [200/0]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
   via Ethernet1, directly connected
>B  2001:10:100:2::/64 [200/42]
   via 2001:10:1::100 [0/1]
   via Ethernet1, directly connected
switch#
```

- This command displays IPv6 RIB connected routes.

```
switch# show rib route ipv6 connected
VRF name: default, VRF ID: 0xfe, Protocol: connected
Codes: C - Connected, S - Static, P - Route Input
...
```

1827
B - BGP, 0 - Ospf, O3 - Ospf3, I - Isis
> - Best Route, * - Unresolved Nexthop

switch#
13.3 Ingress and Egress Per-Port for IPv4 and IPv6 Counters

This feature provides support for per-interface ingress and egress packet and byte counters for both IPv4 and IPv6.

This section describes Ingress and Egress per-port for IPv4 and IPv6 counters, including configuration instructions and command descriptions. Topics covered by this chapter include:

- Configuration
- Show Commands
- Dedicated ARP Entry for TX IPv4 and IPv6 Counters
- Limitations

13.3.1 Configuration

IPv4 and IPv6 ingress counters (count bridged and routed traffic, supported only on front-panel ports) can be enabled and disabled using the hardware counter feature ip in command:

```
[n] hardware counter feature ip in
```

For IPv4 and IPv6 ingress and egress counters that include only routed traffic (supported on Layer3 interfaces such as routed ports, L3 subinterfaces only):

On the DCS-7300X, DCS-7250X, DCS-7050X, and DCS-7060X platforms, IPv4 and IPv6 packet counters for only routed traffic do not require any configuration. They are collected by default. Other platforms (DCS-7280SR, DCS-7280CR and DCS-7500-R) need the feature enabled.

```
[n] hardware counter feature ip in layer3
[n] hardware counter feature ip out layer3
```

13.3.2 Show Commands

Use the show interfaces counters ip command to display IPv4, IPv6 packets, and octets.

```
switch#show interfaces counters ip
<table>
<thead>
<tr>
<th>Interface</th>
<th>IPv4InPkts</th>
<th>IPv4InOctets</th>
<th>IPv6InPkts</th>
<th>IPv6InOctets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et1/1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Et1/2</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Et1/3</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Et1/4</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interface</td>
<td>IPv4OutPkts</td>
<td>IPv4OutOctets</td>
<td>IPv6OutPkts</td>
<td>IPv6OutOctets</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>---------------</td>
<td>------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Et1/1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Et1/2</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

1829
The output from the `show interfaces counters ip` can also be queried through SNMP via the ARISTA-IP-MIB.

To clear the the IPv4 or IPv6 counters, use the `clear counters` command.

```bash
switch# clear counters
```

### 13.3.3 Dedicated ARP Entry for TX IPv4 and IPv6 Counters

IPv4/IPv6 egress Layer 3 (`hardware counter feature ip out layer3`) counting on DCS-7280SR, DCS-7280CR and DCS-7500-R platforms work, based on ARP entry of the nexthop. By default, IPv4 next hop and IPv6 next hop both resolve to the same MAC address and interface that have shared ARP entry. To differentiate the counters between IPv4 and IPv6, disable arp entry sharing with following command:

```bash
ip hardware fib next-hop arp dedicated
```

On the DCS-7280SR, DCS-7280CR and DCS-7500-R platforms, this command is required for IPv4 and IPv6 egress counters to operate.

### 13.3.4 Limitations

- Packet sizes greater than 9236 bytes are not counted by per-port IPv4 and IPv6 counters.
- Only the DCS-7260X3, DCS-7368, DCS-7300, DCS-7050SX3, DCS-7050CX3, DCS-7280SR, DCS-7280CR and DCS-7500-R platforms support the `hardware counter feature ip in` command.
- Only the DCS-7280SR, DCS-7280CR and DCS-7500-R platforms support the `hardware counter feature ip [in|out] layer3` command.
13.4 ACLs and Route Maps

The switch uses rule-based lists to control packet access to ports and to select routes for redistribution to routing domains defined by dynamic routing protocols. This section describes the construction of Access Control Lists (ACLs), prefix lists, and route maps.

This section includes the following topics:

• ACL, Service ACL, Route Map, Prefix List, and RACL Divergence Introduction
• Access Control Lists
• Service ACLs
• Sub-interface ACLs
• RACL Sharing on SVIs
• Route Maps
• Prefix Lists
• Port ACLs with User-Defined Fields
• ACL, Route Map, and Prefix List Commands

13.4.1 ACL, Service ACL, Route Map, Prefix List, and RACL Divergence Introduction

Access Control Lists (ACLs), Service ACLs, route maps, and prefix lists are all processed in order, beginning with the first rule and proceeding until a match is encountered.

An Access Control List (ACL) is a list of rules that control the inbound flow of packets into Ethernet interfaces, subinterfaces, and port channel interfaces or the switch control plane. The switch supports the implementation of a wide variety of filtering criteria including IP and MAC addresses, TCP/UDP ports with include/exclude options without compromising its performance or feature set. Filtering syntax is industry standard.

A Service ACL is an ACL applied by a control-plane process to control connections to, or packets processed by, the agent process.

A route map is a list of rules that control the redistribution of IP routes into a protocol domain on the basis of such criteria as route metrics, access control lists, next hop addresses, and route tags. Route maps can also alter parameters of routes as they are redistributed.

A prefix list is a list of rules that defines route redistribution access for a specified IP address space. Route maps often use prefix lists to filter routes.

The RACL divergence optimizes the usage of hardware resources occupied on each forwarding ASIC by installing ACLs only on the hardware components corresponding to the member interfaces belonging to the SVIs on which ACL is applied. Hence, saving the hardware resources used and enables RACLs to scale-up to a larger configuration. The show commands are used to display the interface mapping, TCAM entries, and TCAM utilization information.

13.4.2 Access Control Lists

These sections describe access control lists:

• ACL Types
• ACL Configuration
• Applying ACLs

13.4.2.1 ACL Types

The switch supports the following ACL types:
Layer 3 Configuration

- **IPv4** can match on IPv4 source or destination addresses, with L4 modifiers including protocol, port number, and DSCP value.
- **IPv6** can match on IPv6 source or destination addresses, with L4 modifiers including protocol, port number, etc.
- **Standard IPv4** can match only on source IPv4 address.
- **Standard IPv6** can match only on source IPv6 address.
- **MAC** can match on L2 source and destination addresses.

ACLs can also be made dynamic (not persisting in the EOS), and the payload keyword can be used to turn an ACL into a User-Defined Field (UDF) alias for use in other ACLs.

13.4.2.1.1 ACL Structure

An ACL is an ordered list of rules that defines access restrictions for the entities (the control plane, or an interface) to which it is applied. ACLs are also used by route maps to select routes for redistribution into specified routing domains.

ACL rules specify the data to which packet contents are compared when filtering data.

- The interface forwards packets that match all commands in a permit rule.
- The interface drops packets that match all commands in a deny rule.
- The interface drops packets that do not match at least one rule.

Upon its arrival at an interface, a packet’s fields are compared to the first rule of the ACL applied to the interface. Packets that match the rule are forwarded (permit rule) or dropped (deny rule). Packets that do not match the rule are compared to the next rule in the list. This process continues until the packet either matches a rule or the rule list is exhausted. The interface drops packets not matching a rule.

The sequence number designates the rule’s placement in the ACL.

13.4.2.1.2 ACL Rules

ACL rules consist of a command list that is compared to inbound packet fields. When all of a rule’s criteria match a packet’s contents, the interface performs the action specified by the rule.

The set of available commands depend on the ACL type and the specified protocol within the rule. The following is a list of commands available for supported ACL types

**IPv4 ACL Rule Parameters**

All rules in IPv4 ACLs include the following criteria:

- **Protocol**: The packet’s IP protocol. Valid rule inputs include:
  - Protocol name for a limited set of common protocols.
  - Assigned protocol number for all IP protocols.
- **Source Address**: The packet’s source IPv4 address. Valid rule inputs include:
  - A subnet address (CIDR or address-mask). Discontiguous masks are supported.
  - A host IP address (dotted decimal notation).
  - `any` to denote that the rule matches all source addresses.
- **Destination Address**: The packet’s destination IP address. Valid rule inputs include:
  - A subnet address (CIDR or address-mask). Discontiguous masks are supported.
  - A host IP address (dotted decimal notation).
  - `any` to denote that the rule matches all destination addresses.

All rules in IPv4 ACLs **may** include the following criteria:

- **Fragment**: Rules filter on the fragment bit.
• **Time-to-live**: Compares the TTL (time-to-live) value in the packet to a specified value. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform. Comparison options include:
  - **Equal**: Packets match if packet value equals statement value.
  - **Greater than**: Packets match if packet value is greater than statement value.
  - **Less than**: Packets match if packet value is less than statement value.
  - **Not equal**: Packets match if packet value does not equal statement value.

The availability of the following optional criteria depends on the specified protocol:

• **Source Ports / Destination Ports**: A rule filters on ports when the specified protocol supports IP address-port combinations. Rules provide one of these port filtering values:
  - `any` denotes that the rule matches all ports.
  - A list of ports that matches the packet port. Maximum list size is 10 ports.
  - Negative port list. The rule matches any port not in the list. Maximum list size is 10 ports.
  - Integer (lower bound): The rule matches any port with a number larger than the integer.
  - Integer (upper bound): The rule matches any port with a number smaller than the integer.
  - Range integers: The rule matches any port whose number is between the integers.

• **Flag bits**: Rules filter TCP packets on flag bits.

• **Message type**: Rules filter ICMP type or code.

• **Tracked**: Matches packets in existing ICMP, UDP, or TCP connections. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform.

**IPv6 ACL Rule Parameters**

**Note**: When calculating the size of ACLs, be aware that Arista switches install four rules in every IPv6 ACL so that ICMPv6 neighbor discovery packets bypass the default drop rule.

All rules in IPv6 ACLs include the following criteria:

• **Protocol**: All rules filter on the packet's IP protocol field. Rule input options include:
  - Protocol name for a limited set of common protocols.
  - Assigned protocol number for all IP protocols.

• **Source Address**: The packet's source IPv6 address. Valid rule inputs include:
  - An IPv6 prefix (CIDR). Discontiguous masks are supported.
  - A host IP address (dotted decimal notation).
  - `any` to denote that the rule matches all addresses.

• **Destination Address**: The packet's destination IP address. Valid rule inputs include:
  - A subnet address (CIDR or address-mask). Discontiguous masks are supported.
  - A host IP address (dotted decimal notation).
  - `any` to denote that the rule matches all addresses.

All rules in IPv6 ACLs **may** include the following criteria:

• **Fragment**: Rules filter on the fragment bit.

• **HOP**
  
  Compares the packet’s hop-limit value to a specified value. Comparison options include:
  
  - `eq`: Packets match if hop-limit value equals statement value.
  - `gt`: Packets match if hop-limit value is greater than statement value.
  - `lt`: Packets match if hop-limit value is less than statement value.
  - `neq`: Packets match if hop-limit value is not equal to statement value.

The availability of the following optional criteria depends on the specified protocol:

• **Source Ports / Destination Ports**: A rule filters on ports when the specified protocol supports IP address-port combinations. Rules provide one of these port filtering values:
• **any** denotes that the rule matches all ports.
• A list of ports that matches the packet port. Maximum list size is 10 ports.
• Negative port list. The rule matches any port not in the list. Maximum list size is 10 ports.
• Integer (lower bound): The rule matches any port with a number larger than the integer.
• Integer (upper bound): The rule matches any port with a number smaller than the integer.
• Range integers: The rule matches any port whose number is between the integers.
• **Flag bits**: Rules filter TCP packets on flag bits.
• **Message type**: Rules filter ICMP type or code.
• **Tracked**: Matches packets in existing ICMP, UDP, or TCP connections. Valid in ACLs applied to the control plane. Validity in ACLs applied to the data plane varies by switch platform.

### Standard IPv4 and IPv6 ACL Rule Parameters

**Note:** When calculating the size of ACLs, be aware that Arista switches install four rules in every IPv6 ACL so that ICMPv6 neighbor discovery packets bypass the default drop rule.

Standard ACLs filter only on the source address.

### MAC ACL Rule Parameters

MAC ACLs filter traffic on a packet’s layer 2 header. Criteria that MAC ACLs use to filter packets include:

• **Source Address** and **Mask**: The packet’s source MAC address. Valid rule inputs include:
  • MAC address range (address-mask in 3x4 dotted hexadecimal notation).
  • **any** to denote that the rule matches all source addresses.
• **Destination Address** and **Mask**: The packet’s destination MAC address. Valid rule inputs include:
  • MAC address range (address-mask in 3x4 dotted hexadecimal notation).
  • **any** to denote that the rule matches all destination addresses.
• **Protocol**: The packet’s protocol as specified by its EtherType field contents. Valid inputs include:
  • Protocol name for a limited set of common protocols.
  • Assigned protocol number for all protocols.

### 13.4.2.1.3 Creating and Modifying Lists

The switch provides configuration modes for creating and modifying ACLs. The command that enters an ACL configuration mode specifies the name of the list that the mode modifies. The switch saves the list to the running configuration when the configuration mode is exited.

• ACLs are created and modified in ACL configuration mode.
• Standard ACLs are created and modified in Standard-ACL-configuration mode.
• MAC ACLs are created and modified in MAC-ACL-configuration mode.

Lists that are created in one mode cannot be modified in any other mode.

A sequence number designates the rule’s placement in a list. New rules are inserted into a list according to their sequence numbers. A rule’s sequence number can be referenced when deleting it from a list.

**ACL Configuration** describes procedures for configuring ACLs.
13.4.2.1.4 Implementing Access Control Lists

An Access Control List (ACL) is implemented by assigning the list to an Ethernet interface or subinterface, to a port channel interface, or to the control plane. The switch assigns a default ACL to the control plane unless the configuration contains a valid control-plane ACL assignment statement. Ethernet and port channel interfaces are not assigned an ACL by default. Standard ACLs are applied to interfaces in the same manner as other ACLs.

IPv4 and MAC ACLs are separately applied for inbound and outbound packets. An interface or subinterface can be assigned multiple ACLs, with a limit of one ACL per packet direction per ACL type. Egress ACLs are supported on a subset of all available switches. The control-plane does not support egress ACLs.

Applying ACLs describes procedures for applying ACLs to interfaces or the control plane.

13.4.2.1.5 ACL Rule Tracking

ACL rule tracking determines the impact of ACL rules on the traffic accessing interfaces upon which they are applied. ACLs provide two tracking mechanisms:

- **ACL logging**: A syslog entry is logged when a packet matches specified ACL rules.
- **ACL counters**: ACL counters increment when a packet matches a rule in specified ACLs.

**ACL Logging**

ACL rules provide a log option that produces a log message when a packet matches the rule. ACL logging creates a syslog entry when a packet matches an ACL rule where logging is enabled. Packets that match a logging-enabled ACL rule are copied to the CPU by the hardware. These packets trigger the creation of a syslog entry. The information provided in the entry depends on the ACL type or the protocol specified by the ACL. Hardware rate limiting is applied to packets written to the CPU, avoiding potential DoS attacks. The rate of logging is also software limited to avoid the creation of syslog lists that are too large for practical use by human operators.

**ACL Rule Tracking Configuration** describes procedures for configuring and enabling ACL logging.

**ACL Counters**

An ACL counter is assigned to each ACL rule. The activity of the ACL counters for rules within a list depend on the list's counter state. When the list is in counting state, the ACL counter of a rule increments when the rule matches a packet. When the list is in a non-counting state, the counter does not increment. A list's counter state applies to all rules in the ACL. The default state for new ACLs is non-counting.

When an ACL changes from counting state to non-counting state, or when the ACL is no longer applied to any interfaces that increment counters, counters for all rules in the list maintain their values and do not reset. When the ACL returns to counting mode or is applied to an interface that increments counters, the counter operation resumes from its most recent value.

Counters never decrement and are reset only through CLI commands.

**ACL Rule Tracking Configuration** describes procedures for configuring and enabling ACL counters.

13.4.2.1.6 Egress ACL Counters

Egress ACL counters count the number of packets hitting rules associated with egress ACLs applied to various interfaces in a switch.
13.4.2.1.6.1 Configuring Egress ACL Counters

To enable egress ACL counters for a specific ACL, use the counter per-entry command in the configuration mode for the ACL.

**Example**

In the following example, configure the `counters per-entry` command in the ACL configuration mode.

```
switch(config)#ip access-list acl1
switch(config-acl-acl1)#counters per-entry
```

Enabling Egress Counters Globally

Both IPv4 and IPv6 egress ACL counters are enabled in the global configuration mode by using the `hardware counter feature acl out` command.

**Example**

The following example shows how to enable IPv4 egress ACL counters.

```
switch(config)#hardware counter feature acl out ipv4
switch(config)#
```

The following example shows how to enable IPv6 egress ACL counters.

```
switch(config)#hardware counter feature acl out ipv6
switch(config)#
```

Disabling Egress Counters Globally

Both IPv4 and IPv6 egress ACL counters are also disabled in the global configuration mode by using the `hardware counter feature acl out` command.

The following example shows how to disable IPv4 egress ACL counters.

```
switch(config)#no hardware counter feature acl out ipv4
switch(config)#
```

The following example shows how to disable IPv6 egress ACL counters.

```
switch(config)#no hardware counter feature acl out ipv6
switch(config)#
```

Egress Counter Roll Over in the Global Mode

The counters roll over when the counter value for an ACL rule exceeds $2^{64}$. IPv4 egress ACL counters are enabled by default, but IPv6 egress ACL counters require explicit configuration.

**Example**

In the following example, the `hardware counter feature acl ipv6 out` command is configured using units and packets.

```
switch(config)#hardware counter feature acl ipv6 out units packets
switch(config)#
```

The `clear ip access-lists counters` command clears the counters for all of the IPv4 ACLs or a specific IPv4 ACL, either globally or per-CLI session.
Example
In the following example the ACL list named red is selected.

```
switch(config)#clear ip access-list counters red session
switch(config)#
```

The IPv6 egress ACL counters do not work in unshared mode.

Example
Use the hardware access-lists resource sharing vlan ipv6 out command to enable egress IPv6 ACL sharing.

```
switch(config)#hardware access-list resource sharing vlan ipv6 out
switch(config)#
```

The clear ipv6 access-list counters command clears the counters for all of the IPv6 ACLs or a specific IPv6 ACL, either globally or per-CLI session.

Example
In the following example the ACL list named green is selected.

```
switch(config)#clear ipv6 access-list counters green session
switch(config)#
```

13.4.2.1.6.2 Displaying Egress ACL Counters
Use the following show commands to display Egress ACL Counters information.

Use the show ip access-lists command to display all the IPv4 ACLs, or a specific IPv4 ACL configured in a switch. The output contains details such as rules in an ACL and respective counter values with each rule.

```
switch(config)#show ip access-list acl1
IP Access List acl1
    counter per-entry
    10 deny ip 11.1.1.0/24 any dscp af11
    20 deny ip any any [match 39080716, 0:00:00 ago]
```

Use the show ipv6 access-lists command to display all the IPv6 ACLs or a specific IPv6 ACL configured in a switch. The output contains details such as rules in an ACL and respective counter values with each rule.

```
switch(config)#show ipv6 access-list acl1
IPV6 Access List acl1
    counter per-entry
    10 permit ipv6 any any [match 3450000, 0:00:10 ago]
    20 deny ipv6 any any
```

The counter name EgressAclDropCounter in the output of this show command signifies the aggregate counter value for the remaining egress IPv4 ACL. In this example the deny rules, whose per rule counters, are not allocated. The per rule counters is not allocated when the user does not configure the counter per-entry parameter for the respective ACL.

```
switch(config)#show hardware counter drop
Summary:
Total Adverse (A) Drops: 0
Total Congestion (C) Drops: 0
Total Packet Processor (P) Drops: 250
```
13.4.2.2 ACL Configuration

Access control lists are created and modified in an ACL-configuration mode. A list can be edited only in the mode where it was created. The switch provides five configuration modes for creating and modifying access control lists:

- **ACL configuration mode** for IPv4 access control lists.
- **IPv6-ACL configuration mode** for IPv6 access control lists.
- **Std-ACL configuration mode** for Standard IPv4 access control lists.
- **Std-IPv6-ACL configuration mode** for Standard IPv6 access control lists.
- **MAC-ACL configuration mode** for MAC access control lists.

These sections describe the creation and modification of ACLs:

- Managing ACLs
- Modifying an ACL
- ACL Rule Tracking Configuration
- Displaying ACLs
- Configuring Per-Port Per-VLAN QoS
- Displaying Per-Port Per-VLAN QoS
- Configuring Mirror Access Control Lists

13.4.2.2.1 Managing ACLs

Creating and Opening a List

To create an ACL, enter one of the following commands, followed by the name of the list:

- `ip access-list` for IPv4 ACLs.
- `ipv6 access-list` for IPv6 ACLs.
- `ip access-list standard` for standard IPv4 ACLs.
- `ipv6 access-list standard` for standard IPv6 ACLs.
- `mac access-list` for MAC ACLs.

The switch enters the appropriate ACL configuration mode for the list. If the command is followed by the name of an existing ACL, subsequent commands edit that list (see Modifying an ACL for additional information).

Examples

- This command places the switch in **ACL** configuration mode to create an ACL named `test1`.

  ```
  switch(config)#ip access-list test1
  switch(config-acl-test1)#
  ```

- This command places the switch in Standard-ACL-configuration mode to create a Standard ACL named `stest1`.

  ```
  switch(config)#ip access-list standard stest1
  switch(config-std-acl-stest1)#
  ```
• This command places the switch in **MAC-ACL** configuration mode to create an MAC ACL named *mtest1*.

```
switch(config)#mac access-list mtest1
switch(config-mac-acl-mtest1)#
```

**Saving List Modifications**

ACL configuration modes are group-change modes. Changes made in a group-change mode are saved by exiting the mode. To exit the group-change mode, changes can also be discarded using the ‘abort’ command instead of exit.

**Examples**

• These commands enter the first three rules into a new ACL.

```
switch(config-acl-test1)#permit ip 10.10.10.0/24 any
switch(config-acl-test1)#permit ip any host 10.20.10.1
switch(config-acl-test1)#deny ip host 10.10.10.1 host 10.20.10.1
```

• To view the edited list, type *show*.

```
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

Because the changes were not yet saved, the ACL remains empty, as shown by *show ip access-lists*.

```
switch(config-acl-test1)#show ip access-lists test1
switch(config-acl-test1)#
```

To save all current changes to the ACL and exit ACL configuration mode, type *exit*.

```
switch(config-acl-test1)#exit
switch(config)#show ip access-lists test1
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

**Discarding List Changes**

The *abort* command exits ACL configuration mode without saving pending changes.

**Examples**

• These commands enter the first three rules into a new ACL.

```
switch(config-acl-test1)#permit ip 10.10.10.0/24 any
switch(config-acl-test1)#permit ip any host 10.20.10.1
switch(config-acl-test1)#deny ip host 10.10.10.1 host 10.20.10.1
```
• To view the edited list, type `show`.

```
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

To discard the changes, enter `abort`. If the ACL existed before entering ACL-configuration mode, `abort` restores the version that existed before entering ACL-configuration mode. Otherwise, `show ip access-lists` shows the ACL was not created.

```
switch(config-acl-test1)#abort
switch(config)#
```

13.4.2.2.2 Modifying an ACL

An existing ACL, including those currently applied to interfaces, can be modified by entering the appropriate configuration mode for the ACL as described in Creating and Opening a List. By default, while an ACL is being modified all traffic is blocked on any interface to which the ACL has been applied.

Permit All Traffic During ACL Update

Because blocking ports during ACL modifications can result in packet loss and can interfere with features such as routing and dynamic NAT, 7050X, 7060X, 7150, 7250X, 7280, 7280R, 7300X, 7320X, and 7500 series switches can be configured instead to permit all traffic on Ethernet and VLAN interfaces while ACLs applied to those interfaces are being modified. This is done with the `hardware access-list update default-result permit` command.

These commands add deny rules to the appropriate ACL:

- `deny (IPv4 ACL)` adds a deny rule to an IPv4 ACL.
- `deny (IPv6 ACL)` adds a deny rule to an IPv6 ACL.
- `deny (Standard IPv4 ACL)` adds a deny rule to an IPv4 standard ACL.
- `deny (Standard IPv6 ACL)` adds a deny rule to an IPv6 standard ACL.
- `deny (MAC ACL)` adds a deny rule to a MAC ACL.

These commands add permit rules to the appropriate ACL:

- `permit (IPv4 ACL)` adds a permit rule to an IPv4 ACL.
- `permit (IPv6 ACL)` adds a permit rule to an IPv6 ACL.
- `permit (Standard IPv4 ACL)` adds a permit rule to an IPv4 standard ACL.
- `permit (Standard IPv6 ACL)` adds a permit rule to an IPv6 standard ACL.
- `permit (MAC ACL)` adds a permit rule to a MAC ACL.

Adding a Rule

To append a rule to the end of a list, enter the rule without a sequence number while in ACL configuration mode for the list. The new rule’s sequence number is derived by adding 10 to the last rule’s sequence number.
Examples

- This command configures the switch to permit all traffic during ACL modifications on interfaces to which the ACL has been applied. The rules in modified ACLs are applied after exiting ACL configuration mode, and after the ACL rules have been populated in hardware.

  ```
  switch(config)#hardware access-list update default-result permit
  ```

- These commands enter the first three rules into a new ACL.

  ```
  switch(config-acl-test1)#permit ip 10.10.10.0/24 any
  switch(config-acl-test1)#permit ip any host 10.20.10.1
  switch(config-acl-test1)#deny ip host 10.10.10.1 host 10.20.10.1
  ```

- To view the edited list, type `show`.

  ```
  switch(config-acl-test1)#show
  IP Access List test1
    10 permit ip 10.10.10.0/24 any
    20 permit ip any host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
  ```

- This command appends a rule to the ACL. The new rule's sequence number is 40.

  ```
  switch(config-acl-test1)#permit ip any any
  switch(config-acl-test1)#show
  IP Access List test1
    10 permit ip 10.10.10.0/24 any
    20 permit ip any host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
    40 permit ip any any
  ```

Inserting a Rule

To insert a rule into a ACL, enter the rule with a sequence number between the existing rules’ numbers.

Example

This command inserts a rule between the first two rules by assigning it the sequence number 15.

  ```
  Switch(config-acl-test1)#15 permit ip 10.30.10.0/24 host 10.20.10.1
  Switch(config-acl-test1)#show
  IP Access List test1
    10 permit ip 10.10.10.0/24 any
    15 permit ip 10.30.10.0/24 host 10.20.10.1
    20 permit ip any host 10.20.10.1
    30 deny ip host 10.10.10.1 host 10.20.10.1
    40 permit ip any any
  ```

Deleting a Rule

To remove a rule from the current ACL, perform one of these commands:

- Enter `no`, followed by the sequence number of the rule to be deleted.
- Enter `no`, followed by the rule be deleted.
- Enter `default`, followed by the rule to be deleted.
Examples

- These equivalent commands remove rule 20 from the list.

```bash
switch(config-acl-test1)#no 20
switch(config-acl-test1)#no permit ip any host 10.20.10.1
```

- This ACL results from entering one of the preceding commands.

```bash
switch(config-acl-test1)#show
ip access list test1
  10 permit ip 10.10.10.0/24 any
  15 permit ip 10.30.10.0/24 host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
```

Resequencing Rule Numbers

Sequence numbers determine the order of the rules in an access control list. After a list editing session where existing rules are deleted and new rules are inserted between existing rules, the sequence number distribution may not be uniform. Resequencing rule numbers changes the sequence number of rules to provide a constant difference between adjacent rules. The resequence (ACLs) command adjusts the sequence numbers of ACL rules.

Example

The resequence (ACLs) command renumbers rules in the test1 ACL. The sequence number of the first rule is 100; subsequent rules numbers are incremented by 20.

```bash
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  25 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  50 permit ip any any
  90 remark end of list
switch(config-acl-test1)#resequence 100 20
switch(config-acl-test1)#show
IP Access List test1
  100 permit ip 10.10.10.0/24 any
  120 permit ip any host 10.20.10.1
  140 deny ip host 10.10.10.1 host 10.20.10.1
  160 permit ip any any
  180 remark end of list
```

13.4.2.2.3  ACL Rule Tracking Configuration

ACL rules provide a log option that produces a syslog message about the packets matching packet. ACL logging creates a syslog entry when a packet matches an ACL rule with logging enabled.

This feature is currently available on Arad switches and on 7100 series switches. On 7100 series switches, matches are logged only on ingress, not on egress.

Example

This command creates an ACL rule with logging enabled.

```bash
switch(config-acl-test1)#15 permit ip 10.30.10.0/24 host 10.20.10.1 log
```

1843
The format of the generated Syslog message depends on the ACL type and the specified protocol:

- Messages generated by a TCP or UDP packet matching an IP ACL use this format:
  
  **IPACCESS:** list acl intf filter protocol src-ip(src_port) -> dst-ip(dst_port)

- Messages generated by ICMP packets matching an IP ACL use this format:

  **IPACCESS:** list acl intf filter icmp src-ip(src-port) -> dst-ip(dst-port) type= n code= m

- Messages generated by all other IP packets matching an IP ACL use this format:

  **IPACCESS:** list acl intf filter protocol src-ip -> dst-ip

- Messages generated by packets matching a MAC ACL use this format:

  **MACACCESS:** list acl intf filter vlan ether src_mac -> dst_mac

- Messages generated by a TCP or UDP packet matching a MAC ACL use this format:

  **MACACCESS:** list acl intf filter vlan ether ip-prt src-mac src-ip : src-prt -> dst-mac dst-ip : dst-prt

- Messages generated by any other IP packet matching a MAC ACL use this format:

  **MACACCESS:** list acl intf filter vlan ether src_mac src_ip -> dst_mac dst_ip

Variables in the Syslog messages display the following values:

- acl   Name of ACL.
- intf  Name of interface that received the packet.
- filter Action triggered by ACL (denied or permitted).
- protocol   IP protocol specified by packet.
- vlan  Number of VLAN receiving packet.
- ether  EtherType protocol specified by packet.
- src-ip and dst-ip source and destination IP addresses.
- src-prt and dst-prt source and destination ports.
- src-mac and dst-mac source and destination MAC addresses.

ACLs provide a command that configures its counter state (counting or non-counting). The counter state applies to all rules in the ACL. The initial state for new ACLs is non-counting.

The **counters per-entry (ACL configuration modes)** command places the ACL in counting mode.

This command places the configuration mode ACL in counting mode.

```
switch(config-acl-test1)#counters per-entry
switch(config-acl-test1)#exit
switch(config-acl-test1)#show ip access-list test1
IP Access List test1
counters per-entry
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```

The **clear ip access-lists counters** and **clear ipv6 access-lists counters** commands set the IP access list counters to zero for the specified IP access list.

This command clears the ACL counter for the test1 ACL.

```
switch(config)#clear ip access-lists counters test1
switch(config)#
```
13.4.2.2.4 Displaying ACLs

ACLs can be displayed by a `show running-config` command. The `show ip access-lists` also displays ACL rosters and contents, as specified by command parameters.

When editing an ACL, the `show (ACL configuration modes)` command displays the current or pending list, as specified by command parameters.

**Displaying a List of ACLs**

To display the roster of ACLs on the switch, enter `show ip access-lists` with the `summary` option.

**Example**

This command lists the available access control lists.

```
switch(config)#show ip access-list summary
IPV4 ACL default-control-plane-acl
    Total rules configured: 12
    Configured on: control-plane
    Active on    : control-plane
IPV4 ACL list2
    Total rules configured: 3
IPV4 ACL test1
    Total rules configured: 6
IPV4 ACL test_1
    Total rules configured: 1
IPV4 ACL test_3
    Total rules configured: 0
switch(config)#
```

**Displaying Contents of an ACL**

These commands display ACL contents.

- `show ip access-lists`
- `show ipv6 access-lists`
- `show mac access-lists`

Each command can display the contents of one ACL or of all ACLs of the type specified by the command:

- To display the contents of one ACL, enter `show ip access-lists` followed by the name of the ACL.
- To display the contents of all ACLs on the switch, enter the command without any options.

ACLs that are in counting mode display the number of inbound packets each rule in the list matched and the elapsed time since the last match.

**Examples**

- This command displays the rules in the `default-control-plane-acl` ACL.

```
switch#show ip access-lists default-control-plane-acl
IP Access List default-control-plane-acl [readonly]
    counters per-entry
    10 permit icmp any any
    20 permit ip any any tracked [match 1725, 0:00:00 ago]
    30 permit ospf any any
```
40 permit tcp any any eq ssh telnet www snmp bgp https
50 permit udp any any eq bootps bootpc snmp [match 993, 0:00:29 ago]
60 permit tcp any any eq mlag ttl eq 255
70 permit udp any any eq mlag ttl eq 255
80 permit vrrp any any
90 permit ahp any any
100 permit pim any any
110 permit igmp any any [match 1316, 0:00:23 ago]
120 permit tcp any any range 5900 5910

• This command displays the rules in all ACLs on the switch.

```
switch#show ip access-lists
IP Access List default-control-plane-acl [readonly] counters per-entry
  10 permit icmp any any
  20 permit ip any any tracked [match 1371, 0:00:00 ago]
  30 permit ospf any any
  40 permit tcp any any eq ssh telnet www snmp bgp https
  50 permit udp any any eq bootps bootpc snmp
  60 permit tcp any any eq mlag ttl eq 255
  70 permit udp any any eq mlag ttl eq 255
  80 permit vrrp any any
  90 permit ahp any any
 100 permit pim any any
110 permit igmp any any [match 1316, 0:00:23 ago]
120 permit tcp any any range 5900 5910
```

```
IP Access List list2
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.30.10.0/24 host 10.20.10.1
  30 permit ip any host 10.20.10.1
  40 deny ip host 10.10.10.1 host 10.20.10.1
  50 permit ip any any
```

```
IP Access List test1
Switch(config)#
```

**Displaying ACL Modifications**

While editing an ACL in ACL-configuration mode, the `show (ACL configuration modes)` command provides options for displaying ACL contents.

• To display the list, as modified in ACL configuration mode, enter `show` or `show pending`.
• To display the list, as stored in `running-config`, enter `show active`.
• To display differences between the pending list and the stored list, enter `show diff`.

**Examples**

The examples in this section assume these ACL commands were previously entered.

These commands are stored in the configuration:

```
10 permit ip 10.10.10.0/24 any
20 permit ip any host 10.21.10.1
30 deny ip host 10.10.10.1 host 10.20.10.1
40 permit ip any any
50 remark end of list
```
The current edit session removed this command. This change is not yet stored to **running-config**:

20 permit ip any host 10.21.10.1

The current edit session added these commands ACL. They are not yet stored to **running-config**:

20 permit ip 10.10.0.0/16 any
25 permit tcp 10.10.20.0/24 any
45 deny pim 239.24.124.0/24 10.5.8.4/30

This command displays the pending ACL, as modified in **ACL** configuration mode.

```bash
switch(config-acl-test_1)#show pending
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.10.0.0/16 any
  25 permit tcp 10.10.20.0/24 any
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  45 deny pim 239.24.124.0/24 10.5.8.4/30
  50 remark end of list
```

This command displays the ACL, as stored in the configuration.

```bash
switch(config-acl-test_1)#show active
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.21.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```

This command displays the difference between the saved and modified ACLs.

- Rules added to the pending list are denoted with a plus sign (+).
- Rules removed from the saved list are denoted with a minus sign (-).

```bash
switch(config-acl-test_1)#show diff
---
+++  
@@ -1,7 +1,9 @@
   IP Access List test_1
      10 permit ip 10.10.10.0/24 any
      - 20 permit ip any host 10.21.10.1
       + 20 permit ip 10.10.0.0/16 any
       + 25 permit tcp 10.10.20.0/24 any

```

### 13.4.2.2.5 Configuring Per-Port Per-VLAN QoS

To configure per-port per-VLAN QoS, first, configure the ACL policing for QoS, and then apply the policy-map on a single Ethernet or port-channel interfaces on a per-port per-VLAN basis. The per port per VLAN QoS allows a class-map to match traffic for a single VLAN or for a range of VLANs separated by commas. Per-port per-VLAN works with QoS-based class-maps only.

To configure per-port per-VLAN QoS on DCS-7280(R) and DCS-7500(R), change the TCAM profile to QoS as shown below.
1. Change the TCAM profile to QoS.

   ```
   switch#config
   switch(config)#hardware tcam profile qos
   ```

2. Create an ACL and then match the traffic packets based on the VLAN value and the VLAN mask configured in the ACL.

   ```
   switch(config)#ip access-list acl1
   switch(config-acl-acl1)#permit vlan 100 0xfff ip any any
   switch(config-acl-acl1)#exit
   ```

3. Similarly, create a class-map and then match the traffic packets based on the range of VLAN values configured in the class-map.

   ```
   switch(config)#class-map match-any class1
   switch(config-cmap-qos-class1)#match vlan 20-40, 1000-1250, 2000
   switch(config-cmap-qos-class1)#exit
   ```

13.4.2.2.6 Displaying Per-Port Per-VLAN QoS

   The following show commands display the status, traffic hit counts, tcam profile information, and policy-maps configured on an interface.

   The **show policy-map** command displays the policy-map information of the configured policy-map.

   **Examples**

   ```
   switch#show policy-map policy1
   Service-policy policy1
   Class-map: class1 (match-any)
   Match: ip access-group name acl1
   Police cir 512000 bps bc 96000 bytes
   Class-map: class-default (match-any)
   ```

   ```
   switch#show policy-map interface ethernet 1
   Service-policy input: p1
   Hardware programming status: Successful
   Class-map: c2001 (match-any)
   Match: vlan 2001 0xfff
   set dscp 4
   Class-map: c2002 (match-any)
   Match: vlan 2002 0xfff
   set dscp 8
   Class-map: c2003 (match-any)
   Match: vlan 2003 0xfff
   set dscp 12
   ```

13.4.2.2.7 Configuring Mirror Access Control Lists

   Access Control Lists (ACLs) are configured to permit or deny traffic between source and destination ports on Strata-based platforms. Mirror ACLs are used in mirroring traffic by matching VLAN ID of the configured ACLs. Mirror ACLs are applied for IPv4, IPv6, and MAC ACLs.

   **Note:** Mirror ACLs work in receiving direction only.

   **Examples**
• These commands configure ACL to permit VLAN traffic between any source and destination host.

```
switch(config)#ip access-list acl1
switch(config-acl-acl1)#permit vlan 1234 0x0 ip any any
```

• These commands configure monitor session `sess1` with `Ethernet 1` as source port and `Ethernet 2` as destination port for an ingress ip `acl1`.

```
switch(config)#monitor session sess1 source ethernet 1 rx ip access-group acl1
switch(config)#monitor session sess1 destination ethernet 2
```

### 13.4.2.3 Applying ACLs

Access Control Lists become active when they are assigned to an interface or subinterface or to the control plane. This section describes the process of adding and removing ACL interface assignments.

#### Applying an ACL to an Interface

The switch must be in interface configuration mode to assign an ACL to an interface or subinterface.

- The `ip access-group` command applies the specified IP or standard IP ACL to the configuration mode interface or subinterface.
- The `ip access-group` command applies the specified IP or standard IP ACL to the control-plane traffic.
- The `mac access-group` command applies the specified MAC ACL to the configuration mode interface.

IPv4, IPv6, and MAC ACLs are separately applied for inbound and outbound packets. An interface or subinterface can be assigned with multiple ACLs, with a limit of one ACL per packet direction per ACL type. Egress ACLs are supported on a subset of all available switches. IPv6 egress ACLs have limited availability, and IPv6 egress ACLs applied to routed interfaces or subinterfaces across the same chip on the DCS-7500E and the DCS-7280E series can be shared. In addition to that, the DSCP value can match on IPv6 egress ACLs. This result in a more efficient utilization of system resources, and is particularly useful for environments with few, potentially large, IPv6 egress ACLs applied across multiple routed interfaces.

#### Examples

- These commands assign `test1` ACL to `interface ethernet 3`, then verify the assignment.

```
switch(config)#interface ethernet 3
switch(config-if-Et3)#ip access-group test1 in
switch(config-if-Et3)#show running-config interfaces ethernet 3
interface Ethernet3
  ip access-group test1 in
switch(config-if-Et3)#
```

- These commands place the switch in control plane configuration mode and applies the ACL assignment to the control-plane traffic.

```
switch(config)#control-plane
switch(config-cp)#ip access-group test_cp in
```

- This command enables shared ACLs.

```
switch(config)#hardware access-list resource sharing vlan ipv6 out
switch(config)#
```
• This command disables shared ACLs.

```plaintext
switch(config)#no hardware access-list resource sharing vlan ipv6 out
```

• These commands apply an IPv4 ACL named **test_ACL** to ingress traffic on **interface ethernet 5.1**.

```plaintext
switch(config)#interface ethernet 5.1
switch(config-if-Et5.1)#ipv4 access-group test_ACL in
```

---

**Removing an ACL from an Interface**

The `no ip access-group` command removes an IP ACL assignment statement from **running-config** for the configuration mode interface. After an ACL is removed, the interface is not associated with an IP ACL.

The `no mac ip access-group` command removes a MAC ACL assignment statement from **running-config** for the configuration mode interface. After a MAC ACL is removed, the interface is not associated with a MAC ACL.

To remove an ACL from the control plane, enter the `no ip access-group` command in control plane configuration mode. Removing the control plane ACL command from **running-config** reinstates **default-control-plane-acl** as the control plane ACL.

**Examples**

• These commands remove the assigned IPv4 ACL from **interface ethernet 3**.

```plaintext
switch(config)#interface ethernet 3
switch(config-if-Et3)#no ip access-group test in
```

• These commands place the switch in control plane configuration mode and remove the ACL assignment from **running-config**, restoring **default-control-plane-acl** as the control plane ACL.

```plaintext
switch(config)#control-plane
switch(config-cp)#no ip access-group test_cp in
```

---

**13.4.3 Service ACLs**

These sections describe Service ACLs:

• **Service ACL Description**
• **Configuring Service ACLs and Displaying Status and Counters**

**13.4.3.1 Service ACL Description**

Service ACL enforcement is a feature added to a control plane service (the SSH server, the SNMP server, routing protocols, etc) that allows the switch administrator to restrict the processing of packets and connections by the control plane processes that implement that service. The control plane program run by the control plane process checks already received packets and connections against a user configurable Access Control List (ACL), a Service ACL. The Service ACL contains permit and deny rules matching any of the source address, destination address, and TCP or UDP ports of received packets or connections. After receiving a packet or connection, the control plane process evaluates the packet or connection against the rules of the Service ACL configured for the control plane process, and if the received packet or connection matches a deny rule the control plane process drops or closes it without further processing.
Control Plane Process Enforced Access Control enables the system administrator to restrict which systems on the network can access the services provided by the switch. Each service has its own access control list, giving the system administrator fine grained control over access to the switch’s control plane services. The CLI for this uses the familiar pattern of access control lists assigned for a specific purpose, in this case for each control plane service.

13.4.3.2 Configuring Service ACLs and Displaying Status and Counters

13.4.3.2.1 SSH Server

To apply the SSH server Service ACLs for IPv4 and IPv6 traffic, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands in `mgt-ssh` configuration mode as shown below.

```
switch(config)#management ssh
switch(config-mgmt-ssh)#ip access-group <acl_name> [vrf <vrf_name>] in
switch(config-mgmt-ssh)#ipv6 access-group <acl_name> [vrf <vrf_name>] in
```

In Release EOS-4.19.0, all VRFs are required to use the same SSH server Service ACL. The Service ACL assigned without the `vrf` keyword is applied to all VRFs where the SSH server is enabled.

To display the status and counters of the SSH server Service ACLs, use the following commands.

```
switch>show management ssh ip access-list
switch>show management ssh ipv6 access-list
```

13.4.3.2.2 SNMP Server

To apply the SNMP server Service ACLs to restrict which hosts can access SNMP services on the switch, use the `snmp-server community` command as shown below.

```
snmp-server community community-name [view viewname] [ro | rw] acl_name
snmp-server community community-name [view viewname] [ro | rw] ipv6 ipv6_acl_name
```

13.4.3.2.3 EAPI

To apply Service ACLs to the EOS application programming interface (EAPI) server, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands as shown below.

```
switch(config)#management api http-commands
switch(config-mgmt-api-http-cmds)#vrf <vrf_name>
switch(config-mgmt-api-http-cmds-vrf-<vrf>)#ip access-group <acl_name>
switch(config-mgmt-api-http-cmds-vrf-<vrf>)#ipv6 access-group <ipv6_acl_name>
```

To display the status and counters of the EAPI server Service ACLs, use the following commands.

```
switch>show management api http-commands ip access-list
switch>show management api http-commands ipv6 access-list
```

13.4.3.2.4 BGP

To apply Service ACLs for controlling connections to the BGP routing protocol agent, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands as shown below.

```
switch(config)#router bgp <asn>
```
To display the status and counters of the BGP routing protocol Service ACLs, use the following commands.

```
switch>show bgp ipv4 access-list
switch>show bgp ipv6 access-list
```

### 13.4.3.2.5 UCMP auto adjust for BGP

UnequalCost Multi-Path (UCMP) for BGP forwards traffic based on weight assignments for next hops of routes of ECMP traffic. The weights are programmed in the FIB. By disseminating BGP link-bandwidth extended community attribute information with BGP routes, the receiver device of all routes, programs the next hops in the FIB using the received link-bandwidth values. The percentage of interface speed is appended to the received link bandwidth extended community value of the route. The weight ratio of the traffic sent over egress ports is adjusted to forward more traffic towards the peer with higher interface speed.

#### Configuring UCMP auto adjust for BGP

The following command enables the weight adjustment.

```
switch(config-router-bgp)#neighbor group1 link-bandwidth adjust auto percent 62.3
```

**PERCENT** is a float value between 0.0 to 100.0 and is optional.

### 13.4.3.2.6 OSPF

To apply Service ACLs for controlling packets processed by the OSPF routing protocol agent, use the **ip access-group (Service ACLs)** and **ipv6 access-group (Service ACLs)** commands as shown below.

```
switch(config)#router ospf <id>
switch(config-router-ospf)#ip access-group <acl_name>
switch(config-router-ospf)#ipv6 access-group <ipv6_acl_name>
```

When using VRFs, each per-VRF OSPF instance must be assigned its Service ACL explicitly.

To display the status and counters of the OSPF routing protocol Service ACLs, use the following commands.

```
switch>show ospf ipv4 access-list
switch>show ospf ipv6 access-list
```
13.4.3.7 PIM

To apply Service ACLs for controlling packets processed by the PIM routing protocol agent, use the `access-group` command as shown below.

```
switch(config)#router pim
switch(config-router-pim)#ipv4
switch(config-router-pim-ipv4)#access-group <acl_name>
switch(config-router-pim-ipv4)#vrf <vrf_name>
switch(config-router-pim-vrf-<vrf>)#ipv4
switch(config-router-pim-vrf-<vrf>-ipv4)#access-group <acl_name>
```

To display the status and counters of the PIM routing protocol Service ACLs, use the following commands.

```
switch>show ip pim access-list
```

13.4.3.8 IGMP

To apply Service ACLs for controlling packets processed by the IGMP management protocol agent, use the `ip igmp access-group` command as shown below.

```
switch(config)#router igmp
switch(config-router-igmp)#ip igmp access-group <acl_name>
switch(config-router-igmp)#vrf <vrf_name>
switch(config-router-igmp-vrf-<vrf>)#ip igmp access-group <acl_name>
```

To display the status and counters of the IGMP management protocol Service ACLs, use the following commands.

```
switch>show ip igmp access-list
```

13.4.3.9 DHCP Relay

To apply Service ACLs for controlling packets processed by the DHCP relay agent, use the `ip dhcp relay access-group` and `ipv6 dhcp relay access-group` commands as shown below.

```
switch(config)#ip dhcp relay access-group <acl_name> [vrf <vrf_name>]
switch(config)#ipv6 dhcp relay access-group <acl_name> [vrf <vrf_name>]
```

To display the status and counters of the DHCP relay agent Service ACLs, use the following commands.

```
switch>show ip dhcp relay access-list
switch>show ipv6 dhcp relay access-list
```

13.4.3.10 LDP

To apply Service ACLs for controlling packets and connections processed by the LDP MPLS label distribution protocol, use the command as shown below.

```
ip access-group (Service ACLs)

switch(config)#mpls ldp
switch(config-mpls-ldp)#ip access-group <acl_name>
```
To display the status and counters of the LDP Service ACLs, use the following command.

```
switch>show mpls ldp access-list
```

13.4.3.2.11 LANZ

To apply Service ACLs for controlling connections accepted by the LANZ agent, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands as shown below.

```
switch(config)#queue-monitor streaming
switch(config-qm-streaming)#ip access-group <acl_name>
switch(config-qm-streaming)#ipv6 access-group <ipv6_acl_name>
```

To display the status and counters of the LDP Service ACLs, use the following command.

```
switch>show queue-monitor streaming access-lists
```

13.4.3.2.12 MPLS Ping and Traceroute

To apply Service ACLs for controlling connections accepted by the MPLS Ping agent, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands as shown below.

```
switch(config)#mpls ping
switch(config-mpls-ping)#ip access-group <acl_name> [vrf <vrf_name>]
switch(config-mpls-ping)#ipv6 access-group <ipv6_acl_name> [vrf <vrf_name>]
```

13.4.3.2.13 Telnet Server

To apply Service ACLs to the Telnet server, use the `ip access-group (Service ACLs)` and `ipv6 access-group (Service ACLs)` commands as shown below.

```
switch(config)#management telnet
switch(config-mgmt-telnet)#ip access-group <acl_name> [vrf <vrf_name>] in
switch(config-mgmt-telnet)#ipv6 access-group <ipv6_acl_name> [vrf <vrf_name>] in
```

In **EOS 4.19.0**, all VRFs are required to use the same Telnet server Service ACL. The Service ACL assigned without the `vrf` keyword is applied to all VRFs where the Telnet server is enabled.

To display the status and counters of the LDP Service ACLs, use the following commands.

```
switch>show management telnet ip access-list
switch>show management telnet ipv6 access-list
```

13.4.4 Sub-interface ACLs

This Sub-interface ACLs feature enables ACL functionality on subinterfaces.

13.4.4.1 Configuring Sub-interface ACLs

Configure the ACLs on subinterfaces, use the following command:

```
ip|ipv6 access-group acl-name in | out
```

To unconfigure the ACLs on subinterfaces, use the following command:

```
no ip|ipv6 access-group in | out
```
13.4.4.2 Sub-interface ACLs Limitations

The sub-interface ACLs feature contains the following limitations:

- Egress IPv4 ACLs on subinterfaces are not supported when sharing mode is disabled for Egress IPv4 RACLs.
- Egress IPv6 ACL deny logging is not supported on subinterfaces.
- Blocking traffic while modifying ACLs is not supported on Egress IPv4 ACLs on subinterfaces.

13.4.4.3 Sub-interface ACLs Show Commands

The `show ip|ipv6 access-lists` displays the summary of a configured ACL including the subinterface on which the ACL is configured and active.

```
show ip|ipv6 access-lists acl-name summary
```

Examples

```
switch(config)#show ip access-lists acl1 summary
IPV4 ACL acl1
  Total rules configured: 1
  Configured on Ingress: Et5.1
  Active on Ingress: Et5.1

switch(config)#show ipv6 access-lists acl1 summary
IPV6 ACL acl1
  Total rules configured: 1
  Configured on Egress: Et5.1
  Active on Egress: Et5.1
```

13.4.5 RACL Sharing on SVIs

13.4.5.1 IPv4 Ingress Sharing

The IPv4 ingress sharing optimizes the utilization of hardware resources by sharing the hardware resources between different VLAN interfaces when they have same ACL attached.

Larger deployments are benefited with this function, where IPv4 ingress sharing is applied on multiple SVIs with member interfaces on same forwarding ASIC. For example, a trunk port carrying multiple VLANs and an ingress sharing is applied on all VLANs, it occupies lesser hardware resources irrespective of number of VLANs. By default, IPv4 ingress sharing is disabled on the switches.

To enable IPv4 Ingress Sharing use `no hardware access-list resource sharing vlan in` command. Note, enabling or disabling the IPv4 ingress sharing requires the restart of software agents on the switches which is a disruptive process and will impact the traffic forwarding. The `no` form of the command disables the IPv4 ingress sharing on the switch. To display the IPv4 ingress sharing information use `show platform trident` command on the switch.

13.4.5.2 IPv4 Egress Sharing

The IPv4 Egress Sharing optimizes the utilization of hardware resources by sharing TCAM entries for a group of SVIs on which IPv4 ACLs shared. The TCAM entries are shared for all the SVIs per chip, hence, saving a lot of hardware resources and enabling ACLs to scale to a larger configurations.

Larger deployments are benefited, where IPv4 Egress Sharing is applied on multiple SVIs with member interfaces on same forwarding ASIC. For example, a trunk port carrying multiple VLANs, and when Egress Sharing is applied on all VLANs it occupies lesser hardware resources irrespective of number of VLANs. By default, IPv4 Egress Sharing is enabled on the switches. However, both IPv4 Egress Sharing and uRPF cannot be enabled at the same time. Disabling IPv4 RACL sharing will allow...
uRPF configuration and make sure RACL configuration, non-shared mode, is configured at the same time.

To enable unicast Reverse Path Forwarding (uRPF) on the switch, the IPv4 Egress Sharing must be disabled using the `no hardware access-list resource sharing vlan ipv4 out` command.

To enable IPv4 Egress Sharing if previously disabled from the default configuration, use `hardware access-list resource sharing vlan ipv4 out` command. Note, enabling or disabling the IPv4 Egress Sharing requires the restart of software agents on the switches which is a disruptive process and will impact the traffic forwarding.

The following `show` commands can be used to verify the IPv4 Egress Sharing information on the switch.

- `show ip access-lists`
- `show vlan`
- `show platform arad acl tcam`
- `show ip route`
- `show platform arad ip route`

### 13.4.5.3 Configuring IPv4 Egress Sharing

Use `hardware access-list resource sharing vlan ipv4 out` command to enable the IPv4 Egress Sharing on the switch. By default, IPv4 Egress Sharing is enabled on the switch. The `no` form of the command disables the IPv4 Egress Sharing on the switch and user is allowed to configure the uRPF on the switch.

### 13.4.5.4 Displaying IPv4 Egress Sharing Information

**Examples**

- The `show ip access-lists` command displays the list of all the configured IPv4 ACLs.

  switch#`show ip access-lists summary`
  IPV4 ACL default-control-plane-acl [readonly]
  Total rules configured: 17
  Configured on Ingress: control-plane(default VRF)
  Active on Ingress: control-plane(default VRF)

  IPV4 ACL ipAclLimitTest
  Total rules configured: 0
  Configured on Egress: V12148,2700
  Active on Egress: V12148,2700

- The `show vlan` command displays the list of all the member interfaces under each SVI.

  switch#`show vlan`
  VLAN Name Status Ports
  ----- ----------- ---------------
  1 default active
  2148 VLAN2148 active Cpu, Et1, Et26
  2700 VLAN2700 active Cpu, Et18

- The `show platform arad acl tcam` command displays the number of TCAM entries (hardware resources) occupied by the ACL on each forwarding ASIC and the percentage of TCAM utilization per forwarding ASIC.

  switch#`show platform arad acl tcam detail`
  ip access-list ipAclLimitTest (Shared RACL, 0 rules, 1 entries, direction out,
Layer 3 Configuration

Fap: Arad0, Shared: true, Interfaces: Vl2148, Vl2700
Bank Offset Entries
0 0 1
Fap: Arad1, Shared: true, Interfaces: Vl2148
Bank Offset Entries
0 0 1

Switch#show platform arad acl tcam summary
The total number of TCAM lines per bank is 1024.

Arad0:

Bank_offset Entries
0 0 1
Total Number of TCAM lines used is: 1

Arad1:

Bank_offset Entries
0 0 1
Total Number of TCAM lines used is: 1

• The show ip route command displays the unicast ip routes installed in the system.

sw itch#show ip route
VRF name: default
Codes: C - connected, S - static, K - kernel,
O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP,
R - RIP, I - ISIS, A B - BGP Aggregate, A O - OSPF Summary,
NG - Nexthop Group Static Route

Gateway of last resort is not set
C 10.1.0.0/16 is directly connected, Vlan2659
C 10.2.0.0/16 is directly connected, Vlan2148

13.4.6 Route Maps

A route map is an ordered set of rules that control the redistribution of IP routes into a protocol domain on the basis of such criteria as route metrics, access control lists, next hop addresses, and route tags. Route maps can also alter parameters of routes as they are redistributed.

13.4.6.1 Route Map Description

Route maps are composed of route map statements, each of which consists of a list of match and set commands.

Route Map Statements

Route map statements are categorized by the resolution of routes that the statement filters.

- Permit statements facilitate the redistribution of matched routes.
- Deny statements prevent the redistribution of matched routes.

Route map statement elements include name, sequence number, filter type, match commands, set commands, and continue commands.

- **name** identifies the route map to which the statement belongs.
- **sequence number** designates the statement’s placement within the route map.
- **filter type** specifies the route resolution. Valid types are **permit** and **deny**.
- **match commands** specify criteria that select routes that the statement is evaluating for redistribution.
- **set commands** modify route parameters for redistributed routes.
- **continue commands** prolong the route map evaluation of routes that match a statement.

Statements filter routes for redistribution. Routes that statements pass are redistributed (permit statements) or rejected (deny statements). Routes that statements fail are filtered by the next statement in the route map.

- When a statement does not contain a **match** command, the statement passes all routes.
- When a statement contains a single **match** command that lists a single object, the statement passes routes whose parameters match the object.
- When a statement contains a single **match** command that lists multiple objects, the statement passes routes whose parameters match at least one object.
- When a statement contains multiple **match** commands, the statement passes routes whose parameters match all match commands.

**Set** commands modify parameters for redistributed routes. **Set** commands are valid in permit statements.

**Example**

The following route map statement is named **MAP_1** with sequence number **10**. The statement matches all routes from BGP Autonomous System 10 and redistributes them with a local preference set to **100**. Routes that do not match the statement are evaluated against the next statement in the route map.

```
switch#route-map MAP_1 permit 10
  match as 10
  set local-preference 100
```

**Route Maps with Multiple Statements**

A route map consists of statements with the same name and different sequence numbers. Statements filter routes in ascending order of their sequence numbers. When a statement passes a route, the
redistribution action is performed as specified by the filter type and all subsequent statements are ignored. When the statement fails the route, the statement with the smallest sequence number that is larger than the current one filters the route.

All route maps have an implied final statement that contains a single deny statement with no match command. This denies redistribution to routes that are not passed by any statement.

**Example**

The following route map is named `MAP_1` with two permit statements. Routes that do not match either statement are denied redistribution into the target protocol domain.

```
switch#route-map MAP_1 permit 10
   match as 10
   set local-preference 100
!
switch#route-map MAP_1 permit 20
   match metric-type type-1
   match as 100
```

**Route Map Configuration** describes route map configuration procedures.

**Route Maps with Multiple Statements and Continue Commands**

Route map statements that contain a `continue (route map)` command support additional route map evaluation of routes whose parameters meet the statement’s match commands. Routes that match a statement containing a `continue` command are evaluated against the statement specified by the `continue` command.

When a route matches multiple route map statements, the filter action (deny or permit) is determined by the last statement that the route matches. The `set` commands in all statements matching the route are applied to the route after the route map evaluation is complete. Multiple set commands are applied in the same order by which the route was evaluated against the statements containing them.

**Example**

The following route map is named `MAP_1` with a permit statement and a deny statement. The permit statement contains a continue command. Routes that match statement 10 are evaluated against statement 20.

```
route-map MAP_2 permit 10
   match as 10
   continue 20
   set local-preference 100
!
route-map MAP_2 deny 20
   match metric-type type-1
   match as 100
```

The route is redistributed if it passes statement 10 and is rejected by statement 20. The route is denied redistribution in all other instances. The `continue` command guarantees the evaluation of all routes against both statements.

**13.4.6.2 Route Map Configuration**

Route maps are created and modified in route map configuration mode. These sections describe the configuration mode and its commands.

- **Route Map Creation and Editing**
- **Modifying Route Map Components**
13.4.6.2.1  Route Map Creation and Editing

Creating a Route Map Statement
To create a route map, enter `route-map` followed by the map name and filter type (`deny` or `permit`). The default sequence number is assigned to the statement if the command does not include a number.

**Example**
This command places the switch in `route map` configuration mode to create a route map statement named `map1` with a sequence number of 50.

```
switch(config)#route-map map1 permit 50
switch(config-route-map-map1)#
```

Editing a Route Map Statement
To edit an existing route map statement, enter `route-map` with the map’s name and statement’s number. The switch enters route map configuration mode for the statement. Subsequent `match (route-map)` and `set (route-map)` commands add the corresponding commands to the statement.

The `show` command displays contents of the existing route map.

**Example**
This command places the switch in route map configuration mode to edit an existing route map statement. The `show` command displays contents of all statements in the route map.

```
switch(config)#route-map MAP2
switch(config-route-map-MAP2)#show
  Match clauses:
  match as 10
  match tag 333
  Set clauses:
  set local-preference 100
switch(config-route-map-MAP2)#
```

Saving Route Map Modifications
Route map configuration mode is a group-change mode. Changes are saved by exiting the mode, either with an explicit `exit` command or by switching directly to another configuration mode. This includes switching to the configuration mode for a different route map.

**Example**
The first command creates the `map1` statement with sequence number of 10. The second command is not yet saved to the route map, as displayed by the `show` command.

```
switch(config)#route-map map1 permit
switch(config-route-map-map1)#match as 100
switch(config-route-map-map1)#show
switch(config-route-map-map1)#
```

The `exit` command saves the `match` command.

```
switch(config-route-map-map1)#exit
switch(config)#show route-map map1
route-map map1 permit 10
  Match clauses:
```
Discarding Route Map Modifications

The `abort` command discards all pending changes and exits route map configuration mode.

Example

The `abort` command discards the pending `match` command and restores the original route map.

```
switch(config)#route-map map1 permit
switch(config-route-map-map1)#match as 100
switch(config-route-map-map1)#abort
switch(config)#show route-map map1
```

13.4.6.2.2 Modifying Route Map Components

These commands add rules to the configuration mode route map:

- `match (route-map)` adds a match rule to a route map.
- `set (route-map)` adds a set rule to a route map.

Inserting a Statement

To insert a new statement into an existing route map, create a new statement with a sequence number that differs from any existing statement in the map.

Example

This command adds statement 50 to the `Map1` route map, then displays the new route map.

```
switch(config)#route-map Map1 permit 50
switch(config-route-map-Map1)#match as 150
switch(config-route-map-Map1)#exit
switch(config)#show route-map Map1
route-map Map1 deny 10
  Match clauses:
  match as 10
  match tag 333
  Set clauses:
  set local-preference 100
route-map Map1 permit 50
  Match clauses:
  match as 150
  Set clauses:
```

Deleting Route Map Components

To remove a component from a route map, perform one of the following:

- To remove a command from a statement, enter `no`, followed by the command to be removed.
- To remove a statement, enter no, followed by the route map with the filter type and the sequence number of the statement to be removed.
- To remove a route map, enter `no` followed by the route map without a sequence number.
13.4.6.3 Using Route Maps

Protocol redistribution commands include a route map parameter that determines the routes to be redistributed into the specified protocol domain.

Example

This command uses Map1 route map to select OSPFv2 routes for redistribution into BGP AS1.

```
switch(config)#router bgp 1
switch(config-router-bgp)#redistribute ospf route-map Map1
switch(config-router-bgp)#exit
switch(config)#
```
13.4.7 Prefix Lists

A prefix list is an ordered set of rules that defines route redistribution access for a specified IP address space. A prefix list rule consists of a filter action (deny or permit), a network address (IPv4 subnet or IPv6 prefix), and a sequence number.

Prefix lists are referenced by route map match commands when filtering routes for redistribution.

- **Prefix List Configuration** describes the prefix list configuration process.
- **Using Prefix Lists** describes the use of prefix lists.
- **Static Routes Redistribution into IGPs** describes redistribution of routes whose configured next-hops satisfy the route-map policy.

13.4.7.1 Prefix List Configuration

A prefix list is an ordered set of rules that defines route redistribution access for a specified IP address space. A prefix list rule consists of a filter action (deny or permit), a network address (IPv4 subnet or IPv6 prefix), and a sequence number. A rule may also include an alternate mask size.

The switch supports IPv4 and IPv6 prefix lists. The switch is placed in a Prefix-list configuration mode to create and edit IPv4 or IPv6 prefix lists.

13.4.7.1.1 IPv4 Prefix Lists

IPv4 prefix lists are created or modified by adding an IPv4 prefix list rule in the Prefix-list configuration mode. Each rule includes the name of a prefix list, in addition to the sequence number, network address, and filter action. A list consists of all rules that have the same prefix list name.

The **ip prefix-list** command creates a prefix list or adds a rule to an existing list. Route map match commands use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains.

**Creating an IPv4 Prefix List**

To create an IPv4 prefix list, enter the **ip prefix-list** command, followed by the name of the list. The switch enters **IPv4 prefix-list** configuration mode for the list. If the command is followed by the name of an existing ACL, subsequent commands edit that list.

**Examples**

- This command places the switch in **IPv4 prefix list** configuration mode to create an IPv4 prefix list named route-one.

  ```
  switch(config)#ip prefix-list route-one
  switch(config-ip-pfx)#
  ```

- These commands create four different rules for the prefix-list named **route-one**.

  ```
  switch(config)#ip prefix-list route-one
  switch(config-ip-pfx)#seq 10 deny 10.1.1.0/24
  switch(config-ip-pfx)#seq 20 deny 10.1.0.0/16
  switch(config-ip-pfx)#seq 30 permit 12.15.4.9/32
  switch(config-ip-pfx)#seq 40 deny 1.1.1.0/24
  ```

To view the list, save the rules by exiting the **Prefix-list** command mode, then re-enter the configuration mode and type **show active**.

  ```
  switch(config-ip-pfx)#exit
  switch(config)#ip prefix-list route-one
  switch(config-ip-pfx)#show active
  ip prefix-list route-one
  ```
Layer 3 Configuration

```
seq 10 deny 10.1.1.0/24
seq 20 deny 10.1.0.0/16
seq 30 permit 12.15.4.9/32
seq 40 deny 1.1.1.0/24
switch(config-ip-pfx)#ip prefix-list route-one
```

IPv4 prefix lists are referenced in `match (route-map)` command.

### 13.4.7.1.2 IPv6 Prefix Lists

**Creating an IPv6 Prefix List**

The switch provides `IPv6 prefix-list` configuration mode for creating and modifying IPv6 prefix lists. A list can be edited only in the mode where it was created.

To create an IP ACL, enter the `ipv6 prefix-list` command, followed by the name of the list. The switch enters `IPv6 prefix-list` configuration mode for the list. If the command is followed by the name of an existing ACL, subsequent commands edit that list.

**Example**

This command places the switch in `IPv6 prefix list` configuration mode to create an IPv6 prefix list named `map1`.

```
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#
```

**Adding a Rule**

To append a rule to the end of a list, enter the rule without a sequence number while in `Prefix-List` configuration mode for the list. The new rule’s sequence number is derived by adding 10 to the last rule’s sequence number.

**Example**

These commands enter the first two rules into a new prefix list.

```
switch(config-ipv6-pfx)#permit 3:4e96:8ca1:33cf::/64
switch(config-ipv6-pfx)#permit 3:11b1:8fe4:1aac::/64
```

To view the list, save the rules by exiting the `prefix-list` command mode, then re-enter the configuration mode and type `show active`.

```
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#show active
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
switch(config-ipv6-pfx)#
```

This command appends a rule to the end of the prefix list. The new rule’s sequence number is 30.

```
switch(config-ipv6-pfx)#permit 3:1bca:1141:ab34::/64
switch(config-ipv6-pfx)#exit
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#show active
ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
```

1865
Inserting a Rule

To insert a rule into a prefix list, use the **seq (IPv6 Prefix Lists)** command to enter a rule with a sequence number that is between numbers of two existing rules.

**Example**

This command inserts a rule between the first two rules by assigning it the sequence number **15**.

```
switch(config-ipv6-pfx)#seq 15 deny 3:4400::/64
switch(config-ipv6-pfx)#exit
```

Deleting a Rule

To remove a rule from the configuration mode prefix list, enter **no seq** (see **seq (IPv6 Prefix Lists)**), followed by the sequence number of the rule to be removed.

**Example**

These commands remove rule 20 from the prefix list, then displays the resultant prefix list.

```
switch(config-ipv6-pfx)#no seq 20
switch(config-ipv6-pfx)#exit
```

13.4.7.2 Using Prefix Lists

Route map match commands include an option that matches a specified prefix list.

**Example**

The **MAP_1** route map uses a match command that references the **PL_1** prefix list.

```
switch(config)#route-map MAP_1 permit
switch(config-route-map-MAP_1)#match ip address prefix-list PL_1
switch(config-route-map-MAP_1)#set community 500
switch(config-route-map-MAP_1)#exit
```

13.4.7.3 Static Routes Redistribution into IGPs

Use **match ip next-hop** route-map, while redistributing static routes into IGPs to redistribute the static routes whose **configured** next-hops satisfies the route-map policy.
The following example applies match ip next-hop clause for static routes redistributed into IGPs for multi-agent mode as well. The following configures a static route.

```
switch(config)# ip route 10.20.30.0/24 1.2.3.4
```

The following configures a prefix-list.

```
switch (config)#ip prefix-list prefixListName
switch(config-ip-pfx)#permit 1.2.3.4/32
```

1.2.3.4 is a configured next-hop for static route 10.20.30.0/24.

The following configures a route map.

```
switch(config)#route-map routeMapName
switch(config-route-map-routeMapName)#match ip next-hop prefix-list prefixListName
```

To redistribute static routes with ‘match ip next-hop’ route-map clause in IS-IS.

```
switch(config-router-isis)#redistribute static route-map routeMapName
```

Redistributed routes can be seen using the following show commands. If routes are redistributed into IS-IS then show isis database detail. If routes are redistributed into OSPFv2 then show ip ospf database detail.

```
switch#show ip route
VRF: default
Gateway of last resort is not set
...
I L2 10.20.30.0/24 [115/10] via 1.2.3.4, Ethernet1
```

```
switch#show isis database detail
IS-IS Instance: B VRF: default
IS-IS Level 1 Link State Database
LSPID        Seq Num   Cksum  Life  IS Flags
...
IS-IS Level 2 Link State Database
LSPID        Seq Num   Cksum  Life  IS Flags
0000.0000.0001.00-00 6 10364 840 L2 <>
...
Reachability     : 10.20.30.0/24 Metric: 0 Type: 1 Up
...
13.4.8 Port ACLs with User-Defined Fields

Describes the support for specifying User-Defined Fields (UDF) in Port ACLs including IPv4, IPv6, and MAC ACLs. The purpose of the User-Defined Fields feature is to permit or deny packets based on custom offset pattern matching.

User-Defined Fields, or UDFs, are defined as part of an access-list filter and are comprised of an offset, length, pattern match and mask. This describes a single portion of any incoming packet to match the provided value upon.

UDFs may also be defined via aliases. Aliases are a way to save a UDF configuration for reuse in multiple access-lists and or access-list rules. An alias may substitute for a fully defined UDF including the offset, pattern and mask. The pattern or mask may be overridden when the alias is used in an access-list rule.

The behavior, CLI syntax and configuration of UDFs are identical to Traffic Steering UDF and Mirroring ACL UDF.

This section describes port ACLs with user-defined fields, including configuration instructions. Topics covered by this section include:

- Configuring Port ACLs with User-Defined Fields
- Port ACLs with User-Defined Fields Limitations

13.4.8.1 Configuring Port ACLs with User-Defined Fields

User-Defined Fields are specified as part of an access-list. The type of access-list however, dictates the base position of the UDF and the options available. In addition, a TCAM profile must be configured to include UDFs as part of the Port ACL feature’s key.

13.4.8.1.1 TCAM Profile

User-Defined Fields are defined as additional fields in the Port ACL feature’s key. By default, UDFs are not included in the keys for the Port ACL features. Adding a UDF to the key requires removal of different key fields to fit within the TCAM width restrictions.

>Note: Each UDF is either 16 bits wide or 32 bits wide.

Below are example configurations of the TCAM profile.

13.4.8.1.1.1 IPv4 Port ACL

The following configurations create a new profile based on the default profile. This new profile replaces the Layer 4 port key fields with 1 16-bit UDF and 1 32-bit UDF.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#profile ipv4Udf copy default
switch(config-hw-tcam-profile-ipv4Udf)#feature acl port ip
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#no key field
14-ops
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#no key field
14-src-port
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#no key field
14-dst-port
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#key field
udf-16b-1
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#key field
udf-32b-1
switch(config-hw-tcam-profile-ipv4Udf-feature-acl-port-ip)#exit
switch(config-hw-tcam-profile-ipv4Udf)#exit
```
Layer 3 Configuration

Example-16-bit IPv4 Header Match
The following configurations match IPv4 packets based on the Identification(ID) field. Packets ingressing into *Ethernet Interface 7* with an ID equal to 1000 is forwarded. Packets with an ID different than 1000 is dropped.

```
(config)#ip access-list udfAcl
(config-udfAcl)#permit ip any any payload header start offset 1
  pattern 0x03E80000 mask 0x0000FFFF
(config-udfAcl)#deny ip any any
(config-udfAcl)#exit
(config)#interface ethernet 7
(config-if-Et7)#
```

13.4.8.1.1.2 IPv6 Port ACL
The following configurations create a new profile based on the default profile. This new profile replaces the destination IPv6 address key field with 2 32-bit UDFs.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#profile ipv6Udf copy default
switch(config-hw-tcam-profile-ipv6Udf)#feature acl port ipv6
switch(config-hw-tcam-profile-ipv6Udf-feature-acl-port-ipv6)#no key field dst-ipv6
switch(config-hw-tcam-profile-ipv6Udf-feature-acl-port-ipv6)#key field udf-32b-1
switch(config-hw-tcam-profile-ipv6Udf-feature-acl-port-ipv6)#key field udf-32b-2
switch(config-hw-tcam-profile-ipv6Udf-feature-acl-port-ipv6)#exit
switch(config-hw-tcam-profile-ipv6Udf)#exit
switch(config-hw-tcam)#system profile ipv6Udf
```

Example-32-bit IPv6 Payload Match
The following configurations match IPv6 UDP packets based on the first 32 bits of the packet payload. UDP packets ingressing into *Ethernet Interface 7* that starts with 0x1234567X (where X can be any valid hexadecimal) in the payload are forwarded. Any other packets are dropped. The offset is set to 2 (2 x 4-byte words) to skip the UDP header.

```
(config)#ipv6 access-list udfAcl
(config-ipv6-udfAcl)#permit udp any any payload offset 2 pattern
  0x12345670 mask 0x0000000f
(config-ipv6-udfAcl)#deny ipv6 any any
(config-ipv6-udfAcl)#exit
(config)#interface ethernet 7
(config-if-Et7)#ipv6 access-group udfAcl in
```

13.4.8.2 Port ACLs with User-Defined Fields Limitations
User-defined fields consume a limited set of copy resources. For each unique offset, if a pattern is specified that is masked to be > 16 bits wide, then a 32-bit resource is used. If no 32-bit resource is available, then two 16-bit resources are used, if available. Copy resources are dependent upon the number of UDF key fields added to the feature key. Each UDF key field maps to one copy resource. Using the above TCAM profile configurations:
- IPv4: 1 x 16-bit pattern + 1 x 32-bit pattern.
- IPv6: 2 x 32-bit pattern.
- MAC: 1 x 16-bit pattern + 1 x 32-bit pattern.

Other limitations include:

- Maximum offset value is 31, which is 31 4-byte words, or 124 bytes.
- UDFs only work on ingress Port ACLs.
13.4.9 ACL, Route Map, and Prefix List Commands

This section describes CLI commands that this chapter references.

ACL Creation and Access Commands
• hardware access-list resource sharing vlan in
• hardware access-list resource sharing vlan ipv4 out
• ip access-list
• ip access-list standard
• ipv6 access-list
• ipv6 access-list standard
• mac access-list
• system profile

ACL Implementation Commands
• ip access-group
• ipv6 access-group
• mac access-group

Service ACL Implementation Commands
• ip access-group (Service ACLs)
• ipv6 access-group (Service ACLs)

ACL Edit Commands
• counters per-entry (ACL configuration modes)
• hardware access-list update default-result permit
• no <sequence number> (ACLs)
• resequence (ACLs)
• show (ACL configuration modes)

ACL Rule Commands
• deny (IPv4 ACL)
• deny (IPv6 ACL)
• deny (MAC ACL)
• deny (Standard IPv4 ACL)
• deny (Standard IPv6 ACL)
• permit (IPv4 ACL)
• permit (IPv6 ACL)
• permit (MAC ACL)
• permit (Standard IPv4 ACL)
• permit (Standard IPv6 ACL)
• remark

ACL List Counter Commands
• clear ip access-lists counters
• clear ipv6 access-lists counters
• hardware counter feature acl out
ACL Display Commands
- show ip access-lists
- show ipv6 access-lists
- show mac access-lists

Prefix List Creation and Access Commands
- ip prefix-list
- ipv6 prefix-list

Prefix List Edit Commands
- deny (IPv6 Prefix List)
- permit (IPv6 Prefix List)
- seq (IPv6 Prefix Lists)

Prefix List Display Commands
- show hardware tcam profile
- show ip prefix-list
- show ipv6 prefix-list
- show platform trident tcam
- show platform fap acl
- show platform fap acl tcam
- show platform fap acl tcam hw
- show platform fap acl tcam summary
- show platform arad acl tcam
- show platform arad acl tcam summary
- show platform arad mapping
- show platform fap acl tcam hw

Route Map Creation and Access Command
- route-map

Route Map Edit Commands
- continue (route map)
- description (route map)
- match (route-map)
- set (route-map)
- set as-path prepend
- set as-path match
- set community (route-map)
- set extcommunity (route-map)

Route Map Display Commands
- show route-map
13.4.9.1 clear ip access-lists counters

The `clear ip access-lists counters` command sets ACL counters to zero for the specified IPv4 Access Control List (ACL). The `session` parameter limits ACL counter clearing to the current CLI session.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear ip access-lists counters [ACL_NAME] [SCOPE]

**Parameters**
- **ACL_NAME** Name of ACL. Options include:
  - `no parameter` all ACLs.
  - `access_list` name of ACL.
- **SCOPE** Session affected by command. Options include:
  - `no parameter` command affects counters on all CLI sessions.
  - `session` affects only current CLI session.

**Example**
This command resets all IPv4 ACL counters.

```
switch(config)#clear ip access-lists counters
switch(config)#
```
13.4.9.2  clear ipv6 access-lists counters

The `clear ipv6 access-lists counters` command sets ACL counters to zero for the specified IPv6 Access Control List (ACL). The `session` parameter limits ACL counter clearing to the current CLI session.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear ipv6 access-lists counters [ACL_NAME][SCOPE]
```

**Parameters**
- **ACL_NAME** name of ACL. Options include:
  - `no parameter` all IPv6 ACLs.
  - `access_list` name of IPv6 ACL.
- **SCOPE** Session affected by command. Options include:
  - `no parameter` command affects counters on all CLI sessions.
  - `session` affects only current CLI session.

**Example**
This command resets all IPv6 ACL counters.

```
switch(config)#clear ipv6 access-lists counters
switch(config)#
```
The continue command creates a route map statement entry that enables additional route map evaluation of routes whose parameters meet the statement's matching criteria.

A statement typically contains a match (route-map) and a set (route-map) command. The evaluation of routes whose settings are the same as match command parameters normally ends and the statement's set commands are applied to the route. Routes that match a statement containing a continue command are evaluated against the statement specified by the continue command.

When a route matches multiple route map commands, the filter action (deny or permit) is determined by the last statement that the route matches. The set commands in all statements matching the route are applied to the route after the route map evaluation is complete. Multiple set commands are applied in the same order by which the route was evaluated against the statement containing them.

The no continue and default continue commands remove the corresponding continue command from the configuration mode route map statement by deleting the corresponding command from running-config.

Command Mode
Route-Map Configuration

Command Syntax
continue NEXT_SEQ
no continue NEXT_SEQ
default continue NEXT_SEQ

Parameters
NEXT_SEQ Specifies next statement for evaluating matching routes. Options include:

- **no parameter** Next statement in the route map, as determined by sequence number.
- **seq_number** Specifies the number of the next statement. Values range from 1 to 16777215.

Restrictions
A continue command cannot specify a sequence number smaller than the sequence number of its route map statement.

Related Command
route-map command enters route map configuration mode.

Example
This command creates route map map1, statement 40 with a match command, a set command, and a continue command. Routes that match the statement are subsequently evaluated against statement 100. The set local-preference command is applied to matching routes regardless of subsequent matching operations.

```
switch(config)#route-map map1 deny 40
switch(config-route-map-map1)#match as 15
switch(config-route-map-map1)#continue 100
switch(config-route-map-map1)#set local-preference 50
switch(config-route-map-map1)#
```
13.4.9.4 counters per-entry (ACL configuration modes)

The `counters per-entry` command places the ACL in counting mode. An ACL in counting mode displays the number of instances each rule in the list matches an inbound packet and the elapsed time since the last match. The `show access list` commands display the statistics next to each rule in the ACL.

On the FM6000 platform, this command has no effect when used in an ACL that is part of a PBR class map.

The `no counters per-entry` and `default counters per-entry` commands place the ACL in non-counting mode.

**Command Mode**

ACL Configuration
IPv6-ACL Configuration
Std-ACL Configuration
Std-IPv6-ACL Configuration
MAC-ACL Configuration

**Command Syntax**

`counters per-entry`
`no counters per-entry`
`default counters per-entry`

**Examples**

- This command places the `test1` ACL in counting mode.

```
switch(config)#ip access-list test1
switch(config-acl-test1)#counters per-entry
switch(config-acl-test1)#
```

- This command displays the ACL, with counter information, for an ACL in counting mode.

```
switch#show ip access-lists
IP Access List default-control-plane-acl [readonly]
   counters per-entry
   10 permit icmp any any
   20 permit ip any any tracked [match 12041, 0:00:00 ago]
   30 permit ospf any any
   40 permit tcp any any eq ssh telnet www snmp bgp https [match 11, 1:41:07 ago]
   50 permit udp any any eq bootps bootpc snmp rip [match 78, 0:00:27 ago]
   60 permit tcp any any eq mlag ttl eq 255
   70 permit udp any any eq mlag ttl eq 255
   80 permit vrrp any any
   90 permit ahp any any
   100 permit pim any any
   110 permit igmp any any [match 14, 0:23:27 ago]
   120 permit tcp any any range 5900 5910
   130 permit tcp any any range 50000 50100
   140 permit udp any any range 51000 51100
```
13.4.9.5  deny (IPv4 ACL)

The **deny** command adds a deny rule to the configuration mode IPv4 Access Control List (ACL). Packets filtered by a **deny** rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding **10** to the number of the ACL’s last rule.

The **no deny** and **default deny** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**

ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [FLAGS][MESSAGE][fragments][tracked][DSCP_FILTER][TTL_FILTER][log]
```

```
no deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT][FLAGS] [MESSAGE][fragments][tracked][DSCP_FILTER][TTL_FILTER][log]
```

```
default deny PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [FLAGS][MESSAGE][fragments][tracked][DSCP_FILTER][TTL_FILTER][log]
```

- **Note:** Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a deny rule.

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - **no parameter** Number is derived by adding 10 to the number of the ACL’s last rule.
  - **14294967295** Number assigned to entry.
- **PROTOCOL** protocol field filter. Values include:
  - **ahp** Authentication Header Protocol (51).
  - **icmp** Internet Control Message Protocol (1).
  - **igmp** Internet Group Management Protocol (2).
  - **ip** Internet Protocol v4 (4).
  - **ospf** Open Shortest Path First (89).
  - **pim** Protocol Independent Multicast (103).
  - **tcp** Transmission Control Protocol (6).
  - **udp** User datagram protocol (17).
  - **vrrp** Virtual Router Redundancy Protocol (112).
  - **protocol_num** Integer corresponding to an IP protocol. Values range from **0** to **255**.
- **SOURCE_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - **network_addr** Subnet address (CIDR or address-mask).
  - **any** Packets from all addresses are filtered.
  - **host ip_addr** IP address (dotted decimal notation).
  - Subnet addresses support discontiguous masks.
- **SOURCE_PORT** and **DEST_PORT** Source and destination port filters. Options include:
  - **any** All ports.
  - **eq port-1 port-2 ... port-n** A list of ports. Maximum list size is 10 ports.
  - **neq port-1 port-2 ... port-n** The set of all ports not listed. Maximum list size is 10 ports.
  - **gt port** The set of ports with larger numbers than the listed port.
  - **lt port** The set of ports with smaller numbers than the listed port.
Layer 3 Configuration

- **range port_1 port_2** The set of ports whose numbers are between the range.
- **fragments** Filters packets with FO bit set (indicates a non-initial fragment packet).
- **FLAGS** Flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
- **MESSAGE** Message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
- **tracked** Rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **DSCP_FILTER** Rule filters packet by its DSCP value. Values include:
  - *no parameter* Rule does not use DSCP to filter packets.
  - *dscp dscp_value* Packets match if DSCP field in packet is equal to *dscp_value*.
- **TTL_FILTER** Rule filters packet by its TTL (time-to-live) value. Values include:
  - *ttl eq ttl_value* Packets match if TTL in packet is equal to *ttl_value*.
  - *ttl gt ttl_value* Packets match if TTL in packet is greater than *ttl_value*.
  - *ttl lt ttl_value* Packets match if TTL in packet is less than *ttl_value*.
  - *ttl neq ttl_value* Packets match if TTL in packet is not equal to *ttl_value*.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **log** Triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

Examples

- This command appends a *deny* statement at the end of the ACL. The *deny* statement drops OSPF packets from *10.10.1.0/24* to any host.

```
switch(config)#ip access-list text1
switch(config-acl-text1)#deny ospf 10.1.0/24 any
switch(config-acl-text1)#
```

- This command inserts a *deny* statement with the sequence number 65. The *deny* statement drops all PIM packets.

```
switch(config-acl-text1)#65 deny pim any any
switch(config-acl-text1)#
```
13.4.9.6  deny (IPv6 ACL)

The `deny` command adds a deny rule to the configuration mode IPv6 Access Control List (ACL). Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL's last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

Command Mode
IPv6-ACL Configuration

Command Syntax

```
[SEQ_NUM] deny PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT][FLAG][MSG][hop][DSCP_FILTER][log]
```

```
no deny PROT SRC_ADDR [SOURCE_PT] DEST_ADDR [DEST_PT][FLAG][MSG][hop][tracked][DSCP_FILTER][log]
```

```
default deny PROT SRC_ADDR [SOURCE_PT] DEST_ADDR [DEST_PT][FLAG][MSG][hop][tracked][DSCP_FILTER][log]
```

Note: Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a deny rule.

Parameters

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL's last rule.
  - `1 - 4294967295` Number assigned to entry.
- **PROT** Protocol field filter. Values include:
  - `icmpv6` Internet Control Message Protocol for version 6 (58).
  - `ipv6` Internet Protocol IPv6 (41).
  - `ospf` Open Shortest Path First (89).
  - `tcp` Transmission Control Protocol (6).
  - `udp` User Datagram Protocol (17).
  - `protocol_num` Integer corresponding to an IP protocol. Values range from 0 to 255.
- **SRC_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.
- **SRC_PT** and **DEST_PT** Source and destination port filters. Options include:
  - `any` All ports.
  - `eq port-1 port-2 ... port-n` A list of ports. Maximum list size is 10 ports.
  - `neq port-1 port-2 ... port-n` The set of all ports not listed. Maximum list size is 10 ports.
  - `gt port` The set of ports with larger numbers than the listed port.
  - `lt port` The set of ports with smaller numbers than the listed port.
  - `range port_1 port_2` The set of ports whose numbers are between the range.
- **HOP** Filters by packet's hop-limit value. Options include:
  - `no parameter` Rule does not use hop limit to filter packets.
  - `hop-limit eq hop_value` Packets match if hop-limit value in packet equals `hop_value`.
  - `hop-limit gt hop_value` Packets match if hop-limit in packet is greater than `hop_value`.  

• hop-limit lt hop_value Packets match if hop-limit in packet is less than hop_value.
• hop-limit neq hop_value Packets match if hop-limit in packet is not equal to hop_value.
• FLAG Flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
• MSG Message type filters (ICMPv6 packets). Use CLI syntax assistance (?) to display options.
• tracked Rule filters packets in existing ICMP, UDP, or TCP connections.
  • Valid in ACLs applied to the control plane.
  • Validity in ACLs applied to data plane varies by switch platform.
• DSCP_FILTER Rule filters packet by its DSCP value. Values include:
  • no parameter Rule does not use DSCP to filter packets.
  • dscp dscp_value Packets match if DSCP field in packet is equal to dscp_value.
  • log Triggers an informational log message to the console about the matching packet.
  • Valid in ACLs applied to the control plane.
  • Validity in ACLs applied to data plane varies by switch platform.

Example
This command appends a deny statement at the end of the ACL. The deny statement drops IPv6 packets from 3710:249a:c643:ef11::/64 to any host.

```
switch(config)#ipv6 access-list text1
switch(config-acl-text1)#deny ipv6 3710:249a:c643:ef11::/64 any
switch(config-acl-text1)#
```
13.4.9.7 deny (IPv6 Prefix List)

The `deny` command adds a rule to the configuration mode IPv6 prefix list. Route map match commands use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains. Routes are denied access when they match the prefix that a `deny` statement specifies.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode prefix list. The `no seq (IPv6 Prefix Lists)` command also removes the specified rule from the prefix list.

**Command Mode**
IPv6-pfx Configuration

**Command Syntax**

```
[SEQUENCE] deny ipv6_prefix [MASK]
```

**Parameters**

- **SEQUENCE** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the list's last rule.
  - `seq seq_num` Number is specified by `seq_num`. Value ranges from 0 to 65535.
- **ipv6_prefix** IPv6 prefix upon which command filters routes (CIDR notation).
- **MASK** Range of the prefix to be matched.
  - `no parameter` Exact match with the subnet mask is required.
  - `eq mask_e` Prefix length is equal to `mask_e`.
  - `ge mask_g` Range is from `mask_g` to 128.
  - `le mask_l` Range is from subnet mask length to `mask_l`.
  - `ge mask_l le mask_g` Range is from `mask_g` to `mask_l`.
  - When `le` and `ge` are specified, subnet mask `mask_g mask_l`.

**Example**

This command appends a `deny` statement at the end of the text1 prefix list. The `deny` statement denies redistribution of routes with the specified prefix.

```bash
switch(config)#ipv6 prefix-list route-five
switch(config-ipv6-pfx)#deny 3100::/64
switch(config-ipv6-pfx)#
```
13.4.9.8  deny (MAC ACL)

The `deny` command adds a deny rule to the configuration mode MAC Access Control List (ACL). Packets filtered by a deny rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**
MAC-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

```
no deny SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

```
default deny SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `1 - 4294967295` Number assigned to entry.
- **SOURCE_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - `mac_address mac_mask` MAC address and mask.
  - `any` Packets from all addresses are filtered.
  - `mac_address` specifies a MAC address in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh).
  - `mac_mask` specifies a MAC address mask in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh).
  - 0 bits require an exact match to filter.
  - 1 bits filter on any value.
- **PROTOCOL** Protocol field filter. Values include:
  - `aarp` Appletalk Address Resolution Protocol (0x80f3).
  - `appletalk` Appletalk (0x809b).
  - `arp` Address Resolution Protocol (0x806).
  - `ip` Internet Protocol Version 4 (0x800).
  - `ipx` Internet Packet Exchange (0x8137).
  - `lldp` LLDP (0x88cc).
  - `novell` Novell (0x8138).
  - `rarp` Reverse Address Resolution Protocol (0x8035).
  - `protocol_num` Integer corresponding to a MAC protocol. Values range from 0 to 65535.
- **log** Triggers an informational log message to the console about the matching packet.

**Examples**

- This command appends a permit statement at the end of the ACL. The deny statement drops all aarp packets from 10.1000.0000 through 10.1000.FFFF to any host.

```
switch(config)#mac access-list text1
switch(config-mac-acl-text1)#deny 10.1000.0000 0.0.FFFF any aarp
```
• This command inserts a permit statement with the sequence number 25. The deny statement drops all packets through the interface.

```bash
switch(config-mac-acl-text1)#25 deny any any
```
13.4.9.9 deny (Standard IPv4 ACL)

The `deny` command adds a deny rule to the configuration mode standard IPv4 Access Control List (ACL). Standard ACL rules filter on the source field.

Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL's last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

Std-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] deny SOURCE_ADDR [log]
no deny SOURCE_ADDR [log]
default deny SOURCE_ADDR [log]
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `1 - 4294967295` Number assigned to entry.
- **SOURCE_ADDR** Source address filter. Options include:
  - `network_addr` Subnet address (CIDR or address-mask).
  - `any` Packets from all addresses are filtered.
  - `host ip_addr` IP address (dotted decimal notation).
    - Subnet addresses support discontiguous masks.
  - `log` Triggers an informational log message to the console about the matching packet.
    - Valid in ACLs applied to the control plane.
    - Validity in ACLs applied to data plane varies by switch platform.

**Example**

This command appends a `deny` statement at the end of the ACL. The `deny` statement drops packets from `10.10.1.1/24`.

```
switch(config)#ip access-list standard text1
switch(config-std-acl-text1)#deny 10.1.1.1/24
switch(config-std-acl-text1)#
```
13.4.9.10  deny (Standard IPv6 ACL)

The `deny` command adds a deny rule to the configuration mode standard IPv6 Access Control List (ACL). Standard ACL rules filter on the source field.

Packets filtered by a `deny` rule are dropped by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no deny` and `default deny` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

Command Mode

Std-IPv6-ACL Configuration

Command Syntax

```
[SEQ_NUM] deny SOURCE_ADDR
no deny SOURCE_ADDR
default deny SOURCE_ADDR
```

Parameters

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `1 - 4294967295` Number assigned to entry.
- **SOURCE_ADDR** Source address filter. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.

Example

This command appends a `deny` statement at the end of the ACL. The `deny` statement drops packets from `2103::/64`.

```
switch(config)#ipv6 access-list standard text1
switch(config-std-acl-ipv6-text1)#deny 2103::/64
switch(config-std-acl-ipv6-text1)#
```
13.4.9.11 **description (route map)**

The `description` command adds a text string to the configuration mode route map. The string has no functional impact on the route map.

The `no description` and `default description` commands remove the text string from the configuration mode route map by deleting the corresponding `description` command from running-config.

**Command Mode**
Route-Map Configuration

**Command Syntax**

description *label_text*

no description

default description

**Parameters**

*label_text* Character string assigned to the route map configuration.

**Related Command**

route-map.

**Example**

These commands add description text to the *XYZ-1* route map.

```
switch(config)#route-map XYZ-1
switch(config-route-map-XYZ-1)#description This is the first map.
switch(config-route-map-XYZ-1)#exit
switch(config)#show route-map XYZ-1
route-map XYZ-1 permit 10
  Description:
    description This is the first map.
  Match clauses:
  Set clauses:
switch(config)#
```
13.4.9.12  hardware access-list resource sharing vlan in

The `hardware access-list resource sharing vlan in` command enables the IPv4 Ingress Sharing of hardware resources on the switch. The same ACL is applied on different VLANs.

The `no hardware access-list resource sharing vlan in` command disables the IPv4 Ingress Sharing of hardware resources on the switch.

**Command Mode**

Global Configuration

**Command Syntax**

```
hardware access-list resource sharing vlan in
no hardware access-list resource sharing vlan in
```

**Guidelines**

- This command is compatible only with the DCS-7010 and DCS-7050x series switches.
- Enabling IPv4 Ingress Sharing requires the restart of software agents on the platform. This is a disruptive process and impacts traffic forwarding.

Use the `show platform trident` command to verify the Ingress IPv4 Sharing information.
13.4.9.13  **hardware access-list resource sharing vlan ipv4 out**

The **hardware access-list resource sharing vlan ipv4 out** command enables the IPv4 Egress RACL TCAM sharing on the switch.

The **no hardware access-list resource sharing vlan ipv4 out** command disables the IPv4 Egress RACL TCAM sharing on the switch. By default, the IPv4 Egress RACL sharing is enabled on the switch.

**Command Mode**

Global Configuration

**Command Syntax**

**hardware access-list resource sharing vlan ipv4 out**

**no hardware access-list resource sharing vlan ipv4 out**

**Guidelines**

- This command is compatible only with the DCS-7280E and DCS-7500E series switches.
- Disabling IPv4 RACL sharing requires the restart of software agents on the platform. This is a disruptive process and impacts traffic forwarding.
- Enabling IPv4 RACL sharing, if previously disabled from the default configuration, requires the restart of software agents on the platform. This is a disruptive process and impacts traffic forwarding. Enabling IPv4 RACL sharing if uRPF is configured will disable uRPF.
- Use the **show running-config all | include sharing** command to verify whether or not sharing for egress IPv4 RACLs is enabled.

**Example**

This command verifies whether IPv4 RACL sharing is enabled or disabled.

```
switch#show running-config all | include sharing

hardware access-list resource sharing vlan ipv4 out

---->It returns the following output if IPv4 RACL sharing is enabled.
```

1889
The `hardware access-list update default-result permit` command configures the switch to permit all traffic on Ethernet and VLAN interfaces with ACLs applied to them while those ACLs are being modified. Traffic is permitted when the ACL is available for modification using one of the `ip access-list` commands, and ends when the ACL configuration mode is exited and rules are populated in hardware. This command is disabled by default.

The `no hardware access-list update default-result permit` and `default hardware access-list update default-result permit` commands restore the switch to its default state (blocking traffic during ACL modifications) by removing the corresponding `hardware access-list update default-result permit` command from the `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
hardware access-list update default-result permit
no hardware access-list update default-result permit
default hardware access-list update default-result permit
```

**Restrictions**
This command is available on the Arista 7050X, 7060X, 7150, 7250X, 7280, 7280R, 7300X, 7320X, and 7500 series switches.

This command does not support egress ACLs.

While this command is enabled, static NAT, and ACL-based mirroring are affected during ACL updates.

**Example**
This command configures a 7150 series switch to permit all traffic on Ethernet and VLAN interfaces with ACLs applied to them while those ACLs are being modified.

```
switch(config)#hardware access-list update default-result permit
switch(config)#
```
13.4.9.15  hardware counter feature acl out

The `hardware counter feature acl out` command enables egress ACL hardware counters for IPv4 or IPv6, which count the number of packets hitting rules associated with egress ACLs applied to various interfaces on a switch.

The `no hardware counter feature acl out` and `default hardware counter feature acl out` commands disable or return the egress ACL hardware counters to the default state.

**Command Mode**
Global Configuration

**Command Syntax**

```
hardware counter feature acl out [OPTIONS]
no hardware counter feature acl out [OPTIONS]
default hardware counter feature acl out [OPTIONS]
```

**Parameters**

- **OPTIONS** ACL hardware counter options include:
  - `ipv4` Address family IPv4.
  - `ipv6` Address family IPv6.

**Examples**

- This command enables IPv4 egress ACL hardware counters.

```
switch(config)#hardware counter feature acl out ipv4
switch(config)#
```

- This command disables IPv4 egress ACL hardware counters.

```
switch(config)#no hardware counter feature acl out ipv4
switch(config)#
```
13.4.9.16  ip access-group (Service ACLs)

The ip access-group (Service ACLs) command configures a Service ACL to be applied by a control-plane service. The service is specified by the command mode in which the Service ACL is applied.

The no ip access-group (Service ACLs) and default ip access-group (Service ACLs) commands remove the corresponding ip access-group (Service ACLs) command from running-config.

Command Mode
Mgmt-SSH Configuration
Mgmt-API Configuration
Router-BGP Configuration
Router-OSPF Configuration
Router-IGMP Configuration
MPLS-LDP Configuration
Queue-Monitor-Streaming Configuration
MPLS-Ping Configuration
Mgmt-Telnet Configuration

Command Syntax
ip access-group acl_name [vrf vrf_name][in]
no ip access-group acl_name [vrf vrf_name][in]
default ip access-group acl_name [vrf vrf_name][in]

Parameters
Parameters vary by process.

- **acl_name** Name of the Service ACL assigned to control-plane service.
- **vrf vrf_name** Specifies the VRF in which the Service ACL is to be applied.
- **in** Specifies inbound connections or packets only (keyword required for SSH and Telnet services).

Example

These commands apply the Service ACL bgpacl to the BGP routing protocol in VRF purple.

```
(config)#router bgp 5
(config-router-bgp)#vrf purple
(config-router-bgp-vrf-purple)#ip access-group bgpacl
```

For additional configuration examples, see Configuring Service ACLs and Displaying Status and Counters.
13.4.9.17  ip access-group

The ip access-group command applies an IPv4 or standard IPv4 access control list (ACL) to the configuration mode interface or subinterface.

The no ip access-group and default ip access-group commands remove the corresponding ip access-group command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

ip access-group list_name DIRECTION
no ip access-group list_name DIRECTION
default ip access-group list_name DIRECTION

Parameters

• list_name Name of ACL assigned to interface.
• DIRECTION Transmission direction of packets, relative to interface. Valid options include:
  • in  Inbound packets.
  • out Outbound packets.

Restrictions

Filtering of outbound packets by ACLs is not supported on Petra platform switches.
Filtering of outbound packets by ACLs on FM6000 switches is supported on physical interfaces only (Ethernet and port channels).

ACLs on sub-interfaces are supported on DCS-7280E, DCS-7500E, DCS-7280R, and DCS-7500R.

Example

These commands apply the IPv4 ACL named test2 to interface ethernet 3.

switch(config)#interface ethernet 3
switch(config-if-Et3)#ip access-group test2 in
switch(config-if-Et3)#
The `ip access-list standard` command places the switch in std-ACL configuration mode, which is a group change mode that modifies a standard IPv4 access control list. The command specifies the name of the standard IPv4 ACL that subsequent commands modify, and creates an ACL if it references a nonexistent list. All group change mode edit session changes are pending until the session ends.

The `exit` command saves pending ACL changes to `running-config`, then returns the switch to global configuration mode. Pending changes are also saved by entering a different configuration mode.

The `abort` command discards pending ACL changes, returning the switch to global configuration mode.

The `no ip access-list standard` and `default ip access-list standard` commands delete the specified ACL.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
ip access-list standard list_name
no ip access-list standard list_name
default ip access-list standard list_name
```

**Parameters**

`list_name` Name of standard ACL. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in std-ACL configuration mode:**

- `deny (Standard IPv4 ACL)`
- `no <sequence number> (ACLs)`
- `permit (Standard IPv4 ACL)`
- `remark`
- `resequence (ACLs)`
- `show (ACL configuration modes)`

**Related Commands**

- `ip access-list` Enters ACL configuration mode for editing IPv4 ACLs.
- `show ip access-lists` Displays IPv4 and standard IPv4 ACLs.

**Examples**

- This command places the switch in std-ACL configuration mode to modify the `filter2` IPv4 ACL.

  ```plaintext
  switch(config)#ip access-list standard filter2
  switch(config-std-acl-filter2)#
  ```

- This command saves changes to `filter2` ACL, then returns the switch to global configuration mode.

  ```plaintext
  switch(config-std-acl-filter2)#exit
  switch(config)#
  ```

- This command discards changes to `filter2`, then returns the switch to global configuration mode.

  ```plaintext
  switch(config-std-acl-filter2)#abort
  switch(config)#
  ```
The `ip access-list` command places the switch in ACL configuration mode, which is a group change mode that modifies an IPv4 access control list. The command specifies the name of the IPv4 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The `exit` command saves pending ACL changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending ACL changes, returning the switch to global configuration mode.

The `no ip access-list` and `default ip access-list` commands delete the specified IPv4 ACL.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip access-list list_name
no ip access-list list_name
default ip access-list list_name
```

**Parameters**

`list_name` Name of ACL. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in ACL configuration mode:**

- deny (IPv4 ACL)
- no <sequence number> (ACLs)
- permit (IPv4 ACL)
- remark
- resequence (ACLs)
- show (ACL configuration modes)

**Related Commands:**

- `ip access-list standard` Enters `std-acl` configuration mode for editing standard IP ACLs.
- `show ip access-lists` Displays IP and standard ACLs.

**Examples**

- This command places the switch in ACL configuration mode to modify the `filter1` IPv4 ACL.

  ```
  switch(config)#ip access-list filter1
  switch(config-acl-filter1)#
  ```

- This command saves changes to `filter1` ACL, then returns the switch to global configuration mode.

  ```
  switch(config-acl-filter1)#exit
  switch(config)#
  ```

- This command discards changes to `filter1`, then returns the switch to global configuration mode.

  ```
  switch(config-acl-filter1)#abort
  switch(config)#
  ```
The `ip prefix-list` command creates a prefix list or adds an entry to an existing list. Route map match commands use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains.

A prefix list comprises all prefix list entries with the same label. The sequence numbers of the rules in a prefix list specify the order that the rules are applied to a route that the match command is evaluating.

The `no ip prefix-list` and `default ip prefix-list` commands delete the specified prefix list entry by removing the corresponding `ip prefix-list` statement from `running-config`. If the `no` or `default ip prefix-list` command does not list a sequence number, the command deletes all entries of the prefix list.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip prefix-list list_name [SEQUENCE] FILTER_TYPE network_addr [MASK]
no ip prefix-list list_name [SEQUENCE]
default ip prefix-list list_name [SEQUENCE]
```

**Parameters**

- `list_name` The label that identifies the prefix list.
- `SEQUENCE` Sequence number of the prefix list entry. Options include:
  - `no parameter` Entry's number is ten plus highest sequence number in current list.
  - `seq seq_num` Number assigned to entry. Value ranges from 0 to 65535.
- `FILTER_TYPE` Specifies route access when it matches IP prefix list. Options include:
  - `permit` Routes are permitted access when they match the specified subnet.
  - `deny` Routes are denied access when they match the specified subnet.
- `network_addr` Subnet upon which command filters routes. Format is CIDR or address-mask.
- `MASK` Range of the prefix to be matched.
  - `eq mask_e` Prefix length is equal to `mask_e`.
  - `ge mask_g` Range is from 1 to 32.
  - `le mask_l` Range is from `subnet` mask length to `mask_l`.
  - `ge mask_g` to `mask_l`
  - `eq mask_e`, `mask_l`, and `mask_g` range from 1 to 32. When `le` and `ge` are specified, `subnet mask mask_g>mask_l`.

**Example**

- This command places the switch in IPv4 prefix list configuration mode to create an IPv4 prefix list named `route-one`.

```bash
switch(config)#ip prefix-list route-one
switch(config-ip-pfx)#
```

- These commands create four different rules for the prefix-list named `route-one`.

```bash
switch(config)#ip prefix-list route-one
switch(config-ip-pfx)#seq 10 deny 10.1.1.0/24
switch(config-ip-pfx)#seq 20 deny 10.1.0.0/16
switch(config-ip-pfx)#seq 30 permit 12.15.4.9/32
switch(config-ip-pfx)#seq 40 deny 1.1.1.0/24
```
13.4.9.21  ipv6 access-group (Service ACLs)

The `ipv6 access-group` (Service ACLs) command configures an IPv6 or standard IPv6 Service ACL to be applied by a control-plane service. The service is specified by the command mode in which the Service ACL is applied.

The `no ipv6 access-group` (Service ACLs) and `default ipv6 access-group` (Service ACLs) commands remove the corresponding `ipv6 access-group` (Service ACLs) command from `running-config`.

**Command Mode**

Mgmt-SSH Configuration
Mgmt-API Configuration
Router-BGP Configuration
Router-OSPF Configuration
MPLS-LDP Configuration
Queue-Monitor-Streaming Configuration
MPLS-Ping Configuration
Mgmt-Telnet Configuration

**Command Syntax**

```
ipv6 access-group ipv6_acl_name [vrf vrf_name][in]
no ipv6 access-group [ipv6_acl_name][vrf vrf_name][in]
default ipv6 access-group ipv6_acl_name [vrf vrf_name][in]
```

**Parameters**

Parameters vary by process.

- `ipv6_acl_name` Name of the IPv6 Service ACL assigned to control-plane service.
- `vrf vrf_name` Specifies the VRF in which the Service ACL is to be applied.
- `in` Specifies inbound connections or packets only (keyword required for SSH and Telnet services).

**Example**

These commands apply the IPv6 Service ACL `bgpacl` to the BGP routing protocol in VRF `purple`.

```
(config)#router bgp 5
(config-router-bgp)#vrf purple
(config-router-bgp-vrf-purple)#ipv6 access-group bgpacl
```

For additional configuration examples, see Configuring Service ACLs and Displaying Status and Counters.
13.4.9.22 ipv6 access-group

The `ipv6 access-group` command applies an IPv6 or standard IPv6 Access Control List (ACL) to the configuration mode interface.

The `no ipv6 access-group` and `default ipv6 access-group` commands remove the corresponding `ipv6 access-group` command from `running-config`.

Command Mode

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

Command Syntax

```
ipv6 access-group list_name DIRECTION
no ipv6 access-group list_name DIRECTION
default ipv6 access-group list_name DIRECTION
```

Parameters

- `list_name` Name of ACL assigned to interface.
- `DIRECTION` Transmission direction of packets, relative to interface. Valid options include:
  - `in` Inbound packets.
  - `out` Outbound packets.

Examples

These commands assign the IPv6 ACL named `test2` to the `interface ethernet 3`.

```
switch(config)#interface ethernet 3
switch(config-if-Et3)#ipv6 access-group test2 in
switch(config-if-Et3)#
```
13.4.9.23  ipv6 access-list standard

The `ipv6 access-list standard` command places the switch in std-IPv6-ACL-configuration mode, which is a group change mode that modifies a standard IPv6 access control list. The command specifies the name of the standard IPv6 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All group change mode edit session changes are pending until the session ends.

The `exit` command saves pending ACL changes to `running-config`, then returns the switch to global configuration mode. Pending changes are also saved by entering a different configuration mode.

The `abort` command discards pending ACL changes, returning the switch to global configuration mode.

The `no ipv6 access-list standard` and `default ipv6 access-list standard` commands delete the specified ACL.

**Command Mode**
Global Configuration

**Command Syntax**

- `ipv6 access-list standard list_name`
- `no ipv6 access-list standard list_name`
- `default ipv6 access-list standard list_name`

**Parameters**

- `list_name` Name of ACL. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in std-IPv6-ACL configuration mode:**

- `deny (Standard IPv6ACL)`
- `no <sequence number> (ACLs)`
- `permit (Standard IPv6ACL)`
- `remark`
- `resequence (ACLs)`
- `show (ACL configuration modes)`

**Related Commands**

- `ipv6 access-list` Enters IPv6-ACL configuration mode for editing IPv6 ACLs.
- `show ipv6 access-lists` Displays IPv6 and standard IPv6 ACLs.

**Examples**

- This command places the switch in Std-IPv6 ACL configuration mode to modify the `filter2` ACL.

```
switch(config)#ipv6 access-list standard filter2
switch(config-std-ipv6-acl-filter2)#
```

- This command saves changes to `filter2` ACL, then returns the switch to global configuration mode.

```
switch(config-std-ipv6-acl-filter2)#exit
switch(config)#
```

- This command discards changes to `filter2`, then returns the switch to global configuration mode.

```
switch(config-std-ipv6-acl-filter2)#abort
switch(config)#
```
ipv6 access-list

The `ipv6 access-list` command places the switch in IPv6-ACL configuration mode, which is a group change mode that modifies an IPv6 access control list. The command specifies the name of the IPv6 ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The `exit` command saves pending ACL changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending ACL changes, returning the switch to global configuration mode.

The `no ipv6 access-list` and `default ipv6 access-list` commands delete the specified IPv6 ACL.

**Command Mode**

Global Configuration

**Command Syntax**

```
ipv6 access-list list_name
no ipv6 access-list list_name
default ipv6 access-list list_name
```

**Parameters**

`list_name` Name of ACL. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in IPv6-ACL configuration mode:**

- `deny` (IPv6 ACL)
- `no <sequence number>` (ACLs)
- `permit` (IPv6 ACL)
- `remark`
- `resequence` (ACLs)
- `show` (ACL configuration modes)

**Related Commands**

- `ipv6 access-list standard` Enters `std-ipv6-acl` configuration mode for editing standard IPv6 ACLs.
- `show ipv6 access-lists` Displays IPv6 and standard IPv6 ACLs.

**Examples**

- This command places the switch in IPv6-ACL configuration mode to modify the `filter1` IPv6 ACL.

```
switch(config)#ipv6 access-list filter1
switch(config-ipv6-acl-filter1)#
```

- This command saves changes to `filter1` ACL, then returns the switch to global configuration mode.

```
switch(config-ipv6-acl-filter1)#exit
switch(config)#
```

- This command discards changes to `filter1`, then returns the switch to global configuration mode.

```
switch(config-ipv6-acl-filter1)#abort
switch(config)#
```
13.4.9.25 **ipv6 prefix-list**

The `ip prefix-list` command places the switch in **IPv6 prefix-list** configuration mode, which is a group change mode that modifies an IPv6 prefix list. The command specifies the name of the IPv6 prefix list that subsequent commands modify and creates a prefix list if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The `exit` command saves pending prefix list changes to **running-config**, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending changes, returning the switch to global configuration mode.

The `no ipv6 prefix-list` and `default ipv6 prefix-list` commands delete the specified IPv6 prefix list.

**Command Mode**

Global Configuration

**Command Syntax**

```
ipv6 prefix-list list_name
no ipv6 prefix-list list_name
default ipv6 prefix-list list_name
```

**Parameter**

`list_name` Name of prefix list. Must begin with an alphabetic character. Cannot contain spaces or quotation marks.

**Commands Available in IPv6-pfx configuration mode:**

- `deny (IPv6 Prefix List)`
- `permit (IPv6 Prefix List)`
- `seq (IPv6 Prefix Lists)`

**Examples**

- This command places the switch in **IPv6 prefix-list** configuration mode to modify the `route-five` prefix list.

  ```
  switch(config)#ipv6 prefix-list route-five
  switch(config-ipv6-pfx)#
  ```

- This command saves changes to the prefix list, then returns the switch to global configuration mode.

  ```
  switch(config-ipv6-pfx)#exit
  switch(config)#
  ```

- This command saves changes to the prefix list, then places the switch in `interface-ethernet` mode.

  ```
  switch(config-ipv6-pfx)#interface ethernet 3
  switch(config-if-Et3)#
  ```

- This command discards changes to the prefix list, then returns the switch to global configuration mode.

  ```
  switch(config-ipv6-pfx)#abort
  switch(config)#
  ```
13.4.9.26  mac access-group

The `mac access-group` command applies a MAC Access Control List (MAC ACL) to the configuration mode interface.

The `no mac access-group` and `default mac access-group` commands remove the specified `mac access-group` command from `running-config`.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration

Command Syntax

- `mac access-group list_name DIRECTION`
- `no mac access-group list_name DIRECTION`
- `default mac access-group list_name DIRECTION`

Parameters

- `list_name` Name of MAC ACL.
- `DIRECTION` Transmission direction of packets, relative to interface. Valid options include:
  - `in` Inbound packets.
  - `out` Outbound packets.

Restrictions

Filtering of outbound packets by MAC ACLs is supported only on Helix, Trident, and Trident II platform switches.

Example

These commands assign the MAC ACL named `mtest2` to `interface ethernet 3` to filter inbound packets.

```
switch(config)#interface ethernet 3
switch(config-if-Et3)#mac access-group mtest2 in
switch(config-if-Et3)#
```
13.4.9.27  mac access-list

The `mac access-list` command places the switch in `MAC-ACL` configuration mode, which is a group change mode that modifies a MAC access control list. The command specifies the name of the MAC ACL that subsequent commands modify and creates an ACL if it references a nonexistent list. All changes in a group change mode edit session are pending until the end of the session.

The `exit` command saves pending ACL changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending ACL changes, returning the switch to global configuration mode.

The `no mac access-list` and `default mac access-list` commands delete the specified list.

**Command Mode**
Global Configuration

**Command Syntax**
```
mac access-list list_name
no mac access-list list_name
default mac access-list list_name
```

**Parameters**
`list_name` Name of MAC ACL. Names must begin with an alphabetic character and cannot contain a space or quotation mark.

**Commands Available in MAC-ACL configuration mode:**
- `deny (MAC ACL)`
- `no <sequence number> (ACLs)`
- `permit (MAC ACL)`
- `remark`
- `resequence (ACLs)`
- `show (ACL configuration modes)`

**Examples**
- This command places the switch in `MAC-ACL` configuration mode to modify the `mfilter1` MAC ACL.

```
switch(config)#mac access-list mfilter1
switch(config-mac-acl-mfilter1)#
```

- This command saves changes to `mfilter1` ACL, then returns the switch to global configuration mode.

```
switch(config-mac-acl-mfilter1)#exit
switch(config)#
```

- This command saves changes to `mfilter1` ACL, then places the switch in `interface-ethernet` mode.

```
switch(config-mac-acl-mfilter1)#interface ethernet 3
switch(config-if-Et3)#
```

- This command discards changes to `mfilter1`, then returns the switch to global configuration mode.

```
switch(config-mac-acl-mfilter1)#abort
switch(config)#
```
13.4.9.28 match (route-map)

The **match** command creates a route map statement entry that specifies one route filtering command. When a statement contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each **match** command. When a route properties do not equal the command parameters, the route is evaluated against the next statement in the route map, as determined by sequence number. If all statements fail to permit or deny the route, the route is denied.

The **no match** and **default match** commands remove the **match** command from the configuration mode route map statement by deleting the corresponding command from **running-config**.

**Note:** The route map configuration supports only standard ACL.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
match CONDITION
no match CONDITION
default match CONDITION
```

**Parameters**

- **CONDITION** Specifies criteria for evaluating a route. Options include:
  - **aggregate-role** Role in BGP contributor-aggregate relation. Options include:
    - **contributor** BGP aggregate's contributor.
    - **aggregate-attributes** Route map to apply against the aggregate route.
    - **as** 1 to 4294967295 BGP Autonomous System number.
    - **as-path** *path_name* BGP Autonomous System path access list.
    - **community** *NAME* BGP community. Options for *NAME* include:
      - **listname** BGP community.
      - **listname exact-match** BGP community; list must match set that is present.
    - **extcommunity** *listname* BGP extended community. Options for *NAME* include:
      - **listname** BGP community.
      - **listname exact-match** BGP community; list must match set that is present.
    - **interface** *INTF_NAME* Specifies an interface. Options for *INTF_NAME* include:
      - **ethernet** *e_num* Ethernet interface.
      - **loopback** *l_num* Loopback interface.
      - **port-channel** *p_num* Port channel interface.
      - **vlan** *v_num* VLAN interface.
  - **invert-result** Invert sub route map result.
  - **ip address** *LIST* IPv4 address filtered by an ACL or prefix list. *LIST* options include:
    - **access-list acl_name** IPv4 address filtered by access control list (ACL).
    - **prefix-list plv4_name** IPv4 address filtered by IP prefix list.
  - **ip next-hop prefix-list** *plv4_name* IPv4 next-hop filtered by IP prefix list.
  - **ip resolved-next-hop prefix-list** *plv4_name* IPv4 resolved next-hop filtered by IP prefix list.
  - **ipv6 address prefix-list** *plv6_name* IPv6 address filtered by IPv6 prefix list.
  - **ipv6 next-hop prefix-list** *plv6_name* IPv6 next-hop filtered by IPv6 prefix list.
  - **ipv6 resolved-next-hop prefix-list** *plv6_name* IPv6 resolved next-hop filtered by IPv6 prefix list.
• **local-preference** 1 to 4294967295 BGP local preference metric.
• **metric** 1 to 4294967295 Route metric.
• **metric-type** OSPF_TYPE OSPF metric type. Options include:
  • **type-1** OSPF type 1 metric.
  • **type-2** OSPF type 2 metric.
• **source-protocol** protocol_type Routing protocol of route’s source. Options include:
  • bgp
  • connected
  • ospf
  • rip
  • static
  • **tag** 1 to 4294967295 Route tag.

**Related Command**

route-map.

**Example**

This command creates a route map match rule that filters routes from BGP **AS 15**.

```
switch(config)#route-map map1
switch(config-route-map-map1)#match as 15
switch(config-route-map-map1)#
```
13.4.9.29 no <sequence number> (ACLs)

The no <sequence number> command removes the rule with the specified sequence number from
the ACL. The default <sequence number> command also removes the specified rule.

Command Mode

ACL Configuration
IPv6-ACL Configuration
Std-ACL Configuration
Std-IPv6-ACL Configuration
MAC-ACL Configuration

Command Syntax

no line_num
default line_num

Parameters

line_num Sequence number of rule to be deleted. Values range from 1 - 4294967295.

Example

This command removes statement 30 from the list.

```
switch(config-acl-test1)#show IP Access List test1
   10 permit ip 10.10.10.0/24 any
   20 permit ip any host 10.20.10.1
   30 deny ip host 10.10.10.1 host 10.20.10.1
   40 permit ip any any
   50 remark end of list
switch(config-acl-test1)#no 30
switch(config-acl-test1)#show IP Access List test1
   10 permit ip 10.10.10.0/24 any
   20 permit ip any host 10.20.10.1
   40 permit ip any any
   50 remark end of list
```
Layer 3 Configuration

13.4.9.30  permit (IPv4 ACL)

The **permit** command adds a permit rule to the configuration mode IPv4 Access Control List (ACL). Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The **no permit** and **default permit** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes a specified rule from the ACL.

**Command Mode**

ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [FLAGS][MESSAGE][fragments][tracked][DSCP_FILTER][TTL_FILTER][log]
```

```
no permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT][FLAGS][MESSAGE] [fragments] [tracked][DSCP_FILTER][TTL_FILTER][log]
```

```
default permit PROTOCOL SOURCE_ADDR [SOURCE_PORT] DEST_ADDR [DEST_PORT] [FLAGS][MESSAGE][fragments][tracked][DSCP_FILTER][TTL_FILTER][log]
```

Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - **no parameter** Number is derived by adding **10** to the number of the ACL’s last rule.
  - **1 - 4294967295** Number assigned to entry.
- **PROTOCOL** Protocol field filter. Values include:
  - **ahp** Authentication Header Protocol (51).
  - **gre** Generic Routing Encapsulation.
  - **gtp** GPRS Tunneling Protocol.
  - **icmp** Internet Control Message Protocol (1).
  - **igmp** Internet Group Management Protocol (2).
  - **ip** Any Internet Protocol v4 (4).
  - **ospf** Open Shortest Path First (89).
  - **pim** Protocol Independent Multicast (103).
  - **tcp** Transmission Control Protocol (6).
  - **udp** User datagram protocol (17).
  - **vlan** Enter VLAN number and mask. VLAN value ranges from 1 to 4094; mask value ranges from 0x000-0xFFF.
  - **vrrp** Virtual Router Redundancy Protocol (112).
  - **protocol_num** Integer corresponding to an IP protocol. Values range from **0 to 255**.
- **SOURCE_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - **network_addr** subnet address (CIDR or address-mask).
  - **any** Packets from all addresses are filtered.
  - **host ip_addr** IP address (dotted decimal notation).
    Source and destination subnet addresses support discontiguous masks.
- **SOURCE_PORT** and **DEST_PORT** Source and destination port filters. Options include:
  - **any** All ports.
- **eq** *port-1* *port-2* ... *port-n* A list of ports. Maximum list size is 10 ports.
- **neq** *port-1* *port-2* ... *port-n* The set of all ports not listed. Maximum list size is 10 ports.
- **gt** *port* The set of ports with larger numbers than the listed port.
- **lt** *port* The set of ports with smaller numbers than the listed port.
- **range** *port_1* *port_2* The set of ports whose numbers are between the range.
- **fragments** Filters packets with FO bit set (indicates a non-initial fragment packet).
- **FLAGS** Flags bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
- **MESSAGE** Message type filters (ICMP packets). Use CLI syntax assistance (?) to display options.
- **tracked** Rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **DSCP_FILTER** Rule filters packet by its DSCP value. Values include:
  - **no parameter** Rule does not use DSCP to filter packets.
  - **dscp** *dscp_value* Packets match if DSCP field in packet is equal to *dscp_value*.
- **TTL_FILTER** Rule filters packet by its TTL (time-to-live) value. Values include:
  - **ttl eq** *ttl_value* Packets match if *ttl* in packet is equal to *ttl_value*.
  - **ttl gt** *ttl_value* Packets match if *ttl* in packet is greater than *ttl_value*.
  - **ttl lt** *ttl_value* Packets match if *ttl* in packet is less than *ttl_value*.
  - **ttl neq** *ttl_value* Packets match if *ttl* in packet is not equal to *ttl_value*.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.
- **log** Triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Examples**

- This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all OSPF packets from *10.10.1.0/24* to any host.

```bash
switch(config)#ip access-list text1
switch(config-acl-text1)#permit ospf 10.1.1.0/24 any
switch(config-acl-text1)#
```

- This command inserts a **permit** statement with the sequence number **25**. The **permit** statement passes all PIM packets through the interface.

```bash
switch(config-acl-text1)#25 permit pim any any
switch(config-acl-text1)#
```

- These commands configure ACL to permit VLAN traffic between any source and destination host.

```bash
switch(config)#ip access-list acl1
switch(config-acl-acl1)#permit vlan 1234 0x0 ip any any
```
Layer 3 Configuration

13.4.9.31  permit (IPv6 ACL)

   The `permit` command adds a permit rule to the configuration mode IPv6 Access Control List (ACL). Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

   The `no permit` and `default permit` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes a specified rule from the ACL.

Command Mode
IPv6-ACL Configuration

Command Syntax

```
[SEQ_NUM] permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT][FLAG] [MSG] [HOP] [tracked] [DSCP_FILTER] [log]
no permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT][FLAG][MSG] [HOP][tracked] [DSCP_FILTER][log]
default permit PROT SRC_ADDR [SRC_PT] DEST_ADDR [DEST_PT][FLAG][MSG] [HOP] [tracked][DSCP_FILTER][log]
```

Note: Commands use a subset of the listed fields. Available parameters depend on specified protocol. Use CLI syntax assistance to view options for specific protocols when creating a permit rule.

Parameters

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `1 - 4294967295` Number assigned to entry.
- **PROT** Protocol field filter. Values include:
  - `icmpv6` Internet Control Message Protocol for v6 (58).
  - `ipv6` Internet Protocol IPv6 (41).
  - `ospf` Open Shortest Path First (89).
  - `tcp` Transmission Control Protocol (6).
  - `udp` User Datagram Protocol (17).
  - `vlan` Enter VLAN number. Value ranges from 1 to 4094.
  - `protocol_num` Integer corresponding to an IP protocol. Values range from 0 to 255.
- **SRC_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.
- **SRC_PT** and **DEST_PT** Source and destination port filters. Options include:
  - `any` All ports.
  - `eq port-1 port-2 ... port-n` A list of ports. Maximum list size is 10 ports.
  - `neq port-1 port-2 ... port-n` The set of all ports not listed. Maximum list size is 10 ports.
  - `gt port` The set of ports with larger numbers than the listed port.
  - `lt port` The set of ports with smaller numbers than the listed port.
  - `range port_1 port_2` The set of ports whose numbers are between the range.
- **HOP** Filters by packet’s hop-limit value. Options include:
  - `no parameter` Rule does not use hop limit to filter packets.
• **hop-limit eq hop_value** Packets match if **hop-limit** value in packet equals **hop_value**.
• **hop-limit gt hop_value** Packets match if **hop-limit** in packet is greater than **hop_value**.
• **hop-limit lt hop_value** Packets match if **hop-limit** in packet is less than **hop_value**.
• **hop-limit neq hop_value** Packets match if **hop-limit** in packet is not equal to **hop_value**.
• **FLAG** Flag bit filters (TCP packets). Use CLI syntax assistance (?) to display options.
• **MSG** Message type filters (ICMPv6 packets). Use CLI syntax assistance (?) to display options.

• **tracked** Rule filters packets in existing ICMP, UDP, or TCP connections.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

• **DSCP_FILTER** Rule filters packet by its DSCP value. Values include:
  - **no parameter** Rule does not use DSCP to filter packets.
  - **dscp dscp_value** Packets match if DSCP field in packet is equal to **dscp_value**.
• **log** Triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Examples**

• This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all IPv6 packets with the source address **3710:249a:c643:ef11::/64** and with any destination address.

```
switch(config)#ipv6 access-list text1
switch(config-acl-text1)#permit ipv6 3710:249a:c643:ef11::/64 any
```

• These commands configure ACL to permit VLAN traffic between any source and destination host.

```
switch(config)#ip access-list acl1
switch(config-acl-acl1)#permit ipv6 vlan 1234 0x0 ip any any
```
13.4.9.32 permit (IPv6 Prefix List)

The `permit` command adds a rule to the configuration mode IPv6 prefix list. Route map match commands use prefix lists to filter routes for redistribution into OSPF, RIP, or BGP domains. Routes are redistributed into the specified domain when they match the prefix that a `permit` statement specifies.

The `no permit` and `default permit` commands remove the specified rule from the configuration mode prefix list. The `no seq (IPv6 Prefix Lists)` command also removes the specified rule from the prefix list.

Command Mode
IPv6-pfx Configuration

Command Syntax

```
[SEQUENCE] permit ipv6_prefix [MASK]
```

Parameters

- **SEQUENCE** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the list's last rule.
  - `seq seq_num` Number is specified by `seq_num`. Value ranges from 0 to 65535.
- **ipv6_prefix** IPv6 prefix upon which command filters routes (CIDR notation).
- **MASK** Range of the prefix to be matched.
  - `no parameter` Exact match with the subnet mask is required.
  - `eq mask_e` Prefix length is equal to `mask_e`.
  - `ge mask_g` Range is from `mask_g` to 128.
  - `le mask_l` Range is from subnet mask length to `mask_l`.
  - `ge mask_g le mask_l` Range is from `mask_g` to `mask_l`.
  - `mask_e, mask_g, and mask_l` Range from 1 to 128.
  - When `le` and `ge` are specified, the prefix list size `mask_g mask_l`.

Example

This command appends a `permit` statement at the end of the text1 prefix list. The `permit` statement allows redistribution of routes with the specified prefix.

```
switch(config)#ipv6 prefix-list route-five
switch(config-ipv6-pfx)#permit 3100::/64
switch(config-ipv6-pfx)#
```
13.4.9.33  permit (MAC ACL)

The `permit` command adds a permit rule to the configuration mode MAC access control list packets through the interface to which the list is applied. Rule filters include protocol, source, and destination.

The `no permit` and `default permit` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

MAC-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

```
no permit SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

```
default permit SOURCE_ADDR DEST_ADDR [PROTOCOL][log]
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding **10** to the number of the ACL’s last rule.
  - **1 - 4294967295** Number assigned to entry.
- **SOURCE_ADDR** and **DEST_ADDR** Source and destination address filters. Options include:
  - `mac_address` `mac_mask` MAC address and mask.
  - `any` Packets from all addresses are filtered.
  - `mac_address` Specifies a MAC address in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh).
  - `mac_mask` Specifies a MAC address mask in 3x4 dotted hexadecimal notation (hhhh.hhhh.hhhh).
  - **0** bits require an exact match to filter.
  - **1** bits filter on any value.
- **PROTOCOL** Protocol field filter. Values include:
  - `aarp` Appletalk Address Resolution Protocol (0x80f3).
  - `appletalk` Appletalk (0x809b).
  - `arp` Address Resolution Protocol (0x806).
  - `ip` Internet Protocol Version 4 (0x800).
  - `ipx` Internet Packet Exchange (0x8137).
  - `lldp` LLDP (0x88cc).
  - `novell` Novell (0x8138).
  - `rarp` Reverse Address Resolution Protocol (0x8035).
  - `protocol_num` Integer corresponding to a MAC protocol. Values range from **0 to 65535**.
- **log** Triggers an informational log message to the console about the matching packet.

**Examples**

- This command appends a `permit` statement at the end of the ACL. The `permit` statement passes all aarp packets from **10.1000.0000** through **10.1000.FFFF** to any host.

  ```
  switch(config)#mac access-list text1
  switch(config-mac-acl-text1)#permit 10.1000.0000 0.0.FFFF any aarp
  switch(config-mac-acl-text1)#
  ```

- This command inserts a `permit` statement with the sequence number **25**. The `permit` statement passes all packets through the interface.

  ```
  switch(config-mac-acl-text1)#25 permit any any
  ```
switch(config-mac-acl-text1)#
13.4.9.34  permit (Standard IPv4 ACL)

The **permit** command adds a permit rule to the configuration mode standard IPv4 Access Control List (ACL). Standard ACL rules filter on the source field.

Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The **no permit** and **default permit** commands remove the specified rule from the configuration mode ACL. The **no <sequence number> (ACLs)** command also removes the specified rule from the ACL.

**Command Mode**
Std-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR [log]
no permit SOURCE_ADDR [log]
default permit SOURCE_ADDR [log]
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - *no parameter* Number is derived by adding 10 to the number of the ACL’s last rule.
  - *1 - 4294967295* Number assigned to entry.
- **SOURCE_ADDR** Source address filter. Options include:
  - *network_addr* Subnet address (CIDR or address-mask).
  - *any* Packets from all addresses are filtered.
  - *host ip_addr* IP address (dotted decimal notation).

Subnet addresses support discontiguous masks.

- **log** Triggers an informational log message to the console about the matching packet.
  - Valid in ACLs applied to the control plane.
  - Validity in ACLs applied to data plane varies by switch platform.

**Example**

This command appends a **permit** statement at the end of the ACL. The **permit** statement passes all packets with a source address of **10.1.1.1/24**.

```
switch(config)#ip access-list standard text1
switch(config-std-acl-text1)#permit 10.1.1.1/24
```

13.4.9.35  permit (Standard IPv6 ACL)

The `permit` command adds a permit rule to the configuration mode standard IPv6 access control list. Standard ACL rules filter on the source field.

Packets filtered by a permit rule are accepted by interfaces to which the ACL is applied. Sequence numbers determine rule placement in the ACL. Sequence numbers for commands without numbers are derived by adding 10 to the number of the ACL’s last rule.

The `no permit` and `default permit` commands remove the specified rule from the configuration mode ACL. The `no <sequence number> (ACLs)` command also removes the specified rule from the ACL.

**Command Mode**

Std-IPv6-ACL Configuration

**Command Syntax**

```
[SEQ_NUM] permit SOURCE_ADDR
no permit SOURCE_ADDR
default permit SOURCE_ADDR
```

**Parameters**

- **SEQ_NUM** Sequence number assigned to the rule. Options include:
  - `no parameter` Number is derived by adding 10 to the number of the ACL’s last rule.
  - `1 - 4294967295` Number assigned to entry.
- **SOURCE_ADDR** Source address filter. Options include:
  - `ipv6_prefix` IPv6 address with prefix length (CIDR notation).
  - `any` Packets from all addresses are filtered.
  - `host ipv6_addr` IPv6 host address.

**Example**

This command appends a `permit` statement at the end of the ACL. The `permit` statement drops packets with a source address of `2103::/64`.

```
switch(config)#ipv6 access-list standard text1
switch(config-std-acl-ipv6-text1)#permit 2103::/64
```

13.4.9.36  remark

The remark command adds a non-executable comment statement into the pending ACL. Remarks entered without a sequence number are appended to the end of the list. Remarks entered with a sequence number are inserted into the list as specified by the sequence number.

The default remark command removes the comment statement from the ACL.

The no remark command removes the comment statement from the ACL. The command can specify the remark by content or by sequence number.

**Command Mode**

ACL Configuration
IPv6-ACL Configuration
Std-ACL Configuration
Std-IPv6-ACL Configuration
MAC-ACL Configuration

**Command Syntax**

remark text

line_num remark [text]

no remark text

default remark text

**Parameters**

- **text** The comment text.
- **line_num** Sequence number assigned to the remark statement. Value ranges from 1 - 4294967295.

**Example**

This command appends a comment to the list.

```
switch(config-acl-test1)#remark end of list
switch(config-acl-test1)#show
IP Access List test1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```
13.4.9.37  resequence (ACLs)

The resequence command assigns sequence numbers to rules in the configuration mode ACL. Command parameters specify the number of the first rule and the numeric interval between consecutive rules.

Maximum rule sequence number is 4294967295.

Command Mode
ACL Configuration
IPv6-ACL Configuration
Std-ACL Configuration
Std-IPv6-ACL Configuration
MAC-ACL Configuration

Command Syntax
resequence [start_num [inc_num]]

Parameters
- **start_num** Sequence number assigned to the first rule. Default is 10.
- **inc_num** Numeric interval between consecutive rules. Default is 10.

Example
The resequence command renumbers the list, starting the first command at number 100 and incrementing subsequent lines by 20.

```
switch(config-acl-test1)#show
IP Access List test1
  10  permit ip 10.10.10.0/24 any
  20  permit ip any host 10.20.10.1
  30  deny ip host 10.10.10.1 host 10.20.10.1
  40  permit ip any any
  50  remark end of list
switch(config-acl-test1)#resequence 100 20
switch(config-acl-test1)#show
IP Access List test1
  100 permit ip 10.10.10.0/24 any
  120 permit ip any host 10.20.10.1
  140 deny ip host 10.10.10.1 host 10.20.10.1
  160 permit ip any any
  180 remark end of list
```
The `route-map` command places the switch in route map configuration mode, which is a group change mode that modifies a route map statement. The command specifies the name and number of the route map statement that subsequent commands modify and creates a route map statement if it references a nonexistent statement. All changes in a group change mode edit session are pending until the end of the session.

Route maps define commands for redistributing routes between routing protocols. A route map statement is identified by a name, filter type (permit or deny), and sequence number. Statements with the same name are components of a single route map; the sequence number determines the order in which the statements are compared to a route.

The `exit` command saves pending route map statement changes to `running-config`, then returns the switch to global configuration mode. ACL changes are also saved by entering a different configuration mode.

The `abort` command discards pending changes, returning the switch to global configuration mode.

The `no route-map` and `default route-map` commands delete the specified route map statement from `running-config`.

Note: The route map configuration supports only standard ACL.

Command Mode
Global Configuration

Command Syntax

```
routemap  map_name [FILTER_TYPE] [sequence_number]
no route-map map_name[FILTER_TYPE] [sequence_number]
default route-map map_name [FILTER_TYPE][sequence_number]
```

Parameters

- `map_name` Label assigned to route map. Protocols reference this label to access the route map.
- `FILTER_TYPE` Disposition of routes matching commands specified by route map statement.
  - `permit` Routes are redistributed when they match route map statement.
  - `deny` Routes are not redistributed when they match route map statement.
  - `no parameter` Sssigns `permit` as the `FILTER_TYPE`.

When a route does not match the route map criteria, the next statement within the route map is evaluated to determine the redistribution action for the route.

- `sequence_number` The route map position relative to other statements with the same name.
  - `no parameter` Sequence number of 10 (default) is assigned to the route map.
  - `1-16777215` Specifies sequence number assigned to route map.

Commands Available in route map configuration mode:

- `continue (route map)`
- `match (route-map)`
- `set (route-map)`

Examples

- This command creates the route map named `map1` and places the switch in route map configuration mode. The route map is configured as a permit map.

```
switch(config)#route-map map1 permit 20
```
switch(config-route-map-map1)#

- This command saves changes to `map1` route map, then returns the switch to global configuration mode.

  switch(config-route-map-map1)#exit
  switch(config)#

- This command saves changes to `map1` route map, then places the switch in interface-Ethernet mode.

  switch(config-route-map-map1)#interface ethernet 3
  switch(config-if-Et3)#

- This command discards changes to `map1` route map, then returns the switch to global configuration mode.

  switch(config-route-map-map1)#abort
  switch(config)#
13.4.9.39  seq (IPv6 Prefix Lists)

The **no seq** command removes the rule with the specified sequence number from the ACL. The **default seq** command also removes the specified rule.

The **seq** keyword is a command option used at the beginning of **deny (IPv6 Prefix List)** and **permit (IPv6 Prefix List)** commands that places a new rule between two existing rules.

**Command Mode**

IPv6-pfx Configuration

**Command Syntax**

```
no seq  line_num
default seq  line_num
```

**Parameters**

- **line_num**: Sequence number of rule to be deleted. Valid rule numbers range from 0 to 65535.

**Example**

These commands remove rule 20 from the **map1** prefix list, then displays the resultant list.

```
switch(config)#ipv6 prefix-list map1
switch(config-ipv6-pfx)#no seq 20
switch(config-ipv6-pfx)#exit
switch(config)#show ipv6 prefix-list map1
ipv6 prefix-list map1
seq 10 permit 3::4e96:8ca1:33cf::/64
seq 15 deny 3::4400::/64
seq 30 permit 3:1bca:3ff2:634a::/64
seq 40 permit 3:1bca:1141:ab34::/64
switch(config)#
```
13.4.9.40  set (route-map)

The `set` command specifies modifications to routes that are selected for redistribution by the configuration mode route map.

The `no set` and `default set` commands remove the specified `set` command from the configuration mode route map statement by deleting the corresponding `set` command from `running-config`.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
set CONDITION
no set CONDITION
default set CONDITION
```

**Parameters**

- **CONDITION** Specifies the route modification parameter and value. Options include:
  - `as-path prepend` BGP AS number that is prepended to as-path. For details, see the `set as-path prepend` command.
    - `1 - 4294967295` BGP AS number to prepend.
    - `auto` Use peer AS number for inbound and local AS for outbound to prepend.
  - `distance 1 - 255` Protocol independent administrative distance.
  - `ip next-hop ipv4_address` Next hop IPv4 address.
  - `ip next-hop peer-address` Use BGP peering address as next hop IPv4 address.
  - `ipv6 next-hop ipv6_address` Next hop IPv6 address.
  - `ipv6 next-hop peer-address` Use BGP peering address as next hop IPv6 address.
  - `local-preference 1 - 4294967295` BGP local preference metric.
  - `metric 1 - 4294967295` Route metric.
  - `metric + 1 - 4294967295` Add specified value to current route metric.
  - `metric - 1 - 4294967295` Subtract specified value to current route metric.
  - `metric-type OSPF_TYPE` OSPF metric type. Options include:
    - `type-1` OSPF type 1 metric.
    - `type-2` OSPF type 2 metric.
  - `origin O_TYPE` BGP origin attribute. Options for `O_TYPE` include:
    - `egp` Exterior BGP route.
    - `igp` Interior BGP route.
    - `incomplete` BGP route of unknown origin.
  - `tag 1 - 4294967295` Route tag.
  - `weight 1 - 65535` BGP weight parameter.

**Related Commands**

- `route-map` enters `route-map` configuration mode.
- `set (route-map)` specifies community modifications for the redistributed routes.
- `set community (route-map)` specifies extended community modifications for the redistributed routes.

**Example**
This command creates a route map entry that sets the local preference metric to 100 on redistributed routes.

switch(config)#route-map map1
switch(config-route-map-map1)#set local-preference 100
switch(config-route-map-map1)#
13.4.9.41 set as-path match

The set as-path match command configures the AS_PATH attribute for prefixes that are either received from a BGP neighbor or advertised to a BGP neighbor in the route map configuration mode.

The no set as-path match command removes the AS path specified for the BGP prefix.

Command Mode
Route-Map Configuration

Command Syntax

set as-path match all replacement [[none | auto] as_path]

no set as-path match all replacement [[none | auto] as_path]

Parameters

• none Replaces the AS-Path of the matching routes with a null or an empty AS-Path.
• auto if the specific route map is applied as an inbound policy to a corresponding BGP neighbor statement, then replace the AS_PATH of the prefixes received from this neighbor with the neighbor’s AS number. If this route map is applied as an outbound policy to a corresponding neighbor statement, then replace the AS_PATH of the prefixes advertised to this neighbor with the locally configured AS number.
• as_path Replaces the AS-Path of the matching routes with an arbitrary AS-Path.

Examples

• This command replaces the AS-Path with the none option.

```
switch# show ip bgp neighbors 80.80.1.2 advertised-routes

</tr>
</tbody>
</table>

The AS-Path of matching prefixes are replaced with the locally configured AS **200** and **500 600**.

*
set as-path prepend

The `set as-path prepend` command adds a set statement to a route map to prepend one or more Autonomous System (AS) numbers to the AS_PATH attribute of a BGP route.

The `no set as-path prepend` and `default set as-path prepend` commands remove the specified set statements from the route map and update all corresponding routes.

Command Mode
Route-Map Configuration

Command Syntax

- **set as-path prepend**`{(auto | as_number... [auto | as_number]) | last-as count}`
- **no set as-path prepend**`{(auto | as_number... [auto | as_number]) | last-as count}`
- **default set as-path prepend**`{(auto | as_number... [auto | as_number]) | last-as count}`

Parameters

- **auto** Prepends the peer AS number for peer inbound route maps and the local AS number for peer outbound route maps.
- **as_number** Prepends the specified AS number. Can be entered in plain notation (values range from `1-4294967295`) or in asdot notation as described in RFC 5396. In asdot notation, AS numbers from `1-65535` are entered in plain notation, and AS numbers from `65536 to 4294967295` are entered as two values separated by a dot. The first value is high-order and represents a multiple of `65536`; the second value is low-order and represents a decimal integer. For example, AS number `65552` can be entered as either `65552` or `1.16` (i.e., `1*65536+16`). However they are entered, AS numbers are stored internally in plain decimal notation and will appear that way in `show` outputs.
- **last-as count** Prepends the last AS number in the AS path `count` times. Values range from `1 to 15`. This is mutually exclusive with the use of the `auto` keyword or the entry of one or more specified AS numbers, and is not supported in multi-agent mode.

Examples

- These commands create a route-map entry that prepends AS number `64496` and prepends either the peer or local AS number twice.

```
switch(config)#route-map map1
switch(config-route-map-map1)#set as-path prepend 64496 auto auto
switch(config-route-map-map1)#exit
switch(config)#show route-map map1
route-map map1 permit 10
  Description:  
  Match clauses:  
  SubRouteMap:  
  Set clauses:    set as-path prepend 64496 auto auto
switch(config)#
```

- The commands create a route-map entry that prepends AS numbers `64496, 64498, and 65552`.

```
switch(config)#route-map map2
switch(config-route-map-map2)#set as-path prepend 64496 64498 1.16
switch(config-route-map-map2)#exit
switch(config)#show route-map map2
route-map map2 permit 10
  Description:  
  Match clauses:  
  SubRouteMap:  
  Set clauses:    set as-path prepend 64496 64498 65552
```
• These commands create a route map entry that prepends the last AS number **12** times.

```
switch(config)#

switch(config)#route-map map3
switch(config-route-map-map3)#set as-path prepend last-as 12
switch(config-route-map-map3)#exit
switch(config)#show route-map map3
route-map map3 permit 10
  Description:
  Match clauses:
  SubRouteMap:
  Set clauses:
    set as-path prepend last-as 12
switch(config)#
```
The `set community` command specifies community attribute modifications to routes that are selected for redistribution by the configuration mode route map. The `set community none` command removes community attributes from the route.

The `no set community` and `default set community` commands remove the specified community from the configuration mode route map statement by deleting the corresponding statement from the `running config`.

**Command Mode**

Route-Map Configuration

**Command Syntax**

```
set community [GSHUT | aa:nn | community-list | internet | local-as | no-advertise | no-export | none | number]
```

```
no set community [GSHUT | aa:nn | additive | community-list | delete | internet | local-as | no-advertise | no-export | none | number]
```

```
default set community [GSHUT | aa:nn | additive | community-list | delete | internet | local-as | no-advertise | no-export | none | number]
```

**Parameters**

- **GSHUT** Configures a graceful shutdown in BGP.
- **aa:nn** Configures the community AS and network number, separated by colon. Value ranges from 0:0 to 65535:65535.
- **community-list** A label for community list.
- **internet** Advertises route to the Internet community.
- **local-as** Advertises route only to local peers.
- **no-advertise** Does not advertise route to any peer.
- **no-export** Advertises route only within BGP AS boundary.
- **none** Does not provide any community attributes.
- **number** Configures the community number. Value ranges from 1 to 4294967040.
- **additive** Adds specified attributes to the current community.
- **delete** Removes specified attributes from the current community.

**Related Commands**

- `ip community-list`
- `route-map`
- `set (route-map)`
- `set community (route-map)`

**Guideline**

EOS does not support disabling the process of graceful shutdown community.

**Example**

This command advertises routes only to local peers.

```bash
switch(config-route-map-map1)#show active
route-map map1 permit 10
    match community instances <= 50
    set community 0:456 0:2345
switch(config-route-map-map1)#set community local-as
switch(config-route-map-map1)#ip community-list 345 permit 23
switch(config)#route-map map1
switch(config-route-map-map1)#show active
```
route-map map1 permit 10
    match community instances <= 50
    set community 0:456 0:2345 local-as
switch(config-route-map-map1)#
13.4.9.44  set extcommunity (route-map)

The set extcommunity command specifies extended community attribute modifications to routes that are selected for redistribution by the configuration mode route map. The set extcommunity none command removes extended community attributes from the route.

The no set extcommunity and default set extcommunity commands remove the specified set extcommunity command from the configuration mode route map statement by deleting the corresponding statement from running-config.

Command Mode
Route-Map Configuration

Command Syntax

set extcommunity COND_X [COND_2][COND_N][MOD_TYPE]
set extcommunity none
no set extcommunity COND_X[COND_2][COND_N][MOD_TYPE]
no set extcommunity none
default set extcommunity COND_X [COND_2][COND_N][MOD_TYPE]
default set extcommunity none

Parameters

• COND_X Specifies extended community route map modification. Command may contain multiple attributes. Options include:
  • rt ASN:nn Route target attribute (AS:network number).
  • rt IP-address:nn Route target attribute (IP address: network number).
  • soo ASN:nn Site of origin attribute (AS:network number).
  • soo IP-address:nn Site of origin attribute (IP address: network number).
• MOD_TYPE Specifies route map modification method. Options include:
  • no parameter Command replaces existing route map with specified parameters.
  • additive Command adds specified parameters to existing route map.
  • delete Command removes specified parameters from existing route map.

Related Commands
• route-map enters route map configuration mode.
• set (route-map) specifies attribute modifications for the redistributed routes.
• set (route-map) specifies community modifications for the redistributed routes.

Example
This command creates a route map entry in map1 that sets the route target extended community attribute.

switch(config)#route-map map1
switch(config-route-map-map1)#set extcommunity rt 10.13.2.4:100
switch(config-route-map-map1)#
13.4.9.45  **show (ACL configuration modes)**

The `show` command displays the contents of an Access Control List (ACL).

- **show** or **show pending** displays the list as modified in ACL configuration mode.
- **show active** displays the list as stored in running-config.
- **show comment** displays the comment stored with the list.
- **show diff** displays the modified and stored lists, with flags denoting the modified rules.

Exiting the ACL configuration mode stores all pending ACL changes to **running-config**.

**Command Mode**

ACL Configuration

IPv6-ACL Configuration

Std-ACL Configuration

Std-IPv6-ACL Configuration

MAC-ACL Configuration

**Command Syntax**

`show`

`show active`

`show comment`

`show diff`

`show pending`

**Examples**

The examples in this section assume these ACL commands are entered as specified.

These commands are stored in **none**:

```
10 permit ip 10.10.10.0/24 any
20 permit ip any host 10.21.10.1
30 deny ip host 10.10.10.1 host 10.20.10.1
40 permit ip any any
50 remark end of list
```

The current edit session removed this command. This change is not yet stored to **none**:

```
20 permit ip any host 10.21.10.1
```

The current edit session added these commands ACL. They are not yet stored to **none**:

```
20 permit ip 10.10.0.0/16 any
25 permit tcp 10.10.20.0/24 any
45 deny pim 239.24.124.0/24 10.5.8.4/30
```

- This command displays the ACL, as stored in the configuration.

```
switch(config-acl-test_1)#show active
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.21.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  50 remark end of list
```
• This command displays the pending ACL, as modified in ACL configuration mode.

```bash
switch(config-acl-test_1)#show pending
IP Access List test_1
  10 permit ip 10.10.10.0/24 any
  20 permit ip 10.10.0.0/16 any
  25 permit tcp 10.10.20.0/24 any
  30 deny ip host 10.10.10.1 host 10.20.10.1
  40 permit ip any any
  45 deny pim 239.24.124.0/24 10.5.8.4/30
  50 remark end of list
```

• This command displays the difference between the saved and modified ACLs.
  • Rules added to the pending list are denoted with a plus sign (+).
  • Rules removed from the saved list are denoted with a minus sign (-)

```bash
switch(config-acl-test_1)#show diff
---
+++ @@ -1,7 +1,9 @@

13.4.9.46  show hardware tcam profile

The `show hardware tcam profile` command displays the hardware specific information for the current operational TCAM profile in the running configuration.

This command is applicable to DCS-7280(E/R) and DCS-7500(E/R) series switches only.

**Command Mode**

EXEC

**Command Syntax**

`show hardware tcam profile`

**Parameters**

- `tcam` Specifies the TCAM information.
- `profile` Specifies the TCAM profile information.

**Example**

This command displays the current operational TCAM profile details.

```
switch# show hardware tcam profile
Configuration        Status
FixedSystem          default              default
```
13.4.9.47 show ip access-lists

The `show ip access-list` command displays the contents of IPv4 and standard IPv4 Access Control List (ACLs) on the switch. Use the `summary` option to display only the name of the lists and the number of lines in each list.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show ip access-list [LIST][SCOPE]
```

**Parameters**
- **LIST** Name of lists to be displayed. Selection options include:
  - `no parameter` All IPv4 ACLs are displayed.
  - `list_name` Specified IPv4 ACL is displayed.
- **SCOPE** Information displayed. Selection options include:
  - `no parameter` All rules in the specified lists are displayed.
  - `summary` The number of rules in the specified lists are displayed.

**Examples**
- This command displays all rules in `test1` IPv4 ACL.
  ```
  switch#show ip access-list list2
  IP Access List list2
  10 permit ip 10.10.10.0/24 any
  20 permit ip any host 10.20.10.1
  30 deny ip host 10.10.10.1 host 10.20.10.1
  switch#
  ```
- This command displays the name of, and number of rules in, each list on the switch.
  ```
  switch#show ip access-list summary
  IPV4 ACL default-control-plane-acl
  Total rules configured: 12
  Configured on: control-plane
  Active on    : control-plane

  IPV4 ACL list2
  Total rules configured: 3

  IPV4 ACL test1
  Total rules configured: 6

  Standard IPV4 ACL test_1
  Total rules configured: 1

  IPV4 ACL test_3
  Total rules configured: 0
  switch#
  ```
- This command displays the summary and lists all the configured IPv4 ACLs.
  ```
  switch #show ip access-lists summary
  IPV4 ACL default-control-plane-acl [readonly]
  Total rules configured: 17
  Configured on Ingress: control-plane(default VRF)
  Active on Ingress: control-plane(default VRF)
  ```
IPV4 ACL ipAclLimitTest
Total rules configured: 0
Configured on Egress: V12148,2700
Active on Egress: V12148,2700
The `show ip prefix-list` command displays all rules for the specified IPv4 prefix list. The command displays all IPv4 prefix list rules if a prefix list name is not specified.

**Command Mode**

EXEC

**Command Syntax**

`show ip prefix-list` [DISPLAY_ITEMS]

**Parameters**

DISPLAY_ITEMS Specifies the name of prefix lists for which rules are displayed. Options include:

- **no parameter** All IPv4 prefix list rules are displayed.
- **list_name** Specifies the IPv4 prefix list for which rules are displayed.

**Example**

This command displays all rules in the route-one IPv4 prefix list.

```
switch(config-ip-pfx)#show ip prefix-list
ip prefix-list route-one
  seq 10 deny 10.1.1.0/24
  seq 20 deny 10.1.0.0/16
  seq 30 permit 12.15.4.9/32
  seq 40 deny 1.1.1.0/24
switch(config-ip-pfx)#
```
13.4.9.49  show ipv6 access-lists

The `show ipv6 access-list` command displays the contents of all IPv6 Access Control List (ACLs) on the switch. Use the `summary` option to display only the name of the lists and the number of lines in each list.

Command Mode
Privileged EXEC

Command Syntax
`show ipv6 access-list [LIST][SCOPE]`

Parameters
- `LIST` Name of lists to be displayed. Selection options include:
  - `no parameter` All IPv6 ACLs are displayed.
  - `list_name` Specified IPv6 ACL is displayed.
- `SCOPE` Information displayed. Selection options include:
  - `no parameter` All rules in the specified lists are displayed.
  - `summary` The number of rules in the specified lists are displayed.

Examples
- This command displays all rules in test1 IPv6 ACL.

```
switch# show ipv6 access-list list2
IP Access List list2
  10 permit ipv6 3891:3c58:6300::/64 any
  20 permit ipv6 any host 2fe1:b468:024a::
  30 deny ipv6 host 3411:91c1:: host 4210:cc23:d2de::
switch#
```

- This command displays the name of, and number of rules in, each list on the switch.

```
switch# show ipv6 access-list summary
IPV6 ACL list2
  Total rules configured: 3

IPV6 ACL test1
  Total rules configured: 6

IPV6 ACL test_1
  Total rules configured: 1

Standard IPV6 ACL test_3
  Total rules configured: 0
switch#
```
The `show ipv6 prefix-list` command displays all rules for the specified IPv6 prefix list. The command displays all IPv6 prefix lists if a prefix list name is not specified.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 prefix-list [DISPLAY_ITEMS]
```

**Parameters**

`DISPLAY_ITEMS` Specifies the name of prefix lists for which rules are displayed. Options include:

- `no parameter` All IPv6 prefix lists are displayed.
- `list_name` Specifies the IPv6 prefix list for which rules are displayed.

**Examples**

- This command displays all rules in the `map1` IPv6 prefix list:

  ```
  switch>show ipv6 prefix-list map1
  ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
  seq 40 permit 3:1bca:1141:ab34::/64
  switch>
  ```

- This command displays all prefix lists:

  ```
  switch>show ipv6 prefix-list
  ipv6 prefix-list map1
  seq 10 permit 3:4e96:8ca1:33cf::/64
  seq 15 deny 3:4400::/64
  seq 20 permit 3:11b1:8fe4:1aac::/64
  seq 30 permit 3:1bca:3ff2:634a::/64
  seq 40 permit 3:1bca:1141:ab34::/64
  ipv6 prefix-list FREDD
  ipv6 prefix-list route-five
  ipv6 prefix-list map2
  seq 10 deny 10:1:1:1::/64 ge 72 le 80
  seq 20 deny 10:1::/32
  switch>
  ```
13.4.9.51  show mac access-lists

The `show mac access-list` command displays the contents of all MAC Access Control List (ACLs) on the switch. Use the summary to display only the name of the lists and the number of lines in each list.

Command Mode
Privileged EXEC

Command Syntax

```
show mac access-lists [LIST][SCOPE]
```

Parameters

- **LIST** Name of lists to be displayed. Selection options include:
  - `no parameter` Command displays all ACLs.
  - `list_name` Command displays ACL specified by parameter.
- **SCOPE** Information displayed. Selection options include:
  - `no parameter` Command displays all rules in specified lists.
  - `summary` Command displays the number of rules in specified lists.

Examples

- This command displays all rules in *mtest2* MAC ACL.

  ```
  switch#show mac access-list mlist2
  IP Access List mlist2
  10 permit 1024.4510.F125 0.0.0 any aarp
  20 permit any 4100.4500.0000 0.FF.FFFF novell
  30 deny any any
  switch#
  ```

- This command displays the number of rules in each MAC ACL on the switch.

  ```
  switch#show mac access-list summary
  MAC ACL mlist1
  Total rules configured: 6
  MAC ACL mlist2
  Total rules configured: 3
  MAC ACL mlist3
  Total rules configured: 1
  MAC ACL mlist4
  Total rules configured: 0
  switch#
  ```
13.4.9.52  show platform arad acl tcam summary

The `show platform arad acl tcam summary` command displays the percentage of TCAM utilization per forwarding ASIC.

**Command Mode**

EXEC

**Command Syntax**

`show platform arad acl tcam summary`

**Parameter**

`summary` Displays the ACL TCAM summary.

**Example**

This command displays the percentage of TCAM utilization per forwarding ASIC.

```
switch#show platform arad acl tcam summary
The total number of TCAM lines per bank is 1024.

========================================================
Arad3/0:
========================================================
Bank     Used     Used %     Used By
       1       4         0       IP RACLs
Total Number of TCAM lines used is: 4

========================================================
Arad3/4:
========================================================
Bank     Used     Used %     Used By
       1       2         0       IP RACLs
Total Number of TCAM lines used is: 2
```
13.4.9.53  show platform arad acl tcam

The `show platform arad acl tcam` command displays the number of TCAM entries (hardware resources) occupied by the ACL on each forwarding ASIC.

This command is applicable only on DCS-7500E, DCS-7280E series switches.

Command Mode
EXEC

Command Syntax
`show platform arad acl tcam [scope]`

Parameters
`scope` Specifies the information displayed. Options include:
- `detail` Displays the ACL TCAM details.
- `diff` Displays the difference between hardware and shadow.
- `hw` Displays the ACL entries from hardware.
- `shadow` Displays the ACL entries from shadow.
- `summary` Displays the ACL TCAM summary.

Examples
- This command displays the number of TCAM entries used by Arad0 ASIC. In this example, ACL is applied on 2 VLANs (`VI2148` and `VI2700`) but number of TCAM entries occupied is only 1.

```
switch#show platform arad acl tcam detail
ip access-list ipAclLimitTest (Shared RACL, 0 rules, 1 entries, direction out, state success, Acl Label 2)
Fap: Arad0, Shared: true, Interfaces: Vl2148, Vl2700
Bank Offset Entries
0 0 1
Fap: Arad1, Shared: true, Interfaces: Vl2148
Bank Offset Entries
0 0 1
```

- This command displays the percentage of TCAM utilization per forwarding ASIC.

```
switch#show platform arad acl tcam summary
The total number of TCAM lines per bank is 1024.

Arad0:
Bank Used Used % Used By
0 1 0 IP Egress PACLs/RACLs
Total Number of TCAM lines used is: 1

Arad1:
Bank Used Used % Used By
0 1 0 IP Egress PACLs/RACLs
Total Number of TCAM lines used is: 1
```
The `show platform arad mapping` command displays the mapping between the interfaces and the forwarding ASICs.

**Command Mode**

EXEC

**Command Syntax**

`show platform arad chip_name mapping`

**Parameter**

`chip_name` Specifies the Arad chip name.

**Example**

This command displays the mapping between the interfaces and the forwarding ASICs on the Arad3/0 chip.

```
switch# show platform arad arad3/0 mapping
Arad3/0  Port  SysPhyPort  Voq  { Fap,FapPort}  Xlge  Serdes
-------------------------------------------------------------------------------------------------
Ethernet3/1/1  34  288  (0, 2)  n/a  (20)
```

<table>
<thead>
<tr>
<th>Arad3/0</th>
<th>Port</th>
<th>SysPhyPort</th>
<th>Voq</th>
<th>{ Fap,FapPort}</th>
<th>Xlge</th>
<th>Serdes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet3/1/1</td>
<td>34</td>
<td>288</td>
<td>(0, 2)</td>
<td>n/a</td>
<td>(20)</td>
<td></td>
</tr>
</tbody>
</table>
The `show platform fap acl` command displays the ACL information of Sand platform devices.

**Command Mode**
Privileged EXEC

**Command Syntax**
```
show platform fap acl [ipkgv | l4ops | mirroring | opkgv | pmf | tcam | udf | vsicfg]
```

**Parameters**
- `ipkgv` Displays the ACL Ingress Interface Specification (IPKGV) information.
- `l4ops` Displays the ACL Layer 4 Options (L4OPS) information.
- `mirroring` Displays the mirroring ACL information.
- `opkgv` Displays the ACL Egress Interface Specification (OPKGV) information.
- `pmf` Displays the Pmf.
- `tcam` Displays the ACL TCAM information.
- `udf` Displays the ACL UDF information.
- `vsicfg` Displays the ACL Virtual Switch Instance (VSI) CONFIG information.

**Guidelines**
This command is supported on DCS-7280SE and DCS-7500E series platforms only.

**Example**
This command displays the brief information of all installed mirroring ACLs.

```
switch(config)#show platform fap acl mirroring

======================
Aggregate ACLs
======================

  (list2:0->2) type=2; version=0
    - list2 [ prio 0 ] => session 2

  (list1:10->1,list3:20->3) type=0; version=13
    - list3 [ prio 20 ] => session 3
    - list1 [ prio 10 ] => session 1

======================
Interface-ACL Mapping
======================

  Ethernet1 => (list1:10->1,list3:20->3) [ ipv4 ]
  Ethernet33 => (list2:0->2) [ mac ]
```
13.4.9.56  show platform fap acl tcam

The show platform fap tcam command displays the number of TCAM entries (hardware resources) occupied by the ACL on each forwarding ASIC of Sand platform devices.

Command Mode
Privileged EXEC

Command Syntax

show platform fap acl tcam [detail | diff | hw | shadow | summary]

Parameter

- **detail** Displays the number of TCAM entries (hardware resources) occupied by the ACL on each forwarding ASIC.
- **diff** Displays the difference between hardware and shadow.
- **hw** Displays ACL entries from hardware.
- **shadow** Displays ACL entries from shadow.
- **summary** Displays the percentage of TCAM utilization per forwarding ASIC.

Example

This command displays the number of TCAM entries and other ACL TCAM detail.

```
switch# show platform fap acl tcam detail
ip access-list ipAc10000 (RACL, 1 rules, 2 entries, direction in, state success)
  Shared: false
  Interface: Vlan0002
--------------
  Fap: Arad3/0
  Bank Offset Entries
  1  0  2
  Interface: Vlan0003
--------------
  Fap: Arad3/0
  Bank Offset Entries
  1  2  2
  Fap: Arad3/4
  Bank Offset Entries
  1  0  2
```
13.4.9.57  show platform fap acl tcam hw

The `show platform fap acl tcam hw` command displays the TCAM entries configured for each TCAM bank including policy-maps and corresponding traffic match.

This command is applicable only on DCS-7280(E/R), DCS-7500(E/R) series switches.

**Command Mode**
EXEC

**Command Syntax**
`show platform fap fap_name acl tcam hw`

**Parameters**
- **fap_name** Specifies the switch chip-set name.
- **acl** Specifies the Arad ACL information.
- **tcam** Specifies the Arad TCAM information.
- **hw** Specifies the ACL entries for hardware.

**Example**
This command displays the TCAM entries configured for each TCAM bank including policy maps and corresponding traffic matches.

```
switch#show platform fap Arad1 acl tcam hw

13.4.9.58 show platform fap acl tcam summary

The `show platform fap acl tcam summary` command displays for each forwarding ASIC, the number of TCAM entries consumed per ACL type, and in which TCAM bank the entries are installed. A mirroring ACL does not consume TCAM resources unless attached to a mirroring source interface, and a mirroring destination is configured. If the mirroring destination is a GRE tunnel, at least one nexthop entry for the tunnel destination must be resolved before a TCAM entry is installed.

**Command Mode**

EXEC

**Command Syntax**

`show platform fap acl tcam summary`

**Example**

This command displays the number of TCAM entries consumed per ACL type, the bank installed, and ASIC. Three TCAM entries are consumed across two forwarding ASICs, two for IP ACLs, and one for MAC ACLs.

```
switch#show platform fap acl tcam summary

Arad0:

<table>
<thead>
<tr>
<th>Bank</th>
<th>Used</th>
<th>Used %</th>
<th>Used By</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 1</td>
<td>2</td>
<td>0</td>
<td>IP Mirroring</td>
</tr>
</tbody>
</table>

Total Number of TCAM lines used is: 4

Arad1:

<table>
<thead>
<tr>
<th>Bank</th>
<th>Used</th>
<th>Used %</th>
<th>Used By</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
<td>Mac Mirroring</td>
</tr>
</tbody>
</table>
```
show platform trident tcam

The `show platform trident tcam` command displays the TCAM entries configured for each TCAM group including policy maps and corresponding hits.

**Command Mode**

EXEC

**Command Syntax**

```
show platform trident tcam [acl | cpu-bound | detail | entry | mirror | pbr | pipe | qos | shared | summary]
```

**Parameters**

- **no parameters** Displays TCAM entries for each TCAM group.
- **acl** Displays the trident ACL information.
- **cpu-bound** Displays the trident cpu-bound information.
- **detail** Lists all TCAM entries.
- **entry** Displays the TCAM entry information.
- **mirror** Displays the trident Mirroring ACL information.
- **pbr** Displays the trident PBR ACL information.
- **pipe** Allows to specify a pipe for filtering.
- **qos** Displays the trident QOS information.
- **shared** Displays the ACL Sharing information.
- **summary** Displays the TCAM allocation information.

**Guidelines**

This command is applicable only on DCS-7010, DCS-7050/DCS-7050X, DCS7250X, DCS-7300X series switches.

**Examples**

- This command displays the Trident mirroring ACL information.

  ```
  switch(config)#show platform trident tcam mirror
  === Mirroring ACLs on switch Linecard0/0 ===
  Session: mir-sess2
  INGRESS ACL mirAcl2* uses 2 entries
  Assigned to ports: Ethernet32/1
  ```

- This command displays detailed information for the TCAM group.

  ```
  switch#show platform trident tcam detail
  === TCAM detail for switch Linecard0/0 ===
  TCAM group 9 uses 42 entries and can use up to 1238 more.
  Mlag control traffic uses 4 entries.
  589826 0 hits - MLAG - SrcPort UDP Entry
  589827 0 hits - MLAG - DstPort UDP Entry
  589828 0 hits - MLAG - SrcPort TCP Entry
  589829 0 hits - MLAG - DstPort TCP Entry
  CVX traffic reserves 6 entries (0 used).
  L3 Control Priority uses 23 entries.
  589836 0 hits - URM - SelfIp UDP Entry
  589837 0 hits - URM - SelfIp TCP Entry
  589848 0 hits - OSPF - unicast
  589849 71196 hits - OSPFv2 - Multicast
  589850 0 hits - OSPFv3 - Multicast
  589851 0 hits - OSPF Auth ESP - Multicast
  589852 0 hits - OSPF Auth ESP - Unicast
  589853 0 hits - IP packets with GRE type and ISIS protocol
  589854 0 hits - RouterL3 Vlan Priority 6,7 Elevator
  589855 0 hits - RouterL3 DSCP 48-63 Elevator
  ```
IGMP Snooping Flooding reserves 8 entries (6 used).
IGMP Snooping Restricted Flooding L3 from local mlag peer
IGMP Snooping Restricted Flooding L3
L4 MicroBfd traffic reserves 1 entries (0 used).
TCAM group 13 uses 99 entries and can use up to 1181 more.
Dot1x MAB traffic uses 1 entries.
Dot1x MAB traffic uses 1 entries.
13.4.9.60  show route-map

The show route-map command displays the contents of configured route maps.

Command Mode
EXEC

Command Syntax
show route-map [map_name]

Parameters
• no parameter Displays the content of all configured route maps.
• map_name Displays the content of the specified route map.

Examples
• This command displays the map1 route map.

```
switch(config)#show route-map map1
route-map map1 permit 10
  Description:
  Match clauses:
  SubRouteMap:
  Set clauses:
    set as-path prepend last-as 12
    set as-path prepend auto auto
```

• This command displays the map route map.

```
switch>show route-map map
route-map map permit 5
  Match clauses:
    match as 456
Set clauses:
route-map map permit 10
  Match clauses:
  match ip next-hop 2.3.4.5
    match as-path path_2
  Set clauses:
    set local-preference 100
```
13.4.9.61  system profile

The `system profile` command creates a new Ternary Content-Addressable Memory (TCAM) profile in the running configuration.

The `default system profile` and `no system profile` commands delete non-default TCAM profiles from the running configuration.

**Command Mode**

Hardware TCAM

**Command Syntax**

```
system profile [profile_name | default | mirroring-acl | pbr-match-nexthop-group | qos | tap-aggregation-default | tap-aggregation-extended | tc-counters]
```

`default system profile`

`no system profile`

**Parameters**

- `profile_name` Creates a profile with the specified name.
- `default` Creates a default profile.
- `mirroring-acl` Creates a mirroring-ACL profile.
- `pbr-match-nexthop-group` Creates a pbr-match-nexthop-group profile.
- `qos` Creates a Quality of Service (QoS) profile.
- `tap-aggregation-default` Creates a tap-aggregation-default profile.
- `tap-aggregation-extended` Creates a tap-aggregation-extended profile.
- `tc-counters` Creates a tc-counters profile.

**Guideline**

These commands are compatible with the DCS-7280SE and DCS-7500E series switches only.

**Examples**

- These commands create a mirroring-ACL profile.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#system profile mirroring-acl
switch(config-hw-tcam)#show hardware tcam profile

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>FixedSystem</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>switch(config-hw-tcam)#</td>
<td></td>
</tr>
</tbody>
</table>
```

- These commands delete non-default TCAM profiles.

```
switch(config)#hardware tcam
switch(config-hw-tcam)#show hardware tcam profile

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linecard9</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>Linecard8</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>Linecard3</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>Linecard4</td>
<td>mirroring-acl</td>
</tr>
<tr>
<td>Linecard6</td>
<td>mirroring-acl</td>
</tr>
</tbody>
</table>
| switch(config-hw-tcam)#default system profile
switch(config-hw-tcam)#show hardware tcam profile

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linecard9</td>
<td>default</td>
</tr>
<tr>
<td>Linecard8</td>
<td>default</td>
</tr>
<tr>
<td>Linecard3</td>
<td>default</td>
</tr>
<tr>
<td>Linecard4</td>
<td>default</td>
</tr>
<tr>
<td>Linecard6</td>
<td>default</td>
</tr>
</tbody>
</table>
```
Layer 3 Configuration

- These commands delete TCAM profiles.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linecard9</td>
<td>tc-counters</td>
</tr>
<tr>
<td>Linecard8</td>

<td>tc-counters</td>
</tr>
<tr>
<td>Linecard4</td>
<td>tc-counters</td>
</tr>
<tr>
<td>Linecard6</td>
<td>tc-counters</td>
</tr>
</tbody>
</table>

```
switch(config-hw-tcam)#

switch(config-hw-tcam)#show hardware tcam profile
Configuration     Status
Linecard9          tc-counters    tc-counters
Linecard8          tc-counters    tc-counters
Linecard3          tc-counters    tc-counters
Linecard4          tc-counters    tc-counters
Linecard6          tc-counters    tc-counters

switch(config-hw-tcam)#no system profile
switch(config-hw-tcam)#show hardware tcam profile
Configuration     Status
Linecard9          default       default
Linecard8          default       default
Linecard3          default       default
Linecard4          default       default
Linecard6          default       default

switch(config-hw-tcam)#
```
13.5 VARP

Virtual-ARP (VARP) allows multiple switches to simultaneously route packets from a common IP address in an active-active router configuration. Each switch is configured with the same set of virtual IP addresses on corresponding VLAN interfaces and a common virtual MAC address. In MLAG configurations, VARP is preferred over VRRP because VARP does not require traffic to traverse the peer-link to the master router as VRRP would.

A maximum of 500 virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address.

VARP functions by having each switch respond to ARP and GARP requests for the configured router IP address with the virtual MAC address. The virtual MAC address is only for inbound packets and never used in the source field of outbound packets.

When ip routing is enabled, packets to the virtual MAC address are routed to the next hop destination.

---

**Figure 30: VARP Configuration**

The following sections are included in this chapter:

- VRRP and VARP Conceptual Overview
- VRRP and VARP Implementation Procedures
- VRRP and VARP Implementation Examples
- VRRP and VARP Configuration Commands

### 13.5.1 VRRP and VARP Conceptual Overview

This section review the following topics:

- VRRPv2
- VRRPv3
- VARP

#### 13.5.1.1 VRRPv2

A virtual router, also known as a virtual router group, is defined by a Virtual Router Identifier (VRID) and a virtual IP address. A virtual routers mapping of VRID and IP address must be consistent among all switches implementing the virtual router group. A virtual routers scope is restricted to a single LAN.

A LAN may contain multiple virtual routers for distributing traffic. Each virtual router on a LAN is assigned a unique VRID. A switch may be configured with virtual routers among multiple LANs.

VRRP uses priority ratings to assign Master or Backup roles for each VRRP router configured for a virtual router group. The Master router sends periodic VRRP Advertisement messages along the LAN.
and forwards packets received by the virtual router to their destination. Backup routers are inactive but are available to assume Master router duties when the current Master fails.

A VRRP can be configured to allow VRRP routers with higher priority to take over Master router duties. Alternatively, the group can be configured to prevent a router from preemptively assuming the Master role. A VRRP router is always assigned the Master of any virtual router configured with the address owned by the VRRP router, regardless of the preemption prevention setting.

On 7280R3, 7500R3 and 7800R3 series, maximally 14 unique VRRP groups can be configured along with VARP and MLAG Peer gateway virtual MAC capabilities.

13.5.1.2  VRRPv3
RFC 5798 defines version 3 of the Virtual Router Redundancy Protocol (VRRP) for both IPv4 and IPv6. It is based on version 2 of VRRP, as defined in RFC 3768.

13.5.2  VRRP and VARP Implementation Procedures
This section contains the following configuration instructions:

- VRRP Configuration for IPv4
- VRRP Configuration for IPv6
- VARP Configuration

13.5.2.1  VRRP Configuration for IPv4
To implement a virtual router, it must be configured and enabled. A virtual router is typically configured before it is enabled; this ensures that the VRRP router operates as required before its priority settings immediately make it the master virtual router. Because assigning a primary address to a virtual router enables it, address assignment is normally performed after all other configuration tasks.

The no vrrp command removes all VRRP commands for the specified virtual router from running-config.

13.5.2.1.1  Virtual Router Configuration
Most configuration tasks are optional because all mandatory parameters have a default value. The following virtual router parameters are configurable:

- VRRP version (default = version 2)
- Router priority (default = 100)
- Preemption option (default is enabled)
- Advertisement timer (default = one second)
- Description (optional parameter)
- Peer authentication (optional parameter)
- Secondary IP addresses (optional parameter)

VRRP Version
The vrrp ipv4 version command sets the version of VRRP for the corresponding IPv4 virtual router. IPv6 version is not configurable as it only supports version 3. The version selected in a VRRP group can either be the same for all group members or independent of each other. By default, Arista switches use VRRP version 2, which supports only IPv4 environments. VRRP version 3 supports both IPv4 and IPv6 environments.

Example
Layer 3 Configuration

This command causes VLAN 20 to use VRRP version 3.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 1 ipv4 version 3
switch(config-if-vl20)#
```

Master and Backup Router

The VRRP routers within a virtual router group determine the Master router through priority settings. Priority values range from 254 (highest priority) to 1 (lowest priority). Priority is either set by a CLI command or is assigned the default value of 100. A switch specifies priority settings for each of its virtual routers. Once set, VRRP priority level can also be changed by a tracked object. The `vrrp tracked-object` command configures the VRRP client process to track an object created by the `track` command and react if its status changes to `down`.

Preemption mode determines when a VRRP router with a higher priority rating becomes the Master router. If preemption is enabled, the VRRP router with the highest priority immediately becomes the Master router. If preemption is disabled, a VRRP router with a higher priority value does not become the Master router unless the current Master becomes unavailable; this is applicable when a new VRRP router becomes available on the LAN or VRRP routers priority value changes for the virtual router.

The `vrrp priority-level` command configures the switch's priority setting for the specified virtual router.

Example

This command sets the priority value of 250 for the virtual router with VRID 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 priority-level 250
switch(config-if-vl20)#
```

The `vrrp preempt` command controls the preempt mode setting of the specified virtual router. By default, preempt mode is enabled.

Examples

- This command disables preempt mode for the virtual router 15 on VLAN 20.

```
switch(config-if-vl20)#no vrrp 15 preempt
switch(config-if-vl20)#
```

- This command enables preempt mode for the virtual router 30 on VLAN 20.

```
switch(config-if-vl20)#vrrp 30 preempt
switch(config-if-vl20)#
```

The `vrrp preempt delay` command configures a period between an event that elevates a switch to master VRRP router status and the switch's assumption of master VRRP router role. Command options configure delays during normal operation and after a switch reboot.

Advertisement Interval

The Master router sends periodic VRRP Advertisement messages to other VRRP routers. The `vrrp advertisement interval` command specifies the interval between successive advertisement message transmissions.

The advertisement interval also defines the timeout that determines when the switch assumes the Master router role. This timeout interval is three times the advertisement interval.

Example
This command sets the advertisement interval of 10 seconds for virtual router 35 on VLAN 100.

```
switch(config-if-vl100)#vrrp 35 advertisement interval 10
switch(config-if-vl100)#
```

**Description**

The `vrrp session description` command associates a text string to the specified virtual router. The maximum string length is 80 characters. The string has no functional impact on the virtual router.

**Example**

This command associates the text string *Laboratory Router* to virtual router 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 session description Laboratory Router
switch(config-if-vl20)#
```

**Peer Authentication**

VRRP peer authentication validates VRRP advertisement packets that the switch receives from other VRRP routers in a specified virtual router group. When a virtual router uses authentication, all VRRP routers in the group must use the same authentication parameters.

The `vrrp peer authentication` command configures virtual router authentication parameters for the specified virtual router.

**Example**

This command implements plain-text authentication, using 12345 as the key, for virtual router 40 on VLAN 100.

```
switch(config-if-vl100)#vrrp 40 peer authentication text 12345
switch(config-if-vl100)#
```

**Secondary Addresses**

The `vrrp ipv4 secondary` command assigns a secondary IP address to a virtual router. Secondary addresses are optional; a virtual routers configuration may include more than one secondary address command. The primary and secondary address list must be identical for all switches in a virtual router group.

A primary IP address is assigned to a virtual router with the `vrrp ipv4` command (Virtual Router Enabling and the Primary IP address).

**Example**

This command assigns the IP address of 10.2.4.5 as the secondary IP address for the virtual router 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 ipv4 10.2.4.5 secondary
switch(config-if-vl20)#
```

### 13.5.2.1.2 Virtual Router Enabling and the Primary IP address

The `vrrp ipv4` command configures the primary IP address of the specified virtual router and enables the virtual router if the primary address is contained within the configuration mode interfaces IP address subnet. A virtual routers configuration may contain only one primary IP address assignment command; subsequent `vrrp ipv4` commands reassign the virtual routers primary IP address.

**Example**
This command enables virtual router group 15 (VRID) on VLAN 20 and assigns 10.1.1.5 as the virtual routers primary address.

```
switch(config-if-vl20)#vrrp 15 ipv4 10.1.1.5
switch(config-if-vl20)#
```

### 13.5.2.1.3 Disabling VRRP

The `vrrp disabled` command places the switch in stopped state for the specified virtual router. While in stopped state, the switch cannot act as a Master or backup router for the virtual router group. The `no vrrp disabled` command changes the switchs virtual router state to backup or master if the virtual router is properly configured.

VRRP can also be shut down when the status of a tracked object configured by the `vrrp tracked-object` command changes to `down`.

**Examples**

- This command places the switch in stopped mode for virtual router 24 on VLAN 20.

```
switch(config-if-vl20)#vrrp 24 disabled
switch(config-if-vl20)#
```

- This command moves the switch out of stopped mode for virtual router 24 on VLAN 20.

```
switch(config-if-vl20)#no vrrp 24 disabled
switch(config-if-vl20)#
```

- This command configures the switch to enter stopped mode for virtual router 24 on VLAN 20 if the status of `tracked-object interface E6/48` changes to `down`.

```
switch(config-if-vl20)#vrrp 24 tracked-object interface E6/48 shutdown
switch(config-if-vl20)#
```

The `no vrrp` and `no vrrp ipv4` commands delete the specified virtual IP address from the interface. Additionally, the `no vrrp` command removes all residual VRRP commands for the virtual router.

**Examples**

- This command removes all VRRP configuration commands for virtual router 10 on VLAN 15.

```
switch(config-if-vl15)#no vrrp 10
switch(config-if-vl15)#
```

- This command disables virtual router 25 on VLAN 20 and removes the primary IP address from its configuration.

```
switch(config-if-vl20)#no vrrp 25 ipv4 10.1.1.5
switch(config-if-vl20)#
```

### 13.5.2.2 VRRP Configuration for IPv6

To implement a virtual router, it must be configured and enabled. A virtual router is typically configured before it is enabled; this ensures that the VRRP router operates as required before its priority settings immediately make it the master virtual router. Because assigning a primary address to a virtual router enables it, address assignment is normally performed after all other configuration tasks.

The `no vrrp` command removes all VRRP commands for the specified virtual router from `running-config`.

---

1957
13.5.2.2.1 Configuring VRRP for IPv6

Specify the VRRP Version

The `vrrp ipv4 version` command sets the version of VRRP used on an interface. The version selected in a VRRP group must be the same for all group members. By default, Arista switches use VRRP version 2, which is not compatible with IPv6.

Example

This command causes VLAN 20 to use VRRP version 3.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 1 ipv4 version 3
switch(config-if-vl20)#
```

Create a VRRP Group and Configure a Virtual IPv6 Address

The `vrrp ipv6` command assigns an IPv6 address to the interface being configured and creates a VRRP group.

Example

These commands create VRRP group 3 and configure a virtual IPv6 address for the VRRP group on the VLAN 20 interface.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 3 ipv6 2001:db8:0:1::1
switch(config-if-vl20)#
```

Configure Tracking

The `vrrp tracked-object` command configures the VRRP client process to track an object created by the `track` command and react if its status changes to `down`.

Example

This command causes interface VLAN 20 to disable VRRP when tracked object ETH8 changes state.

```
switch(config-if-vl20)#vrrp 1 tracked-object ETH8 shutdown
switch(config-if-vl20)#
```

Configure the Priority Level

The `vrrp priority-level` command configures the switchs priority setting for the specified virtual router.

Example

This command sets the priority value of 250 for the virtual router with VRID 15 on VLAN 20.

```
switch(config-if-vl20)#vrrp 15 priority-level 250
switch(config-if-vl20)#
```

Configure the Preemption Mode

Preemption mode determines when a VRRP router with a higher priority rating becomes the Master router. If preemption is enabled, the VRRP router with the highest priority immediately becomes the Master router. If preemption is disabled, a VRRP router with a higher priority value does not become
the Master router unless the current Master becomes unavailable; this is applicable when a new VRRP router becomes available on the LAN or VRRP routers priority value changes for the virtual router.

The `vrrp preempt` command controls the preempt mode setting of the specified virtual router. By default, preempt mode is enabled.

**Example**

This command enables preempt mode for the virtual router 30 on VLAN 20.

```
switch(config-if-vl20)#vrrp 30 preempt
```

**Configure the VRRP Advertisement Interval**

The `ip virtual-router mac-address advertisement-interval` command specifies the interval between advertisement packets sent by the master router to the VRRP group members.

**Example**

This command configures a MAC address advertisement interval of one minute (60 seconds).

```
switch(config)#interface vlan 20
switch(config-if-vl20)#ip virtual-router mac-address advertisement-interval 60
switch(config-if-vl20)#
```

### 13.5.2.2 Verify VRRP IPv6 Configurations

Use the following commands to display the VRRP configurations and status.

**Show VRRP Group**

The `show vrrp` command displays information about the Virtual Router Redundancy Protocol (VRRP) groups configured on a specified interface.

**Example**

This command displays a table of information for VRRP groups on the switch.

```
switch#show vrrp interface vlan 3060 brief
Interface Id  Ver Pri Time  State   VrIps
Vlan3060 1   3   100 3609 Master  2001::2
        2   3   100 3609 Master  2002::2
switch#
```

### 13.5.2.3 VARP Configuration

Implementing VARP consists of assigning virtual IP addresses to VLAN interfaces and configuring a virtual MAC address.

**Virtual IP Addresses**

The `ip virtual-router address` command assigns a virtual IP address to the VLAN interface being configured. Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A virtual IPv4 address may optionally be configured with a subnet, but doing so will modify the behavior of ARP requests sent from the router. When the router sends an ARP request for an IPv4 address in a virtual subnet, the ARP request will use the virtual IPv4 address as the source IP address.
and the virtual MAC address as the source MAC address inside the ARP header. For virtual IP addresses configured without the subnet option, no modifications are made to outgoing ARP requests.

**Examples**

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address for **VLAN 10**.

  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 10.0.0.6
  switch(config-if-Vl10)#ipv6 address 2001::1/64
  switch(config-if-Vl10)#ipv6 virtual-router address 2001::2
  switch(config-if-Vl10)#exit
  switch(config)#

- These commands configure a Switch Virtual Interface (SVI) and a virtual IPv4 address with a subnet for **VLAN 10**. A static route is added to indicate that the virtual subnet is reachable through **VLAN 10**.

  switch(config)#ip route 192.0.0.0/24 vlan 10
  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 192.0.0.6/24
  switch(config-if-Vl10)#exit
  switch(config)#

**Virtual MAC Address**

The `ip virtual-router mac-address` command assigns a virtual MAC address to the switch. The switch maps all virtual router IP addresses to this MAC address. The address is receive-only; the switch never sends packets with this address as the source.

When the destination MAC of a packet destined to a remote network matches the virtual MAC address, the MLAG peer forwards the traffic to the next hop destination. Each MLAG peer must have the same routes available, either though static configuration or learned through a dynamic routing protocol.

**Example**

This command configures a virtual MAC address.

  switch(config)#ip virtual-router mac-address 001c.7300.0099
  switch(config)#

**Show Virtual MAC Address**

To display the virtual router MAC and IP addresses, enter the `show ip virtual-router` command.

**Example**

This command displays the virtual router addresses assigned on the switch.

<table>
<thead>
<tr>
<th>Interface Protocol</th>
<th>IP Address</th>
<th>Virtual IP Address</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vlan15</td>
<td>10.1.1.3/24</td>
<td>10.1.1.15</td>
<td>up</td>
</tr>
<tr>
<td>Vlan15</td>
<td>10.1.1.3/24</td>
<td>10.1.1.16</td>
<td>up</td>
</tr>
<tr>
<td>Vlan15</td>
<td>10.1.1.3/24</td>
<td>10.1.1.17</td>
<td>up</td>
</tr>
<tr>
<td>Vlan20</td>
<td>10.12.1.6/24</td>
<td>10.1.1.51</td>
<td>up</td>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Show IPv6 Virtual-Router

The `show ipv6 virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IPv6 addresses assigned to each VLAN interface.

**Example**

This command displays a table of information for IPv6 VRRP groups on the switch.

```
switch#show ipv6 virtual-router
IP virtual router is configured with MAC address: 001c.7300.0099
MAC address advertisement interval: 30 seconds
Interface Vlan4094
  State is up
  Protocol is up
  IPv6 address
    2001:b8:2001::1011/64
  Virtual IPv6 address
    2001:db8:ac10:fe01::<1961>
switch#
```

13.5.3 VRRP and VARP Implementation Examples

This section contains the following example set:

- **VRRP Examples**
- **VARP Example**

13.5.3.1 VRRP Examples

This section provides code that implements three VRRP configurations:

- Example 1 configures two switches in a single virtual router group. This implementation protects the LAN against the failure of one router.
- Example 2 configures two switches into two virtual routers within a single LAN. This implementation protects the LAN against the failure of one router and balances traffic between the routers.
- Example 3 configures three switches to implement virtual routers on two LANs. Each LAN contains two virtual routers. One switch is configured into four virtual routers – two on each LAN.

13.5.3.1.1 VRRP Example 1: One Virtual Router on One LAN

The network diagram displays the Example 1 network. Two switches are configured as VRRP routers to form one virtual router.

![Figure 31: VRRP Example 1 Network Diagram](image)

The following code configures the first switch (*Router A*) as the master router and the second switch (*Router B*) as a backup router for virtual router **10** on **VLAN 50**. *Router A* becomes the Master virtual router by setting its priority at **200**; *Router B* maintains the default priority of **100**. The advertisement interval is three seconds on both switches. Priority preemption is enabled by default.
Switch Code that Implements Router A on the First Switch

```bash
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#no vrrp 10
switch-A(config-if-vl50)#vrrp 10 priority 200
switch-A(config-if-vl50)#vrrp 10 advertisement interval 3
switch-A(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl50)#exit
```

Switch Code that Implements Router B on the Second Switch

```bash
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#no vrrp 10
switch-B(config-if-vl50)#vrrp 10 advertisement interval 3
switch-B(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl50)#exit
```

13.5.3.1.2 VRRP Example 2: Two Virtual Routers on One LAN

The network diagram displays Example 2. Two switches are configured as VRRP routers to form two virtual routers on one LAN. Using two virtual routers distributes the LAN traffic between the switches.

![VRRP Example 2 Network Diagram](image)

**Figure 32: VRRP Example 2 Network Diagram**

The following code configures two switches as a master and a backup router for two virtual routers on VLAN 50.

- **Router A** is the master for virtual router 10 and backup for virtual router 20.
- **Router B** is the master for virtual router 20 and backup for virtual router 10.
- VRRP advertisement interval is 3 seconds on virtual router 10 and 5 seconds on virtual router 20.
- Priority preemption is enabled by default for both virtual routers.

Switch Code that Implements Router A on the First Switch

```bash
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#no vrrp 10
switch-A(config-if-vl50)#vrrp 10 priority 200
switch-A(config-if-vl50)#vrrp 10 advertisement interval 3
switch-A(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl50)#no vrrp 20
switch-A(config-if-vl50)#vrrp 20 advertisement interval 5
switch-A(config-if-vl50)#vrrp 20 ip 10.10.4.20
switch-A(config-if-vl50)#exit
```
Switch Code that Implements Router B on the Second Switch

```plaintext
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#no vrrp 10
switch-B(config-if-vl50)#vrrp 10 advertisement interval 3
switch-B(config-if-vl50)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl50)#no vrrp 20
switch-B(config-if-vl50)#vrrp 20 priority 200
switch-B(config-if-vl50)#vrrp 20 advertisement interval 5
switch-B(config-if-vl50)#vrrp 20 ip 10.10.4.20
switch-B(config-if-vl50)#exit
```

13.5.3.1.3 VRRP Example 3: Two Virtual Routers on Two LANs

The network diagram displays Example 3. Three switches are configured as VRRP routers to form four virtual router groups two groups on each of two LANs.

![VLAN Diagram](image)

Figure 33: VRRP Example 3 Network Diagram

The following code configures the three switches as follows:

- **Router A** is the master for virtual router 10 and backup for virtual router 20 on VLAN 100.
- **Router A** is the master for virtual router 30 and backup for virtual router 40 on VLAN 150.
- **Router B** is the master for virtual router 20 and backup for virtual router 10 on VLAN 100.
- **Router C** is the master for virtual router 40 and backup for virtual router 30 on VLAN 150.
- VRRP advertisement interval is set to one second on all virtual routers.
- Priority preemption is disabled on all virtual routers.

Switch Code that Implements Router A on the First Switch

```plaintext
switch-A(config)#interface vlan 100
switch-A(config-if-vl100)#ip address 10.10.4.4/24
switch-A(config-if-vl100)#no vrrp 10
switch-A(config-if-vl100)#vrrp 10 priority 200
switch-A(config-if-vl100)#no vrrp 10 preempt
switch-A(config-if-vl100)#vrrp 10 ip 10.10.4.10
switch-A(config-if-vl100)#vrrp 10 advertisement interval 1
switch-A(config-if-vl100)#no vrrp 20
switch-A(config-if-vl100)#no vrrp 20 preempt
switch-A(config-if-vl100)#vrrp 20 ip 10.10.4.20
```
Switch Code that Implements Router B on the Second Switch

```
switch-B(config)#interface vlan 100
switch-B(config-if-vl100)#ip address 10.10.4.2/24
switch-B(config-if-vl100)#no vrrp 10
switch-B(config-if-vl100)#no vrrp 10 preempt
switch-B(config-if-vl100)#vrrp 10 ip 10.10.4.10
switch-B(config-if-vl100)#no vrrp 20
switch-B(config-if-vl100)#vrrp 20 priority 200
switch-B(config-if-vl100)#no vrrp 20 preempt
switch-B(config-if-vl100)#vrrp 20 ip 10.10.4.20
switch-A(config-if-vl100)#vrrp 20 advertisement interval 1
switch-B(config-if-vl100)#exit
```

Switch Code that Implements Router C on the Third Switch

```
switch-C(config)#interface vlan 150
switch-C(config-if-vl150)#ip address 40.10.5.8/24
switch-C(config-if-vl150)#no vrrp 30
switch-C(config-if-vl150)#no vrrp 30 preempt
switch-C(config-if-vl150)#vrrp 30 ip 40.10.5.31
switch-C(config-if-vl150)#no vrrp 40
switch-C(config-if-vl150)#vrrp 40 priority 200
switch-C(config-if-vl150)#no vrrp 40 preempt
switch-C(config-if-vl150)#vrrp 40 ip 40.10.5.32
switch-A(config-if-vl100)#vrrp 40 advertisement interval 1
switch-C(config-if-vl150)#exit
```

13.5.3.2 VARP Example

This section provides code that implements a VARP configuration. The network diagram displays the Example 1 network. Two switches in an MLAG domain are configured as VARP routers.

The following code configures 10.10.4.10 as the virtual IP address for VLAN 50, 10.24.4.1 as the virtual IP address for VLAN 70, and 001c.7300.0999 as the virtual MAC address on both switches.
Switch Code that Implements VARP on the First Switch

```bash
switch-A(config)#ip virtual-router mac-address 001c.7300.0999
switch-A(config)#interface vlan 50
switch-A(config-if-vl50)#ip address 10.10.4.1/24
switch-A(config-if-vl50)#ip virtual-router address 10.10.4.10
switch-A(config-if-vl50)#interface vlan 70
switch-A(config-if-vl70)#ip address 10.24.4.17/24
switch-A(config-if-vl70)#ip virtual-router address 10.24.4.1
switch-A(config-if-vl70)#exit
```

Switch Code that Implements VARP on the Second Switch

```bash
switch-B(config)#ip virtual-router mac-address 001c.7300.0999
switch-B(config)#interface vlan 50
switch-B(config-if-vl50)#ip address 10.10.4.2/24
switch-B(config-if-vl50)#ip virtual-router address 10.10.4.10
switch-B(config-if-vl50)#interface vlan 70
switch-B(config-if-vl70)#ip address 10.24.4.18/24
switch-B(config-if-vl70)#ip virtual-router address 10.24.4.1
switch-B(config-if-vl70)#exit
```
13.5.4 VRRP and VARP Configuration Commands

This section contains descriptions of CLI commands that support VRRP and VARP.

Global Configuration Commands
- `ip fhrp accept-mode`
- `ip virtual-router mac-address`
- `ip virtual-router mac-address advertisement-interval`

Interface Configuration Commands Ethernet, Port Channel, and VLAN Interfaces
- `ip virtual-router address`
- `ipv6 virtual-router address`
- `no vrrp`
- `vrrp advertisement interval`
- `vrrp disabled`
- `vrrp ipv4`
- `vrrp ipv4 checksum pseudo-header exclude`
- `vrrp ipv4 secondary`
- `vrrp ipv4 version`
- `vrrp ipv6`
- `vrrp mac-address advertisement-interval`
- `vrrp peer authentication`
- `vrrp preempt`
- `vrrp preempt delay`
- `vrrp priority-level`
- `vrrp session description`
- `vrrp timers delay reload`
- `vrrp tracked-object`

Privileged EXEC Commands
- `show ip virtual-router`
- `show ipv6 virtual-router`
- `show vrrp`
13.5.4.1 ip fhrp accept-mode

The `ip fhrp accept-mode` command configures the switch to permit SSH access to the VRRP Master and VARP Master router. All routers within a VRRP or VARP group should be configured consistently. By default, SSH access to the VRRP and VARP Master routers is not permitted.

The `no ip fhrp accept-mode` and `default ip fhrp accept-mode` commands restores the default SSH access availability by removing the `ip fhrp accept-mode` command from `running-config`.

Command Mode
Global Configuration

Command Syntax
`ip fhrp accept-mode`
`no ip fhrp accept-mode`
`default ip fhrp accept-mode`

Example
This command configures the switch to permit SSH access to the VRRP and VARP Master routers.

```
switch(config)#ip fhrp accept-mode
switch(config)#show running-config
!
ip fhrp accept-mode
!
```

switch(config)#
13.5.4.2 ip virtual-router address

The `ip virtual-router address` command assigns a virtual IPv4 address to the VLAN interface being configured. (To assign a virtual IPv6 address to a VLAN interface, use the `ipv6 virtual-router address` command.) Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A virtual IP address may optionally be configured with a subnet, but doing so will modify the behavior of ARP requests sent from the router. When the router sends an ARP request for an IP address in a virtual subnet, the ARP request will use the virtual IP address as the source IP address and the virtual MAC address as the source MAC address inside the ARP header. For virtual IP addresses configured without the subnet option, no modifications are made to outgoing ARP requests.

A maximum of **500** virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address configured through the `ip virtual-router mac-address` command.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG.

The `no ip virtual-router address` and `default ip virtual-router address` commands remove the specified virtual IP address from the configuration mode interface by deleting the corresponding `ip virtual-router address` command from `running-config`. If the command does not specify an address, all virtual IPv4 addresses are removed from the interface.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

- `ip virtual-router address ipv4_addr`
- `no ip virtual-router address [ipv4_addr]`
- `default ip virtual-router address [ipv4_addr]`

**Parameter**

`ipv4_addr` IP address of router. Dotted decimal notation.

**Examples**

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address for **VLAN 10**.

  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 10.0.0.6
  switch(config-if-Vl10)#exit

- These commands configure a Switch Virtual Interface (SVI) and a virtual IP address with a subnet for **VLAN 10**. A static route is added to indicate that the virtual subnet is reachable through **VLAN 10**.

  switch(config)#ip route 192.0.0.0/24 vlan 10
  switch(config)#interface vlan 10
  switch(config-if-Vl10)#ip address 10.0.0.2/24
  switch(config-if-Vl10)#ip virtual-router address 192.0.0.6/24
  switch(config-if-Vl10)#exit
13.5.4.3  ip virtual-router mac-address advertisement-interval

The `ip virtual-router mac-address advertisement interval` command specifies the period between the transmission of consecutive gratuitous ARP requests that contain the virtual router mac address for each virtual-router IP address configured on the switch. The default period is 30 seconds.

The `no ip virtual-router mac-address advertisement-interval` command restores the default period of 30 seconds by removing the `ip virtual-router mac-address advertisement-interval` command from `running-config`.

**Command Mode**
Global Configuration

**Command Syntax**

```
ip virtual-router mac-address advertisement-interval period
no ip virtual-router mac-address advertisement-interval
default ip virtual-router mac-address advertisement-interval
```

**Parameter**

`period` advertisement interval (seconds). Values range from 0 to 86400. Default is 30.

**Example**

This command configures a MAC address advertisement interval of one minute (60 seconds).

```
switch(config)#ip virtual-router mac-address advertisement-interval 60
switch(config)#
```
**13.5.4.4 ip virtual-router mac-address**

The `ip virtual-router mac-address` command assigns a virtual MAC address to the switch. The switch maps all virtual router IP addresses to this MAC address. The address is receive-only; the switch never sends packets with this address as the source. The virtual router is not configured on the switch until this virtual mac-address is assigned.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG. When the destination MAC of a packet destined to a remote network matches the virtual MAC address, the MLAG peer forwards the traffic to the next hop destination. Each MLAG peer must have the same routes available, either though static configuration or learned through a dynamic routing protocol.

The `no ip virtual-router mac-address` command removes a virtual MAC address from the interface by deleting the corresponding `ip virtual-router mac-address` command from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```
ip virtual-router mac-address mac_addr
no ip virtual-router mac address [mac_addr]
```

**Parameter**

*mac_addr* MAC IP address (dotted hex notation). Select an address that will not otherwise appear on the switch.

**Example**

This command configures a virtual MAC address.

```
switch(config)#ip virtual-router mac-address 001c.7300.0099
switch(config)#
```
13.5.4.5 ipv6 virtual-router address

The `ipv6 virtual-router address` command assigns a virtual IPv6 address to the VLAN interface being configured. (To assign a virtual IPv4 address to a VLAN interface, use the `ip virtual-router address` command.) Unlike VRRP, the virtual IP address does not have to be in the same subnet as the physical interface.

A maximum of 500 virtual IP addresses can be assigned to a VLAN interface. All virtual addresses on all VLAN interfaces resolve to the same virtual MAC address configured through the `ip virtual-router mac-address` command.

This command is typically used in MLAG configurations to create identical virtual routers on switches connected to the MLAG domain through an MLAG.

The `no ipv6 virtual-router address` and `default ipv6 virtual-router address` commands remove the specified virtual IPv6 address from the configuration mode interface by deleting the corresponding `ipv6 virtual-router address` command from `running-config`. If the command does not specify an address, all virtual IPv6 addresses are removed from the interface.

**Command Mode**

Interface-VLAN Configuration

**Command Syntax**

```
ipv6 virtual-router address net_addr
no ipv6 virtual-router address [net_addr]
default ipv6 virtual-router address [net_addr]
```

**Parameter**

`net_addr` network IPv6 address.

**Example**

These commands configure a Switch Virtual Interface (SVI) and a virtual IPv6 address for VLAN 10.

```
switch(config)#interface vlan 10
switch(config-if-Vl10)#ipv6 address 2001:0DB8:0:1::1/64
switch(config-if-Vl10)#ipv6 virtual-router address 2001:0DB8:0:1::2
switch(config-if-Vl10)#exit
```
13.5.4.6 no vrrp

The no vrrp command removes all VRRP configuration commands for the specified virtual router on the configuration mode interface. The default vrrp command also reverts VRRP configuration parameters to default settings by removing the corresponding vrrp commands.

Commands removed by the no vrrp command include:

- vrrp advertisement interval
- vrrp disabled
- vrrp ipv4
- vrrp ipv4 secondary
- vrrp peer authentication
- vrrp preempt
- vrrp preempt delay
- vrrp priority-level
- vrrp session description

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

no vrrp group
default vrrp group

Parameter

group Virtual Router Identifier (VRID). Values range from 1 to 255.

Example

This command removes all VRRP configuration commands for virtual router group 10 on VLAN 15.

```
switch(config)#interface vlan 15
switch(config-if-vl15)#no vrrp 10
switch(config-if-vl15)#
```
13.5.4.7  show ip virtual-router

The `show ip virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IP addresses assigned to each VLAN interface.

**Command Mode**

EXEC

**Command Syntax**

`show ip virtual-router`

**Messages**

- **IP virtual router is not configured** a virtual MAC address is not assigned to the switch.
- **No interface with virtual IP address** no virtual IP addresses are assigned to any VLAN interfaces.

**Examples**

- This command displays a table of information for VRRP groups on the switch.

```
switch#show ip virtual-router
IP virtual router is configured with MAC address: 24cd.5a29.cc31
Interface       IP Address  Virtual IP Address  Status
Protocol
Vlan15          10.1.1.3/24  10.1.1.15         up             up
Vlan15          10.1.2.3/24  10.1.1.16         up             up
Vlan15          10.1.2.3/24  10.1.1.17         up             up
Vlan20          10.12.1.6/24 10.1.1.51         up             up
Vlan20          10.12.1.6/24 10.1.1.53         up             up
Vlan20          10.12.1.6/24 10.1.1.55         up             up
switch#
```

- This command generates a response that indicates a virtual MAC address is not assigned to the switch.

```
switch#show ip virtual-router
IP virtual router is not configured
switch#
```
13.5.4.8  show ipv6 virtual-router

The `show ipv6 virtual-router` command displays the virtual MAC address assigned to the switch and all virtual IPv6 addresses assigned to each VLAN interface.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 virtual-router`

**Messages**

- **IPv6 virtual router is not configured** a virtual MAC address is not assigned to the switch.
- **No interface with virtual IPv6 address** no virtual IPv6 addresses are assigned to any VLAN interfaces.

**Example**

This command displays a table of information for IPv6 VRRP groups on the switch.

```bash
switch# show ipv6 virtual-router
IP virtual router is configured with MAC address: 001c.7300.0099
MAC address advertisement interval: 30 seconds
Interface Vlan4094
  State is up
  Protocol is up
  IPv6 address
    2001:b8:2001::1011/64
  Virtual IPv6 address
    2001:db8:ac10:fe01::
switch#
```
13.5.4.9  show vrrp

The `show vrrp` command displays information about the Virtual Router Redundancy Protocol (VRRP) groups configured on a specified interface. Parameter options control the amount and formatting of the displayed information.

**Command Mode**
Privileged EXEC

**Command Syntax**

```
show vrrp [INFO_LEVEL] [STATES]
show vrrp INTF GROUP_NUM [INFO_LEVEL] [STATES]
show vrrp GROUP_NUM INTF_GROUP [INFO_LEVEL] [STATES]
```

**Parameters**

- **INTF** specifies the VRRP groups for which the command displays status. When the parameter is omitted or specifies only an interface, the group list is filtered by the STATES parameter.
  - *no parameter* specified groups on all interfaces.
  - *interface ethernet e_num* specified groups on Ethernet interface.
  - *interface loopback l_num* specified groups on loopback interface.
  - *interface management m_num* specified groups on management interface.
  - *interface port-channel p_num* specified groups on port channel interface.
  - *interface vlan v_num* specified groups on VLAN interface.
  - *interface vxlan vx_num* specified groups on VXLAN interface.

- **GROUP_NUM** the VRRP ID number of the group for which the command displays status.
  - *no parameter* all groups on specified interface.
  - *vrid_num* Virtual Router Identifier (VRID). Value ranges from 1 to 255.

- **INFO_LEVEL** Specifies format and amount of displayed information. Options include:
  - *no parameter* displays a block of data for each VRRP group.
  - *brief* displays a single table that lists information for all VRRP groups.

- **STATES** Specifies the groups, by VRRP router state, that are displayed. Options include:
  - *no parameter* displays data for groups in the master or backup states.
  - *all* displays all groups, including groups in the stopped and interface down states.

**Examples**

- This command displays a table of information for VRRP groups on the switch.

```
switch#show vrrp brief
Interface Id  Ver Pri Time  State   VrIps
Vlan1006   3   2   100 3609  Master  127.38.10.2
Vlan1006   4   3   100 3609  Master  127.38.10.10
Vlan1010   1   2   100 3609  Master  128.44.5.3
Vlan1014   2   2   100 3609  Master  127.16.14.2
switch>
```

- This command displays data blocks for all VRRP groups on VLAN 46, regardless of the VRRP state.

```
switch#show vrrp interface vlan 1006 all
Vlan1010 - Group 1
  VRRP Version 2
  State is Stopped
  Virtual IPv4 address is 128.44.5.3
  Virtual MAC address is 0000.5e00.0101
```
Mac Address Advertisement interval is 30s
VRRP Advertisement interval is 1s
Preemption is enabled
Preemption delay is 0s
Preemption reload delay is 0s
Priority is 100
Master Router is 0.0.0.0
Master Advertisement interval is 1s
Skew time is 0.609s
Master Down interval is 3.609s

• This command displays data for all VRRP group 2 on VLAN 1014.

switch#show vrrp interface vlan 1014 group 2
Vlan1006 - Group 2
  VRRP Version 2
  State is Master
  Virtual IPv4 address is 127.38.10.2
  Virtual MAC address is 0000.5e00.0103
  Mac Address Advertisement interval is 30s
  VRRP Advertisement interval is 1s
  Preemption is enabled
  Preemption delay is 0s
  Preemption reload delay is 0s
  Priority is 100
  Master Router is 127.38.10.1 (local), priority is 100
  Master Advertisement interval is 1s
  Skew time is 0.609s
  Master Down interval is 3.609s

switch#
13.5.4.10  vrrp advertisement interval

The vrrp advertisement interval command configures the interval between successive advertisement messages that the switch sends to VRRP routers in the specified virtual router group. The switch must be the groups Master virtual router to send advertisement messages. The advertisement interval must be configured identically on all physical routers in the virtual router group.

The advertisement interval also influences the timeout interval that defines when the virtual router becomes the master virtual router. When preemption is enabled, the virtual router becomes the master when three times the advertisement interval elapses after the switch detects master router priority conditions.

The no vrrp advertisement interval and default vrrp advertisement interval commands restore the default advertisement interval of one second for the specified virtual router by removing the corresponding vrrp advertisement interval command from running-config. The no vrrp command also removes the vrrp advertisement interval command for the specified virtual router.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax
vrrp group advertisement interval adv_time
no vrrp group advertisement interval
default vrrp group advertisement interval

Parameters
• group Virtual Router Identifier (VRID). Values range from 1 to 255.
• adv_time advertisement interval (seconds). Values range from 1 to 255. Default value is 1.

Example
This command sets the advertisement interval of five seconds for the virtual router 35 on VLAN 100.

```
switch(config)#interface vlan 100
switch(config-if-vl100)#vrrp 35 advertisement interval 5
switch(config-if-vl100)#
```
13.5.4.11 vrrp disabled

The `vrrp disabled` command places the switch in stopped state for the specified virtual router. While in stopped state, the switch cannot act as a `master` or `backup` router for the virtual router group.

The `no vrrp disabled` and `default vrrp disabled` commands remove the corresponding `vrrp disabled` command from `running-config`. This changes the switch's virtual router state to `backup` or `master` if the virtual router is properly configured.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
- `vrrp group disabled`
- `no vrrp group disabled`
- `default vrrp group disabled`

**Parameter**
- `group` Virtual Router Identifier (VRID). Values range from 1 to 255.

**Examples**
- These commands place the switch in stopped mode for virtual router 24 on VLAN 20.
  ```
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 24 disabled
  switch(config-if-vl20)#
  ```
- This command moves the switch out of stopped mode for virtual router 24 on VLAN 20.
  ```
  switch(config-if-vl20)#no vrrp 24 disabled
  switch(config-if-vl20)#
  ```
**13.5.4.12**  **vrrp ipv4 checksum pseudo-header exclude**

This command excludes the pseudo-header in IPv4 VRRPv3 checksum calculation on the VRRP group on the configuration mode interface of the switch and supports IPv4 VRRPv3 interoperability.

The **no** form of the command deletes the **vrrp ipv4 checksum pseudo-header exclude** configuration from the Ethernet interface on the switch.

The **exit** command returns the switch to global configuration mode.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

```plaintext
vrrp group ipv4 checksum pseudo-header exclude
no vrrp group ipv4 checksum pseudo-header exclude
```

**Parameter**

*group* Virtual Router Identifier (VRID). Values range from **1 to 255**.

**Example**

This command excludes the pseudo-header in IPv4 VRRPv3 checksum calculation on VRRP **group 1** on **interface ethernet 1**.

```plaintext
switch(config-if-Et1)#vrrp 1 ipv4 checksum pseudo-header exclude
```
13.5.4.13  vrrp ipv4 secondary

The `vrrp ipv4 secondary` command assigns a secondary IP address to the specified virtual router. Secondary IP addresses are an optional virtual router parameter. A virtual router may contain multiple secondary address commands. The IP address list must be identical for all VRRP routers in a virtual router group.

The virtual router is assigned a primary IP address with the `vrrp ipv4` command.

The `no vrrp ipv4 secondary` and `default vrrp ipv4 secondary` commands remove the secondary IP address for the specified VRRP virtual router by deleting the corresponding `vrrp ipv4 secondary` statement from running-config. The `no vrrp` command also removes all `vrrp ipv4 secondary` commands for the specified virtual router.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

```
vrrp group ipv4 ipv4_addr secondary
no vrrp group ipv4 ipv4_addr secondary
default vrrp group ipv4 ipv4_addr secondary
```

Parameters

- `group` Virtual Router Identifier (VRID). Values range from 1 to 255.
- `ipv4_addr` secondary IPv4 address of the virtual router.

Related Command

`vrrp ipv4`

Example

This command assigns the IP address of 10.2.4.5 as the secondary IP address for the virtual router with VRID of 15 on VLAN 20.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 15 ipv4 10.2.4.5 secondary
switch(config-if-vl20)#
```
13.5.4.14 vrrp ipv4 version

The `vrrp ipv4 version` command enables VRRP on the configuration mode interface and configures the VRRP version for the specified VRRP virtual router.

The `no vrrp ipv4 version` and `default vrrp ipv4 version` commands restore the default VRRP version to VRRPv2 by removing the corresponding `vrrp ipv4 version` statement from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

`vrrp group ipv4 version VERSION_NUMBER`

`no vrrp group ipv4 version`

`default vrrp group ipv4 version`

**Parameters**

- `group` Virtual Router Identifier (VRID). Values range from 1 to 255.
- `VERSION_NUMBER` Specifies VRRP version that the switch uses. Default value is 2 (VRRPv2)

Options include:

- 2 VRRP v2 supports IPv4 environment.
- 3 VRRP v3 supports IPv4 and IPv6 environment.

**Examples**

- This command enables VRRPv3 for IPv6 on `interface ethernet 3`.

  ```
  switch#(config)#interface ethernet 3
  switch#(config-if-Et3)#vrrp 1 ipv4 version 3
  ```

- This command removes VRRPv3 from `interface ethernet 3` and reverts to the default VRRPv2.

  ```
  switch#(config)#interface ethernet 3
  switch#(config-if-Et3)#no vrrp 1 ipv4 version
  ```
13.5.4.15  **vrrp ipv4**

The **vrrp ipv4** command configures the primary IP address for the specified VRRP virtual router. The command also activates the virtual router if the primary address is contained in the interfaces subnet. A VRRP virtual routers configuration may contain only one primary IP address assignment command; subsequent **vrrp ipv4** commands replace the existing primary address assignment.

The **vrrp ipv4 secondary** command assigns a secondary IP address to the VRRP virtual router. The **no vrrp ipv4** and **default vrrp ipv4** commands disable the VRRP virtual router and deletes the primary IP address by removing the corresponding **vrrp ipv4** statement from **running-config**. The **no vrrp** command also removes the **vrrp ipv4** command for the specified virtual router.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
 vrrp group ipv4 ipv4_address
 no vrrp group ipv4 ipv4_address
 default vrrp group ipv4 ipv4_address
```

**Parameters**
- **group** Virtual Router Identifier (VRID). Values range from 1 to 255.
- **ipv4_address** IPv4 address of the virtual router.

**Related Command**

**vrrp ipv4 secondary**

**Example**

This command enables virtual router 15 on VLAN 20 and designates 10.1.1.5 as the virtual routers primary address.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 15 ipv4 10.1.1.5
switch(config-if-vl20)#
```
The `vrrp ipv6` command configures the IPv6 address for the specified VRRP virtual router. The command also activates the virtual router if the primary address is contained in the interfaces subnet.

The no `vrrp ipv6` and default `vrrp ipv6` commands disable the VRRP virtual router and deletes the IPv6 address by removing the corresponding `vrrp ipv6` statement from `running-config`. The no `vrrp` command also removes the `vrrp ipv6` command for the specified virtual router.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

`vrrp group ip ipv6_address`

`no vrrp group ip ipv6_address`

`default vrrp group ip ipv6_address`

**Parameters**

- `group` Virtual Router Identifier (VRID). Values range from 1 to 255.
- `ipv6_address` IPv6 address of the virtual router.

**Examples**

- This command enables address `2001:db8:0:1::1` for IPv6 VRRP on VLAN 20.

  ```bash
  switch(config)#interface vlan 20
  switch(config-if-vl20)#vrrp 3 ipv6 2001:db8:0:1::1
  switch(config-if-vl20)#
  ```

- This command disables VRRPv3 on VLAN 20 from virtual router 3.

  ```bash
  switch(config)#interface vlan 20
  switch(config-if-vl20)#no vrrp 3 ipv6 2001:db8:0:1::1
  switch(config-if-vl20)#
  ```
13.5.4.17 \texttt{vrrp mac-address advertisement-interval}

The \texttt{vrrp mac-address advertisement-interval} command specifies the interval between advertisement packets sent by the master router to the VRRP group members.

The \texttt{vrrp mac-address advertisement-interval 0}, \texttt{no vrrp mac-address advertisement-interval} and \texttt{default vrrp mac-address advertisement-interval} commands disable the feature by removing the \texttt{vrrp mac-address advertisement-interval} command from \texttt{running-config}.

\textbf{Command Mode}

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

\textbf{Command Syntax}

\begin{verbatim}
 vrrp group mac-address advertisement-interval period
 no vrrp group mac-address
 default vrrp group mac-address
\end{verbatim}

\textbf{Parameters}

- \texttt{group} Virtual Router Identifier (VRID). Values range from \texttt{1 to 255}.
- \texttt{period} interval in which the master router sends advertisement packets (seconds). Value ranges from \texttt{0 to 3600}. Selecting \texttt{0} as the interval disables this feature.

\textbf{Examples}

- This command specifies the interval between advertisement packets sent to the members of VRRP group \texttt{3} on \texttt{VLAN 20}.

\begin{verbatim}
 switch(config)#interface vlan 20
 switch(config-if-vl20)#vrrp 3 mac-address advertisement-interval 60
 switch(config-if-vl20)#
\end{verbatim}

- This command disables the feature on \texttt{vlan 20}.

\begin{verbatim}
 switch(config)#interface vlan 20
 switch(config-if-vl20)#no vrrp 3 mac-address advertisement-interval
 switch(config-if-vl20)#
\end{verbatim}
13.5.4.18  vrrp peer authentication

The vrrp peer authentication command configures parameters the switch uses to authenticate virtual router packets it receives from other VRRP routers in the group.

The no vrrp peer authentication and default vrrp peer authentication commands disable VRRP peer authentication of packets from the specified virtual router by removing the corresponding vrrp peer authentication command from running-config. The no vrrp command also removes the vrrp peer authentication command for the specified virtual router.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax
vrrp group peer authentication AUTH_PARAMETER
no vrrp group peer authentication
default vrrp group peer authentication

Parameters
• group Virtual Router Identifier (VRID). Values range from 1 to 255.
• AUTH_PARAMETER encryption level and authentication key used by router. Options include:
  • text text_key plain-text authentication, text_key is text.
  • text_key plain-text authentication, text_key is text.
  • ietf-md5 key-string 0 text_key IP authentication of MD5 key hash, text_key is text.
  • ietf-md5 key-string text_key IP authentication of MD5 key hash, text_key is text.
  • ietf-md5 key-string 7 coded_key IP authentication of MD5 key hash, coded_key is MD5 hash.

Guidelines
This command is applicable to VRRPv2 which supports IPv4 addresses only.

Examples
• This command implements plain-text authentication, using 12345 as the key, for virtual router 40 on VLAN 100.

```
switch(config)#interface vlan 100
switch(config-if-vl100)#vrrp 40 peer authentication text 12345
switch(config-if-vl100)#
```

• This command implements ietf-md5 authentication, using 12345 as the key.

```
switch(config-if-vl100)#vrrp 40 peer authentication ietf-md5 key-string 0 12345
switch(config-if-vl100)#
```

• This command implements ietf-md5 authentication, using 12345 as the key. The key is entered as the MD5 hash equivalent of the text string.

```
switch(config-if-vl100)#vrrp 40 peer authentication ietf-md5 key-string 7 EA3TUPxdddFCLYT8mb+kxw==
switch(config-if-vl100)#
```
13.5.4.19  vrrp preempt delay

The vrrp preempt delay command specifies the interval between a VRRP preemption event and the point when the switch becomes the master VRRP router. A preemption event is any event that results in the switch having the highest virtual router priority setting while preemption is enabled. The vrrp preempt command enables preemption for a specified virtual router.

The command configures two delay periods:

• minimum time delays master VRRP takeover when VRRP is fully implemented.
• reload time delays master VRRP takeover after VRRP is initialized following a switch reload (boot).
  The switch bypasses the reload time to become the VRRP master immediately if it senses there are no other active switches in the virtual router group.

Running-config maintains separate delay statements for minimum and reload parameters. Commands may list both parameters. Commands that list one parameter do not affect the omitted parameter. Values range from 0 to 3600 seconds (one hour). The default delay is zero seconds for both parameters.

The no vrrp preempt delay and default vrrp preempt delay commands reset the specified delay to the default of zero seconds. Commands that do not list either parameter resets both periods to zero. The no vrrp command also removes all vrrp preempt delay commands for the specified virtual router.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

vrrp group preempt delay [MINIMUM_INTERVAL] [RELOAD_INTERVAL]
no vrrp group preempt delay [DELAY_TYPE]
default vrrp group preempt delay [DELAY_TYPE]

Parameters

• group Virtual Router Identifier (VRID). Values range from 1 to 255.
• MINIMUM_INTERVAL period between preemption event and takeover of master VRRP router role.
  • no parameter minimum delay is not altered by command.
  • minimum min_time delay during normal operation (seconds). Values range from 0 to 3600.
• RELOAD_INTERVAL period after reboot-VRRP initialization and takeover of master VRRP router role.
  • no parameter reload delay is not altered by command.
  • reload reload_time delay after reboot (seconds). Values range from 0 to 3600.
• DELAY_TYPE delay type that is reset to default value.
  • no parameter reload and minimum delays are reset to default.
  • minimum minimum delay is reset to default.
  • reload reload delay is reset to default.

(Delay_TYPE parameter is only used in no vrrp preempt delay and default vrrp preempt delay commands).

Related Command
vrrp preempt

Examples
• This command sets the minimum preempt time of 90 seconds for virtual router 20 on VLAN 40.

```bash
switch(config)#interface vlan 40
switch(config-if-vl40)#vrrp 20 preempt delay minimum 90
switch(config-if-vl40)#
```

• This command sets the minimum and reload preempt time to 0 for virtual router 20 on VLAN 40.

```bash
switch(config-if-vl40)#no vrrp 20 preempt delay
switch(config-if-vl40)#
```
13.5.4.20  **vrrp preempt**

The **vrrp preempt** command controls a virtual routers preempt mode setting. When preempt mode is enabled, if the switch has a higher priority it will preempt the current master virtual router. When preempt mode is disabled, the switch can become the master virtual router only when a master virtual router is not present on the subnet, regardless of VRRP priority level settings. By default, preempt mode is enabled.

The **no vrrp preempt** cmd and **default vrrp preempt** commands disable preempt mode for the specified virtual router; the **default vrrp preempt** command stores a corresponding **no vrrp preempt** statement in **running-config**. The **vrrp preempt** command enables preempt mode by removing the corresponding **no vrrp preempt** statement from **running-config**.

The **no vrrp** command also enables preempt mode by removing the **no vrrp preempt** command for the specified virtual router.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

- **vrrp group preempt**
- **no vrrp group preempt**
- **default vrrp group preempt**

**Parameter**

- **group** Virtual Router Identifier (VRID). Values range from **1 to 255**.

**Related Command**

- **vrrp preempt delay**

**Examples**

- This command disables preempt mode for virtual router **20** on **VLAN 40**.

  ```
  switch(config)#interface vlan 40
  switch(config-if-vl40)#no vrrp 20 preempt
  switch(config-if-vl40)#
  ```

- This command enables preempt mode for virtual router **20** on **VLAN 40**.

  ```
  switch(config-if-vl40)#vrrp 20 preempt
  switch(config-if-vl40)#
  ```
13.5.4.21  vrrp priority-level

The **vrrp priority-level** command configures the switch's priority setting for a VRRP virtual router. Priority values range from 1 to 254. The default value is **100**.

The router with the highest VRRP priority level setting for a group becomes the master virtual router for that group. The master virtual router controls the IP address and is responsible for forwarding traffic sent. The **vrrp preempt** command controls the time when a switch can become the master virtual router.

The **no vrrp priority-level** and **default vrrp priority-level** commands restore the default priority of 100 to the virtual router on the configuration mode interface by removing the corresponding **vrrp priority-level** command from **running-config**. The **no vrrp** command also removes the **vrrp priority-level** command for the specified virtual router.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

```
vrrp group priority-level level
no vrrp group priority-level level
default vrrp group priority-level level
```

**Parameters**

- **group** Virtual Router Identifier (VRID). Values range from 1 to 255.
- **level** priority setting for the specified virtual router. Values range from 1 to 254.

**Example**

This command sets the virtual router priority value of **250** for virtual router **group 45** on **vlan 20**.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 45 priority-level 250
switch(config-if-vl20)#
```
13.5.4.22  **vrrp session description**

The **vrrp session description** command associates a text string to a VRRP virtual router on the configuration mode interface. The string has no functional impact on the virtual router. The maximum length of the string is **80** characters.

The **no vrrp session description** and **default vrrp session description** commands remove the text string association from the VRRP virtual router by deleting the corresponding **vrrp session description** command from **running-config**. The **no vrrp** command also removes the **vrrp session description** command for the specified virtual router.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

```
vrrp group session description label_text

no vrrp group session description

default vrrp group session description
```

**Parameters**

- **group** Virtual Router Identifier (VRID). Values range from **1 to 255**.
- **label_text** text that describes the virtual router. Maximum string length is **80** characters.

**Example**

This command associates the text string **Laboratory Router** to virtual router **15 on vlan 20**.

```
switch(config)#interface vlan 20
switch(config-if-vl20)#vrrp 15 session description Laboratory Router
switch(config-if-vl20)#
```
13.5.4.23 vrrp timers delay reload

The `vrrp timers delay reload` command delays the time for VRRP initialization after a system reboot.

The `no vrrp timers delay reload` and `default vrrp timers delay reload` commands restore the default value of 0 by deleting the `vrrp timers delay reload` statement from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
vrrp group timers delay reload [INTERVAL]
no vrrp group timers delay reload
default vrrp group timers delay reload
```

**Parameters**

**INTERVAL** The number of seconds for the delay (seconds). Options include:

- **no parameter** Default value of 0 seconds.
- **0 to 3600** seconds. Ranges between 0 to 60 minutes.

**Examples**

- These commands configure the VRRP reload delay interval to 15 minutes.
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#vrrp 2 timers delay reload 900
  switch(config-if-Vl100)#
  ```

- These commands removes the VRRP reload delay interval.
  ```
  switch(config)#interface vlan 100
  switch(config-if-Vl100)#no vrrp 2 timers delay reload
  switch(config-if-Vl100)#
  ```
13.5.4.24 **vrrp tracked-object**

The `vrrp tracked-object` command configures the VRRP client process on the configuration mode interface to track the specified tracked object and react when its status changes to **down**. The tracked object is created by the `track` command.

The `no vrrp tracked-object` and `default vrrp tracked-object` commands cause the VRRP client process to stop tracking the specified tracked object by removing the corresponding `vrrp tracked-object` command from running-config.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

```
vrrp group tracked-object object_name ACTION amount
no vrrp group tracked-object object_name ACTION
default vrrp group tracked-object object_name ACTION
```

**Parameters**

- **group** virtual router identifier (VRID). Values range from 1 to 255.
- **object_name** name of tracked object.
- **amount** amount to decrement VRRP priority level. Values range from 1 to 254.
- **ACTION** The action that VRRP is to take when the tracked objects status changes to **down**.
  
  Options include:

  - **decrement** decrease VRRP priority level by **amount**.
  - **shutdown** shut down VRRP on the configuration mode interface.

  If both **decrement** and **shutdown** are configured on the same interface for the same VRRP group, then VRRP will be shut down on the interface if the tracked object is down.

**Related Commands**

`track`

**Example**

This command causes `interface ethernet 5` to disable VRRP when tracked object **ETH8** changes state.

```
switch(config-if-Et5)#vrrp 1 tracked-object ETH8 shutdown
switch(config-if-Et5)#
```
13.6 **OpenFlow**

This section describes Arista's OpenFlow implementation. Topics in this section include:

- OpenFlow Introduction
- OpenFlow Description
- OpenFlow Configuration
- OpenFlow Commands

13.6.1 **OpenFlow Introduction**

Arista EOS supports OpenFlow 1.0 controlled by OpenFlow controllers for filtering and redirecting traffic.

13.6.2 **OpenFlow Description**

OpenFlow is a programmable network protocol that manages and directs traffic among Ethernet switches, routers, and wireless access points over the network in support of Software-Defined Networking (SDN) applications.

OpenFlow can be used for traffic flow management in metro, WAN, and data center networks, and also security management in enterprise and campus data center applications, and other applications with the appropriate use of OpenFlow controllers.

13.6.2.1 **OpenFlow Controller**

The Arista device supports an active controller connection for which the Arista device will initiate (seek) the TCP connection to a given OpenFlow Controller address.

![Figure 35: Reactive and proactive modes](image)

The controller can be any standard OpenFlow controller.

Switch consists of three parts:

- A flow table, to tell the switch how to process the flow.
- A channel that connects the switch to a remote controller, allowing commands and packets to be sent between a controller and the switch.
- The OpenFlow Protocol, which provides a way for a controller to communicate with a switch.

An OpenFlow-enabled device supports an OpenFlow Client (control plane software), which communicates with an OpenFlow Controller using the OpenFlow protocol. The OpenFlow Controller runs on a server or a server cluster. OpenFlow-enabled devices support the abstraction of a flow table, which is manipulated by the OpenFlow Controller. A flow is a collection of packets where some selected header fields match particular values for those fields. The flow table is sorted by flow priority, which is defined by the controller.
Flow Table
Forwarding decisions for incoming packets are decided by a simple lookup on its flow-table entries. Packets that don't match any flow entry are dropped by default. Every flow entry in the flow-table contains:

- Header fields to match against packets: Each entry contains a specific value, or ANY, which matches any value.

<table>
<thead>
<tr>
<th>Ingress Port</th>
<th>Ether Source</th>
<th>Ether Dst</th>
<th>Ether Type</th>
<th>VLAN Id</th>
<th>IP Proto</th>
<th>Src Port</th>
<th>Dst Port</th>
</tr>
</thead>
</table>

- Counters to update for matching packet: These counters are used for statistics purposes, in order to keep track of the number of packets and bytes for each flow and the time that has elapsed since the flow initiation.

- Actions to apply to matching packets: The action specifies the way in which the packets of a flow will be processed. An action can be one of the following:
  1. forward the packet to a given port or ports, after optionally rewriting some header fields,
  2. ,
  3. forward the packet to the controller.

Channel
The channel is the interface that connects each OpenFlow switch to a controller. Through this interface the controller exchanges messages with the switches in order to configure and manage them.

13.6.2.2 OpenFlow Modes

Bind Modes
The switch can be configured to divide traffic entering the switch in either of two ways:

- By interface, so that only packets arriving on certain interfaces are processed by OpenFlow (interface bind mode, the default).
- By VLAN, so that only packets associated with certain VLAN IDs are processed by OpenFlow (VLAN bind mode).

Other packets are forwarded normally according to the MAC address table, filtered by ACLs, mirrored to other ports.

Note: The hybrid mode of operation is experimental.

The switch can also be configured to apply a limited set of OpenFlow actions to any packets, regardless of ingress interface or VLAN, as well as forward the packets normally (monitor bind mode).

Interface Bind Mode
When the switch is configured in interface bind mode, the ingress interface of a packet is processed according to entries in the OpenFlow table.

Only interfaces bound to OpenFlow are mapped to OpenFlow ports and exposed to the controller via features reply and port status messages. Output actions in flow table entries and in packet out messages can refer only to mapped ports. Use the show openflow ports command to see which interfaces the switch maps to OpenFlow ports and exposes to the controller.

- In OpenFlow configuration mode, use the bind mode (OpenFlow) command to select interface bind mode.
- In the OpenFlow configuration mode, use the bind interface command to bind one or more interfaces to OpenFlow.
When an interface is bound to OpenFlow, certain switch functions are disabled on the interface, including spanning tree protocol (STP). The OpenFlow controller and application must ensure that flow table entries do not allow traffic to loop in the network.

Only Ethernet and Port-Channel interfaces can be bound to OpenFlow. If an Ethernet interface is configured as a member of a LAG, attempting to bind the interface to OpenFlow has no effect. However, the Port-Channel interface of which it is a member may itself be bound to OpenFlow.

**VLAN Bind Mode**

When a packet arrives at a switch interface, the switch assigns it a VLAN for internal processing, based on the switchport configuration of the ingress interface and on the packet's VLAN tag (if any). If the switch is configured in VLAN bind mode, the internal VLAN determines whether the packet is processed according to entries in the OpenFlow table and whether the packet is matched by a given entry in the OpenFlow table. After the switch has processed the packet, the switchport configuration of each potential egress interface controls whether the packet is transmitted tagged with the internal VLAN ID, transmitted untagged, or filtered.

Several configuration commands affect whether packets received on a given interface are processed by OpenFlow, and whether packets directed to an interface via an OpenFlow output action are transmitted or filtered:

- Use the VLAN configuration mode command to create the VLANs to be accepted by the switch and processed by OpenFlow.

In the interface configuration mode, use switchport commands to configure the interface as either an access port or a trunk port. For an access port, set the VLAN to an OpenFlow VLAN; for a trunk port, configure which OpenFlow VLANs are allowed.

In OpenFlow configuration mode, use the `bind mode (OpenFlow)` command to select VLAN bind mode, and use the `bind vlan (OpenFlow)` command to bind one or more VLANs to OpenFlow.

**Untagged Packet Processing in VLAN Bind Mode**

The OpenFlow protocol also allows a flow table entry to explicitly match untagged packets, or to strip the VLAN tag from matched packets. Since the switch actually assigns a VLAN internally to packets received without a tag, the OpenFlow function on the switch must be configured with a single "native" VLAN ID in order to make sense of such flow entries. When an OpenFlow native VLAN is configured:

- A flow table entry defined to match untagged packets actually matches packets whose internal VLAN is the OpenFlow native VLAN.
- A flow table entry with a strip VLAN tag action actually sets the packet's internal VLAN to the OpenFlow native VLAN.
- Packets sent to the controller via a packet-in message are sent untagged if they are assigned to the native VLAN, and tagged otherwise.
- Untagged packets received from the controller via a packet-out message are assigned to the native VLAN.

In contrast, when no OpenFlow native VLAN is configured:

- Flow table entries defined to match untagged packets or with a strip VLAN tag action are rejected.
- All packets sent to the controller via a packet-in message are sent tagged.
- Untagged packets received from the controller via a packet-out message are dropped.

There is no explicit command to configure the OpenFlow native VLAN. To configure a VLAN as the OpenFlow native VLAN:

- Use the VLAN configuration mode command.
- Every interface handling the OpenFlow traffic, in interface configuration mode, uses switchport commands to configure the interface as either an access port or a trunk port. For an access port,
set the access VLAN to N; for a trunk port, either set the native VLAN to N or configure the interface
to drop untagged frames.

- In OpenFlow configuration mode, use the `bind vlan (OpenFlow)` command to assign VLAN N to
  OpenFlow.

Configuring two interfaces as access ports with different OpenFlow-bound VLANs, or as trunk ports
with different native OpenFlow-bound VLANs, violates these constraints and causes the OpenFlow
function to behave as no OpenFlow native VLAN is configured.

Use the `show openflow` command to see whether an OpenFlow native VLAN has been configured.

**Spanning Tree Protocol in VLAN Bind Mode**

STP can operate on OpenFlow-bound VLANs. The switch default STP configuration is one multiple
spanning tree (MST) instance containing all VLANs, including OpenFlow-bound VLANs. When STP is
configured on OpenFlow-bound VLANs, packets received from or sent to blocked ports are dropped,
regardless of the rules defined in the OpenFlow flow table.

For some applications, you may want to disable STP on OpenFlow-bound VLANs. Before doing so, be
sure that the OpenFlow controller and application is configured properly to manage multiple redundant
paths through the network without allowing traffic to loop.

To ensure proper operation of STP on the switch and to support OpenFlow applications that inter-
operate with STP, OpenFlow forwards inbound STP packets both to the spanning tree agent on the
switch and to the OpenFlow controller as packet-in messages. This behavior overrides any flow table
entries that might otherwise match STP packets, and is not configurable.

**Monitor Bind Mode**

Unlike interface and VLAN bind modes, monitor bind mode is tailored for specific applications. The
switch both forwards traffic normally and selectively mirrors packets under OpenFlow control.

When the switch is configured in monitor bind mode, all traffic entering the switch is forwarded
normally, regardless of ingress interface or internal VLAN. All Ethernet and Port-Channel interfaces are
mapped to OpenFlow ports and exposed to the controller (except LAG members and mirror destination
ports). In this mode, the entire switch is bound to OpenFlow, and OpenFlow processing is applied to
packets in addition to the normal forwarding behavior.

Currently the only actions that can be performed on packets in monitor bind mode are:

- Output normally.
- Copy to mirror destination port.

In monitor bind mode, the default action taken on packets that are not matched by any flow table entry
is output normally. The switch rejects flow entries not conforming to these restrictions.

**Routing Between the OpenFlow and Non-OpenFlow Domain**

The switch can be configured to perform standard IP routing of traffic processed by OpenFlow. From
the controller’s point of view, the switch appears to have a virtual port `40000` (OpenFlowRouter) in
addition to the physical ports.

Packets sent out the OpenFlowRouter port can undergo standard IP routing into a different IP subnet.
After routing, those packets can either exit the switch or be processed by OpenFlow again.

### 13.6.2.2.1 Port Mapping

For switches that support QSFP+ modules, a 40G interface can be configured as four 10G ports.
These Ethernet interfaces are mapped to OpenFlow ports according to the formula `port = M * 200 + N`
for EthernetM/N. For example, interface `Ethernet1/1` is mapped to OpenFlow port `201`; `Ethernet1/2` to
OpenFlow port 202, Ethernet16/1 to OpenFlow port 3201, Ethernet16/2 to OpenFlow port 3202, and so on.

When IP routing is configured, the OpenFlow Router interface is mapped to OpenFlow port 40000.

Port-Channel (LAG) interfaces are mapped to OpenFlow ports according to the formula port = 40000 + N for Port-ChannelN. For example, interface Port-Channel23 is mapped to OpenFlow port 40023.

The OpenFlow virtual ports all and flood refer to all Ethernet interfaces on the switch, but normal VLAN egress policies apply: a packet tagged with a given OpenFlow-bound VLAN (or untagged, if a native OpenFlow VLAN is configured) will egress a given interface only if the interface is configured to handle traffic for that VLAN. If an interface is not configured to handle traffic for any OpenFlow-bound VLAN, then no packets sent to all or flood will egress on that interface.

### 13.6.2.2.2 Queue Mapping

All multicast transmit queues that are configured to be mapped from a QoS traffic class are mapped to OpenFlow. OpenFlow-mapped queues can be used by the enqueue action in flow table entries and are included in queue stats reply messages. By default, all the multicast queues 0 to 3 are mapped.

Use the `show qos maps` command to view the current mapping of traffic class to multicast transmit queue, and use the `qos map traffic-class to mc-tx-queue` configuration command to modify it. If no traffic class is mapped to a given multicast transmit queue, the queue will not be mapped to OpenFlow and will be unavailable for use by the enqueue action.

### 13.6.2.2.3 Table Size

The switch supports one flow table. OpenFlow packet processing is performed in hardware; software forwarding (via the switch CPU) is not supported.

The switch advertises the table size for the l2-match profile. This should be taken as an approximation, as other switch features such as ACLs can consume hardware resources shared with OpenFlow. If the controller attempts to add a flow entry but there are insufficient resources to implement it in hardware, the switch returns an error message.

### 13.6.2.2.4 Match Fields

A flow table entry can specify an exact value or wildcard for any of the following fields:

- L2 source and destination addresses
- VLAN ID (and untagged packets, if the native OpenFlow VLAN is configured)
- VLAN priority
- L2 frame type
- IPv4 source and destination addresses with subnet masking
- IPv4 TOS/DSCP field
- IPv4 protocol
- TCP/UDP source and destination port numbers

Matching the IPv4 source or destination address within an ARP message is not supported, nor is matching the ARP opcode.

### 13.6.2.2.5 Actions

In VLAN and interface bind modes, the following flow entry actions are supported:

- Copy packet on ingress to a mirror destination port (vendor-specific extension)
- Set L2 source and destination addresses
- Strip VLAN tag (if the native OpenFlow VLAN is configured)
- Set VLAN ID
• Set VLAN priority
• Set IPv4 TOS/DSCP
• Output or enqueue to physical port (see OpenFlow Limitations for restrictions on multiple output actions)
• Output or enqueue to all or flood (see OpenFlow Limitations)
• Output to controller (buffering not supported; entire packet contents are always sent)
• Drop (no action)
• Copy packet on egress to a mirror destination port (vendor-specific extension)

In monitor bind mode, only the following actions are supported:

• Copy packet on ingress to a mirror destination port (vendor-specific extension)
• Output per normal forwarding (this action is required in every flow entry)
• Copy packet on egress to a mirror destination port (vendor-specific extension)

13.6.2.3 OpenFlow Limitations

Consider the following when using OpenFlow:

• OpenFlow is supported on both the 7050 and 7050X series of switches.
• OpenFlow Hybrid mode is not supported.
• Output to an ingress port is silently dropped. Flow table entries with an output to ingress port action are accepted by the switch, but matching packets are not actually forwarded via the ingress port. (But for packet-out, the output to ingress port action is supported.)
• Output/enqueue actions must follow modify actions. The switch will return an error if a modify action follows an output/enqueue action.
• Each action can be performed at most once. The switch will return an error if the same action appears more than once. Output and enqueue actions may appear at most once per port.
• Support output to only one queue. The switch will return an error if multiple enqueue actions appear with different queue ids, or if both enqueue and output actions appear.
• Packet is sent at most once per port even if there are overlapping output or enqueue actions. For example, the switch will accept a rule with actions output to all ports and output to a specific port 12, but will transmit the packet on port 12 only once even though it is contained in both actions.
• Flow entry priority is always respected, even for exact-match flow entries. The switch does not force exact-match flow entries to be processed at the highest priority.
• For packet-out messages, only output actions are supported (to a physical port, or to all, flood, or ingress port). The switch will return an error if a packet-out message is received with any other action.
• The switch-to-controller connection is plain TCP. The switch does not support encrypted TLS connections to the controller.
• Matching source and destination IP and operation code in ARP packets is not supported. Flow entries with matching the ARP Ethernet type are accepted by the switch, but the source and destination IP and protocol (opcode) match field values are ignored (i.e. the fields are wildcarded).
• A flow mod message with modify or modify_strict command does not modify the cookie value of existing flow entries. If the modify is treated as an add, however, the new entry will be assigned the specified cookie value.
• Matching all 802.3 packets without SNAP headers is not supported. The switch does not treat a dl_type value of 0x5ff as special.
• The port_mod message is not supported. It is not possible to modify the behavior of physical ports via the port_mod message. In particular, the no_flood port_config bit cannot be used to exclude ports from the flood virtual output port set.
• Changing the list of controllers causes the current controller connection to be dropped. When the OpenFlow feature is enabled and the list of controllers is changed in any fashion (e.g. by adding or deleting a controller), the current controller connection will be dropped.
• When adding a large number of flow table entries, add higher-priority entries before lower-priority entries. Due to hardware limitations, the switch will take much longer to add a new flow entry if the table already contains many entries with lower priority.

13.6.3  OpenFlow Configuration

By default, the OpenFlow feature is disabled on Arista devices. You must first enable the OpenFlow feature on the device. These sections describe OpenFlow configuration tasks:

• Configuration Procedures
• Enabling Basic OpenFlow
• Optional OpenFlow Commands
• Displaying OpenFlow Configurations

13.6.3.1  Configuration Procedures

Use the OpenFlow configuration mode commands to configure the following basic parameters:

• openflow: places the switch in OpenFlow configuration mode.
• controller (OpenFlow): set the controller IP address and port.
• bind interface (OpenFlow): bind interfaces to OpenFlow.
• shutdown (OpenFlow): enable or disable OpenFlow.

13.6.3.2  Enabling Basic OpenFlow

Configure the management interface. Assign an IP address to the interface and set the default gateway IP address, allowing the OpenFlow function on the switch establish a TCP connection with the OpenFlow controller.

The following commands turn on OpenFlow pointing to a controller, ready to receive flow setup messages to be programmed in hardware for all traffic.

• The openflow command places the switch in OpenFlow configuration mode.

```
switch(config)#openflow
switch(config-OpenFlow)#
```

• The controller (OpenFlow) command points to the primary OpenFlow controller. Others can be configured as a standby list.

```
switch(config)#controller tcp:15.16.15.16:6633
switch(config-OpenFlow)#
```

• The bind vlan (OpenFlow) command dictates what VLAN or interfaces are tied to OpenFlow. Since hybrid mode is not supported, Arista recommends binding all VLANs or all interfaces to OpenFlow.

```
switch(config)#bind vlan 1
switch(config-OpenFlow)#
```

• The shutdown (OpenFlow) command determines if the configuration takes effect or not. The following command enables OpenFlow on the switch.

```
switch(config-OpenFlow)#no shutdown
switch(config-OpenFlow)#
```
### 13.6.3.3 Optional OpenFlow Commands

#### Keepalive

The **keepalive (OpenFlow)** command allows you to set the interval for switch to controller keepalives (default of 10 seconds scales best for large scale multi-node OpenFlow switch networks). After three consecutive reply (from the controller) misses, the switch will try to connect to the second configured controller, if configured.

```bash
switch(config-OpenFlow)# keepalive
```

#### Profile

The **profile (OpenFlow)** command determines the type of flows. To double flow table size (in case all flows are L2 only), setting a profile of l2-match is best suited. Default is full-match (includes L3/4 field match).

```bash
switch(config-OpenFlow)# profile l2-match
```

#### Default-action

The **default-action (OpenFlow)** command tells the Arista OpenFlow agent the action that needs to be taken for packets (drop or send-to-controller) that don't match any existing flows programmed locally on the hardware.

```bash
switch(config-OpenFlow)# default-action drop
```

### 13.6.3.4 Displaying OpenFlow Configurations

Show commands display the state of OpenFlow running on the Arista switch.

- The **show openflow** command displays the configuration state of the OpenFlow feature and the flows that are actively installed in the hardware of the Arista switch.

```bash
switch(config)# show openflow
OpenFlow configuration: Enabled
DPID: 0x0000001c73111a92
Description: sw3-Arista
Controllers:
  configured: tcp:172.22.28.228:6633
  connected: tcp:172.22.28.228:6633
  connection count: 3
  keepalive period: 10 sec
Flow table state: Enabled
Flow table profile: full-match
Bind mode: VLAN
  VLANs: 1-2
  native VLAN: 1
IP routing state: Disabled
Shell command execution: Disabled
Total matched: 7977645 packets
```

- The **show openflow flows** command show the default flow that is installed when OpenFlow is enabled.

```bash
switch(config)# show OpenFlow flows
```
Flow flow00000000000000000005:
  priority: 100
  cookie: 45035996453121666 (0xa000000ab1ae82)
  match:
    ingress interface: Ethernet3
    Ethernet type: IPv4
    source IPv4 address: 10.0.0.0/255.255.255.0
  actions:
    output interfaces: Ethernet11
  matched: 0 packets, 0 bytes
Flow __default__:
  priority: -1
  cookie: 0 (0x0)
  match:
  actions:
    output to controller
  matched: 5519922 packets, 433188045 bytes
13.6.4 OpenFlow Commands

OpenFlow Global Configuration Mode

• openflow

Openflow Configuration Commands

• bind interface (OpenFlow)
• bind mode (OpenFlow)
• bind vlan (OpenFlow)
• controller (OpenFlow)
• default-action (OpenFlow)
• description (OpenFlow)
• keepalive (OpenFlow)
• profile (OpenFlow)
• routing recirculation-interface (OpenFlow)
• routing vlan (OpenFlow)
• shell-command allowed (OpenFlow)
• shutdown (Openflow)

OpenFlow Display and Clear Commands

• clear openflow statistics
• show openflow
• show openflow flows
• show openflow ports
• show openflow profiles
• show openflow queues
• show openflow statistics
13.6.4.1 bind interface (OpenFlow)

When the switch is configured in interface bind mode, the ingress interface of a packet determines whether the packet is processed according to entries in the OpenFlow table or forwarded normally by the switch.

Only interfaces bound to OpenFlow are mapped to OpenFlow ports and exposed to the controller via features reply and port status messages. Output actions in flow table entries and in packet out messages can refer only to mapped ports. Use the `show openflow ports` command to see which interfaces the switch maps to OpenFlow ports and exposes to the controller.

In the OpenFlow configuration mode, use the `bind mode interface` command to select the interface bind mode.

When an interface is bound to OpenFlow, certain switch functions are disabled on the interface, including Spanning Tree Protocol (STP). The OpenFlow controller and application must ensure that flow table entries do not allow traffic to loop in the network.

Only Ethernet and Port-Channel interfaces can be bound to OpenFlow. If an Ethernet interface is configured as a member of a LAG, attempting to bind the interface to OpenFlow has no effect. However, the Port-Channel interface of which it is a member may itself be bound to OpenFlow.

The `no bind interface` and `default bind interface` commands revert the specified list configuration to its default by removing the corresponding `bind interface` command from `running-config`.

**Command Mode**
OpenFlow Configuration

**Command Syntax**

bind interface INTF

no bind interface [INTF ]

default bind interface [INTF ]

**Parameters**

INTF Interface that are tied to OpenFlow. Options include:

- **ethernet e_range** Ethernet interfaces specified by `e_range`.
- **port-channel p_range** port channel interfaces specified by `p_range`.

Valid `e_range` and `p_range` formats include number, range, or comma-delimited list of numbers and ranges.

**Example**

This command binds `ethernet 1` to OpenFlow.

```
switch(config)# openflow
switch(config-openflow)#bind interface ethernet 1
```
13.6.4.2  bind mode (OpenFlow)

The bind mode command controls the way packets are divided on ingress between OpenFlow processing and normal switch processing.

The switch can be configured to divide traffic entering the switch in the following ways:

- **Interface bind mode**: Packets entering the switch from certain interfaces are only processed by OpenFlow according to flow table entries; packets entering from other interfaces are forwarded normally. (interface bind mode is the default).
- **VLAN bind mode**: Only packets associated with certain VLAN IDs are processed by OpenFlow.
- **Monitor bind mode**: All packets are forwarded normally, and are also processed by OpenFlow; a restricted set of actions are applied to packets matching a flow table entry.

Other packets are forwarded normally according to the MAC address table, filtered by ACLs, mirrored to other ports.

The switch can also be configured to apply a limited set of OpenFlow actions to any packets, regardless of ingress interface or VLAN, as well as forward the packets normally (monitor bind mode).

The no bind mode and default bind mode commands revert the specified list configuration to its default by removing the corresponding bind mode command from running-config.

**Command Mode**

Open flow Configuration

**Command Syntax**

bind mode METHOD

no bind mode

default bind mode

**Parameters**

METHOD bind interfaces to OpenFlow. Options include:

- **interface** Only packets arriving on certain interfaces are processed by OpenFlow.
- **monitor** All packets are forwarded normally, and are also processed by OpenFlow.
- **vlan** Only packets associated with certain VLAN IDs are processed by OpenFlow.

**Example**

In this example, packets received without VLAN tags are assigned to the default vlan 1 upon entering the switch and are processed by OpenFlow. All VLAN-tagged packets are dropped.

```
switch#enable
switch#configure
switch(config)#interface et1-48
switch(config-if-Et1-48)#switchport mode access
switch(config-if-Et1-48)#switchport access vlan 1
switch(config-if-Et1-48)#exit
switch(config)#openflow
switch(config-openflow)#controller tcp:1.2.3.4:6633
switch(config-openflow)#bind mode vlan
switch(config-openflow)#bind vlan 1
```
13.6.4.3  bind vlan (OpenFlow)

The `bind vlan` command adds one or more VLAN IDs to the set of VLANs that are processed by OpenFlow in VLAN bind mode. The VLANs must be created separately using the VLAN configuration mode commands.

If you specify a nonexistent VLAN with the `bind vlan` command, the binding will be stored in the running configuration but will not take effect until the VLAN is created.

A range of VLANs may be passed to the `bind vlan` command to add more than one at a time.

The number of VLANs that may be bound to OpenFlow depends on available hardware resources, which are shared with other features including IP routing and ACLs. On the 7050 Series switches the maximum number is 1024.

Use the `show openflow` command to verify which VLANs are bound to OpenFlow; this command reflects the actual hardware state rather than the configuration.

The `no bind vlan` and `default bind vlan` commands removes one or more VLANs from the set of VLANs that are processed by OpenFlow in VLAN bind mode.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

```
bind vlan [v_range]
no bind vlan [v_range]
default bind vlan [v_range]
```

**Parameter**

`v_range` VLAN list. VLAN numbers range from 1 to 4094.

**Example**

These command bind VLANs 1 and 2 to OpenFlow.

```
switch(config-openflow)#bind mode vlan
switch(config-openflow)#bind vlan 1,2
```
13.6.4.4  clear openflow statistics

The clear openflow statistics command resets the flow statistics for OpenFlow.

Command Mode
Privileged EXEC

Command Syntax
clear openflow statistics

Example
This command resets the OpenFlow counters.

```
switch #clear openflow statistics
switch#
```
13.6.4.5 controller (OpenFlow)

The `controller` command adds the address of an OpenFlow controller to which the switch should connect. The parameter must take the form `tcp:1.2.3.4:6633` where `1.2.3.4` is the IP address of the controller and `6633` is the TCP port number.

The `controller` command may be used multiple times to add multiple controllers. The switch will attempt to connect to the first controller in the list of controllers. If the connection attempt fails, or the current connection terminates, the switch will try the next controller in that list, and so on. If the switch cannot connect to the last controller in the list, it will retry with the first controller in the list.

The order in which controllers are added is the order that the switch uses to establish controller connections. This ordering can be seen in the output of the `show openflow` command.

The `no controller` command either removes the specified controller from the list of controllers if a controller address is given as a parameter, or removes all controllers from the list of controllers if `no` parameter is given. If there are no controllers remaining after this command is executed, the OpenFlow function is effectively disabled.

**Note:** Adding or removing a controller will cause the current controller connection to be dropped. The switch will then attempt to connect to the first controller in the list of controllers, then second controller, and so on.

The `no controller` and `default controller` commands delete the `controller` statement from `running-config`.

**Command Mode**
OpenFlow Configuration

**Command Syntax**
- `controller tcp:ip_address:tcp_port`
- `no controller tcp:ipaddress:tcp_port`
- `default controller tcp:ipaddress:tcp_port`

**Parameters**
- `ip_address` ip address used for OpenFlow. Dotted decimal location.
- `tcp_port` name of the TCP port used for OpenFlow. Value ranges from 0 to 65535.

**Example**
These commands enable OpenFlow and sets the controller for an OpenFlow instance.

```
switch(config)#openflow
switch(config-OpenFlow)#controller tcp:1.2.3.4:6633
```
13.6.4.6 default-action (OpenFlow)

The `default-action` command sets the action for the default flow table entry. This entry is automatically added by the switch. It has the lowest priority, and matches packets that are not matched by any other entry.

Use `default-action drop` to change the default entry's action to drop packets instead of sending them to the controller. (Note: In this mode, the switch deviates from the OpenFlow specification.)

The `no default-action` command restores the default entry's action to send packets to the controller.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

`default-action` **ACTION_TYPE**

`no default-action`

`default default-action`

**Parameters**

**ACTION_TYPE** Action for the default flow table entry. Options include:

- `controller` Sets the default entry's action to send packets to the controller.
- `drop` Changes the default entry's action to drop packets instead of sending them to the controller.

**Example**

This command sets the default entry's action to drop packets instead of sending them to the controller.

```
switch(config)#openflow
switch(config-OpenFlow)#default-action drop
```
13.6.4.7  description (OpenFlow)

The description command allows overriding the switch description string (normally the switch hostname) sent to the controller.

The no description and default description commands remove the description text for the switch hostname from running-config.

Command Mode
OpenFlow Configuration

Command Syntax

description label_text
no description
default description

Parameter

label_text character string up to 256 characters assigned to describe the switch.

Example
These commands add the description test to the switch.

```
switch(config-openflow)#description test
switch(config-openflow)#
```
13.6.4.8 keepalive (OpenFlow)

The **keepalive** command alters how often the switch sends an OpenFlow echo request to the currently connected controller (every 10 seconds by default). If an echo reply is not received after three successive echo requests, the switch disconnects from the controller. It then attempts to establish a new controller connection depending on the controller configuration.

The **no keepalive** command restores the default keepalive period by removing the **keepalive** command from the *running-config*.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

```plaintext
keepalive keep_alive_time
no keepalive
default keepalive
```

**Parameter**

`keep_alive_time` keepalive period, in seconds. Value ranges from 1 to 100000. Default value is 10 seconds.

**Example**

This command sets the keepalive time for OpenFlow to 30 seconds.

```
switch(config)#openflow
switch(config-openflow)#keepalive 30
switch(config-openflow)#
```
13.6.4.9 openflow

The openflow command places the switch in OpenFlow configuration mode.
The no openflow and default openflow commands delete the openflow configuration mode statements from running-config.

OpenFlow configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting OpenFlow configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
Global Configuration

Command Syntax

openflow
no openflow
default openflow

Commands Available in OpenFlow Configuration Mode

• bind interface (OpenFlow)
• bind mode (OpenFlow)
• bind vlan (OpenFlow)
• controller (OpenFlow)
• default-action (OpenFlow)
• description (OpenFlow)
• keepalive (OpenFlow)
• profile (OpenFlow)
• routing recirculation-interface (OpenFlow)
• routing vlan (OpenFlow)
• shell-command allowed (OpenFlow)
• shutdown (OpenFlow)

Examples

• This command places the switch in OpenFlow configuration mode:

  switch(config)#openflow
  switch(config-openflow)#

• This command returns the switch to global management mode:

  switch(config-openflow)#exit
  switch(config)#
13.6.4.10  profile (OpenFlow)

The `profile` command sets an alternate flow table profile. Use the `show openflow profiles` command to see the flow table profiles supported by the switch.

The `no profile` and `default profile` commands restore the default flow table profile by removing the profile command from the running-config.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

```
profile FIELD_TYPE
```

```
no profile
```

```
default profile
```

**Parameters**

- **FIELD_TYPE** Profiles supported by the switch for the active bind mode. Options include:
  - `full-match` Supports matching the full set of OpenFlow match fields.
  - `l2-match` Supports matching only a subset but with a larger maximum number of flow table entries.

**Example**

This command advertises the table size for the full-match flow table profile.

```
switch#(config-openflow)#profile full-match
switch#(config-openflow)#
```
13.6.4.11 routing recirculation-interface (OpenFlow)

The `routing recirculation-interface` command designates a switch interface to recirculate routed OpenFlow traffic for a second pass of processing. Exactly one recirculation interface must be configured to use routing, regardless of the number of VLANs being routed.

Any Ethernet or Port-Channel interface can be used for OpenFlow routing recirculation.

When an interface is configured for OpenFlow routing recirculation:

- The switch programs the hardware into a special MAC loopback mode, so the interface cannot be used to carry normal traffic.
- The link LED turns green and the recirculation function works even if a transceiver is not present or a cable is not inserted.
- The link speed is forced to the maximum.
- Interface configuration commands such as switchport and shutdown are ineffective, although they are preserved in the running configuration and become effective again when the interface is no longer configured for OpenFlow routing recirculation.

The `routing recirculation-interface` and `default routing recirculation-interface` commands revert the configuration to its default by removing the corresponding `routing recirculation-interface` command from `running-config`.

**Command Mode**
OpenFlow Configuration

**Command Syntax**

```
bind interface INTF
no bind interface [INTF]
default bind interface INTF
```

**Parameters**

- **INTF** Options include:
  - `ethernet e_range` Ethernet interfaces specified by `e_range`.
  - `port-channel p_range` port channel interfaces specified by `p_range`.

Valid `e_range` and `p_range` formats include number, range, or comma-delimited list of numbers and ranges.

**Example**

This command recirculates traffic routed to and from `vlan 1` using the routed transit `vlan 401`.

```
switch(config-openflow)#bind mode vlan
switch(config-openflow)#bind vlan 1
switch(config-openflow)#routing recirculation-interface et48
switch(config-openflow)#routing vlan 1 routed-vlan 401
switch(config-openflow)#enable
```
13.6.4.12 routing vlan (OpenFlow)

The **routing vlan** command enables IP routing of traffic processed by OpenFlow for a specific VLAN.

The **no routing vlan** and **default routing vlan** command disables IP routing of traffic processed by OpenFlow for a VLAN.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

```
routing vlan VLAN_ID routed-vlan trans
```

```
no routing vlan VLAN_ID
```

```
default routing vlan VLAN_ID
```

**Parameters**

**VLAN_ID** Options include:

- **v_num** The full form of the command is `routing vlan 123 routed-vlan 456`, where 123 is the VLAN of the OpenFlow traffic to be routed, and 456 is a (non-OpenFlow-bound) VLAN configured for standard IP routing.
- **untagged** To route untagged OpenFlow traffic. use the command `routing vlan untagged routed-vlan 456`.

**Example**

This command associates the VLAN with an untagged **vlan 22** to match during the OpenFlow pass.

```
switch(config-openflow#routing vlan untagged routed-vlan 22
```
13.6.4.13  shell-command allowed (OpenFlow)

The `shell-command allowed` command allows the controller to run shell or CLI vendor extension commands on the switch.

When this extension is enabled, the switch will execute any CLI command sent by the controller, bypassing normal access controls, so enable it only if the controller is trusted.

The `no shell-command allowed` and `default shell-command allowed` commands disables the corresponding `shell-command allowed` from the `running-config`.

**Command Mode**

OpenFlow Configuration

**Command Syntax**

`shell-command allowed`

`no shell-command allowed`

`default shell-command allowed`

**Example**

This command allows the controller to run arbitrary CLI commands on the switch.

```
switch(config)#openflow
switch(config-openflow)#shell-command allowed
switch(config-openflow)#
```
13.6.4.14 show openflow flows

The `show openflow flows` command displays the contents of the flow table, showing each entry with its match rules, actions, packet counters, and timeouts.

The default flow table entry is automatically created by the switch. It always has the lowest priority, and matches packets that are not matched by any other entry. The default entry's action is to send the packet to the controller.

**Command Mode**

EXEC

**Command Syntax**

`show openflow flows`

**Example**

This command displays the contents of the flow table.

```
switch#show openflow flows
Flow flow00000000000000000002:
  priority: 0
  cookie: 0 (0x0)
  idle timeout: 60.0 sec
  match:
    ingress interface: Ethernet2
    source Ethernet address: 00:a9:87:65:43:21
    destination Ethernet address: 00:12:34:56:78:9a
    untagged/native VLAN ID
    VLAN PCP: 0
    Ethernet type: IPv4
    source IPv4 address: 10.0.1.1
    destination IPv4 address: 10.0.1.2
    IPv4 TOS: 0
    IPv4 protocol: ICMP
    source TCP/UDP port or ICMP type: 8
    destination TCP/UDP port or ICMP code: 0
  actions:
    output interfaces: OpenFlowRouter
  matched: 4 packets, 408 bytes
Flow __default__:
  priority: -1
  cookie: 0 (0x0)
  match:
  actions:
    output to controller
switch#
```
13.6.4.15  **show openflow ports**

The *show openflow ports* command displays the mapping between OpenFlow port number and switch interface.

In interface bind mode, all OpenFlow-bound interfaces (except routed ports and LAG members) are mapped to OpenFlow ports and exposed to the controller.

In VLAN bind mode, Ethernet and Port-Channel interfaces (except routed ports and LAG members) configured to carry traffic for one or more OpenFlow-bound VLANs are mapped to OpenFlow ports and exposed to the controller.

In monitor bind mode, all Ethernet and Port-Channel interfaces (except routed ports and LAG members) are mapped to OpenFlow ports and exposed to the controller.

**Command Mode**

EXEC

**Command Syntax**

`show openflow ports`

**Example**

This command displays which interfaces the switch maps to OpenFlow ports.

```
switch#show openflow ports
Port 1: Ethernet1
Port 15: Ethernet15
switch#
```
13.6.4.16  show openflow profiles

The `show openflow profiles` command displays the flow table profiles supported by the switch for the active bind mode. For each profile, it shows:

- Which fields can be matched by a flow table entry and which can be wildcarded.
- Which actions are supported for matched packets (in monitor bind mode, only normal and mirror actions are supported).
- The maximum number of entries that can be added to the flow table.

The hardware resources available to OpenFlow are shared with other switch features like ACLs, so the actual maximum number of flow entries may be lower than the number shown by `show openflow profiles` command.

On Series 7050 switches, two profiles are available: the full-match profile supports matching the full set of OpenFlow match fields with a maximum of 750 flow table entries, while the l2-match profile supports matching only a subset but with a larger maximum number of flow table entries (1500).

**Command Mode**
EXEC

**Command Syntax**
`show openflow profiles`

**Example**
This command displays the flow table profiles.

```
switch#show openflow profiles
full-match:
  Match fields:
    ingress interface
    source Ethernet address
    destination Ethernet address
    VLAN ID
    VLAN PCP
    Ethernet type
    source IPv4 address
    destination IPv4 address
    IPv4 TOS
    IPv4 protocol
    source TCP/UDP port or ICMP type
    destination TCP/UDP port or ICMP code
  Wildcard fields:
    ingress interface
    source Ethernet address
    destination Ethernet address
    VLAN ID
    VLAN PCP
    Ethernet type
    source IPv4 address
    destination IPv4 address
    IPv4 TOS
    IPv4 protocol
    source TCP/UDP port or ICMP type
    destination TCP/UDP port or ICMP code
  Actions:
    copy ingress to mirror dest interfaces
    forward normally
    copy egress to mirror dest interfaces
  Table size: 750 entries max
```

`switch#`
13.6.4.17 show openflow queues

The `show openflow queues` command displays the queues exposed to the OpenFlow controller for each switch interface, and packet and byte counters for each queue.

**Command Mode**

EXEC

**Command Syntax**

`show openflow queues`

**Example**

This command displays the packet and byte counters for each queue on the active OpenFlow interfaces.

```
switch#show openflow queues
Port 1 (Ethernet1):
  Queue 0: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 1: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 2: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 3: 0 packets (0 bytes) transmitted, 0 dropped
Port 15 (Ethernet15):
  Queue 0: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 1: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 2: 0 packets (0 bytes) transmitted, 0 dropped
  Queue 3: 0 packets (0 bytes) transmitted, 0 dropped
switch#
```
13.6.4.18  show openflow statistics

The `show openflow statistics` command displays statistics sampled every 5 seconds over the past 5 minutes:

- Number of entries in the flow table.
- Number of `flow_mod`, `packet_out` and `packet_in` messages processed in the 5-second interval.
- Number of `packet_out` messages dropped in the 5-second interval (the OpenFlow agent starts dropping `packet_out` messages when the transmit queue of the controller TCP connection exceeds 50% of capacity).

**Command Mode**

EXEC

**Command Syntax**

`show openflow statistics`

**Example**

This command displays statistics sampled every 5 seconds.

```
switch# show openflow statistics

+--------------+-----------------+-----------------+-----------------+-----------------+
| entries      | messages processed last 5 sec | dropped last 5 sec |
| 2013-08-16 14:48:06 | 4 | 0 | 0 | 0 | 0 |

```

switch#
13.6.4.19  show openflow

The `show openflow` command shows the effective OpenFlow configuration parameters.

**Command Mode**
EXEC

**Command Syntax**
`show openflow`

**Example**
This command displays the actual hardware state of OpenFlow.

```
switch#show openflow
OpenFlow configuration: Enabled
DPID: 0x000000123456789a
Description: My awesome OpenFlow switch
Controllers:
  configured: tcp:1.2.3.4:6633 tcp:5.6.7.8:6633
  connected: tcp:1.2.3.4:6633
attempted connection count: 24
successful connection count: 1
keepalive period: 10 sec
Flow table state: Enabled
Flow table profile: full-match
Bind mode: interface
  interfaces: Ethernet2, Ethernet4, Ethernet6, Ethernet8
IP routing state: Enabled
recirculation interface: Ethernet44
VLAN untagged: routed to/from VLAN 3636
Shell command execution: Disabled
Total matched: 4601 packets
switch#
```
13.6.4.20 shutdown (Openflow)

The **shutdown** command, in OpenFlow mode, disables OpenFlow on the switch. OpenFlow is disabled by default.

The **no shutdown** and **default shutdown** commands re-enable OpenFlow by removing the **shutdown** command from **running-config**.

**Command Mode**

Openflow Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Examples**

- These commands enable OpenFlow on the switch.

```
switch(config)#openflow
switch(config-openflow)#no shutdown
switch(config-openflow)#
```

- This command disables OpenFlow.

```
switch(config-openflow)#shutdown
```
13.7 DirectFlow

This section describes Arista's DirectFlow implementation. Topics in this section include:

- Introduction
- DirectFlow Configuration
- DirectFlow Feature Interactions
- DirectFlow Commands

13.7.1 Introduction

Like OpenFlow, DirectFlow exposes the underlying forwarding ASICs capabilities through a programmable interface like EAPI or the standard CLI.

Unlike OpenFlow, DirectFlow works in conjunction with all other aspects of standard L2/L3 bridging or forwarding, and DirectFlow traffic is subject to the standard packet processing pipeline within the ASIC. You can think of DirectFlow as a stage in packet processing that processes traffic after ingress checks and before any egress actions.

This feature enables you to configure flows that consist of a matching criteria and actions, and to modify how traffic is processed (for example, by overriding the L2 lookup decision or rewriting a mac address or VLAN).

Features like MAC learning, STP state checks, ingress or egress VLAN membership checks on ports, ACLs, QoS and other features are all respected by DirectFlow. Traffic that doesn't match any programmed flow is processed normally while traffic that matches programmed flows is now subject to the actions specified in the flows.

DirectFlow and OpenFlow are mutually exclusive and you can run only one of the two at any given time.

How DirectFlow is Different from OpenFlow

There is no default flow matching all traffic, so traffic not matched by other rules is forwarded as normal. This means the configuration/controller/application doesn't consume TCAM space programming flows for normal forwarding.

DirectFlow works with other features and so the user can use ACL, rate limiting, STP etc. in their network as normal and not build all of that into the application used to inject flows.

DirectFlow flows can be configured from the CLI or using EAPI, giving users the option of using flow based forwarding without an external controller. This is especially useful where the number of flows is small and static, for example, to process a small subset of the traffic in a different manner to the normal L2/L3 pipeline.

Unlike OpenFlow which requires the switch support OUTPUT NORMAL or re-circulate a packet in order to send a packet from the OpenFlow domain to non-OpenFlow domain, there is just one domain with DirectFlow.

13.7.1.1 DirectFlow Flows

Similar to OpenFlow, you can define a relative priority between flows and define idle or hard timeouts for the flow. DirectFlow also enables you to insert a flow entry that matches on specified criteria, and define actions to be taken on traffic that matches the specified matching conditions. You can define flows to match on TCP flags, IPv6 source and destination addresses, input ports, and more.

For more information, see:

- DirectFlow Non-persistent Flows
- Supported Matches
13.7.1.1 DirectFlow Non-persistent Flows

DirectFlow enables you to configure flows that are not visible in the startup or running configurations and do not persist over a reboot. This feature is designed to be used for flows that are configured by a custom agent using the EOS SDK or eAPI and age out (expire) after a specified time period.

For example, if you are using a custom agent that reacts to traffic sent to the CPU (the redirect to CPU action), and you want to use a flow that will drop all matching traffic for 5 minutes, the agent can program a non-persistent flow that expires after a hard timeout of 300 seconds.

Using a non-persistent flow for this purpose ensures that other administrator actions (for example, saving the configuration) do not result in the flow being resurrected on startup or reverting to the saved configuration. It also removes the need for the agent to delete the expired flow.

Note: By default, all DirectFlow flows are persistent. You must use the no persistent command to configure a non-persistent flow.

13.7.1.2 Supported Matches

DirectFlow supports all matches supported on EOS with OpenFlow 1.0. This includes matches on VLAN, ether type, source or destination MAC address, COS, source or destination IP address, IP protocol, IP TOS, L4 source, destination ports, ICMP type, and code.

In addition, DirectFlow also allows matching on:

- TCP flags
- IPv6 source address
- IPv6 destination address
- Traffic injected from the CPU
- Input port

DirectFlow also permits re-using the same flow on multiple input ports, saving valuable TCAM space.

13.7.1.3 Supported Actions

DirectFlow supports all actions supported on EOS with OpenFlow 1.0, including:

- Setting the source or destination MAC address
- VLAN
- COS
- IP TOS
- Transmit queue
- Output port list and mirroring traffic pre-modification (ingress mirror) and post-modification (egress mirror)
- Redirect to CPU

The redirect to CPU action is useful in cases in which a custom agent is running on EOS and you want to trap specific traffic (matching traffic) and send the trapped traffic to the agent.

13.7.2 DirectFlow Configuration

Consider the following when using DirectFlow.

- DirectFlow takes effect ONLY after exiting the individual flow configuration sub-mode.
- Match criteria are connected with Boolean AND operators i.e. they must all match for the condition to be true and action to be taken.
• CLI is automatically set to match the ethertype to IP if IP fields (such as source or destination address or L4 ports) are chosen as part of other match/ action commands.
• In a single flow, only the following fields can be matched along with IPv6 source and destination addresses:
  • VLAN priority
  • VLAN ID
  • EtherType
  • Source interface
  • Class of Service (CoS)

13.7.2.1 Commands Used to Enable DirectFlow, Configure and Display Flows
A number of different commands are provided for the DirectFlow feature. The different commands enable you to enter the DirectFlow configuration mode, enable DirectFlow, configure flows, and display configured flows.

Note: ALL match criteria specified in a flow definition must match in the packet for the actions specified to be applied to the traffic.

Enter the DirectFlow Configuration Mode
The directflow command places the switch in DirectFlow configuration mode.

```
switch(config)#directflow
switch(config-directflow)#
```

Enable DirectFlow
The shutdown (DirectFlow) command determines if the configuration takes effect or not. To enable DirectFlow, enter the following command.

```
switch(config-directflow)#no shutdown
```

Create the Flow
The flow (DirectFlow) command creates a new flow entry. It must be unique or it will be overwritten by an existing entry.

```
switch(config-directflow)#flow Test-1
switch(config-directflow-Test-1)#
```

Create the DirectFlow Match Criteria
The match (DirectFlow-flow mode) command allows you to configure a rule or a flow which match on L2, L3, L4 fields of a packet and specify a certain action to either modify, drop or redirect the packet.

```
switch(config-directflow-Test-1)#match ethertype ip
switch(config-directflow-Test-1)#match source ip 10.10.10.10
```

Action Set
The action set (DirectFlow-flow mode) command allows you to configure a packet to be routed out a layer three interface using a DirectFlow entry.

```
switch(config-directflow-Test-1)#action egress mirror ethernet 7
```
Finalize the Flow

DirectFlow flows do not take effect until you exit the configuration sub-mode for the specified flow. Use the `exit` command to finalize the flow and put it into effect.

```plaintext
switch(config-directflow-Test-1)#exit
switch(config-directflow)#
```

Redirect to CPU

The `action output interface cpu (DirectFlow-flow mode)` command allows you to configure flows so that traffic that matches the matching conditions specified in the flow is redirected to the CPU.

```plaintext
switch(config)#directflow
switch(config-directflow)#flow redirect-http-cpu
switch(config-directflow-redirect-http-cpu)#match ip protocol tcp
switch(config-directflow-redirect-http-cpu)#match destination port 80
switch(config-directflow-redirect-http-cpu)#action output interface cpu
```

Configuring a Non-persistent Flow

DirectFlow flows are persistent by default. Use the `no persistent` command to configure non-persistent flows.

```plaintext
switch config)#directflow
switch(config-directflow)#flow example-non-persistent
switch(config-directflow-example-non-persistent)#match input interface ethernet 25
switch(config-directflow-example-non-persistent)#action drop
switch(config-directflow-example-non-persistent)#no persistent
switch(config-directflow-example-non-persistent)#timeout hard 300
```

Display Details for Configured Flows

The `detail` option of the `show directflow flows` command enables you to display the details of configured flows. You can use this command to verify that a non-persistent flow is deleted after the timeout period configured for the flow has elapsed.

The following example shows the use of this command to view the configuration of a non-persistent flow before the timeout period has elapsed, and a second time, after the timeout period has expired.

The initial use of the command displays the flow configuration (before the timeout expires).

```plaintext
switch(config-directflow)#show directflow flows example-non-persistent detail
Flow example-non-persistent: (Flow programmed)
persistent: False
priority: 0
hard timeout: 300
idle timeout: 0
match:
ingress interface:
    Et25
actions:
drop
```
The second use of the command displays the flow details (after the timeout expires). The output shows that the flow is no longer programmed.

```
switch(config-directflow)#show directflow flows example-non-persistent detail
Flow example-non-persistent: (Flow not programmed)
persistent: False
priority: 0
hard timeout: 300
idle timeout: 0
match:
  ingress interface:  
    Et25
actions:
  drop
matched: 0 packets, 0 bytes
```

13.7.3 DirectFlow Feature Interactions

DirectFlow flow entries can have one of the following actions:

- A set of egress ports for sending a matched packet
- Copy to CPU
- Redirect to CPU
- Drop
- No specified action (in this case, the traffic is output normally).

The only exception is the ingress or egress mirroring action, where the DirectFlow entry causes the packet to be mirrored.

When the ingress or egress packets are mirrored, the original traffic is sent out normally.

Bridging Features

- DirectFlow entries have precedence over all entries in the MAC table, including static MAC entries and static MAC drop entries. Packets that do not match DirectFlow entries are forwarded based on the MAC address table.
- VLANs: DirectFlow entries can modify the VLAN of a packet. MAC learning takes place in the original VLAN for DirectFlow entries that modify the VLAN. The modified packet will be subject to VLAN membership checks on the egress port. If a packet has no VLAN tag, DirectFlow assumes it came in on the native VLAN for the ingress interface. A VLAN override causes the packet to obey the VLAN rules on the egress port.
- Q-in-Q: Q-in-Q is supported as DirectFlow entries match only on the outer tag.
- Counters: All packets that match DirectFlow entries cause interface counters to increment as usual.

Spanning Tree

DirectFlow runs alongside MSTP, RSTP, and PVST. DirectFlow entries do not match on packets that ingress an STP discarding port. DirectFlow entries that cause a packet to be forwarded out an STP discarding port will result in the packets being dropped on egress.

When STP is enabled, BPDUs will always be trapped to the CPU. When STP is disabled, BPDUs will be subject to DirectFlow entries and not be copied to the CPU by default.
**LLDP, LAGs, and LACP**
- LLDP packets are always trapped to the CPU. DirectFlow entries can never match LLDP packets.
- LAGs are fully supported, and can be part of a match criteria and part of an output action to an interface.
- LACP packets are always trapped to CPU. DirectFlow entries can never match LACP packets.

**sFlow**

sFlow is unaffected by DirectFlow.

**IGMP Snooping**

IGMP control packets are trapped to the CPU when IGMP Snooping is enabled. DirectFlow entries can match IGMP Snooping control traffic and override the trap to CPU.

Link-local-multicast packets are flooded in hardware in the VLAN via a TCAM entry. DirectFlow entries can match link-local-multicast packets and change the flooding behavior. As DirectFlow entries have to specify output interfaces or drop, the action will conflict and so matching DirectFlow entries will get precedence.

When IGMP snooping is enabled, unknown IPV4 multicast packets are flooded to the multicast-router ports in the VLAN. If DirectFlow entries match unknown IPV4 multicast packets, they will override the flooding behavior.

Data packets in groups under IGMP snooping control are sent to the group members through a MAC table entry. Matching DirectFlow entries override the MAC table entries.

**ACLs**

DirectFlow entries are lower priority than any configured Port ACLs (ingress). Packets coming in on a port that match DirectFlow entries obey any configured ACL on that port, and will only apply to packets that have a permit action.

DirectFlow entries are higher priority than any configured RACLs. Packets coming in on an L3 interface that match DirectFlow entries ignore any RACLs configured on that interface.

DirectFlow entries are lower priority than any configured Egress ACLs.

**13.7.3.1 Layer Three Features and DirectFlow**

DirectFlow runs alongside IP routing. If a packet is routed out a layer three interface using a DirectFlow entry, the actions associated with the entry will have to specify the new source MAC and destination MAC for the packet, as well as the physical port or LAG. If there are no output ports specified in an entry, packets that match that entry will be dropped.

**Unicast Routing**

When unicast routing is enabled, DirectFlow entries that match take precedence for all packets that would have been otherwise been routed. The three exceptions are the ingress mirror, egress mirror and copy-to-CPU actions where the packets will be routed normally in addition to the action being performed. Routed packets that do not match DirectFlow entries are forwarding based on the L3 lookup.

**Multicast Routing**

When multicast routing is enabled, DirectFlow entries that match take precedence for all packets that would have otherwise been multicast routed. The packets are not replicated based on the hardware multicast tables, but are forwarded strictly according to the actions specified by the DirectFlow entry.
The entry can specify a set of output interfaces, which will result in the packet being replicated based on the DirectFlow entry.

### 13.7.3.2 Displaying DirectFlow Configurations

To `show directflow flows` command displays the contents of the flow table, showing each entry with its match rules, actions, and packet counters.

- This example shows the status of a default (persistent) flow.

```bash
switch(config-directflow)#show directflow flows
Flow Test1:
priority: 0
match:
ingress interface: Ethernet1
  ethertype ip
source ip address: 10.10.10.10
actions:
output mirror: Ethernet2
matched: 0 packets, 0 bytes
switch(config-directflow)#
```

- This example shows the status of a non-persistent flow. The flow will be deleted once 5 minutes have elapsed.

```bash
switch(config-directflow)#show directflow flows example-non-persistent
Flow example-non-persistent:
persistent: False
priority: 0
hard timeout: 300
idle timeout: 0
match:
ingress interface:
  Et25
actions:
drop
matched: 0 packets, 0 bytes
```
13.7.4 DirectFlow Commands

DirectFlow Global Configuration Mode

• directflow

DirectFlow Configuration Commands

• action drop (DirectFlow-flow mode)
• action mirror (DirectFlow-flow mode)
• action output (DirectFlow-flow mode)
• action output interface cpu (DirectFlow-flow mode)
• action set (DirectFlow-flow mode)
• flow (DirectFlow)
• match (DirectFlow-flow mode)
• persistent
• priority (DirectFlow-flow mode)
• shutdown (DirectFlow)
• timeout (DirectFlow-flow mode)

DirectFlow and Clear Commands

• show directflow
• show directflow flows
13.7.4.1  action drop (DirectFlow-flow mode)

The action drop command configures packets that match an entry to be dropped.

The no action drop and default action drop commands remove the statement from the DirectFlow configuration mode.

Command Mode
Directflow-flow Configuration

Command Syntax

action drop
no action drop
default action drop

Example

This command sets the action for packets from **Test-1** to be dropped.

```
switch(config-directflow-Test-1)#action drop
switch#
```
13.7.4.2  action mirror (DirectFlow-flow mode)

The action mirror command can be used to ingress or egress mirror traffic to a mirror destination. This requires a mirror destination to be setup on the switch. If a packet comes in or goes out an interface that is part of another mirror session, then the destination for that destination as well as the DirectFlow destination will receive a copy of the packet.

The no action mirror and default action mirror commands remove the statement from DirectFlow configuration mode.

Command Mode
Directflow-flow Configuration

Command Syntax
action DIRECTION mirror INT_NAME
no action DIRECTION mirror INT_NAME
default action DIRECTION mirror INT_NAME

Parameters
- DIRECTION transmission direction of traffic to be mirrored.
  - ingress mirrors before any rewrites.
  - egress mirrors after rewrites.
- INT_NAME Source interface for the mirroring session.
  - ethernet e_range Ethernet interfaces specified by e_range.
  - port-channel p_range Port channel interfaces specified by p_range.

Example
This command configures mirror traffic to ethernet 2.

```
switch(config-directflow)# flow Test1
switch(config-directflow-Test1)# match ethertype ip
switch(config-directflow-Test1)# match source ip 10.10.10.10
switch(config-directflow-Test1)# action egress mirror ethernet 2
switch(config-directflow-Test1)#
```
13.7.4.3 action output (DirectFlow-flow mode)

The action output command configures an Ethernet or port channel interface as the output of a specified port mirroring session.

The no action output and default action output commands remove the statement from DirectFlow configuration mode.

Command Mode
Directflow-flow Configuration

Command Syntax
action output DESTINATION
no action output DESTINATION
default action output DESTINATION

Parameters
DESTINATION transmission direction of traffic to be mirrored.

- all mirrors transmitted and received traffic.
- flood mirrors received traffic only.
- interface ethernet e_range Ethernet interfaces specified by e_range.
- interface port-channel p_range Port channel interfaces specified by p_range.
- nexthop vrf vrf_name ip_addr. If the next hop is reachable in the default VRF, the default VRF does not need to be specified.

Examples
• This command configures interface ethernet 7 as the output for the mirroring session.

  switch(config-directflow-Test1)#action output interface ethernet 7
  switch(config-directflow-Test1)#

• The following commands configure a flow redirecting all traffic from 10.10.1.2 to e_range next hop assuming an appropriately configured TCAM profile.

  switch(config-directflow)#flow flow-sip-10_10_1_2-redirect-to-10_30_1_2
  switch(config-directflow-Test1)#match ethertype ip
  switch(config-directflow-Test1)#match source ip 10.10.1.2
  switch(config-directflow-Test1)#action output nexthop 10.30.1.2
  switch(config-directflow-Test1)#
### 13.7.4.4  action output interface cpu (DirectFlow-flow mode)

The **action output interface cpu** command configures the action (other commands are used to define the traffic matching conditions).

The **no action output interface cpu** and **default action output** commands remove the statement from *DirectFlow* configuration mode.

**Command Mode**
Directflow-flow Configuration

**Command Syntax**

```plaintext
action output DESTINATION
no action output DESTINATION
default action output DESTINATION
```

**Parameters**

**DESTINATION** transmission direction of traffic to be mirrored.

- **all** mirrors transmitted and received traffic.
- **flood** mirrors received traffic only.
- **interface cpu** Ethernet interfaces specified by `e_range`.

**Examples**

- This command configures *interface ethernet 7* as the output for the mirroring session.

```
switch(config-directflow-Test1)#action output interface ethernet 7
switch(config-directflow-Test1)#
```

- These commands configure the action to redirect traffic matching the flow to the CPU and the matching conditions for the flow.

```
switch (config)#directflow
switch(config-directflow)#flow redirect-http-cpu
switch(config-directflow-redirect-http-cpu)#match ip protocol tcp
switch(config-directflow-redirect-http-cpu)#match destination port 80
switch(config-directflow-redirect-http-cpu)#action output interface cpu
```
**13.7.4.5 action set (DirectFlow-flow mode)**

The *action set* command allows you to configure a packet to be routed out a layer three interface using a DirectFlow entry. The actions associated with the entry will have to specify the new source MAC and destination MAC for the packet, as well as the physical port or LAG. If there are no output ports specified in an entry, packets that match that entry will be dropped.

The *no action set* and *default action set* commands remove *action set* statement from *DirectFlow* configuration mode.

**Command Mode**

Directflow-flow Configuration

**Command Syntax**

```
action set CONDITION
no action set CONDITION
default action set CONDITION
```

**Parameters**

*CONDITION* specifies parameter and value. Options include:

- *cos 0 to 7* Cost of service.
- *destination mac mac_addr* Dotted hex notation.
- *ip tos 0 to 255* Type of service.
- *source mac mac_addr* Dotted hex notation.
- *traffic-class 0 to 7* Dotted hex notation.
- *vlan 0 to 4094* Number of VLAN.

The *no action set* and *default action set* commands require only the *CONDITION* type without a specific condition value.

**Example**

These commands change the destination MAC of the frame.

```
switch(config-directflow)#flow Test1
switch(config-directflow-Test1)#action egress mirror ethernet 7
switch(config-directflow-Test1)#action set destination mac 0000.aaaa.bbbb
```
13.7.4.6  **directflow**

The **directflow** command places the switch in DirectFlow configuration mode. The **no directflow** and **default directflow** commands delete the DirectFlow configuration mode statements from **running-config**.

DirectFlow configuration mode is not a group change mode; **running-config** is changed immediately upon entering commands. Exiting OpenFlow configuration mode does not affect **running-config**. The **exit** command returns the switch to **global configuration mode**.

**Command Mode**
Global Configuration

**Command Syntax**
directflow
no directflow
default directflow

**Commands Available in DirectFlow-Flow configuration mode:**
- flow (DirectFlow)
- shutdown (DirectFlow)

**Examples**
- This command places the switch in **DirectFlow** configuration mode:

```
switch(config)#directflow
switch(config-directflow)#
```

- This command returns the switch to **global management** mode:

```
switch(config-directflow)#exit
switch(config)#
```
13.7.4.7 flow (DirectFlow)

The `flow` command places the switch in `flow` configuration mode.

The `flow` command specifies the name of the flow that subsequent commands modify and creates a new flow definition if it references a nonexistent flow. All changes in a `flow` configuration mode edit session are pending until the session ends:

- The `exit` command saves pending changes to `running-config` and returns the switch to `DirectFlow` configuration mode. Changes are also saved by entering a different configuration mode.
- The `abort` command discards pending changes, returning the switch to `DirectFlow` configuration mode.

The `no flow` and `default flow` commands delete the specified role by removing the role and its statements from `running-config`.

**Command Mode**
DirectFlow Configuration

**Command Syntax**

```
flow flow_name
no flow flow_name
default flow flow_name
```

**Parameters**

`flow_name` Name of flow.

**Commands Available in DirectFlow-Flow configuration mode:**

- action drop (DirectFlow-flow mode)
- action mirror (DirectFlow-flow mode)
- action output (DirectFlow-flow mode)
- action set (DirectFlow-flow mode)
- match (DirectFlow-flow mode)
13.7.4.8 match (DirectFlow-flow mode)

The `match` command allows you to configure a rule or a flow which could match on L2, L3, L4 fields of a packet and specify a certain action to modify, drop or redirect the packet.

All traffic ingressing on the switch will be matched against the flows installed. In cases where none of the packets match, normal switching or routing behavior will take over. When multiple entries match a packet, precedence is given to the entry that was installed first.

The `no match` and `default match` commands remove the `match` statement from the configuration mode.

**Command Mode**
Directflow-flow Configuration

**Command Syntax**

```
match CONDITION
no match CONDITION
default match CONDITION
```

**Parameters**

`CONDITION` specifies criteria for evaluating a route. Options include:

- `cos 0 to 7` cost of service.
- `destination ip ipv4_sub` destination IPv4 subnet. L3 fields valid only if ethertype is IP (0x0800).
- `destination mac mac_addr` Add to the existing community. Dotted hex notation.
- `destination mac mac_addr mask mac_mask` Add to the string community. Dotted hex notation.
- `destination port 0 to 65535` Fields accepted only if protocol is TCP|UDP.
- `ethertype 0 to 65535` Layer 4 destination port.
- `ethernet ARP` Layer 4 destination port.
- `ethernet IP` Layer 4 destination port.
- `icmp code 0 to 255` Fields accepted only if protocol is ICMP.
- `icmp type 0 to 255` Fields accepted only if protocol is ICMP.
- `input interface ethernet e_num` Ethernet interface specified by `e_num`.
- `input interface port-channel p_num` Port channel interface specified by `p_num`.
- `ip protocol 0 to 255` Type of service.
- `ip protocol icmp` L3 fields valid only if ethertype is IP (0x0800).
- `ip protocol tcp` L3 fields valid only if ethertype is IP (0x0800).
- `ip protocol udp` L3 fields valid only if ethertype is IP (0x0800).
- `ip tos 0 to 255` L3 fields valid only if ethertype is IP (0x0800).
- `source ip ipv4_subnet` L3 fields valid only if ethertype is IP (0x0800).
- `source mac mac_addr` Add to the existing community. Dotted hex notation.
- `source mac mac_addr mask mac_mask` Add to the string community. Dotted hex notation.
- `source port 0 to 65535` Fields accepted only if protocol is TCP|UDP.
- `tcp flag ack` Layer 4 destination port.
- `tcp flag fin` Layer 4 destination port.
- `tcp flag psh` Layer 4 destination port.
- `tcp flag rst` Layer 4 destination port.
- `tcp flag syn` Layer 4 destination port.
- `tcp flag urg` Layer 4 destination port.
- `tcp flag urg` Layer 4 destination port.
- `vlan 1 to 4094 mask 1 to 4095` Number of VLAN.
The `no match` and `default match` commands require only the `CONDITION` type without a specific condition value.

**Example**

This command creates the rules to match on Ethertype IP and Source IP 10.10.10.

```
switch(config-directflow)#flow Test1
switch(config-directflow-Test1)#persistent
switch(config-directflow-Test1)#match ethertype ip
switch(config-directflow-Test1)#match source ip 10.10.10.10
```
13.7.4.9 persistent

DirectFlow flows are persistent by default. Once finalized, they appear in the running configuration, and if saved to startup config they will persist over a reboot. The no form of the persistent command prevents the flow from showing up in running config, ensuring that it will not persist over a reboot.

Command Mode
Directflow-flow Configuration

Command Syntax
persistent
no persistent

Example
These commands create and enable a non-persistent DirectFlow flow.

```bash
switch(config)#directflow
switch(config-directflow)#flow example-non-persistent
switch(config-directflow-example-non-persistent)#match input
  interface ethernet
  25
switch(config-directflow-example-non-persistent)#action drop
switch(config-directflow-example-non-persistent)#no persistent
switch(config-directflow-example-non-persistent)#timeout hard 300
switch(config-directflow-example-non-persistent)#exit
switch(config-directflow)#
```
13.7.4.10 priority (DirectFlow-flow mode)

The `priority` command sets the priority for the flow match rules. Each flow-table entry has an optional priority field, with a higher number indicating a higher priority. Flows with the same priority may be loaded in any order, and the order may be changed at any time. If multiple entries match a packet, precedence is given to the entry that was installed first.

Priority numbers range from **0 to 65535**. The default is **0**. The higher priority rules match first.

The `no priority` and `default priority` commands remove `priority` statement from the `DirectFlow` configuration mode.

**Command Mode**
Directflow-flow Configuration

**Command Syntax**

- `priority priority_value`
- `no priority`
- `default priority`

**Parameter**

`priority_value` priority **xxx**. Value ranges from **0 to 65535**. Default is **0**.

**Example**

These commands assign the priority of **150** to flow **Test-1**.

```
switch(config-directflow-Test-1)#priority 150
switch(config-directflow-Test-1)#
```
13.7.4.11  show directflow flows

The `show directflow flows` command displays the contents of the flow table, showing each entry with its match rules, actions, and packet counters. Including the name of a specific flow limits the output to information about the specified flow.

**Command Mode**

EXEC

**Command Syntax**

`show directflow flows [flow_name [counters | detail]]`

**Parameters**

- `flow_name` name of flow for which to display information. If no flow name is entered, command displays information for all flows.
- `counters` displays DirectFlow counters for the specified flow.
- `detail` displays detailed information for the specified flow.

**Examples**

- This command displays the contents of the flow table.

```plaintext
switch# show directflow flows
Flow test3:
    persistent: True
    priority: 0
    priorityGroupType: default
    tableType: ifp
    hard timeout: 0
    idle timeout: 0
    match:

switch>
13.7.4.12 show directflow

The `show directflow` command displays summary information for DirectFlow. With the `counters` or `details` options, it displays counters or details for all flows configured on the switch.

**Command Mode**

EXEC

**Command Syntax**

`show directflow [counters | details]`

**Examples**

- This command displays summary information for DirectFlow.

  switch# `show directflow`

  DirectFlow configuration: Enabled
  Total matched: 0 packets
  Total programmed flows: 3 flows
  switch#

- This command displays counters for all DirectFlow flows configured on the switch.

  switch# `show directflow counters`

<table>
<thead>

switch#
13.7.4.13 shutdown (DirectFlow)

The `shutdown` command, in DirectFlow mode, disables DirectFlow on the switch. DirectFlow is disabled by default.

The `no shutdown` command re-enables DirectFlow.

**Command Mode**

Directflow Configuration

**Command Syntax**

- `shutdown`
- `no shutdown`
- `default shutdown`

**Examples**

- These commands enable DirectFlow on the switch.

```
switch(config)#directflow
switch(config-directflow)#no shutdown
switch(config-directflow)#
```

- This command disables DirectFlow Flow.

```
switch(config-directflow-Test1)#shutdown
```
13.7.4.14  timeout (DirectFlow-flow mode)

The `timeout` command, in DirectFlow mode, command configures the connection timeout period for connection sessions. The connection timeout period defines the interval between a users most recently entered command and an automatic connection shutdown. Automatic connection timeout is disabled by setting the idle-timeout to zero, which is the default setting.

**Command Mode**

Directflow-flow Configuration

**Command Syntax**

```
no timeout hard
no timeout idle
```

**Parameters**

- `idle` session idle timeout length.
  - `0` Automatic connection timeout is disabled.
  - `1-4294967295` Automatic timeout period (seconds).
- `hard` session hard timeout length.
  - `0` Automatic connection timeout is disabled.
  - `1-4294967295`

**Example**

- These commands enable a hard timeout period of 5 seconds on the switch.

  ```
  switch(config)#directflow
  switch(config-directflow-Test1)#timeout hard 5
  switch(config-directflow-Test1)#
  ```

- These commands enable DirectFlow on the switch.

  ```
  switch(config)#directflow
  switch(config-directflow-Test1)#no timeout hard
  switch(config-directflow-Test1)#
  ```
13.8 Decap Groups

These sections describe the Decap groups:

• Decap Groups Description
• Decap Groups Configuration
• Decap Commands
13.8.1  Decap Groups Description

The decap group is a data structure that receives encapsulated packets and extracts the payload. The switch then processes or forwards the extracted payload as required. Although packets cannot be transmitted through decap groups, nexthop groups can be used to create a packet's reverse path. Decap groups support payload extraction of packets received from Generic Routing Encapsulation (GRE) and IP-in-IP tunnels.

The decap capabilities are further enhanced to support the Generic UDP Encapsulation (GUE). GUE is a general method for encapsulating packets of random IP protocols within a UDP tunnel. GUE provides an extensible header format with optional data.

The switch identifies a GUE packet based on the outer UDP destination port. Then it terminates the tunnel based on the outer destination IP and removes the outer IP/UDP encapsulation. The outer UDP destination port is also used to determine if the inner payload is IP or MPLS. For IP payloads, the first nibble of the inner payload is used to distinguish between IPv4 vs IPv6. The decapsulated packet is then either IP or MPLS forwarded based on the inner payload.

Decap groups have these limitations:
- Tunnels are terminated using destination IP address; source IP address has no influence.
- Packets matching a decap group are not processed through their ingress interface and VLAN.
- During a tunnel termination, ingress ACL filter each decap group packet's inner header.
- Packet counters are not available.
- VRF is not supported.

The decap support over GUE has the following limitations:
- Outer UDP checksum validation is not supported.
- Outer IP options handling is not supported.
- Outer IP TTL check is not performed.
- No exception handling on inner IP packet. Specifically, packets with inner IP TTL=1 or IP options will simply be attempted to be forwarded in HW.
- VXLAN is not supported along with GUE decap option on DCS-7020, DCS-7280R, DCS-7280R2, DCS-7500R, and DCS-7500R2 switch series.
- When GUE is enabled with outer IP hashing, inner IP fields are not included in the load balance key of MPLS over GRE packets in tc-counters TCAM profile on DCS-7020, DCS-7280R, DCS-7280R2, DCS-7500R, and DCS-7500R2 switch series.

Decap groups are defined by their tunnel type and decap IP address:
- **Tunnel type** specifies the tunnel protocol that the switch uses to extract payload.
- **Decap IP address** specifies the IP address where the switch receives decap group packets.

Decap groups support Generic Routing Encapsulation (GRE) and IP-in-IP tunnels.

13.8.1.1  Decap Groups Configuration

Decap groups are configured in **decap-group** configuration mode. The **decap-group** configuration mode is not a group change mode; the **running-config** is changed immediately upon entering commands. However, when exiting, the **decap-group** configuration mode does not affect running-config. The **exit** command returns the switch to **global** configuration mode.

- The static CLI entry for the incoming label is specified by the **mpls static** command.
- The tunnel type is specified by the **tunnel type (Decap Group)** command.
- The Decap IP address is specified by the **tunnel decap-ip (Decap Group)** command.
- The locally configured IP addresses are added to the Layer 3 interfaces using the **tunnel decap-interface (Decap Group)** command for a specified decap group.
Decap groups do not define a default destination address or tunnel type and is not functional until both parameters are configured. A decap group can contain multiple tunnel decap-ip statements.

### Examples

- This command defines a static CLI entry for the incoming-label.

```
switch(config)# mpls static top-label 3400 ethernet 3/3/3
10.14.4.4 pop payload-type ipv4
```

- This command creates a decap group named DC-1 and configures the group to terminate packets from GRE tunnel packets with the destination IP address of 10.14.3.2.

```
switch(config)#ip decap-group DC-1
switch(config-dg-DC-1)# tunnel type gre
switch(config-dg-DC-1)# tunnel decap-ip 10.14.3.2
switch(config-dg-DC-1)# show active
  ip decap-group DC-1
    tunnel type gre
    tunnel decap-ip 10.14.3.2
switch(config-dg-DC-1)# end
switch(config)#
```

### 13.8.1.2 Generic UDP Encapsulation (GUE) Decap Configuration

The ip decap-group configuration is used to specify GUE tunnel termination as follows:

```
switch(config)#ip decap-group test
switch(config-dg-test)# tunnel type UDP
switch(config-dg-test)# tunnel decap-ip 2.2.2.2
switch(config-dg-test)# tunnel decap-interface et1
```

The global UDP destination port to payload type mapping is configured as follows:

```
switch(config)#ip decap-group type udp destination port 6080 payload ip
switch(config)#ip decap-group type udp destination port 5555 payload mpls
```

**Note:** Note that each payload type can be mapped to only one UDP port. Otherwise, the following error will be shown:

```
switch(config)#ip decap-group type udp destination port 6081 payload ip
% There can be only one UDP destination port per payload type
```

### MPLSoverGUE Decap-group Configuration

The MPLSoverGUE decap-group requires the following platform configurations. First, the mpls-over-gre must be enabled since this supports the mpls-over-gre support in hardware:

```
switch(config)#platform fap mpls-over-gre
```

Second, outer IP hashing must be enabled as follows:

```
(config)# load-balance policies
switch(config-load-balance-policies)# load-balance sand profile default
! profile default is a reserved profile
! profile default is the current global profile
```
Note: The above platform configurations are not required on DCS-7280R3, DCS-7500R3, and DCS-7800R3.
13.8.1.3  Decap Commands

Decap Configuration Commands

- ip decap-group
- tunnel decap-interface (Decap Group)
- tunnel decap-ip (Decap Group)
- tunnel type (Decap Group)

Decap Show Command

- show ip decap-group
13.8.1.3.1  ip decap-group

The `ip decap-group` command places the switch in `decap-group` configuration mode, through which decap groups are created or modified. A decap group is a data structure that defines a method of extracting the payload from an encapsulated packet that the switch receives on a specified IP address.

Decap groups do not specify a default IP address group or tunnel type. These parameters must be explicitly configured before a decap group can function.

The `decap-group` configuration mode is not a group change mode; the `running-config` is changed immediately upon entering commands. Exiting the `decap-group` configuration mode does not affect `running-config`. The `exit` command returns the switch to `global` configuration mode.

The `no ip decap-group` and `default ip decap-group` commands delete previously configured commands in the specified `decap-group` mode.

**Command Mode**

Global Configuration

**Command Syntax**

```plaintext
ip decap-group group_name
no ip decap-group group_name
default ip decap-group group_name
```

**Parameters**

`group_name` Decap group name.

**Commands Available in Decap-group Configuration Mode**

- `tunnel decap-ip (Decap Group)` Specifies the IP address of packets handled by the decap group.
- `tunnel type (Decap Group)` Specifies the tunnel protocol for extracting payload.
- `show ip decap-group`

**Examples**

- This command creates a decap group named `DC-1`.

```plaintext
switch(config)#ip decap-group DC-1
switch(config-dg-DC-1)#
```

- This command exits the `decap-group` mode for the `DC-1` decap group.

```plaintext
switch(config-dg-DC-1)#exit
switch(config)#
```

- This command delete the decap group named `DC-1`.

```plaintext
switch(config)#no ip decap-group DC-1
switch(config)#
```
13.8.1.3.2  show ip decap-group

The `show ip decap-group` command displays the IP decap groups that are available in the switch.

Command Mode
Global Configuration

Command Syntax
`show ip decap-group [decap-group name | dynamic]`

Parameters
- **decap-group name**  The decap group name.
- **dynamic** Displays the dynamic entries only.

Related Commands
- `show ip decap-group`
- `tunnel decap-ip (Decap Group)`
- `tunnel type (Decap Group)`

Examples
- This command displays the IP decap groups that are available in a switch.

```
switch(config)#show ip decap-group
NOTE: "D" column indicates dynamic entries
D | Name    | Type   | Info       | Version | Addr Type
---|---------|--------|------------|---------|--------
* | d1      | GRE    | 1.2.3.4    |         |        |
* | d2      | IP-in-IP| Ethernet1/3| IPv4    | primary|
| gre-with-intf | GRE   |            |         |        |
| ipip-with-decapall | IP-in-IP| all       | IPv4    | all    |
| ipip-with-decapall | IP-in-IP| all       | IPv6    | all    |
| ipip-with-intf | IP-in-IP| Ethernet1/3| IPv4    | all    |
| ipip-with-intf | IP-in-IP| Ethernet1/3| IPv6    | all    |
* | ipip-with-ip | IP-in-IP| 1001::1   | IPv6    |        |
| ipip-with-ip | IP-in-IP| 1.1.1.1   | IPv4    |        |
| p1      | GRE    | 100.100.100.100 |         |        |
| p2      | UNKNOWN|          |          |        |
```

- This command displays the UDP decap groups that are available in a switch.

```
switch(config)#show ip decap-group
NOTE: "D" column indicates dynamic entries
D | Name | Type | Info         | Version | Address | UDP Dest | Payload
---|------|------|--------------|---------|---------|----------|---------
| foo  | UDP  | Ethernet1   | IPv4    | primary| 6080    | ip       |
| bar  | UDP  | 2.2.2.2     | IPv4    |         | 6080    | ip       |
```

- The following command displays the decap-groups configured in HW:

```
switch(config)#show platform fap decap-group
DecapIp | LIF
---------|-----
2.2.2.2  | 0
3.3.3.3  | 1
```
13.8.1.3.3  tunnel decap-interface (Decap Group)

The **tunnel decap-interface** command adds all locally configured IP addresses to the specific Layer 3 interface per decap group.

The **no tunnel decap-interface** command and the **default tunnel decap-interface** command restores the default state by removing the locally added IP addresses from the decap group.

**Command Mode**
Decap-Group Configuration

**Command Syntax**

```
tunnel decap-interface { Ethernet | Loopback | Management | Port-Channel | Tunnel | Vlan | Vxlan | all }
```

```
no tunnel decap-interface { Ethernet | Loopback | Management | Port-Channel | Tunnel | Vlan | Vxlan | all }
```

```
default tunnel decap-interface { Ethernet | Loopback | Management | Port-Channel | Tunnel | Vlan | Vxlan | all }
```

**Parameters**

- **Ethernet e_num** Ethernet interface specified by *e_num*. The Ethernet port number ranges from 1 to 36.
- **Loopback l_num** Loopback interface specified by *l_num*. The loopback interface number ranges from 0 to 1000.
- **Management m_num** Management interface specified by *m_num*. The management port number ranges from 1 to 1.
- **Port-channel p_num** Port-channel interface specified by *p_num*. Options include:
  - **Port-channel** interface number. The port-channel interface number ranges from 1 to 2000.
  - **Port-channel** sub interface number. The port-channel sub interface number ranges from 1 to 2000.
  - **tunnel t_num** Tunnel interface specified by *t_num*. The tunnel interface number ranges from 0 to 255.
  - **vlan v_num** VLAN interface specified by *v_num*. The VLAN interface number ranges from 1 to 4094.
  - **vxlan vx_num** VXLAN interface specified by *vx_num*. The VXLAN tunnel interface number ranges from 1 to 1.
- **all address-family** This parameter configures all L3 interfaces as a decap interface.

**Related Commands**

- **ip decap-group**
- **tunnel type (Decap Group)**
- **show ip decap-group**

**Example**

These commands add locally configured IP addresses to the Ethernet interface 1/1 for the **dg1** decap group.

```
switch(config)#ip decap-group dg1
switch(config-dg-dg1)#tunnel decap-interface Ethernet1/1
```

```
switch(config-dg-dg1)#show active
ip decap-group dg1
  tunnel type ipip
  tunnel decap-interface Ethernet1/1
```
tunnel decap-interface all address-family ipv6 address all
13.8.1.3.4  tunnel decap-ip (Decap Group)

The tunnel decap-ip command specifies the IP address of packets that are handled by the configuration mode decap group. A decap group is a data structure that defines a method of extracting the payload from an encapsulated packet that the switch receives on a specified IP address.

Decap groups do not define a default decap-ip address. A decap group is not functional until an IP address is specified. Decap groups can contain only one tunnel decap-ip statement; subsequent commands replace any previously configured statements.

Command Mode
Decap-Group Configuration

Command Syntax
```
tunnel decap-ip ipv4_address
```

Parameters

- **ipv4_addr**: An IPv4 address.

Related Commands
- The ip decap-group command places the switch in decap-group configuration mode.
- The tunnel type (Decap Group) command specifies the tunnel protocol for extracting payload.
- The show ip decap-group command.

Guidelines

A decap group does not specify a default IP address group or tunnel type. These parameters must be explicitly configured before a decap group can function.

Example

These commands configure 10.14.3.2 as the decap-IP address for the DC-1 decap group.

```
switch(config)#ip decap-group DC-1
switch(config-dg-DC-1)#tunnel decap-ip 10.14.3.2
switch(config-dg-DC-1)#show active
  ip decap-group DC-1
  tunnel decap-ip 10.14.3.2
switch(config-dg-DC-1)#
```
13.8.1.3.5  tunnel type (Decap Group)

The tunnel type command specifies the tunnel protocol for extracting payload from encapsulated packets that arrive on the IP address specified for the configuration mode decap group. Supported tunnel protocols include General Routing Encapsulation (GRE) and IP-in-IP.

Decap groups do not define a default tunnel type. A decap group is not functional until an IP address is specified. Decap groups can contain only one tunnel decap-ip statement; subsequent commands replace any previously configured statements.

Command Mode
Decap-group Configuration

Command Syntax

```
tunnel type gre
```

Related Commands

- The ip decap-group command places the switch in decap-group configuration mode.
- The tunnel decap-ip (Decap Group) command specifies the IP address of packets handled by the decap group.
- The show ip decap-group command.

Guidelines

A decap group does not specify a default IP address group or tunnel type. These parameters must be explicitly configured before a decap group can function.

Example

This command configures decap group DC-1 to terminate packets from GRE tunnel packets.

```
switch(config)#ip decap-group DC-1
switch(config-dg-DC-1)#tunnel type gre
switch(config-dg-DC-1)#show active
  ip decap-group DC-1
    tunnel type gre
switch(config-dg-DC-1)#
```
13.9  **Nexthop Groups**

These sections describe the Nexhop groups:
- Nexthop Group Description
- Nexthop Group Configuration
- Support for IPv6 Link-Local Addresses in Nexthop Groups Entries
- Nexthop Group Commands

13.9.1  **Nexthop Group Description**

Each routing table entry provides the next hop address to its specified destination. A nexthop address is the address of the next device on the path to the entry’s specified destination.

A nexthop group is a data structure that defines a list of nexthop addresses and a tunnel type for packets routed to the specified address. When an IP route statement specifies a nexthop group as the nexthop address, the switch configures a static route with a nexthop group member as the nexthop address and encapsulates packets forwarded to that address as required by the group’s tunnel type.

The nexthop group size is a configurable parameter that specifies the number of entries that the group contains. Group entries that are not explicitly configured are filled with drop routes. The switch uses ECMP hashing to select the address within the nexthop group when forwarding packets. When a packet’s hash selects a drop route, the packet is dropped.

Nexthop groups are supported on Trident platform switches and subject to the following restrictions:
- Each switch can support 512 IPv4 or IPv6 Tunnels
- Nexthop groups can contain 256 nexthops.
- The switch supports 1024 nexthop groups.
- Multiple routes can share a tunnel.
- Tunnels do not support IP multicast packets.

Nexthop groups support IP-in-IP tunnels. The entry IP address family within a particular nexthop group cannot be mixed, i.e. either they are all IPv4 or they are all IPv6 entries.

13.9.2  **Nexthop Group Configuration**

Nexthop groups are configured and modified in nexthop-group configuration mode. After a group is created, it is associated to a static route through an `ip route nexthop-group` statement.

These tasks are required to configure a nexthop group and apply it to a static route.
- Creating and Editing Nexthop Groups
- Configuring a Group’s Encapsulation Parameters
- Configuring the Group’s Size
- Creating Nexthop Group Entries
- Displaying Nexthop Groups
- Applying a Nexthop Group to a Static Route

**Creating and Editing Nexthop Groups**

Nexthop groups are created by a `nexthop-group` command that specifies a group that isn’t already configured. The switch enters `nexthop-group` configuration mode for the new group. `nexthop-group` mode is also accessible for modifying existing groups. When in `nexthop-group` configuration mode, the `show active` command displays the group’s configuration.
• This command creates a nexthop group named \textit{NH-1}.

\begin{verbatim}
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#
\end{verbatim}

• These commands enter \textit{nexthop-group} configuration mode for the group named \textit{NH3}, then displays the previously configured group parameters.

\begin{verbatim}
switch(config)#nexthop-group NH3
switch(config-nexthop-group-NH3)#show active
nexthop-group NH3
  size 4
ttl 10
  entry 0 tunnel-destination 10.14.21.3
  entry 1 tunnel-destination 10.14.21.5
  entry 2 tunnel-destination 10.14.22.5
  entry 3 tunnel-destination 10.14.22.6
switch(config-nexthop-group-NH3)#
\end{verbatim}

### Configuring a Group’s Encapsulation Parameters

Packets in static routes that are associated with the nexthop group are encapsulated to support the group’s tunnel type. Nexthop groups support IP-in-IP tunnels. The group also defines the source IP address and TTL field contents that are included in the packet encapsulation.

• This command configures the TTL setting to 32 for nexthop group \textit{NH-1} encapsulation packets.

\begin{verbatim}
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#ttl 32
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
  size 128
ttl 32
switch(config-nexthop-group-NH-1)#
\end{verbatim}

The address is inserted in the encapsulation source IP fields is specified by \textit{tunnel-source (Nexthop Group)}.

• These commands create Loopback interface \textit{100}, assign an IP address to the interface, then specifies that address as the tunnel source for packets designated by nexthop-group \textit{NH-1}.

\begin{verbatim}
switch(config)#interface loopback 100
switch(config-if-Lo100)#ip address 10.1.1.1/32
switch(config-if-Lo100)#exit
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#tunnel-source intf loopback 100
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
  size 256
ttl 32
tunnel-source intf Loopback100
\end{verbatim}
Configuring IP-in-IP Encapsulation

Through IP-in-IP encapsulation, IP packets matching a static Nexthop-Group route are encapsulated within an IP-in-IP tunnel and forwarded.

This command configures a static Nexthop-Group route and an IP-in-IP Nexthop-Group for IP-in-IP encapsulation.

```
switch(config)#ip route 124.0.0.1/32 nexthop-group abc
switch(config)#nexthop-group abc type ip-in-ip
switch(config-nexthop-group-abc)#size 512
switch(config-nexthop-group-abc)#tunnel-source 1.1.1.1
switch(config-nexthop-group-abc)#entry 0 tunnel-destination 1.1.1.2
switch(config-nexthop-group-abc)#entry 1 tunnel-destination 10.1.1.1
switch(config-nexthop-group-abc)#ttl 64
```

Configuring the Group’s Size

The group’s size specifies the number of entries in the group. A group can contain up to 256 entries, which is the default size. The group’s size is specified by size (Nexthop Group).

This command configures the nexthop group NH-1 to contain 128 entries.

```
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#size 128
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
 size 128
ttl 64
```

Creating Nexthop Group Entries

Each entry specifies a nexthop address that is used to forward packets. A nexthop group contains one entry statement for each nexthop address. The group’s size specifies the number of entry statements the group may contain. Each entry statement is assigned an index number to distinguish it from other entries within the group; entry index numbers range from zero to the group size minus one.

Nexthop group entries are configured by entry (Nexthop Group).

- These commands set the nexthop group size at four entries, then create three entries. Packets that are hashed to the fourth entry are dropped.

```
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#size 4
```
switch(config-nexthop-group-NH-1)#entry 0 tunnel-destination 10.13.4.4
switch(config-nexthop-group-NH-1)#entry 1 tunnel-destination 10.15.4.22
switch(config-nexthop-group-NH-1)#entry 2 tunnel-destination 10.15.5.37
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
  size 4
ttl 64
  entry 0 tunnel-destination 10.13.4.4
  entry 1 tunnel-destination 10.15.4.22
  entry 2 tunnel-destination 10.15.5.37
switch(config-nexthop-group-NH-1)#

- These commands configure a nexthop group with three IPv6 nexthop entries.

switch(config)#nexthop-group nhg-v6-mpls type ip
switch(config-nhg-v6-mpls)#size 3
switch(config-nhg-v6-mpls)#entry 0 nexthop 2002::6401:1
switch(config-nhg-v6-mpls)#entry 1 nexthop 2002::6404:1
switch(config-nhg-v6-mpls)#entry 2 nexthop 2002::6404:2
switch(config-nhg-v6-mpls)#

- These commands configure an IPv4 route to point to the nexthop group nhg-v6-mpls. (Both IPv4 routes and IPv6 routes can point to this nexthop group.)

switch#ip route 100.5.0.0/16 Nexthop-Group nhg-v6-mplsp
switch#

Displaying Nexthop Groups

The `show nexthop-group` command displays a group’s configured parameters.

This command displays the properties of the nexthop group named **NH-1**.

```
switch>show nexthop-group NH-1
Name Id type size ttl sourceIp
NH-1 4 ipInIp 256 64 0.0.0.0
switch>
```

Applying a Nexthop Group to a Static Route

The `ip route nexthop-group` associates a nexthop group with a specified destination address and configures the encapsulation method for packets tunneled to that address.

This command creates a static route in the default VRF, using the nexthop group of **NH-1** to determine the next hop address.

```
switch(config)#ip route 10.17.252.0/24 nexthop-group NH-1
switch(config)#
```
The `show ip route` command displays the routing table for a specified VRF. Routes that utilize a nexthop group entry are noted with a route type code of `NG`.

This command displays a routing table that contains a static route with its nexthop specified by a nexthop group.

```
switch>show ip route
Codes: C - connected, S - static, K - kernel, 
      O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1, 
      E2 - OSPF external type 2, N1 - OSPF NSSA external type 1, 
      N2 - OSPF NSSA external type2, B I - iBGP, B E - eBGP, 
      R - RIP, I - ISIS, A B - BGP Aggregate, A O - OSPF

Gateway of last resort is not set

C      10.3.3.1/32 is directly connected, Loopback0
C      10.9.1.0/24 is directly connected, Ethernet51/3
C      10.10.10.0/24 is directly connected, Ethernet51/1
S      10.20.0.0/16 [20/0] via 10.10.10.13, Ethernet51/1
C      10.10.11.0/24 is directly connected, Ethernet3
NG     10.10.3.0/24 [1/0] via ng-test1, 5
C      10.17.0.0/20 is directly connected, Management1

S      10.22.0.0/16 [1/0] via 10.17.0.1, Management1

switch>
```

13.9.3 Support for IPv6 Link-Local Addresses in Nexthop Groups Entries

IPv6 Link-local addresses in Nexthop Groups entries support IPv6 link-local nexthops belonging to a Nexthop Group. Only the MPLS Nexthop Group supports IPv6 and because of this, IPv6 is limited to getting support only by the Nexthop Group of MPLS. An advantage is that you can use these devices even when they are not configured with globally routable IPv4 or IPv6 addresses.

13.9.3.1 Configuration

An MPLS next-hop group with IPv6 address now accepts an interface if the IPv6 address is a link-local. Note the use of percentages between the IPv6 address and the interface.

```
switch(config)#nexthop-group nhg1 type mpls
switch(config-nexthop-group-nhg1)#entry 0 push label-stack 606789 nexthop
   fe80::fe80:2%Ethernet2
switch(config-nexthop-group-nhg1)#entry 1 push label-stack 204164 nexthop
   fe80::fe80:2%Ethernet3
```

13.9.3.2 Show Commands

Use the `show nexthop-group` command to display the current status of the nexthop-groups.

```
switch#show nexthop-group
nhg1
```
<table>
<thead>
<tr>
<th>Id</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>mpls</td>
</tr>
<tr>
<td>Size</td>
<td>12</td>
</tr>
</tbody>
</table>

Entries (left most label is the top of the stack)

0  push label-stack 606789   nexthop fe80::fe80:2   
    Tunnel destination directly connected, Ethernet2  
    00:d4:27:77:e9:77, Ethernet2  

1  push label-stack 204164   nexthop fe80::fe80:2   
    Tunnel destination directly connected, Ethernet3  
    00:79:21:32:0f:32, Ethernet3  

13.9.3.3 Limitations

Review the following limitations for the support of IPv6 link-local address in nexthop group entries:

- Only the nexthop-group of MPLS supports an IPv6 address. Therefore, link-local IPv6 addresses are only supported for this type of nexthop-group.
- Nexthop-groups are configured and exist in the default VRF. The link-local IPv6 addresses for nexthop-group entries can only be resolved for interfaces in the default VRF.
13.9.4 Nexthop Group Commands

Nexthop Commands

- entry (Nexthop Group)
- ip route nexthop-group
- nexthop-group
- size (Nexthop Group)
- ttl (Nexthop Group)
- tunnel-source (Nexthop Group)

Nexthop Show Command

- show nexthop-group
13.9.4.1 entry (Nexthop Group)

The `entry` command defines a nexthop entry in the `nexthop group` configuration mode. Each nexthop entry specifies a nexthop IP address for static routes to which the nexthop group is assigned. The group size (size (Nexthop Group)) specifies the quantity of entries a group contains. Each entry is created by an individual command. Entries within a group are distinguished by an index number.

The `no entry` and `default entry` commands delete the specified nexthop group entry, as referenced by index number, by removing the corresponding `entry` statement from `running-config`.

**Command Mode**

Nexthop-group Configuration

**Command Syntax**

```
entry index tunnel-destination ipv4_address
no entry index
default entry index
```

**Parameters**

- `index` Entry index. Values range from 0 to `group-size – 1`.
- `ipv4_address` Nexthop IPv4 address.
- `group-size` is the group’s entry capacity, as specified by the size (Nexthop Group) command.

**Example**

These commands sets the nexthop group size at four entries, then creates three nexthop entries. Packets that are hashed to the fourth entry are dropped.

```
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#size 4
switch(config-nexthop-group-NH-1)#entry 0 tunnel-destination 10.13.4.4
switch(config-nexthop-group-NH-1)#entry 1 tunnel-destination 10.15.4.22
switch(config-nexthop-group-NH-1)#entry 2 tunnel-destination 10.15.5.37
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
  size 4
  ttl 64
  entry 0 tunnel-destination 10.13.4.4
  entry 1 tunnel-destination 10.15.4.22
  entry 2 tunnel-destination 10.15.5.37
switch(config-nexthop-group-NH-1)#
```
ip route nexthop-group

The `ip route nexthop-group` command creates a static route. The destination is a network segment. The nexthop address is one of the IP addresses that comprise the specified nexthop group. Packets forwarded as a result of this command are encapsulated as specified by the tunnel-type parameter of the specified nexthop group.

When multiple routes exist to a destination prefix, the route with the lowest administrative distance takes precedence. When a route created through this command has the same administrative distance as another static route (ECMP), the route that was created earliest has preference; `running-config` stores static routes in the order that they are created.

By default, the administrative distance assigned to static routes is 1. Assigning a higher administrative distance to a static route configures it to be overridden by dynamic routing data. For example, a static route with a distance value of 200 is overridden by OSPF intra-area routes, which have a default distance of 110.

The `no ip route nexthop-group` and `default ip route nexthop-group` commands delete the specified route by removing the corresponding `ip route nexthop-group` command from `running-config`. `Ip route nexthop-group` statements for an IP address in multiple VRFs must be removed separately.

A `no ip route` or `default ip route` command without a nexthop parameter deletes all corresponding `ip route nexthop-group` statements. Deleting a user-defined VRF also deletes its static routes.

Command Mode
Global Configuration

Command Syntax

```
ip route [VRF_INST] dest_net nexthop-group nhgp_name [dist][TAG_OPTION][RT_NAME]
no ip route [VRF_INST] dest_net [nexthop-group nhgroup_name][distance]
default ip route [VRF_INST] dest_net [nexthop-group nhgroup_name][distance]
```

Parameters

- **VRF_INST**  Specifies the VRF instance being modified.
  - `no parameter`  Changes are made to the default VRF.
  - `vrf vrf_name`  Changes are made to the specified VRF.
- **dest_net**  Destination IPv4 subnet (CIDR or address-mask notation).
- **nhgp_name**  Name of nexthop group.
- **dist**  Administrative distance assigned to route. Options include:
  - `no parameter`  Route assigned default administrative distance of one.
  - `1-255`  The administrative distance assigned to route.
- **TAG_OPTION**  Static route tag. Options include:
  - `no parameter`  Assigns default static route tag of 0.
  - `tag t_value`  Static route tag value. `t_value` ranges from 0 to 4294967295.
- **RT_NAME**  Associates descriptive text to the route. Options include:
  - `no parameter`  No text is associated with the route.
  - `name descriptive_text`  The specified text is assigned to the route.

Related Commands

The `ip route` command creates a static route that specifies the nexthop address without using nexthop groups.
Example
This command creates a static route in the default VRF, using the nexthop group of **NH-1** to determine the next hop address.

```
switch(config)# ip route 10.17.252.0/24 nexthop-group NH-1
switch(config)#
```
13.9.4.3  nexthop-group

The `nexthop-group` command places the switch in `nexthop-group` configuration mode, through which nexthop groups are created or modified. The command also specifies the tunnel protocol for extracting payload from encapsulated packets that arrive through an IP address upon which the group is applied.

A nexthop group is a data structure that defines a list of nexthop addresses and the encapsulation process for packets routed to the specified address. The command either accesses an existing `nexthop group` configuration or creates a new group if it specifies a non-existent group. Supported tunnel protocols include IP ECMP and IP-in-IP.

The `nexthop-group` configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting the `nexthop-group` configuration mode does not affect `running-config`. The `exit` command returns the switch to `global` configuration mode.

The `no nexthop-group` and `default nexthop-group` commands delete previously configured commands in the specified `nexthop-group` mode. When the command does not specify a group, it removes all nexthop-groups. When the command specifies a tunnel type without naming a group, it removes all nexthop-groups of the specified type.

**Command Mode**

Global Configuration

**Command Syntax**

```
 nexthop-group group_name type TUNNEL_TYPE
 no nexthop-group [group_name][type TUNNEL_TYPE]
 default nexthop-group [group_name][type TUNNEL_TYPE]
```

**Parameters**

- `group_name` Nexthop group name.
- `TUNNEL_TYPE` Tunnel protocol of the nexthop-group. Options include:
  - `ip` ECMP nexthop.
  - `ip-in-ip` IP in IP tunnel.
  - `gre` Encapsulates the Layer 3 protocols overs IP networks.
  - `mpls-over-gre` Tunnels MPLS over a non-MPLS network.
    - `entry` Nexthop Group Entry Configuration.
    - `size` Nexthop Group Entry Size.
    - `tos` Tunnel encapsulation IP type of service.
    - `ttl` Tunnel encapsulation TTL value.
    - `tunnel-source` Source Interface or Address.

**Commands Available in Nexthop-group Configuration Mode**

- `entry (Nexthop Group)`
- `size (Nexthop Group)`
- `ttl (Nexthop Group)`
- `tunnel-source (Nexthop Group)`

**Restrictions**

Tunnel type availability varies by switch platform.

**Examples**

- This command creates a nexthop group named `NH-1` that specifies ECMP nexthops.

```
switch(config)#nexthop-group NH-1 type ip
```
• This command exits nexthop-group mode for the **NH-1** nexthop group.

```
switch(config-nexthop-group-NH-1)#exit
switch(config)#
```

• These commands creates a nexthop group **NH-2** of type MPLS over GRE.

```
switch(config)#nexthop-group NH-2 type mpls-over-gre
tunnel-source 11.1.1.1
ttl 32
tos 20
tunnel-destination 11.1.1.2
entry 0 push label-stack 16000
```

```
switch(config)#ip route 100.1.1.1/32 Nexthop-Group NH-2
```

Counters for nexthop group may be enabled using the following command:

```
switch(config)#hardware counter feature nexthop
```
13.9.4 show nexthop-group

The `show nexthop-group` command displays properties of the specified nexthop group.

**Command Mode**
EXEC

**Command Syntax**

```
show nexthop-group nhgroup_name [VRF_INST]
```

**Parameters**

- `nhgroup_name` Name of the group displayed by command.
- `VRF_INST` Specifies the VRF instance for which data is displayed.
  - `no parameter` Context-active VRF.
  - `vrf vrf_name` Specifies the name of VRF instance. System default VRF is specified by `default`.

**Related Commands**

The `show nexthop-group` command places the switch in the `nexthop-group` configuration mode to create a new group or modify an existing group.

**Example**

This command displays the nexthop group information.

```
switch(config)#show nexthop-group
  Id      107
  Type    mplsOverGre
  Size    1 (auto size enabled, programmed size 1)
  TTL     32
  Source IP 11.1.1.1
  Entries (left most label is the top of the stack)
    0  push label-stack 16000  tunnel-destination 11.1.1.2
    Tunnel destination directly connected, Ethernet1
    00:00:aa:aa:aa:aa, Ethernet1

With nexthop group counter enabled
switch(config)#show nexthop-group
  Id      1
  Type    mplsOverGre
  Size    1 (auto size enabled, programmed size 1)
  TTL     64
  Source IP 0.0.0.0
  Entries (left most label is the top of the stack)
    0  push label-stack 16000  tunnel-destination 1.1.1.2
    Tunnel destination directly connected, Ethernet1
    00:00:aa:aa:aa:aa, Ethernet1
    0 packets, 0 bytes

switch(config)#show nexthop-group summary
Number of Nexthop Groups configured: 1
Number of unprogrammed Nexthop Groups: 0

   Nexthop Group Type   Configured
----------------------- -----------
   MPLS over GRE         1

   Nexthop Group Size   Configured
----------------------- -----------
   1                      1
```
13.9.4.5 size (Nexthop Group)

The `size` command configures the quantity of nexthop entries in the `nexthop group` configuration mode. Each entry specifies a nexthop IP address for static routes to which the group is assigned. Entries are configured with the `entry (Nexthop Group)` command. The default size is 256 entries.

The `no size` and `default size` commands restore the size of the configuration mode nexthop group to its default of 256 by removing the corresponding `size` command from `running-config`.

**Command Mode**

Nexthop-group Configuration

**Command Syntax**

```
size entry_size
no size entry_size
default size entry_size
```

**Parameter**

*entry_size* Group size (entries). Value ranges from 1 to 255. Default value is 256.

**Example**

This command configures the nexthop group *NH-1* to contain 128 entries.

```
switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#size 128
switch(config-nexthop-group-NH-1)#show active
nexthop-group NH-1
    size 128
    ttl 64
switch(config-nexthop-group-NH-1)#
```
13.9.4.6  ttl (Nexthop Group)

The `ttl` command specifies the number entered into the TTL (time to live) encapsulation field of packets that are transmitted to the address designated by the configuration mode `nexthop group`. The default TTL value is 64.

The `no ttl` and `default ttl` commands restore the default TTL value written into TTL fields for the `nexthop group` configuration mode by deleting the corresponding `ttl` command from `running-config`.

Command Mode
Nexthop-group Configuration

Command Syntax

```
ttl hop_expiry
no ttl hop_expiry
default ttl hop_expiry
```

Parameters

`hop_expiry`  Period that the packet remains valid (seconds or hops) Value ranges from 1 to 64.

Restrictions

This command is available only to Nexthop groups for tunnels of type IP-in-IP, GRE, MPLS, and MPLS over GRE.

Related Commands

The `nexthop-group` command places the switch in the `nexthop-group` configuration mode.

### Examples

- This command configures the `ttl` setting to 32 for nexthop group `NH-1` packets.

  ```
  switch(config)#nexthop-group NH-1
  switch (config-nexthop-group-NH-1)#ttl 32
  switch (config-nexthop-group-NH-1)#show active
  nexthop-group NH-1
  size 128
ttl 32
  switch (config-nexthop-group-NH-1)#
  ```

- This command restores the `no ttl` setting for nexthop group `NH-1` packets.

  ```
  switch (config-nexthop-group-NH-1)#no ttl
  switch (config-nexthop-group-NH-1)#show active nexthop-group
  NH-1
  size 128
ttl 64
  switch (config-nexthop-group-NH-1)#
  ```
13.9.4.7  tunnel-source (Nexthop Group)

The `tunnel-source` command specifies the address that is entered into the source IP address encapsulation field of packets that are transmitted as designated by the `nexthop group` configuration mode. The command may directly specify an IP address or specify an interface from which an IP address is derived. The default source address IP address is `0.0.0.0`.

The `no tunnel-source` and `default tunnel-source` commands remove the source IP address setting from the configuration mode nexthop group by deleting the `tunnel-source` command from `running-config`.

Command Mode
Nexthop-group Configuration

Command Syntax
```
tunnel-source SOURCE
no tunnel-source SOURCE
default tunnel-source SOURCE
```

Parameters

`SOURCE` IP address or derivation interface. Options include:

- `ipv4_addr` An IPv4 address.
- `intf ethernet e_num` Ethernet interface specified by `e_num`.
- `intf loopback l_num` Loopback interface specified by `l_num`.
- `intf management m_num` Management interface specified by `m_num`.
- `intf port-channel p_num` Port-channel interface specified by `p_num`.
- `intf vlan v_num` VLAN interface specified by `v_num`.

Restrictions

This command is available only to Nexthop groups for tunnels of type `ip-in-ip`.

Related Commands

The `nexthop-group` command places the switch in the `nexthop-group` configuration mode.

Example

These commands create `interface loopback 100`, assign an IP address to the interface, then specifies that address as the tunnel source for packets designated by nexthop-group `NH-1`.

```
switch(config)#interface loopback 100
switch(config-if-Lo100)#ip address 10.1.1.1/32
switch(config-if-Lo100)#exit

switch(config)#nexthop-group NH-1
switch(config-nexthop-group-NH-1)#tunnel-source intf loopback 100
switch(config-nexthop-group-NH-1)#show active nexthop-group NH-1
  size 256
ttl 64
tunnel-source intf Loopback100
switch(config-nexthop-group-NH-1)#show nexthop-group NH-1
Name  Id  type  size  ttl  sourceIp
NH-1  2  ipInIp  256  64  10.1.1.1
```
switch(config-nexthop-group-NH-1)#
13.10 Global Knob to Set MTU for all Layer 3 Interfaces

- Global Layer 3 Maximum Transfer Unit (MTU) feature provides a CLI command to set the MTU value for all Layer 3 interfaces.
- The default value for global Layer 3 MTU and for each interface Layer 3 MTU is **1500**.
- Any interface which has an MTU configured is not affected by the global L3 MTU.
- When the global L3 MTU is changed, any existing interfaces which are using the default are updated to use the new MTU. Any additional interfaces which are configured in the future will also use the new default MTU.

The related sections are:
- Global Knob to Set MTU for all Layer 3 Interfaces Configuration
- Show Commands
- Limitations

13.10.1 Global Knob to Set MTU for all Layer 3 Interfaces Configuration

The global L3 `mtu` command is under `interface-defaults` sub-mode. In this example, the MTU value is set to **1600**.

```
(config)#interface defaults
(config-interface-defaults)#mtu 1600
```

13.10.2 Limitations

The following are limitations for the Global knob to set MTU for all Layer 3 interfaces feature:
- Only Ethernet, Port-Channel, and VLAN interfaces are supported.
- Other interface types, such as Management, Loopback, VXLAN, and Tunnel, are not supported.

13.10.3 Show Commands

Use the `show interface` command to display the current MTU value applied on the selected interface. In the following example, interfaces Ethernet1, Ethernet2, and Ethernet3 are selected for display.

```
(config)#interface Ethernet3
(config-if-Et3)#no switchport
(config-if-Et3)#mtu 1600
(config-if-Et3)#interface defaults
(config-interface-defaults)#mtu 1700
(config-interface-defaults)#show interfaces Ethernet1
...
  IP MTU 1700 bytes (default) , BW 10000000 kbit
...
(config-interface-defaults)#show interfaces Ethernet2
...
  IP MTU 1700 bytes (default) , BW 10000000 kbit
...
(config-interface-defaults)#show interfaces Ethernet3
...```
In this example,

- switch Ethernet3 from Layer 2 to Layer 3 and explicitly set its MTU to **1600**.
- enter the `interface-defaults sub-mode`, set global L3 MTU to **1700**.
- the `show interface` command states Ethernet1 and Ethernet2 are using global L3 MTU value, while Ethernet3 are using its local MTU value.
- the `default` in the output indicates whether or not the interface is using global L3 MTU.
Layer 3 Configuration

13.11 Support for L3 MTU on 7280R3/7500R3/7800R3

Support for Layer 3 Maximum Transmission Unit (MTU) on 7280R3/7500R3/7800R3 switches includes the following:

- Enforces the MTU for Layer 3 packets on 7280R3/7500R3/7800R3 switches. The MTU can be set on any SVI and the MTU of that specific SVI is enforced when the packets egress out of a trunk port. This behavior is not supported on 7280E/R/R2 and 7500E/R/R2 line cards.
- MTU enforcement is done after adding all of the encapsulation headers in the Egress packet. For example, if an interface is configured with an MTU value of 1500 and the packet size is larger than 1500 with all encapsulation headers added, the packet is considered MTU violated. In 7280E/R/R2 and 7500E/R/R2 line cards, MTU is enforced before adding encapsulation headers.
- Actual MTU configured in hardware is MTU configured in the CLI + 18 bytes. 18 bytes is added to accommodate the L2 header. If the outgoing packet is untagged, the actual MTU configured in hardware is the MTU configured in the CLI + four (4) bytes.

13.11.1 Layer 3 MTU Configuration

You can configure Layer 3 MTU on Layer 3 interfaces and SVI’s using the `mtu` command within interface configuration mode.

This command sets the MTU size of 1492 bytes on `interface ethernet 1/1`.

```
(config)#interface ethernet 1/1
(config-if-Et1/1)#mtu 1492
```

MTU is independently configurable on all routable interfaces. The switch supports MTU sizes ranging from 68 to 9214 bytes. The default MTU size is 1500 bytes.

The `no mtu` and `default mtu` commands restore the interface’s MTU to the default value by removing the corresponding `mtu` command from `running-config`.

13.11.2 Layer 3 MTU Show Commands

The `show interfaces` command displays the MTU configured on the L3 interface. In this example, `ethernet 1/1` interface is selected to display. IP MTU represents the Layer 3 MTU of the interface.

```
switch(config-if-Et9/1)#show interfaces ethernet 1/1
... IP MTU 1600 bytes, BW 100000000 kbit Full-duplex, 100Gb/s over 4 lanes, auto negotiation: off, uni-link: n/a ...
```

13.11.3 L3 MTU Limitations

The following limitations apply to support of Layer 3 MTU:

- Only three (3) unique MTU values can be configured on a switch. If the number of unique MTU values exceeds three (3), additional unique MTU definitions will not be enforced on an interface.
• When the number of unique MTU values becomes less than three (3) (after unconfiguring MTU on some interfaces), MTU on interfaces that are previously unprogrammed, are not reprogrammed automatically. CLI commands `no mtu` followed by `mtu` must be called to program MTU on an interface.

• When the startup configuration has more than three (3) unique MTU values defined on different interfaces of the switch, there is no guarantee which unique MTU values will be active when the switch is rebooted.

• L3 MTU is not enforced on Multicast packets for Jericho2 based platforms.
13.12 Segment Security

- Overview
- Configuring Segment Security
- Show Commands
- Limitations
- Segment Security Commands

13.12.1 Overview

The Segment Security provides the convenience of applying policies on segments rather than interfaces or subnets. Hosts or networks are classified into segments based on prefixes. Grouping prefixes into segments allows for definition of policies between segments that govern flow of traffic between them. Policies define inter-segment or intra-segment communication rules. For example, segment A can communicate with segment B but hosts in segment B can not communicate with each other.

By default, traffic destined to a given segment is dropped and explicit allow policies are required to allow communication. Policy configurations in Segment security are unidirectional. To allow or drop traffic between two segments forward or drop policy configuration in both segments is required.

Licensing

The Segment security requires an E license to be fully supported at device level. When running in combination with CloudVision, Cloud Vision Full license is required.

Supported Functionalities

- Maximum of 60 segments can be configured across all VRFs.
- Support for both IPv4 and IPv6 match-list configuration.
- Single segment can be defined using both IPv4 and IPv6 match-lists.
- Feature can be enabled without need to enable routing.
- Built-in policies to permit or drop policy traffic.
- Policies configured are applied to both bridged and routed traffic.
- Traffic from/to VLANs with no SVI configuration are considered to be part of default VRF and subject to policies defined in default VRF.

13.12.2 Configuring Segment Security

Consider the following steps to configure the Segment security in the switch:

1. Define prefix-ipv4, prefix-ipv6 match lists.
2. Define segments using match lists.
3. Define policies between segments.

Define IPv4, IPv6 Match-list

Use `match-list` command under `global` configuration mode to define a IPv4/IPv6 subnet list as shown below. In the below example we have defined two prefix-ipv4 match lists and two prefix-ipv6 lists namely `camera-prefixes` and `admin-prefixes`.

Example

```
switch(config)#match-list input prefix-ipv4 camera-prefixes
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 69.89.31.200/32
```
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 69.89.31.201/32
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 70.89.31.0/24
!
switch(config)#match-list input prefix-ipv6 camera-prefixes
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2001:0:9d38:6ab8::/64
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2002:0:9d38:6ab8::3/128
!
switch(config)#match-list input prefix-ipv4 admin-prefixes
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 80.80.0.0/16
!
switch(config)#match-list input prefix-ipv6 admin-prefixes
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2003:0:9d38:6ab8::/64
!

Match-list name is unique within a type. A match-list can share the same name across IPv4 and IPv6 configuration.

Define Segments using Match-lists

Under router segment-security mode, goto vrf vrf-name sub-mode and create named segments. The segments are bound to the prefix-ipv4 and/or prefix-ipv6 match list created earlier.

Example

```text
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
switch(config-router-seg-sec-vrf-default)#segment camera
switch(config-router-seg-sec-vrf-segment-camera)#definition
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv4 camera-prefixes
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv6 camera-prefixes
!
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
switch(config-router-seg-sec-vrf-default)#segment secure-admin
switch(config-router-seg-sec-vrf-segment-camera)#definition
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv4 admin-prefixes
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv6 admin-prefixes
!
!
```

Note: Top level mode starts with router keyword however feature does not require routing to be enabled on switch.

Define Policies between Segments

There are two built-in policies defined policy-forward-all and policy-drop-all to forward and drop traffic between segments. For example, in the segments defined in the previous section, to allow segment admin access to segment camera, we need to allow bidirectional traffic by using policy-forward-all.
In the policy sub-mode under segment mode, the segment name after from token refers to the source of the flow.

```
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
switch(config-router-seg-sec-vrf-default)#segment camera
switch(config-router-seg-sec-vrf-segment-camera)#definition
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv4 camera-prefixes
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv6 camera-prefixes
!
switch(config)#router segment-security
switch(config-router-seg-sec)#policies
switch(config-router-seg-sec-policies)#from secure-admin policy policy-forward-all
!
```

Enable Segment Security

By default, the Segment security is not enabled in the switch. In order to enable the Segment security, run a no shutdown command within the router segment-security mode. Use the shutdown form of the command to disable the Segment security feature.

```
switch(config)#router segment-security
switch(config-router-seg-sec)#no shutdown
```

Default Drop Behavior

By default, after enabling the Segment security feature, all traffic destined to the defined segment is dropped unless explicitly permitted by policy-forward-all policy rules. This includes intra-segment traffic. To change this default behavior use the following command under router segment-security mode.

```
switch(config)#router segment-security
switch(config-router-seg-sec)#no no segment policy policy-drop-all default
```

After changing default intra-segment traffic is allowed. For example, to limit nodes in the camera’s segment communicating with each other, policy-drop-all rules for intra-segment traffic need to be defined.

```
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
```
13.12.3 Limitations

- Multicast and Link Local prefixes are not supported.
- Traffic disruption during prefix and policy configuration is expected. We do not support atomicity during segment and prefix configuration.
- MSS-Group and URPF feature interaction is not supported. If both features are configured (misconfiguration), the platform gives URPF higher priority and removes any existing segment configurations from hardware.
- Prefixes entries failed to get installed in hardware (because of insufficient hardware resources) are retried periodically till resources become available and prefixes are successfully installed. However, the same is not true for policy entries. There is no retry mechanism implemented for failed policy entries. The user needs to free up hardware resources and re-enable the MSS-Group feature after removing it once.
- Custom policies can not be configured. Clients can choose from two built-in policies ‘policy-drop-all’ and ‘policy-forward-all’.
- A given prefix can only be part of a single segment in VRF. Attempting to configure the same prefix in more than one segment leads to undefined traffic forwarding behavior.
- The same prefix can not be configured in both MSS-Group and MSS-L3 configurations.
- SSU can be performed with MSS-Group configured but the traffic flows for MSS-Group configuration will not be hitless.
- DHCP discovery packets with broadcast destination IP of 255.255.255.255 will only match 0.0.0.0/0 prefix.
- All traffic sourced from and/or destined to switch owned IPs are allowed regardless of MSS-Group configuration.
- Due to source and destination IP lookup being required, the capacity of the LPM table is halved when MSS-G is enabled. The host table capacity is unchanged as the source and destination lookup is always enabled by default.

13.12.4 Show Commands

- Use the `show segment-security` command to verify the state of configuration.

```
switch#show segment-security
VRF : default
Segment     Interfaces   Prefix IPv4     Prefix IPv6     From Segment Policy
----------- ---------- --------------- --------------- ------------- ------------------
camera      camera-prefixes camera-prefixes secure-admin policy-forward-all
secure-admin admin-prefixes admin-prefixes camera policy-forward-all
```

- Use the `show match-list` command to verify the match list.

```
switch#show match-list prefix-ipv4
Name     Prefix
---------- ---------------
admin-prefixes  80.80.0.0/16
```
camera-prefixes 69.89.31.200/32
69.89.31.201/32
70.89.31.0/24

switch#show match-list prefix-ipv6
Name Prefix
--------------- -----------------------
admin-prefixes 2003:0:9d38:6ab8::/64
camera-prefixes 2001:0:9d38:6ab8::/64
2002:0:9d38:6ab8::3/128

- Use the `show segment-security hardware summary` command to display hardware ID allocated to the configured segment, number of prefixes configured and number of prefixes successfully programmed in hardware.

switch#show segment-security hardware summary
VRF: default
Segment Hardware ID Prefixes Programmed
--------------- ------------------------ ----------
camera 63 5 5
secure-admin 62 2 2

- Use the `show segment-security hardware detail` command hardware ID allocated to the configured segment, prefixes programmed in hardware and adjacency index used by prefix (as prefixes use L3 hardware tables).

switch#show segment-security hardware detail
VRF: default
Segment Hardware ID Prefixes Adj Ind  ex
------------- --------------- ------------------------- ---------------
camera 63 69.89.31.200/32 1
69.89.31.201/32 1
70.89.31.0/24 1
2001:0:9d38:6ab8::/64 2
2002:0:9d38:6ab8::3/128 2
secure-admin 62 80.80.0.0/16 1
2003:0:9d38:6ab8::/64 2

- As MSS-Group prefixes use L3 hardware tables which means the prefixes can overlap with FIB routes. There are following three classifications possible for a configured prefix:
  - Prefix is not overlapping with FIB route. In this case Route Type will be classified as Segment prefix `S`.
  - Prefix was also configured in FIB. For example, the same /32 or /128 host prefix was already present in FIB. In this case Route Type will be classified as S,F, i.e. Segment and FIB prefixes are identical.
  - Prefix overlapped with FIB entry. For example /24 prefix was configured and processing logic has detected all FIB routes which fall under /24 need to be classified as segment prefixes. All such classified FIB routes have Route Type `F` i.e. FIB-only.

The `show segment-security hardware routes` command displays the status of route type for programmed prefixes in hardware.

switch#show segment-security hardware routes
Codes: S - Segment prefix
F - FIB route
S,F - Segment prefix which is also present in FIB
VRF: default
Segment Hardware ID Routes Route Type
--------------- ------------------------ ----------
camera 63 69.89.31.200/32 S
• Use the `show segment-security hardware counters` to display the policy and counters for policies configured for segments. For each policy configured between two segments a row shows Hit and Drop counters. Hit counter includes all policy hits regardless of action. Drop counter indicates packets dropped. Drop counter also accounts for packets dropped because of default drop when no policy match fails.

```
switch#show segment-security hardware counters
VRF: default
<table>
<thead>
<tr>
<th>Policy</th>
<th>Hit</th>
<th>Drop</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy-drop-all</td>

13.12.5 Segment Security Commands

Global Configuration Commands
- match-list
- router segment-security

Show Commands
- show match-list
- show segment-security
- show segment-security hardware
13.12.5.1 match-list

The **match-list** command is configured under the *global* configuration mode to define an IPv4/IPv6 subnet list which is then used in the Segment security configuration.

The **no match-list** command removes the IPv4/IPv6 subnet list configuration from the **running-config**.

**Command Mode**

Global Configuration Mode

**Command Syntax**

```
match-list
no match-list
```

**Example**

In the following example, we have defined two prefix-ipv4 match lists and two prefix-ipv6 lists, namely **camera-prefixes** and **admin-prefixes**.

```bash
switch(config)#match-list input prefix-ipv4 camera-prefixes
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 69.89.31.200/32
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 69.89.31.201/32
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 70.89.31.0/24
!
switch(config)#match-list input prefix-ipv6 camera-prefixes
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2001:0:9d38:6ab8::/64
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2002:0:9d38:6ab8::3/128
!
switch(config)#match-list input prefix-ipv4 admin-prefixes
switch(config-match-list-prefix-ipv4-camera-prefixes)#match prefix-ipv4 80.80.0.0/16
!
switch(config)#match-list input prefix-ipv6 admin-prefixes
switch(config-match-list-prefix-ipv6-camera-prefixes)#match prefix-ipv6 2003:0:9d38:6ab8::/64
```
13.12.5.2 router segment-security

The `router segment-security` command to create named segments, later the segments are bound to the prefix-ipv4 and/or prefix-ipv6 match list created earlier. The named segments are created under the VRF submode.

The `no router segment-security` command removes the segment security configuration from the `running-config`.

**Command Mode**
Global Configuration Mode

**Command Syntax**

`router segment-security`

`no router segment-security`

**Example**

In the following example, we are creating segments named `camera` and `secure-admin`.

```
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
switch(config-router-seg-sec-vrf-default)#segment camera
switch(config-router-seg-sec-vrf-segment-camera)#definition
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv4 camera-prefixes
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv6 camera-prefixes
!
switch(config)#router segment-security
switch(config-router-seg-sec)#vrf default
switch(config-router-seg-sec-vrf-default)#segment secure-admin
switch(config-router-seg-sec-vrf-segment-camera)#definition
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv4 admin-prefixes
switch(config-router-seg-sec-vrf-segment-def)#match prefix-ipv6 admin-prefixes
!```
13.12.5.3  show match-list

The show match-list command displays the IPv4 and IPv6 prefix match-list of the configured segments.

Command Mode
Privileged EXEC

Command Syntax
show match-list {prefix-ipv4 | prefix-ipv6} [list-name]

Parameters
• prefix-ipv4 IPv4 prefix list.
• prefix-ipv6 IPv6 prefix list.
• list-name Route Segment name.

Example
This command displays all the IP address matching the prefix list IPv4 and IPv6 mentioned.

```
switch#show match-list prefix-ipv4
Name            Prefix
--------------- ---------------
admin-prefixes  80.80.0.0/16
camera-prefixes 69.89.31.200/32
               69.89.31.201/32
               70.89.31.0/24

switch#show match-list prefix-ipv6
Name            Prefix
--------------- -----------------------
admin-prefixes  2003:0:9d38:6ab8::/64
camera-prefixes 2001:0:9d38:6ab8::/64
                    2002:0:9d38:6ab8::3/128
```
13.12.5.4  show segment-security

The show segment-security command displays the state of segment security configuration.

Command Mode
Privileged EXEC

Command Syntax
show segment-security [vrf vrf-name ]|segment seg-name|

Parameters
• vrf vrf-name VRF name.
• segment seg-name Route Segment name.

Example
This command displays the state of Segment security configuration.

```
switch#show segment-security
VRF : default
Segment Interfaces Prefix IPv4 Prefix IPv6 From Segment Policy
----------- ---------- --------------- --------------- ------------------
camera     ------------ camera-prefixes camera-prefixes secure-admin policy-forward-all
secure-admin admin-prefixes admin-prefixes camera policy-forward-all
```
13.12.5.5  show segment-security hardware

The `show segment-security hardware` command displays the detailed information about the hardware resources used by the Segment security feature.

**Command Mode**

Privileged EXEC

**Command Syntax**

```
show segment-security hardware {summary | detail | routes | counters}[ vrf vrf-name][segment seg-name]
```

**Parameters**

- **summary** displays the hardware ID allocated to the configured segment, number of prefixes configured and number of prefixes successfully programmed in hardware.
- **detail** displays the hardware ID allocated to the configured segment, prefixes programmed in hardware and adjacency index used by prefix (as prefixes use L3 hardware tables).
- **routes** displays the status ‘Route Type’ for programmed prefixes in hardware.
- **counters** displays the policy and counters for policies configured for segments.

**Examples**

- This command displays the hardware ID allocated to the configured segment, number of prefixes configured and number of prefixes successfully programmed in hardware.

  ```
  switch# show segment-security hardware summary
  VRF: default
  Segment              Hardware ID     Prefixes   Programmed
  ------------------- --------------- ---------- ----------
  camera              63              5          5
  secure-admin        62              2          2
  ```

- This command displays the hardware ID allocated to the configured segment, prefixes programmed in hardware and adjacency index used by prefix (as prefixes use L3 hardware tables).

  ```
  switch# show segment-security hardware detail
  VRF: default
  Segment        Hardware ID     Prefixes                 Adj Ind ex
  -------------- --------------- ------------------------ ------------
  camera         63              69.89.31.200/32           1
  69.89.31.201/32           1
  70.89.31.0/24             1
  2001:0:9d38:6ab8::/64     2
  2002:0:9d38:6ab8::3/128   2
  secure-admin   62              80.80.0.0/16              1
  2003:0:9d38:6ab8::/64     2
  ```

- This command displays the status ‘Route Type’ for programmed prefixes in hardware.

  ```
  switch# show segment-security hardware routes
  Codes: S - Segment prefix
          F - FIB route
          S,F - Segment prefix which is also present in FIB
  VRF: default
  Segment       Hardware ID   Routes                     Route Type
  ------------- ------------- -------------------------- ----------
  camera        63            69.89.31.200/32             S
  69.89.31.201/32           S
  70.89.31.0/24             S
  2001:0:9d38:6ab8::/64     S
  ```
This command displays the policy and counters for policies configured for segments.

```
switch# show segment-security hardware counters
VRF: default
Policy                  Hit  Drop
----------------------- ----- ----
policy-drop-all         6     6
policy-forward-all      13    0

Dest Segment      Source Segment      Policy  Hit  Drop
----------------- ------------------------ ------- ---- ----
camera           *                      n/a     0    3
camera           camera                 policy-forward-all 6    6
camera           secure-admin          4     0
secure-admin     *                      n/a     0    12
secure-admin     camera                 9     0
```
Chapter 14

IP Services

The Internet Protocol Services (IP Services) chapter contains the following section(s):

- CloudVision eXchange (CVX)

14.1 CloudVision eXchange (CVX)

CloudVision eXchange (CVX) provides a single access point for real-time provisioning, orchestration and integration with third-party controllers. CVX aggregates and distributes operational state information across a set of EOS switches to support applications that provide network services. See the CloudVision User Guide, https://www.arista.com/en/support/product-documentation, for additional information.

Topics in this section include:

- Upgrading CVX
- CVX Overview
- CVX Services
- Deploying CVX
- CVX Configuration
- CVX Secure out-of-band Connection
- CVX High Availability
- CVX VIP
- CVX Command Descriptions

14.1.1 Upgrading CVX

You can upgrade CVX from a previous version to the current version by performing a few simple tasks. You can use the following procedure to upgrade any previous version of CVX to the current version.

Requirements

Make sure you follow these requirements during the upgrade process.

- If you have CVP, CVX and client switches in your environment, make sure you upgrade each component in the following order:
  - Upgrade CVP first
  - Upgrade the CVX cluster.
  - Upgrade the client switches. The reason for this is to ensure backward compatibility.
  - You must upgrade the CVX cluster before you upgrade the client switches.
  - If the CVX cluster is a 3 node cluster, make sure that only one node of the cluster is down at any one time during the upgrade process. (The order in which you upgrade the nodes does not matter.)

Pre-requisites

Before you begin the upgrade, make sure that:

- You perform a backup to ensure that you can restore data if needed.
Complete the following steps to upgrade CVX.

1. Login to the cluster to be upgraded. (You can login to any node.)
2. Upgrade the node. You must deploy a new image to perform the upgrade.
3. Wait for the node you are upgrading to rejoin the cluster. Once the node has rejoined, go to the next step. (The node automatically rejoins the cluster as a follower node.)
4. Repeat steps 1 through 3 to upgrade the two remaining nodes one node at a time. It does not matter the order in which you upgrade the remaining nodes.

14.1.2 CVX Overview

A CVX deployment includes CVX and a set of CVX clients to which CVX provides services. CVX is not part of the data plane, nor does it receive data-path traffic. All CVX components exist as agents that run on EOS instances.

For more information, see:

• System Requirements
• CVX Infrastructure
• CVX Features
• CVX Clients

14.1.2.1 System Requirements

Certain hardware and software is required to be able to use CloudVision eXchange in your CloudVision virtual appliance implementation.

The CloudVision eXchange should be installed on a single system along with CloudVision Portal.

The following table lists the minimum hardware and software required to use CloudVision eXchange.

**Required Hardware**

The hardware required to use the CloudVision eXchange are:

• CPU: 4 cores (base), 8 cores (recommended)
• RAM: 4G (base), 8G (recommended)
• Disk: 4G

**Required Software**

The software required to use the CloudVision eXchange are:

• EOS switches: Recommend 4.16.8M or later

  **Note:** It is a best practice and highly recommended that the version of CVX should match the version running on the switches.

• CloudVision Portal: version 2016.1

  (CloudVision Portal software is required if you want to use it in conjunction with CloudVision eXchange. If you plan to use only CloudVision eXchange, CloudVision Portal software is not required.)

  **Note:** CVX supports live vMotion.

14.1.2.2 CVX Infrastructure

CVX provides a single integration point into network-wide services running across CVX clients. CVX is typically deployed as an EOS instance running on a VM (vEOS). The CVX infrastructure consists of a CVX instance functioning as a server and a set of CVX clients. The CVX server uses a heartbeat keepalive (KA) mechanism to maintain contact with its clients.

When de-configuring or shutting down CVX, client services should be shut down first.
14.1.2.3  CVX Features

CVX manages communications among the network CVX clients, and provides an integration point for services to those clients. CVX also discovers the physical network topology by aggregating topology information it receives from its client devices.

14.1.2.4  CVX Clients

CVX client is the agent that allows a switch to interact with a CVX server to access CVX services. Enabling the CVX client includes providing the IP address or host name of the device running CVX. The CVX client can then access services that are enabled on the CVX server.

The CVX client must be enabled to access the CVX server and the services it offers. Individual services may require additional configuration statements.

Services should be shut down or de-configured on clients before shutting down or de-configuring CVX. CVX-controlled switch features may continue to run after shutting down CVX if they are not explicitly shut down or de-configured prior to shutting down CVX.

14.1.3  CVX Services

CVX services are applications that run on top of the CVX infrastructure, and are accessed by CVX clients through the CVX server. All CVX services are maintained by version level; client switches negotiate the version they use when connecting to the server. This allows multiple switches that run different EOS versions to connect to the same CVX server.

The following sections briefly describe some of the services available to CVX clients through CVX:

- OpenStack Service
- VXLAN Control Service
- Hardware Switch Controller (HSC) Service
- Network Topology Service
- Static Topology Service

14.1.3.1  OpenStack Service

The OpenStack service on CVX allows the networking component of an OpenStack deployment (also known as Neutron) to share state with CVX.

When deployed, this integration allows CVX to send state about the logical networks created in the OpenStack cloud to the CVX clients that configure the network.

More information on OpenStack software can be found in its online documentation at http://docs.openstack.org/.

14.1.3.2  VXLAN Control Service

The VXLAN control service allows hardware VXLAN tunnel end points (VTEPs) to share state with each other in order to establish VXLAN tunnels without the need for a multicast control plane. Configuration is required both on the client switches and in CVX.

14.1.3.3  Hardware Switch Controller (HSC) Service

Traffic between virtual machines which share a physical host (or between virtual machines and the rest of the network) is forwarded by virtual switches. The management and configuration of virtual switches uses the Open vSwitch Database (OVSDB) management protocol, as described in RFC 7047.
The hardware switch controller (HSC) service provides an integration point between OVSDB controllers and the VXLAN control service, allowing exchange of state information among virtual and hardware switches.

14.1.3.4 Network Topology Service

The network topology service gathers information from CVX clients to provide a view of the physical topology of the network. Aggregated information gathered by the network topology service is used by other CVX services, and can be viewed on the CVX server.

14.1.3.5 Static Topology Service

Static Topology addresses cases where the deployment infrastructure in an OpenStack setup that manages Virtual Machines and Bare Metal servers does not enable LLDP on interfaces connecting hosts to switches. As a result, the topology information does not appear on CVX.

An example of this case is some deployments of OpenStack that do not enable LLDP for DPDK interfaces. Even with the manual configuration of LLDP on hypervisors, the configuration does not persist after OpenStack redeployment.

Static Topology enables the topology configuration statically using the `service topology` command on CVX without running LLDP on the servers connected to switches.

To view the aggregated topology information, use the `show network physical-topology` command on the switch running the CVX server instance.

14.1.4 Deploying CVX

CloudVision Exchange (CVX) can be deployed on KVM and ESXi. The required EOS version and Aboot version vary depending on whether you are deploying CVX on KVM or ESXi.

For the detailed steps to use to deploy CVX, see:

- Deploying CVX on Kernel-based Virtual Machine (KVM)
- Deploying CVX on VMware ESXi

14.1.4.1 Deploying CVX on Kernel-based Virtual Machine (KVM)

Complete the following steps to install CVX on Ubuntu/KVM. Once the installation is complete, you can begin the CVX configuration process.

**Note:** Make sure you select versions of EOS and Aboot that meet the minimum requirements for CVX. The supported versions are:

- EOS (version 4.16.8M or later)
- Aboot-veos-serial-8.0.0.iso (located in the vEOS section of the download)

**Pre-requisites**

Before you begin the procedure, make sure that:

- Install `qemu-kvm`, `libvirt*`, and all related dependencies using `yum` (RHEL7/CentOS7) and `apt-get` (Ubuntu).
- Two bridges are configured for use by the KVM VM, and that you have the names of the bridges. (Steps are included in the procedure to add bridges, if they are not already configured.)

**Note:** The bridges must be configured to persist (`brctl` commands do not persist across reboots). You can use Network Manager (or another application available to you) to complete this configuration.

- You have both `generateXmlForKvm.py` and `cvpTemplate.xml`. They are required to complete the procedure. You can find them in the CVP tarball for Ubuntu.
Complete the following steps to install CVX.

2. Use `sudo su` to acquire superuser privileges, which are required to complete some of the installation steps.
3. Confirm that KVM is running on the server by entering the following command:
   ```bash
   virsh -c qemu:///system listAb
   ``
   The command output should match this example:
   ```
   Id    Name     State
   $  
   ```
4. If the output does not look correct (previous step) go to for additional assistance: https://help.ubuntu.com/community/KVM/Installation.
5. Use the following command to convert the vmdk file to qcow2:
   ```bash
   qemu-img convert
   EOS_4_16_8M.vmdk -O qcow2 EOS.qcow2
   ``
   **Note:** Step 6 and 7 are required if you do not already have 2 bridges defined in different subnets. If the bridges exist, go directly to step 8.
6. Use `brctl` to add bridges for the KVM VM to use (br1 and br2 can be any names you choose).
   ```bash
   brctl addbr br1
   brctl addbr br2
   ```
   `ifconfig` can be used to identify Ethernet ports to be bridged. Once you identify the ports, add them to the bridges.
   **Example**
   ```bash
   brctl addif br1 enx803f5d086eae
   ```
7. Confirm that the bridges are up using `brctl show`.
   - Enter: `ifconfig br1 up`
   - And: `ifconfig br2 up`
   **Note:** The following step uses a number of input parameters (the number required vary depending on your server setup). To ensure the command executes successfully, we recommend that you type it into a scratch pad and edit as needed before typing it into the Linux Terminal.
8. Use the following command to generate `cvx.xml`, which will be used to setup the CVX VM.
   ```bash
   generateXmlForKvm.py
   ```
   **Example**
   ```bash
   python generateXmlForKvm.py -n cvx --device-bridge br1 --cluster-bridge br2 -e /usr/bin/kvm -i cvpTemplate.xml -c /home/mynname/Downloads/Aboot-veos-serial-8.0.0.iso -x /home/mynname/Downloads/EOS.qcow2 -b 8192 -p 2 -t
   ```
   - **-n cvx:** VM name.
   - **--device-bridge br1:** This is the name you gave the bridge - br1 or anything else.
   - **--cluster-bridge br2:** Cluster bridge if clustering servers.
   - **-i cvpTemplate.xml:** Path to XML file input template.
   - **-k:** VM ID number used by virsh. If not entered, a random number is assigned.
   - **-b 8192:** 8G of RAM.
   - **-p 2:** # of CPU cores.
   - **-c:** Path to Aboot file.
   - **-x:** Path to qcow2 file created in step 3.
-t: This parameter indicates the file defined by -x is for CVX.
-e \"/usr/bin/kvm\": Ubuntu path to KVM.
(for RHEL KVM this is: -e \"/usr/libexec/qemu-kvm\")
-o: XML file used by virsh to define the KVM VM.

9. Run the following commands:

```bash
virsh define cvx.xml
virsh start cvx
virsh console cvx
```

10. (Optional) To configure CVX to start automatically, enter:

```bash
virsh autostart cvx
```

You are now ready to begin the CVX configuration (see CVX Configuration).

14.1.4.2  Deploying CVX on VMware ESXi

Complete the following steps to install CVX on ESXi. Once the installation is complete, you can begin the CVX configuration process.

Note: Make sure you select versions of EOS that meet the minimum requirements for CVX. The supported version is EOS (version 4.21.0 or later).

Complete the following steps to install CVX.

2. Select Support > Software Download.
3. From the software download page, expand Active Releases > 4.21 > EOS-4.21.0F to download EOS-4.21.0F.vmdk.
4. Load the files you downloaded into a filestore location within the VMware vSphere environment.

![Figure 36: Loading the files into the VMware vSphere environment](image)

5. Right-click the filestore location you selected, and choose New Virtual Machine.
Figure 37: Selecting New Virtual Machine

The New Virtual Machine dialog appears.

Figure 38: New Virtual Machine dialog

6. In the New Virtual Machine dialog, select **Create a new virtual machine**, then click **Next**.

The dialog refreshes, showing options for the new Virtual Machine.

New Virtual Machine dialog (naming and selecting the location)
7. Enter a name for the new Virtual Machine.
8. Select a location for the new Virtual Machine, then click Next.

9. Select the datastore for the new Virtual Machine configuration files and all of the virtual disks.
   - Click Next.

10. The dialog refreshes, showing operating system selection options.
    Click Next.
The dialog refreshes, showing compatibility options.

Figure 41: New Virtual Machine dialog (compatibility options)

11. Using the Compatible with menu, select the **ESXi compatibility** for the new Virtual Machine.

   **Note:** When adding the VMDK to ESX6, it treats this as sparse by default, whereas in ESX 5 it is thick. Converting the vEOS VMDK file from thin to thick would allow it to boot properly in ESX6: `vmkfstools -i vEOS-lab-4.18.5M.vmdk -d eagerzeroedthick vEOS-lab-4.18.5M-thick.vmdk`.

    Go to [https://eos.arista.com/](https://eos.arista.com/) and refer to the following topics for the issue and solution:
    - Tip for Arista vEOS on VMware ESX 6
    - Common Issues When Deploying CVX 4.18.2F on vCenter 6 or 6.5

    **Note:** If the VM keeps rebooting and showing "This is not a bootable disk. Insert a bootable floppy and press any key to try again", then go to [https://eos.arista.com/](https://eos.arista.com/) and refer to the **Common Issues When Deploying CVX 4.18.2F on vCenter 6 or 6.5** topic.

12. Click **Next**.

    The dialog refreshes, showing operating system selection options.
13. Using the Guest OS Family menu, choose Linux.

14. Using the Guest OS Version menu, choose Other Linux (64-bit).

15. Click Next.

The dialog refreshes, showing options for customizing hardware.
16. Change the default settings for the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>Set to 4 (number of CPUs)</td>
</tr>
<tr>
<td>Memory</td>
<td>Set to 8 GB</td>
</tr>
<tr>
<td>New Hard Disk</td>
<td>Delete the current setting (leave this option empty)</td>
</tr>
<tr>
<td>New Network</td>
<td>Specify connection to Network LAN segment with connectivity to CVX client devices (the Management LAN). Choose VMXNET3 network adapter type. This connection is used for CVX client / server communications.</td>
</tr>
<tr>
<td>Existing Hard Disk</td>
<td>Specify the EOS-4.21.0F.vmdk you downloaded in step 3.</td>
</tr>
</tbody>
</table>

17. (Optional) Delete the floppy drive and SCSI controller.

18. Click Next.

You are now ready to begin the CVX configuration (see CVX Configuration).

14.1.5 CVX Configuration

CVX, its clients, and its services, are independently configured. These sections describe configuration processes for each:

- Ports Used by CVX
- CVX Server Configuration
- CVX Client Configuration
- CVX Client Services Configuration

14.1.5.1 Ports Used by CVX

CVX uses the following ports:

- Controller database (Controllerdb): Port 9979
- Client-server out-of-band connection: Port 50003
• CVX cluster peer out-of-band connection: Port 50004

  Note: All of these connections are TCP.

14.1.5.2 CVX Server Configuration

Enabling CVX on the CVX Server

CVX parameters for the server infrastructure are configured in CVX configuration mode. CVX configuration mode is not a group-change mode; running-config is changed when commands are entered, and exiting the mode does not modify running-config. The cvx command places the switch in CVX configuration mode.

CVX is disabled by default. The no shutdown (CVX) command enables CVX on the switch.

Example

These commands enter CVX-configuration mode and enable CVX.

```
switch(config)#cvx
switch(config-cvx)#no shutdown
switch(config-cvx)#
```

CVX Heartbeat Configuration

CVX synchronizes with its client devices by exchanging heartbeat signals. The heartbeat transmission frequency and timeout period determine when a client’s access to the server is disrupted.

The interval between heartbeat messages that the server transmits is specified by the heartbeat-interval (CVX) command. The CVX timeout period is specified by the heartbeat-timeout (CVX) command. When CVX does not receive a subsequent heartbeat message from a CVX client before the timeout expiry, the server discontinues CVX services to that client.

Best practices dictate that CVX and its client applications configure identical heartbeat interval and heartbeat timeout values.

Example

These commands configure a CVX heartbeat interval of 30 seconds and a server heartbeat timeout period of 90 seconds.

```
switch(config-cvx)#heartbeat-interval 30
switch(config-cvx)#heartbeat-timeout 90
switch(config-cvx)#
```

Disabling CVX on the CVX Server

  Note: Before disabling or de-configuring CVX on the CVX server, CVX client services should be explicitly disabled or shut down. Failure to disable or de-configure services prior to disabling or de-configuring CVS may result in CVX features continuing to run after CVX shutdown.

When disabling the CVX service, service VXLAN configuration may be retained or erased. Be sure to disable or shut down client services prior to disabling the CVX service.

Examples

• These commands shut down the CVX service while retaining the CLI configuration for service VXLAN.

```
localhost(config)#cvx
localhost(config-cvx)#service vxlan
localhost(config-cvx-vxlan)#shutdown
```
IP Services

- These commands shut down the CVX service and also erase service VXLAN CLI configuration.

```plaintext
localhost(config-cvx-vxlan)#
localhost(config)# cvx
localhost(config-cvx-)# no service vxlan
```

14.1.5.3 CVX Client Configuration

This section describes the CVX client configuration and commands that enable CVX services. Most commands for the configuration of the CVX client infrastructure are accessed in Management-CVX configuration mode.

- Enabling CVX on the CVX Client

CVX client parameters are configured in `Management-CVX configuration` mode. Management-CVX configuration mode is not a group-change mode; running-config is changed when commands are entered, and exiting the mode does not modify running-config. The `management cvx` command places the switch in `Management-CVX configuration` mode.

CVX client is disabled by default. The `no shutdown (Management-CVX)` command enables CVX client on the switch.

For the CVX network topology service to create an inventory of all CVX clients, ensure that LLDP is enabled on each client switch using the `lldp run` command.

**Example**

These commands enter `Management-CVX-configuration` mode and enable the CVX client.

```plaintext
switch(config)# lldp run
switch(config)# management cvx
switch(config-mgmt-cvx)# no shutdown
switch(config-mgmt-cvx)#
```

- CVX Client Heartbeat Configuration

A CVX client synchronizes and maintains contact with CVX by exchanging heartbeat signals. The heartbeat transmission frequency and timeout period define when communication with CVX will be considered down.

The interval between heartbeat messages that the CVX client transmits is configured by the `heartbeat-interval (Management-CVX)` command.

The CVX client timeout period is specified by the `heartbeat-timeout (Management-CVX)` command. When a CVX client does not receive a subsequent heartbeat message from CVX within this timeout period, the client assumes that services provided by CVX are no longer available.

Best practices dictate that a CVX client's heartbeat interval and heartbeat timeout values are identical to those of the CVX server to which it connects.

**Example**

This command configures a CVX client heartbeat interval of 30 seconds and client timeout period of 90 seconds.

```plaintext
switch(config-mgmt-cvx)# heartbeat-interval 30
switch(config-mgmt-cvx)# heartbeat-timeout 90
switch(config-mgmt-cvx)#
```

Connecting the CVX Client to a Server

The `server host (Management-CVX)` command identifies the location of the CVX server that the client accesses. The `source-interface (Management-CVX)` command specifies the interface
from which the client derives the IP address it uses as the source in CVX packets that it transmits. And the no shutdown (Management-CVX) command enables CVX on the client switch.

Example
These commands configure the switch as a CVX client, connecting to a CVX server at IP address 10.1.1.14 and using IP address 10.24.24.1 as the source address for its outbound packets.

```
switch(config)#interface loopback 5
switch(config-if-Lo5)#ip address 10.24.24.1/24
switch(config-if-Lo5)#management cvx
switch(config-mgmt-cvx)#server host 10.1.1.14
switch(config-mgmt-cvx)#source-interface loopback 5
switch(config-mgmt-cvx)#no shutdown
```

14.1.5.4  CVX Client Services Configuration
Switches running EOS must be configured as CVX clients to access the network services running on CVX. Individual services may require additional configuration.

Refer to the following for information regarding the services available to a CVX client.

- Configuring OpenStack Service
- Configuring VXLAN Control Service
- Configuring Hardware Switch Controller Service (HSC)
- Configuring Network Topology Service
- Configuring Static Topology Service

14.1.5.4.1 Configuring OpenStack Service
The OpenStack service is enabled from CVX-OpenStack configuration mode, which is accessed by the service openstack command. The no shutdown (CVX-OpenStack) command enables CVX OpenStack services on the CVX server. Additional configuration is necessary to deploy OpenStack (http://docs.openstack.org/).

Example
- These commands enable the CVX-OpenStack service.

```
switch(config-cvx)#service openstack
switch(config-cvx-openstack)#no shutdown
switch(config-cvx-openstack)#
```

14.1.5.4.2 Configuring VXLAN Control Service
The VXLAN control service is enabled on CVX by the no shutdown (CVX-VXLAN) command and on the client switches by enabling CVX and configuring the VXLAN as a controller client. When VXLAN control service is enabled, CVX functions as a VXLAN controller for its clients.

For information about configuring VXLAN on the client switch, see the VXLAN chapter of the User Manual.

Examples
- These commands enable VXLAN control service on the CVX server.

```
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#no shutdown
switch(config-cvx-vxlan)#
```
• These commands enable VXLAN Control Service on the CVX client. (This example assumes that
the VXLAN has already been configured on the client switch. For information about configuring
VXLAN, see the VXLAN chapter of the User Manual).

switch(config)#interface vxlan 1
switch(config-if-Vx1)#vxlan controller-client

14.1.5.4.3 Configuring Hardware Switch Controller Service (HSC)

The HSC service is enabled on the CVX server by the no shutdown (CVX-HSC) command.

Certificate Requirements for CVX Interoperability with VMware NSX 6.2.2 and higher

The certificate type needs to be changed from MD5 to SHA512 for use with VMware NSX 6.2.2.
Complete the following steps to make the change.

1. At the EOS prompt of CVX, use the following commands.

   switch(config)#cvx
   switch(config-cvx)#service hsc
   switch(config-cvx-hsc)#shut

2. Acquire superuser privileges and edit the default.

   switch(config)#bash
   switch(config)#sudo su
   switch(config)#vi /usr/bin/ovs-pki

3. Find and replace default_md with sha512 (from md5).

   default_md =md5
   default_md =sha512

4. Delete all files and folders from /persist/secure/openvswitch/.

   cd /persist/secure/openvswitch/
   bash-4.1#sudo rm -r *

5. Generate the new certificate.

   [admin@CVX ~]$ exit
   logout
   CVX(config-cvx-hsc)#no sh
   CVX(config-cvx-hsc)#end

6. Verify the change using the command:

   CVX#show nsx status

Example

These commands enable the CVX-HSC service.

switch(config)#cvx
switch(config-cvx)#no shutdown
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#no shutdown

The HSC service sends flood lists to each VTEP through CVX. Some controllers (such as VMware
NSX’s Service Nodes) implement replication nodes for head-end replication of unknown packets.
For these controllers, BUM packets should be sent to a single replication node (send-to-any
replication), and the flood list sent by the HSC service is a list of replication nodes. Other controllers
such as Nuage VSP) require each VTEP to perform its own head-end replication. For these, BUM packets should be sent to every known VTEP, and the flood list sent by the HSC service is the list of VTEPs.

The default behavior is to use a send-to-any replication list of VTEPs. If the required behavior is send-to-all replication of, use the all option of the vtep (CVX-HSC) command.

Example

This command configures the CVX-HSC service to use send-to-any replication.

```
switch(config-cvx-hsc)#vtep flood list type all
switch(config-cvx-hsc)#
```

Note: HSC also makes use of the VXLAN control service; ensure that VXLAN control service is enabled and properly configured (see VXLAN Control Service for details).

HSC also requires a connection to an OVSDB controller. Configure the IP address or host name of the controller using the manager command.

Example

This command configures the CVX-HSC service to connect to an OVSDB controller at IP address 192.168.2.5, using the default port 6632.

```
switch(config-cvx-hsc)#manager 192.163.2.5
switch(config-cvx-hsc)#
```

Having established a connection to the OVSDB controller, the HSC service will publish the inventory of switches managed by CVX to OVSDB. For the inventory to succeed, LLDP must be enabled on each CVX client switch with the lldp run command.

Note: LLDP is enabled by default on Arista switches.

Example

This command enables LLDP.

```
switch(config)#lldp run
switch(config)#
```

14.1.5.4.4 Configuring Network Topology Service

A network topology agent runs on each Arista switch whether or not the switch is connected to a CVX server. It requires no configuration. The network topology service on the CVX server is also enabled by default and requires no configuration.

To view the aggregated topology information, use the show network physical-topology command on the switch running the CVX server instance.

Examples

- This command displays all visible hosts.

```
switch#show network physical-topology hosts
Unique Id            Hostname
-------------------- ------------------------------
001c.7385.be69       cvx287.sjc.aristanetworks.com
0000.6401.0000       cvc1
0000.6402.0000       cvc2
0000.6403.0000       cvc3
0000.6404.0000       cvc4
```
This command displays all connections in the topology.

```
switch# show network physical-topology neighbors
cvx287.sjc.aristanetworks.com
```

<table>
<thead>
<tr>
<th>Interface</th>
<th>Neighbor Intf</th>
<th>Neighbor Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet1</td>
<td>Ethernet7</td>
<td>cvc4</td>
</tr>
<tr>
<td>Ethernet2</td>
<td>Ethernet7</td>
<td>cvc2</td>
</tr>
<tr>
<td>Ethernet9</td>
<td>Ethernet7</td>
<td>cvc1</td>
</tr>
<tr>
<td>Ethernet10</td>
<td>Ethernet7</td>
<td>cvc3</td>
</tr>
<tr>
<td>Management</td>
<td>27</td>
<td>dsj14-rack14-tor1</td>
</tr>
</tbody>
</table>

The topology information can be specified using the following command:

```
switch(config-cvx-topology)# network physical-topology switch SWITCH interface INTERFACE neighbor NEIGHBOR-HOST neighbor-interface NEIGHBOR-INTERFACE
```

The format of the hostname in this command could depend on services running on the host. As an example, in OpenStack use cases, it should match the hostname used by openstack services (For example, neutron server and agents) which is an FQDN format. The hostname in the command is case sensitive.

**Optional Parameter**

The neighbor interface is an optional parameter in the above configuration however setting it helps to understand the physical network connectivity between switches and hosts. It also helps in troubleshooting any issue that may arise in the network.

**Limitations**

To avoid mis-configuration in a topology consisting of a switch with a connected host, where LLDP is enabled and static topology is used to configure the physical topology it is recommended to use only one source of configuration, not both. As a mismatch in the configuration can cause wrong configuration on the switch by a feature consuming the topology information.

**14.1.6 CVX Secure out-of-band Connection**

This feature adds support for securing out-of-band connection between CVX server and CVX clients by SSL/TLS transport protocol. SSL/TLS is an application-layer protocol that provides secure transport
between client and server through a combination of authentication, encryption and data integrity. SSL/TLS uses certificates and private-public key pairs to provide this security. We will use the term SSL to mean SSL/TLS.

By default, CVX server and CVX clients communicate over insecure transport (there is no authentication and encryption between CVX server and CVX clients). This poses the possibility of security risks, such as communicating with untrusted CVX server and CVX clients, or eavesdropping CVX server/client communications. This feature can be used to secure the out-of-band connection between CVX server and CVX clients.

**Note:** The CVX client-server out-of-band connection uses port 50003. The CVX cluster peer out-of-band connection uses port 50004. These are TCP ports.

For more information, see:
- **Show Commands**

### 14.1.6.1 Configuring the CVX Secure out-of-band Connection

This feature uses SSL certificate and key management infrastructure for managing certificates, keys and SSL profiles. For more information regarding this infrastructure see SSL Certificate and Key Management in the Arista Users Guide.

1. On CVX server, copy the server certificate and key and also the CA certificate to verify CVX clients.

   ```
   switch(config)#copy <url> certificate:server.crt
   switch(config)#copy <url> sslkey:server.key
   switch(config)#copy <url> certificate:ca.crt
   ```

2. On CVX server, configure SSL profile with the certificates and key as below. Lets call the SSL profile as serverssl.

   ```
   switch(config)#management security
   switch(config-mgmt-security)#ssl profile serverssl
   switch(config-mgmt-sec-ssl-profile-serverssl)#certificate server.crt
   switch(config-mgmt-sec-ssl-profile-serverssl)#key server.key
   switch(config-mgmt-sec-ssl-profile-serverssl)#trust certificate ca.crt
   ```

   **Note:** If you are using intermediate certificates to build a 'Chain of Trust' (such as `server.crt -> intermediate1.crt -> intermediate2.crt -> ca.crt`), then you need to configure the intermediate certificates as part of the SSL profile using the following commands:

   ```
   switch(config-mgmt-sec-ssl-profile-serverssl)#chain certificate intermediate1.crt
   switch(config-mgmt-sec-ssl-profile-serverssl)#chain certificate intermediate2.crt
   ```

3. On CVX server, configure to use the serverssl SSL profile. With this configuration, the CVX server starts listening on a secure port. The CVX server will continue to listen on the default port. i.e., the CVX server will accept connections from CVX clients over both SSL and default non-SSL transports. During a SSL negotiation, the CVX server will authenticate itself to the CVX clients by presenting server.crt and it verifies the authenticity of the CVX client by checking if the CVX client certificate is signed by the trusted certificate ca.crt.

   ```
   switch(config)#cvx
   ```
4. On CVX client, copy the client certificate and key and also the CA certificate to verify CVX server.

```
switch(config)# copy <url> certificate:client.crt
switch(config)# copy <url> sslkey:client.key
switch(config)# copy <url> certificate:ca.crt
```

**Note:** If you are using intermediate certificates to build a 'Chain of Trust' (such as client.crt -> intermediate1.crt -> intermediate2.crt -> ca.crt), then you need to configure the intermediate certificates as part of the SSL profile using the following commands:

```
switch(config-mgmt-sec-ssl-profile-clientssl)# chain certificate intermediate1.crt
switch(config-mgmt-sec-ssl-profile-clientssl)# chain certificate intermediate2.crt
```

5. On CVX client, configure SSL profile with the certificates and key as below. Lets call the SSL profile as clientssl.

```
switch(config)# management security
switch(config-mgmt-security)# ssl profile clientssl
switch(config-mgmt-sec-ssl-profile-clientssl)# certificate client.crt
switch(config-mgmt-sec-ssl-profile-clientssl)# key client.key
switch(config-mgmt-sec-ssl-profile-clientssl)# trust certificate ca.crt
```

6. On CVX client, configure to use the SSL profile clientssl. With this configuration, the CVX client will connect to the secure port of the CVX server over SSL transport. During SSL negotiation, the CVX client will authenticate itself to the CVX server by presenting client.crt and it verifies the authenticity of the CVX server by checking if the CVX server certificate is signed by the trusted certificate ca.crt.

```
switch(config)# management cvx
switch(config-mgmt-cvx)# ssl profile clientssl
```

### 14.1.6.2 Show Commands

For information regarding show commands of SSL certificate, key and profile, please refer to **SSL Certificate and Key Management**.

To show the SSL profile status on CVX server, use the `show cvx` command.

```
switch# show cvx
```

CVX Server
Status: Enabled
UUID: beb19142-dfaa-11e4-b996-001c73105347
Heartbeat interval: 20.0
Heartbeat timeout: 60.0
SSL profile: serverssl
Status: Enabled

The Enabled SSL status means that the SSL profile is enabled for CVX server and the CVX clients can connect to CVX server over SSL transport. If there are any errors, then the status will show Disabled.
and the reason will be listed. In Disabled state, the CVX clients won't be able to connect to CVX server over SSL transport.

To show the SSL connection status of CVX clients on CVX server, use the show cvx connections command.

```
switch# show cvx connections
Switch 00:1c:73:10:53:48
Hostname: sq302
Status: up
Last heartbeat sent: 0:00:04 ago
Last heartbeat received: 0:00:10 ago
Clock offset: -0.00201620385865
Out-of-band connection: SSL secured
In-band connection: Not secured (SSL not supported)
```

The out-of-band connection shows as SSL secured, which means that the CVX client has connected to CVX server over SSL transport. The in-band connection is another connection between CVX server and CVX client. The SSL is not yet supported for this connection and hence it shows as SSL not supported. There is already some level of protection for the in-band connection. The CVX server and CVX client open up the access to in-band connection only if the out-of-band connection is successful. Since the out-of-band connection is configured to use SSL, the in-band connection access is granted only for authentic CVX client and CVX server.

To show SSL profile status and connection status on CVX client, use the show management cvx command.

```
switch# show management cvx
CVX Client
Status: Enabled
Last connected time: 2015-04-14 11:16:19
Connection status: Connected
Out-of-band connection: SSL secured
In-band connection: Not secured (SSL not supported)
Negotiated version: 2
Controller UUID: 0e7dee2e-e2cf-11e4-880f-001c73105347
Controller: 127.0.0.1
Last heartbeat sent: 0:00:00 ago
Last heartbeat received: never
Clock offset: 0.0
SSL profile: clientssl
Status: Enabled
```

The Enabled SSL status means that the SSL profile is enabled and the CVX client can connect to CVX server over SSL transport. If there are any errors, then the status will show as Disabled and the reason will be listed. In Disabled state, the CVX client won't be able to connect to the CVX server.

Similar to the CVX server, the out-of-band connection shows as SSL secured and the SSL is not yet supported for in-band connection.

The possible reasons for Disabled SSL status on CVX server and CVX client are:

- **SSL profile does not exist**: If the SSL profile configured under CVX server/client is not configured under management security, you will see this message. Configure the SSL profile with required certificates and key under management security.

- **Invalid SSL profile**: If the SSL profile configured under CVX server/client is in invalid state, you will see this message. Check `show management security ssl profile <name>` command to see the errors on the SSL profile and fix them.
• **Trusted certificates not configured in SSL profile:** If the SSL profile configured under CVX server/client does not have trusted certificates configured, you will see this message. Please configure trusted CA certificates in the SSL profile.

• **Certificate not configured in SSL profile:** If the SSL profile configured under CVX server/client does not have certificate key pair configured, you will see this message. Please configure certificate and key pair in the SSL profile.

**Diffie-Hellman parameters not yet ready:** When EOS is booted, a Diffie-Hellman parameters file is auto generated by the system if one does not exist. This Diffie-Hellman parameters file is used for symmetric key exchange during SSL negotiation. Only the CVX server uses this file and hence this message can be seen only on `show cvx` command output. If the file is not yet generated, you will see this message. When the file is ready, this message automatically goes away and the SSL profile will become Enabled.

### 14.1.7 CVX High Availability

CVX provides high availability by enabling you to use multiple (redundant) CVX Controllers in the same cluster. Each Controller in the cluster has its own dedicated machine so that if a Controller fails, the failure is isolated to a single machine.

Within a cluster, one of the Controllers is a primary (leader), and the other Controllers are backup (follower) Controllers. If the primary Controller fails, one of the backup Controllers automatically assumes the role of the primary Controller.

CVX high availability does not prevent or compromise the detection of software failures or link failures that may cause Controllers to be unreachable on the network.

The configuration that is required to ensure CVX is set up for high availability involves:

• Configuring the CVX cluster.
• Configuring the CVX clients.

For more information, see:

• [CVX Clusters](#)
• [Handling of CVX Controller Failures](#)
• [CVX Support for EOS Failure Modes](#)
• [Client Interaction](#)
• [Service Agents Interaction](#)
• [Leader Election](#)
• [Configuring CVX Clusters for High Availability](#)
• [Configuring CVX Clients for High Availability](#)

### 14.1.7.1 CVX Clusters

CVX clusters are sets of CVX Controllers (usually 3 Controllers). Within a cluster, each Controller runs on its own dedicated machine, and all of the Controllers run the same version of CVX. Each Controller in the cluster functions as either the primary (leader) Controller, or a backup (follower) Controller.

One of the CVX Controllers is elected by the group of Controllers to be the primary Controller. Once a Controller is elected to be the primary, the other Controllers in the cluster are automatically assigned the role of backup Controllers. Cluster members maintain an out-of-band connection amongst themselves, which is used for the leader election protocol.

CVX Controllers in a cluster that are not the primary Controller always function as backup Controllers. Within the same cluster, only one CVX Controller can assume the role of a primary at any time.

For more information, see:

• [Required Number of Controllers to Support High Availability](#)
• Cluster Configuration Options

14.1.7.1 Required Number of Controllers to Support High Availability

A cluster must have enough Controllers so that in the case of a failure of the primary Controller, there are enough remaining Controllers for the election process to be completed. The election process is used by clusters to select a new primary Controller in the case of failure.

Note: The number of Controllers for a cluster is 3 (one primary and two backup Controllers).

Examples

In a cluster with only two Controllers (one primary and one backup), a simple majority of backup Controllers does not exist after a failure of the primary Controller. A simple majority of two backup Controllers is required for the leader election process.

Related Topics

• Cluster Configuration Options
• Handling of CVX Controller Failures
• CVX Support for EOS Failure Modes
• Client Interaction
• Service Agents Interaction
• Leader Election

14.1.7.2 Cluster Configuration Options

You can configure the cluster for high availability using either of the following modes:

• Cold followers mode - Only the Controllerdb of the primary (leader) CVX Controller mounts from the client switches.
• Warm followers mode - The Controllerdb of every (all) CVX Controllers in the cluster mount from the client switches.

Advantages and disadvantages of the modes

The advantage of the warm follower mode is that if the primary CVX Controller fails, the switchover to the new primary is faster than a switchover in cold follower mode. The reason for this is that the state of the new primary does not have to be rebuilt from scratch. The disadvantage of the warm follower mode is that serialization from the switch is slower compared to cold follower mode.

Related Topics

• Required Number of Controllers to Support High Availability
• Handling of CVX Controller Failures
• CVX Support for EOS Failure Modes
• Client Interaction
• Service Agents Interaction
• Leader Election

14.1.7.2 Handling of CVX Controller Failures

CVX Controllers can fail because of hardware or software faults. Because EOS agents are designed to be software fault-tolerant, an agent that fails is automatically restarted and resumes operation statefully. The most recent saved state in Sysdb for the agent is used to restore the state of the agent.

Unlike software failures, hardware failures are not handled by EOS. CVX handles hardware failures through the use of redundant backup (follower) CVX Controllers that run on their own dedicated machine. Within a cluster, any backup Controller can assume the role of the primary (leader) Controller.
Note: In the event of a network partition, the partition with a majority of the Controllers elects a leader from its Controllers, and the minority partition relinquishes any leadership it might have had.

Related Topics
- CVX Clusters
- CVX Support for EOS Failure Modes
- Client Interaction
- Service Agents Interaction
- Leader Election

14.1.7.3 CVX Support for EOS Failure Modes

CVX supports both EOS failure modes that apply when a CVX Controller fails. The EOS failure modes are:

- Fail-stop
- Fail-recover

Because CVX supports both EOS failure modes, a failed CVX Controller can rejoin the cluster if the following failures occur:

- A crash of the agent or machine running CVX.
- The CVX controller or dedicated machine it runs on is removed (partitioned) from the cluster.

- Leader Election

14.1.7.4 Client Interaction

Client switches maintain an out-of-band connection to all members of the cluster. The connection is used to determine liveness and for communications. The connection is also used to signal a change in leadership (switchover) to the client switches. Switchovers that are changes in leadership within a cluster are executed similarly to CVX Graceful Reboot switchovers.

The ControllerClient agent on the switch is responsible for maintaining liveness with the Controllers and for exchanging metadata. The ControllerClient agent registers with all cluster members. Each Controller's ControllerStatus has an additional flag to record whether the Controller is a leader within the cluster.

If there is more than one leader, the switch automatically waits until only one Controller is designated as the leader in the cluster. Once a single Controller is designated as the leader, the switch executes a graceful switchover to the new leader Controller.

- Service Agents Interaction
- Leader Election
14.1.7.5  Service Agents Interaction

One change to Service Agents is required to support CVX high availability. Service Agents must be modified to include the leader flag (this flag identifies the leader CVX Controller in the cluster). On a leader switchover, Service Agents are deactivated on the old leader Controller and activated on the new leader Controller. The client switches will perform a graceful switchover to the new leader Controller.

• Client Interaction
• Leader Election

14.1.7.6  Leader Election

Leader election is an internal, system-run process that is essential to CVX high availability. The leader election process is used to safely elect a new leader Controller within a cluster following the failure of the current leader Controller, or a network configuration change that results in the loss of the current leader Controller in the cluster.

The leader election process is designed to ensure stability of leader Controllers within clusters. The process is based on an algorithm that provides the mechanism for the backup (follower) Controllers to elect (by consensus), the new leader Controller in the cluster.

14.1.7.7  Configuring CVX Clusters for High Availability

Configuring CVX clusters for high availability is a simple process that involves pointing each cluster member to the other cluster members using the peer host command. The objective of this task is to successfully register each cluster member with the other cluster members. Successful registration of the cluster members with each other ensures that the members can communicate with each other to elect a new leader member if the original leader member fails.

Once you complete the process, the cluster members will be successfully registered with each other. In addition, the cluster members will automatically elect a leader member and assign the leader to that member. The non-leader members are automatically assigned the role of follower.

Requirements

The requirements for setting up clusters for high availability are:

• The number of CVX Controllers in a cluster is 3.
• An odd number of CVX instances (CVX Controllers) are required to form a cluster.

Note: If an even number of CVX Controllers are configured in a cluster, a CVX instance will automatically refuse to participate in the cluster.

• All cluster members must point to each other. This is essential for clusters to operate normally. (The steps required to complete this task are included in the following procedure.)

Procedure

Note: This procedure provides configuration examples for each step. The example cluster used throughout the procedure contains 3 cluster members (named cvs1, cvs2, and cvs3). The IP addresses of the cluster members are:

- cvs1 (10.0.0.1)
- cvs2 (10.0.0.2)
- cvs3 (10.0.0.3).
Complete the following steps to configure clusters for high availability.

1. **Using the peer host command, configure one of the cluster members to point to every other cluster member.**

   This example shows the configuration of cluster member `cvs1` to point to the other cluster members (`cvs2` and `cvs3`).

   ```
   cvs1(config-cvx)#peer host 10.0.0.2 (connects cvs1 to cvs2)
   cvs1(config-cvx)#peer host 10.0.0.3 (connects cvs1 to cvs3)
   ```

2. **Use the `sh cvx` command to check the **Mode** and **Peer registration state** status values for cluster member `cvs1`. The status values should be:**

   - **Mode** = *Cluster*
   - **Peer registration state** = *Connecting*

   **Note:** **Mode** automatically changes from Standalone to Cluster when configuring a CVX cluster. This is because the presence of multiple CVX peers causes the Mode to change to Cluster.

   **Peer registration state** remains in Connecting status after you configure the first cluster member. This is because the two peers must register with each other for the registration of the two members to be successful.

3. **Using the peer host command, configure peer cluster member `cvs2` to point to every other cluster member.**

   This example shows the configuration of cluster member `cvs2` to point to the other cluster members (`cvs1` and `cvs3`).

   ```
   cvs2(config-cvx)#peer host 10.0.0.1 (connects cvs2 to cvs1)
   cvs2(config-cvx)#peer host 10.0.0.3 (connects cvs2 to cvs3)
   ```

4. **Use the `sh cvx` command to check the **Peer registration state** settings for `cvs1`. This is done to verify that peers `cvs1` and `cvs2` are successfully registered with each other.**

   ```
   cvs1(config-cvx)#sh cvx
   ```

**Example**

This example shows the output of the `sh cvx` command for `cvs1`. The **Peer registration state** setting of Registration Complete for peer `cvs2` *indicates a successful registration between cvs1 and cvs2.*

```
CVX Server
Status: Enabled
UUID: 6c208fba-7324-11e5-8fef-1d98cdd3b27a
Mode: Cluster
Heartbeat interval: 20.0
Heartbeat timeout: 60.0
Cluster Status
Name: default
Role: Standby
Leader: 10.0.0.2
Peer timeout: 10.0
Last leader switchover timestamp: 0:00:03 ago
Peer Status for 10.0.0.3
  Peer registration state: Connecting
  Peer service version compatibility : Version mismatch
Peer Status for 10.0.0.2
  Peer Id : 02-01-63-02-00-00
```
5. Using the peer host command, configure peer cluster member `cvs3` to point to every other cluster member.

This example shows the configuration of cluster member `cvs3` to point to the other cluster members (`cvs1` and `cvs2`).

```
cvs3(config-cvx)#peer host 10.0.0.1 (connects cvs3 to cvs1)
cvs3(config-cvx)#peer host 10.0.0.2 (connects cvs3 to cvs2)
```

6. Use the `sh cvx` command to check the Peer registration state settings for `cvs1`. This is done to verify that peers `cvs1` and `cvs3` are successfully registered with each other.

```
cvs1(config-cvx)#sh cvx
```

**Example**

This example shows the output of the `sh cvx` command for `cvs1`. The Peer registration state setting of Registration Complete for peer `cvs3` indicates a successful registration between `cvs1` and `cvs3`.

```
cvs1(config-cvx)#sh cvx

CVX Server

Peer Id : 02-01-63-02-00-00
Peer registration state: Registration complete
Peer service version compatibility : Version ok
```

**Next Step**

You are now ready to configure the CVX clients for high availability (see Configuring CVX Clients for High Availability).

**14.1.7.8 Configuring CVX Clients for High Availability**

Configuring CVX clients for high availability is a simple process that involves pointing each CVX client to every CVX cluster member using the server host command. The objective of this task is to successfully establish connections between each CVX client and every CVX cluster member. The connections are essential to ensure that the CVX clients are aware of the current status of each cluster member.

**Note:** If a CVX client is not pointing to every cluster member, or if it is pointing to a CVX instance (Controller) that is not part of the cluster, the client may not be aware of leadership...
changes in the cluster, or may become confused about which cluster member is currently the leader. Either of these scenarios can result in unexpected errors.

Once you complete the process, the CVX clients will have established connections with each cluster member (the Connection status for each Controller should be Established). In addition, the clients will be aware of which CVX instance (Controller) is currently the leader in the cluster.

Procedure

Note: This procedure provides configuration examples for each step. The example CVX client used throughout the procedure is named cvc1. The IP addresses of the cluster members are 10.0.0.1 (cvs1), 10.0.0.2 (cvs2), and 10.0.0.3 (cvs3).

Complete the following steps to configure CVX clients for high availability.

1. Using the server host command, configure each of the CVX clients to point to every cluster member.

   This example shows the configuration of client cvc1 to point to all of the cluster members (the addresses of the cluster members are 10.0.0.1, 10.0.0.2, and 10.0.0.3).

   cvc1(config-mgmt-cvx)#server host 10.0.0.1 (connects cvc1 to cluster member 10.0.0.1)
   cvc1(config-mgmt-cvx)#server host 10.0.0.2 (connects cvc1 to cluster member 10.0.0.2)
   cvc1(config-mgmt-cvx)#server host 10.0.0.3 (connects cvc1 to cluster member 10.0.0.3)

2. Use the sh man cvx command to check the status of client cvc1.

   The Connection status for each cluster member should be Established. In addition, the client is also aware that cluster member 10.0.0.3 is the current Master.

   cvc1(config-mgmt-cvx)#sh man cvx

   CVX Client
   Status: Enabled
   Source interface: Inactive (Not configured)
   Controller cluster name: default
   Controller status for 10.0.0.1
   Connection status: established
   Out-of-band connection: Not secured
   In-band connection: Not secured (SSL not supported)
   Negotiated version: 2
   Controller UUID: 6c208fba-7324-11e5-8fef-1d98cdd3b27a
   Last heartbeat sent: 0:00:07 ago
   Last heartbeat received: 0:00:07 ago
   Controller status for 10.0.0.3
   Master since 0:03:34 ago
   Connection status: established
   Out-of-band connection: Not secured
   In-band connection: Not secured (SSL not supported)
   Negotiated version: 2
   Controller UUID: c64954b8-7324-11e5-9f33-51f8b016cae8
   Last heartbeat sent: 0:00:14 ago
   Last heartbeat received: 0:00:14 ago
   Controller status for 10.0.0.2
   Connection status: established
   Out-of-band connection: Not secured
   In-band connection: Not secured (SSL not supported)
   Negotiated version: 2
   Controller UUID: 6a0dbf2c-7324-11e5-94f3-ff17a8alcdc8
   Last heartbeat sent: 0:00:05 ago
   Last heartbeat received: 0:00:05 ago
14.1.8  CVX VIP

CVX VIP provides the virtual IP address that actively follows the master controller of the CVX cluster. The virtual IP address of the CVX HA Cluster is configured on a macvlan interface setup on top of a physical management interface of the master controller. The virtual IP and virtual MAC needs to be provided by the customer as part of the controller configuration. This information is available to all controllers as each cluster member has to be configured manually by the user on all controllers.

The macvlan interface created should be designated as `Management0`. `Management0` is currently used for the ManagementActive interface on modular switches. Without explicit configuration of VIP and VMAC, CVX VIP functionality will not work in the CVX HA cluster.

Customers can pick the VMAC from a pool of MAC addresses reserved for use with CVX clusters. The OUI pool, 00:1C:72:00:00:AA “ 00:1C:72:00:00:FF has been reserved for this purpose.

The macvlan interface is setup if all of the following conditions are met:

- VMAC is configured by the user
- The controller instance is a leader
- There are more than one controller instances
- The controller is not being run on a modular system
- CVX VIP
- Data Replication
- SSH Host Key Tagging

14.1.8.1  Configuring VIP

All CLI commands applicable to the management interface of the controller will be allowed on `Management0`, with the exception of Layer 1 / phy level commands. So auto-negotiation or flow control cannot be configured on the `Management0` interface. Instead these commands can only be run on the physical management interfaces. This makes sense as the phy-level configuration really depends on what the interface is physically wire.

To configure VMAC/VIP

```
CVX(config)#interface management 0
CVX(config-if-Ma0)# mac-address 00:1C:72:00:00:FF
CVX(config-if-Ma0)# ip address 10.0.0.2
```

14.1.8.2  Data Replication

At EOS boot time, SSH host keys and Diffie-Hellman parameters are automatically generated and persistently stored on each controller. Multiple SSL profiles / keys / certificates might also be created and used by various agents on the controllers. Since these information contribute to the identity of the master, they will need to follow the master controller for all time.

In case of a controller switchover, the newly elected master controller will need to use the same SSH host keys & SSL profiles / keys / certificates to retain its identity and prevent any kind of network security alarms from being tripped. For example, if an SSH client notices that the host key has changed, it will normally flag an error warning the user of a possible man-in-the-middle type attack. Hence, this data will be replicated from the master to slaves.

14.1.8.3  SSH Host Key Tagging

SSH host keys are tagged with the chassis MAC address to deal with key regeneration issues when a supervisor module is moved from one chassis to another. This behavior will cause regeneration
issues if we replicate the SSH host keys across the cluster resulting in the key fingerprint seen by management tools to be different.

To mitigate this, in addition to the chassis MAC address, the host keys would now be tagged with VMAC of the CVX HA cluster. If CVX VIP and VMAC are configured, SshHostKeysAgent will not regenerate keys if tagged VMAC and configured VMAC are the same, even if there is a mismatch between the chassis MAC and tagged MAC.
14.1.9 CVX Commands

CVX Server Commands

- cvx
- heartbeat-interval (CVX)
- heartbeat-timeout (CVX)
- port (CVX)
- show cvx
- shutdown (CVX)

CVX Client Commands

- management cvx
- heartbeat-interval (Management-CVX)
- heartbeat-timeout (Management-CVX)
- server host (Management-CVX)
- source-interface (Management-CVX)
- shutdown (Management-CVX)

CVX OpenStack Commands

- name-resolution force (CVX-OpenStack)
- name-resolution interval (CVX-OpenStack)
- service openstack
- shutdown (CVX-OpenStack)

CVX VXLAN Control Service Commands

- resync-period
- service vxlan
- shutdown (CVX-VXLAN)
- vtep (CVX-VXLAN)

CVX Hardware Switch Controller (HSC) Commands

- manager
- ovsdb-shutdown
- shutdown (CVX-HSC)
- vtep (CVX-HSC)

CVX Network Topology Service Commands

- Ildp run
- show network physical-topology

CVX Static Topology Service Commands

- service topology
- show network physical-topology

Related Topics

- CVX Overview
- CVX Services
- Deploying CVX
- CVX Configuration
- CVX Secure out-of-band Connection
- CVX High Availability
14.1.9.1  cvx

CVX (CloudVision eXtension) aggregates and shares status across a network of physical switches running EOS. CVX services provide visibility and coordinate activities across a network of switches that are configured as CVX clients.

The `cvx` command enters CVX configuration mode. CVX configuration mode is not a group-change mode; `running-config` is changed immediately upon entering commands. Exiting CVX configuration mode does not affect `running-config`. The `exit` command returns the switch to global configuration mode.

The `no cvx` and `default cvx` commands restore all CVX server defaults by deleting all CVX configuration mode statements from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

```text
cvx
no cvx
default cvx
```

**Commands Available in CVX Configuration Mode**

- `port  (CVX)`
- `service openstack`
- `service vxlan`
- `shutdown  (CVX)`
- `heartbeat-interval  (CVX)`
- `heartbeat-timeout  (CVX)`

**Example**

- These commands enter CVX-configuration mode and display the CVX configuration.

```text
switch(config)#cvx
switch(config-cvx)#show active all

 cvx
 shutdown
 port 9979
 heartbeat-interval 20
 heartbeat-timeout 60
 no service vxlan
 service openstack
 shutdown
 name-resolution interval 21600
switch(config-cvx)#
```
14.1.9.2 heartbeat-interval (CVX)

The **heartbeat-interval** command configures the interval between heartbeat messages that the switch sends as a CVX server. Heartbeat messages are part of the keepalive mechanism between CVX and the CVX clients to which it connects.

The **no heartbeat-interval** and **default heartbeat-interval** commands restore the heartbeat interval to the default setting by removing the **heartbeat-interval** command from running-config.

**Command Mode**

CVX Configuration

**Command Syntax**

```
heartbeat-interval period
no heartbeat-interval
default heartbeat-interval
```

**Parameters**

- **period** Interval duration (seconds). Value ranges from 5 through 60. Default value is 20.

**Related Commands**

- cvx
- heartbeat-timeout (CVX)

**Guidelines**

Heartbeat messages flow independently in both directions between CVX and clients. When a client stops receiving heartbeat messages from the server within a specified period, the client assumes that the CVX server is no longer functioning.

Best practices dictate that CVX and its client applications configure identical heartbeat interval values.

**Examples**

- This command configures a CVX server heartbeat interval of 30 seconds:

```
switch(config)#cvx
switch(config-cvx)#heartbeat-interval 30
switch(config-cvx)#
```
14.1.9.3 heartbeat-interval (Management-CVX)

The `heartbeat-interval` command configures the interval between heartbeat messages that the switch sends as a CVX client. Heartbeat messages are part of the keepalive mechanism between the CVX client and the CVX server to which it connects.

The `no heartbeat-interval` and `default heartbeat-interval` commands revert the heartbeat interval to the default setting by removing the `heartbeat-interval` command from `running-config`.

**Command Mode**
Mgmt-CVX Configuration

**Command Syntax**

```
heartbeat-interval period
no heartbeat-interval
default heartbeat-interval
```

**Parameters**

- **period**: Interval duration (seconds). Value ranges from 5 through 60. Default value is 20.

**Guidelines**

Heartbeat messages flow independently in both directions between CVX and clients. When the server stops receiving heartbeat messages from a client within a specified period, the server assumes that the device it is no longer functioning as a CVX client.

Best practices dictate that the CVX client's heartbeat interval value is identical to that of its CVX server.

**Related Commands**

- `heartbeat-timeout (Management-CVX)` specifies the CVX client timeout interval.

**Example**

These commands configure a CVX client heartbeat interval of 30 seconds:

```
switch(config)#management cvx
switch(config-mgmt-cvx)#heartbeat-interval 30
switch(config-mgmt-cvx)#
```
14.1.9.4 heartbeat-timeout (CVX)

The heartbeat-timeout command specifies the CVX timeout period. When a CVX server does not receive consecutive heartbeat messages from a CVX client within the heartbeat timeout period, the server discontinues providing CVX services to the client device. The default timeout period is 60 seconds.

The no heartbeat-timeout and default heartbeat-timeout commands restore the heartbeat timeout to the default setting by removing the heartbeat-timeout command from running-config.

**Command Mode**
CVX Configuration

**Command Syntax**

```
heartbeat-timeout period
no heartbeat-timeout
default heartbeat-timeout
```

**Related Commands**
- cvx places the switch in CVX configuration mode.
- heartbeat-interval (CVX) specifies the CVX heartbeat interval.

**Parameters**
- period: heartbeat timeout interval (seconds). Value ranges from 15 to 10800. Default value is 60.

**Guidelines**
Best practices dictate that CVX and its client applications configure identical heartbeat timeout values.

**Examples**
- These commands set the CVX timeout period to 90 seconds.

```
switch(config)#cvx
switch(config-cvx)#heartbeat-timeout 90
switch(config-cvx)#
```
14.1.9.5 heartbeat-timeout (Management-CVX)

The `heartbeat-timeout` command specifies the CVX client timeout period. When a CVX client does not receive consecutive heartbeat messages from a CVX server within the period specified by this command, the client assumes that its connection to CVX is disrupted. The default timeout period is 60 seconds.

The `no heartbeat-timeout` and `default heartbeat-timeout` commands restore the CVX client heartbeat timeout to the default setting by removing the `heartbeat-timeout` command from `running-config`.

**Command Mode**
Mgmt-CVX Configuration

**Command Syntax**

```
heartbeat-timeout period
no heartbeat-timeout
default heartbeat-timeout
```

**Parameters**

`period`: heartbeat timeout interval (seconds). Value ranges from 15 to 10800. Default value is 60

**Guidelines**

Best practices dictate that the CVX client's heartbeat timeout value is identical to that of its CVX server.

**Related Commands**

- `heartbeat-interval (Management-CVX)` specifies the CVX client heartbeat interval.

**Example**

These commands set the CVX client timeout period to 90 seconds.

```
switch(config)#management cvx
switch(config-mgmt-cvx)#heartbeat-timeout 90
switch(config-mgmt-cvx)#
```
14.1.9.6  lldp run

The `lldp run` command enables LLDP on the Arista switch.

**Command Mode**
Global Configuration

**Command Syntax**

```plaintext
lldp run
no lldp run
default lldp run
```

**Examples**

- This command enables LLDP globally on the Arista switch.

```plaintext
switch(config)# lldp run
switch(config)#
```

- This command disables LLDP globally on the Arista switch.

```plaintext
switch(config)# no lldp run
switch(config)#
```
14.1.9.7 management cvx

The `management cvx` command places the switch in `mgmt-CVX configuration` mode to configure CVX client parameters.

`Mgmt-CVX` configuration mode is not a group-change mode; `running-config` is changed immediately upon entering commands. Exiting `mgmt-CVX` configuration mode does not affect `running-config`. The `exit` command returns the switch to global configuration mode.

The `no management cvx` and `default management cvx` commands delete all `mgmt-CVX` configuration mode statements from `running-config`.

**Command Mode**

Global Configuration

**Command Syntax**

`management cvx`

`no management cvx`

`default management cvx`

`exit`

**Commands Available in Mgmt-CVX Configuration Mode**

- `heartbeat-interval` (Management-CVX)
- `heartbeat-timeout` (Management-CVX)
- `server host` (Management-CVX)
- `source-interface` (Management-CVX)
- `shutdown` (Management-CVX)

**Examples**

- This command places the switch in `mgmt-CVX configuration mode`:

  ```
  switch(config)#management cvx
  switch(s1)(config-mgmt-cvx)#
  ```

- This command returns the switch to `global management mode`:

  ```
  switch(config-mgmt-cvx)#exit
  switch(config)#
  ```
14.1.9.8  manager

The `manager` command configures the IP address of the OVSDB controller for the HSC service, allowing CVX to connect to the controller.

The `no manager` and `default manager` commands remove the HSC manager configuration from running-config.

**Command Mode**

CVX-HSC Configuration

**Command Syntax**

```
manager ip_address [port]
```

**Parameters**

- **ip_address** IP address of the HSC manager.
- **port** connection port. Values range from 1 to 65535; default value is 6632.

**Related Commands**

- `service hsc` places the switch in CVX-HSC configuration mode.

**Example**

- These commands point the HSC service to a controller at IP address 192.168.2.5 using the default port 6632.

```
switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#manager 192.163.2.5
switch(config-cvx-hsc)#
```
name-resolution force (CVX-OpenStack)

The name-resolution force command initiates an OpenStack controller function that communicates with the OpenStack Keystone and Nova services to update names of VMs and tenants mapped by the local OpenStack instance.

The OpenStack controller accesses the Keystone and Nova services in response to various triggering events (such as the creation of a new tenant, network or VM), and also at a regular interval configured by the name-resolution interval (CVX-OpenStack) command (default interval 6 hours). The name-resolution force command is used to force an immediate update without waiting for a triggering event.

Command Mode
CVX-OpenStack Configuration

Command Syntax
name-resolution force

Related Commands
- service openstack places the switch in CVX-OpenStack configuration mode.
- name-resolution interval (CVX-OpenStack) sets the interval for automatic Keystone updates.

Example
- These commands update the OpenStack instance immediately with data from the Keystone service.

switch(config)#cvx
switch(config-cvx)#service openstack
switch(config-cvx-openstack)#name-resolution force
switch(config-cvx-openstack)#
14.1.9.10 name-resolution interval (CVX-OpenStack)

The name-resolution interval command specifies the period between consecutive requests that the OpenStack controller sends to the Keystone service for VM and tenant name updates. Keystone is OpenStack’s authentication and authorization service.

The default period is 21600 seconds (6 hours).

The name-resolution force (CVX-OpenStack) command performs an immediate update, as opposed to waiting for the periodic update.

Command Mode
CVX-OpenStack Configuration

Command Syntax
name-resolution interval period

Parameters
period: Keystone identity service polling interval (seconds).

Related Command
service openstack places the switch in CVX-OpenStack configuration mode.

Example
These commands set the name resolution interval period at five hours.

```
switch(config)#cvx
switch(config-cvx)#service openstack
switch(config-cvx-openstack)#name-resolution interval 18000
switch(config-cvx-openstack)#
```
14.1.9.11 ovsdb-shutdown

The `ovsdb-shutdown` command shuts down the OVSDB server.

The `no ovsdb-shutdown` and `default ovsdb-shutdown` commands enable the OVSDB server by removing the ovsdb-shutdown command from running-config.

**Command Mode**
CVX-HSC Configuration

**Command Syntax**

- `ovsdb-shutdown`
- `no ovsdb-shutdown`
- `default ovsdb-shutdown`

**Related Commands**

- `service hsc` places the switch in **CVX-HSC configuration** mode.

**Example**

- These commands shut down the OVSDB server used by the HSC service.

```
switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#ovsdb-shutdown
switch(config-cvx-hsc)#
```
14.1.9.12  port (CVX)

The `port` command specifies the TCP port number the CVX server listens on. The default port number is 9979.

The `no port` and `default port` commands restore the default port number by removing the port statement from `running-config`.

**Command Mode**
CVX Configuration

**Command Syntax**

```plaintext
port port_number
no port
default port
```

**Parameters**

- `port_number`: TCP port number. Value ranges from 1 to 65535.

**Related Commands**

- `cvx` places the switch in CVX configuration mode.

**Example**

- These commands configure 9500 as the CVX server port.

```plaintext
switch#config
switch(config)#cvx
switch(config-cvx)#port 9500
switch(config-cvx)#
```

- These commands restore the default port (9979) as the CVX server port.

```plaintext
switch(config-cvx)#no port
switch(config-cvx)#
```
14.1.9.13 resync-period

The `resync-period` command configures the grace period for completion of synchronization between the VXLAN control service and clients after a CVX restart. Arista recommends leaving the grace period set to its default of 300 seconds.

The `no resync-period` command disables VXLAN control service graceful restart. The `default resync-period` command resets the grace period to its default of 300 seconds.

Command Mode
CVX-VXLAN Configuration

Command Syntax

```
resync-period seconds
no resync-period
default resync-period
```

Parameters

- `seconds`: synchronization grace period in seconds. Values range from 30 to 4800; default is 300.

Examples

- These commands reset the VXLAN control service synchronization grace period to 300 seconds.

```
switch(config)#cvx
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#default resync-period
switch(config-cvx-vxlan)#
```
14.1.9.14 server host (Management-CVX)

The server host command configures the IP address or host name of the CVX server to which the CVX client device connects. The configuration of this address is required for the switch to function as a CVX client. By default, no CVX host address is specified.

The no server host and default server host commands remove the CVX host address assignment by removing the server host statement from running-config.

Command Mode
Mgmt-CVX Configuration

Command Syntax
server host host
no server host
default server host

Parameters
• host: IPv4 address (in dotted decimal notation) or FQDN host name of the CVX server.

Examples
• This command specifies 10.1.1.14 as the address of the server to which the CVX client connects.

```
switch(config)#management cvx
switch(config-mgmt-cvx)#server host 10.1.1.14
switch(config-mgmt-cvx)#
```
14.1.9.15  service hsc

The `service hsc` command enters **CVX-HSC configuration** mode where the HSC service is enabled and configured.

CVX-HSC configuration mode is not a group change mode; **running-config** is changed immediately upon entering commands. Exiting **CVX-HSC configuration** mode does not affect **running-config**. The `exit` command returns the switch to global configuration mode.

**Command Mode**
CVX Configuration

**Command Syntax**

```
service hsc
```

**Commands Available in CVX-HSC Configuration Mode**

- `manager`
- `ovsdb-shutdown`
- `shutdown (CVX-HSC)`

**Related Commands**

- `cvx` places the switch in CVX configuration mode.

**Example**

```
These commands enter **CVX-HSC configuration** mode.

switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#
```
14.1.9.16  service openstack

The service openstack command places the switch in CVX-OpenStack configuration mode.

In order to integrate Arista switches into an OpenStack managed cloud network, OpenStack needs to interact with CVX to configure and maintain VLANs on appropriate physical switch ports that connect to hosts where the VMs reside.

CVX-OpenStack configuration mode is not a group change mode; running-config is changed immediately upon entering commands. Exiting CVX-OpenStack configuration mode does not affect running-config. The exit command returns the switch to global configuration mode.

Command Mode
CVX Configuration

Command Syntax

```
service openstack
```

Commands Available in CVX-OpenStack Configuration Mode

- name-resolution force (CVX-OpenStack)
- name-resolution interval (CVX-OpenStack)
- shutdown (CVX-OpenStack)

Related Commands

- cvx places the switch in CVX configuration mode.

Example

- These commands places the switch in CVX-OpenStack configuration mode.

```
switch(config)#cvx
switch(config-cvx)#service openstack
switch(config-cvx-openstack)#
```
service topology

The service topology command configures the topology statically on CVX without running LLDP on the servers connected to switches.

The no service topology command removes the static topology configuration from the running-config.

Command Mode

CVX Configuration Mode

Command Syntax

service topology

no service topology

Example

- The following command configures topology statically on the switch.

```
switch#config
switch(config)#cvx
switch(config-cvx)#service topology
switch(config-cvx-topology)#
```
The service vxlan command enters \texttt{CVX-VXLAN configuration} mode where the VXLAN control service is enabled and configured.

CVX-VXLAN configuration mode is not a group change mode; \texttt{running-config} is changed immediately upon entering commands. Exiting \texttt{CVX-VXLAN configuration} mode does not affect running-config. The \texttt{exit} command returns the switch to global configuration mode.

\textbf{Command Mode}

\texttt{CVX Configuration}

\textbf{Command Syntax}

\texttt{service vxlan}

\textbf{Commands Available in CVX-VXLAN Configuration Mode}

- \texttt{resync-period}
- \texttt{shutdown (CVX-VXLAN)}
- \texttt{vtep (CVX-VXLAN)}

\textbf{Related Commands}

- \texttt{cvx} places the switch in CVX configuration mode.

\textbf{Example}

- These commands enter \texttt{CVX-VXLAN configuration} mode.

```
switch(config)#cvx
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#
```
14.1.9.19  show cvx

The show cvx command displays the enable status and current configuration of CVX.

**Command Mode**
EXEC

**Command Syntax**
show cvx

**Example**
- This command displays status and configuration of CVX.

```
switch(config)#cvx
   cvx
   no shutdown
   heartbeat-interval 30
   heartbeat-timeout 90
switch(config-cvx)#dis
switch>show cvx
CVX Server
   Status: Enabled
   UUID: 75ce27ce-cc04-11e4-a404-233646319a2c
   Heartbeat interval: 30.0
   Heartbeat timeout: 90.0
switch>
```
14.1.9.20  show network physical-topology

The **show network physical-topology** command displays the network topology discovered through CVX.

**Command Mode**

EXEC

**Command Syntax**

`show network physical-topology hosts|neighbors`

**Parameters**

- **hosts** Displays all hosts visible in the topology.
- **neighbors** Displays all connections in the network topology. Table is sorted by host name, and can be optionally filtered by host.

**Example**

- This command displays all visible hosts.

```
switch#show network physical-topology hosts

Unique Id            Hostname
-------------------- ------------------------------
001c.7385.be69       cvx287.sjc.aristanetworks.com

```
14.1.9.21  shutdown (CVX)

The `shutdown` command, in cvx mode, disables or enables the switch as a CVX server. By default, CVX is disabled on the switch.

The `no shutdown` command enables the switch as a CVX server. The `shutdown` and `default shutdown` commands disable the switch as a CVX server by removing the `no shutdown` command from running-config.

**Note:** Be sure to de-configure or shut down all CVX client services before disabling CVX; failure to do so may result in CVX client services continuing to run after CVX has been disabled.

**Command Mode**

CVX Configuration

**Command Syntax**

- `shutdown`
- `no shutdown`
- `default shutdown`

**Related Commands**

- `cvx` places the switch in CVX configuration mode.

**Example**

- These commands enable the switch as a CVX server.

```
switch#config
switch(config)#cvx
switch(config-cvx)#no shutdown
switch(config-cvx)#
```

- This command disables CVX on the switch.

```
switch(config-cvx)#shutdown
switch(config-cvx)#
```
14.1.9.22 shutdown (CVX-HSC)

The shutdown command, in CVX-HSC configuration mode, disables or enables the CVX service on the switch. HSC is disabled by default.

When a CVX server enables HSC, its clients (hardware VTEPs) are able to share state to establish VXLAN tunnels without the need for a multicast control plane. Configuration is also required on the client switches.

The no shutdown command enables the HSC service; the shutdown and default shutdown commands disable the HSC service.

Command Mode

CVX-VXLAN Configuration

Command Syntax

shutdown

no shutdown

default shutdown

Related Commands

• service hsc places the switch in CVX-HSC configuration mode.

Example

• These commands enable the HSC service.

```
switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#no shutdown
switch(config-cvx-hsc)#
```

• These commands disable the HSC service.

```
switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#shutdown
switch(config-cvx-hsc)#
```
14.1.9.23  shutdown (Management-CVX)

The shutdown command, in mgmt-cvx mode, disables or enables CVX client services on the switch. CVX services are disabled by default.

The no shutdown command enables CVX client services. The shutdown and default shutdown commands disable CVX client services by removing the corresponding no shutdown command from running-config.

Command Mode

Mgmt-CVX Configuration

Command Syntax

shutdown
no shutdown
default shutdown

Example

• These commands enable CVX client services.

```
switch(config)#management cvx
switch(config-mgmt-cvx)#no shutdown
switch(config-mgmt-cvx) #
```

• This command disables CVX client services.

```
switch(config-mgmt-cvx)#shutdown
switch(config-mgmt-cvx) #
```
14.1.9.24 shutdown (CVX-OpenStack)

The `shutdown` command, in `cvx-openstack` configuration mode, disables or enables CVX-OpenStack on the switch. CVX-OpenStack is disabled by default.

When a CVX server enables OpenStack services, its clients are accessible to the OpenStack network controller (Neutron). Integrating Arista switches into an OpenStack-managed cloud network requires OpenStack to interact with CVX to configure and maintain VLANs on appropriate physical switch ports that connect to the hosts where the VMs reside.

The `no shutdown` command enables CVX-OpenStack. The `shutdown` and `default shutdown` commands disable CVX-OpenStack by removing the corresponding `no shutdown` command from running-config.

**Command Mode**

CVX-OpenStack Configuration

**Command Syntax**

`shutdown`

`no shutdown`

`default shutdown`

**Related Commands**

- `service openstack` places the switch in `CVX-OpenStack configuration` mode.

**Example**

- These commands enable CVX-OpenStack.

```
switch(config)#cvx
switch(config-cvx)#service openstack
switch(config-cvx-openstack)#no shutdown
switch(config-cvx-openstack)#
```

- These commands disable CVX-OpenStack.

```
switch(config-cvx-openstack)#
switch(config-cvx-openstack)#shutdown
switch(config-cvx-openstack)#```
14.1.9.25 shutdown (CVX-VXLAN)

The `shutdown` command, in **CVX-VXLAN configuration** mode, disables or enables the CVX VXLAN control service on the switch. VXLAN control service is disabled by default.

When a CVX server enables VXLAN control service, its clients (hardware VTEPs) are able to share state to establish VXLAN tunnels without the need for a multicast control plane. Configuration is also required on the client switches.

The `no shutdown` command enables the VXLAN control service. The `shutdown` and `default shutdown` commands disable the VXLAN control service.

**Command Mode**

CVX-VXLAN Configuration

**Command Syntax**

```
shutdown

no shutdown

default shutdown
```

**Related Commands**

- `service vxlan` places the switch in CVX-VXLAN configuration mode.

**Example**

- These commands enable VXLAN control service.

```
switch(config)#cvx
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#no shutdown
switch(config-cvx-vxlan)#
```

- These commands disable VXLAN control service

```
switch(config)#cvx
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#shutdown
switch(config-cvx-vxlan)#
```
14.1.9.26 source-interface (Management-CVX)

The source-interface command specifies the interface from where the IPv4 address is derived for use as the source for outbound CVX packets that the switch sends as a CVX client. There is no default source interface assignment.

The no source-interface and default source-interface commands remove the source interface assignment for the CVX client by deleting the source-interface statement from running-config.

Command Mode
Mgmt-CVX Configuration

Command Syntax
source-interface INT_NAME
no source-interface
default source-interface

Parameters
INT_NAME: Interface type and number. Options include:

- ethernet e_num: Ethernet interface specified by e_num.
- loopback l_num: Loopback interface specified by l_num.
- management m_num: Management interface specified by m_num.
- port-channel p_num: Port-Channel Interface specified by p_num.
- vlan v_num: VLAN interface specified by v_num.

Example

- These commands configure the CVX client to use the IP address 10.24.24.1 as the source address for its outbound packets.

```
switch#config
switch(config)#interface loopback 5
switch(config-if-Lo5)#ip address 10.24.24.1/24
switch(config-if-Lo5)#exit
switch(config)#management cvx
switch(config-mgmt-cvx)#source-interface loopback 5
switch(config-mgmt-cvx)#
```
14.1.9.27 vtep (CVX-HSC)

The HSC service sends flood lists to each VTEP through CVX. Some controllers (such as VMware NSX's Service Nodes) implement replication nodes for head-end replication of unknown packets. For these controllers, BUM packets should be sent to a single replication node (send-to-any replication), and the flood list sent by the HSC service is a list of replication nodes. Other controllers (such as Nuage VSP) require each VTEP to perform its own head-end replication. For these, BUM packets should be sent to every known VTEP, and the flood list sent by the HSC service is the list of VTEPs.

The default behavior is to use a send-to-any replication list of VTEPs. If the required behavior is send-to-all replication of, use the all option of the vtep command in CVX-HSC configuration mode.

Command Mode

CVX-HSC Configuration

Command Syntax

vtep flood list type all | any
no vtep flood list type
default vtep flood list type

Parameters

• all: send-to-all replication; flood list is the list of VTEPs.
• any: send-to-any replication; flood list is a list of replication nodes. This is the default setting.

Example

These commands configure the HSC to use send-to-all replication.

```
switch(config)#cvx
switch(config-cvx)#service hsc
switch(config-cvx-hsc)#vtep flood list type all
switch(config-cvx-hsc)#
```
The OVSDB management protocol includes provisions for control-plane MAC learning, which allows MAC addresses to be distributed among VTEPs without using the data plane. Some controllers (such as VMware NSX) take advantage of this facility; others (such as Nuage VSP) do not. By default, CVX uses control-plane MAC learning.

To switch to data plane MAC learning, use the `vtep` command in CVX-VXLAN configuration mode, as shown below.

**Command Mode**

CVX-VXLAN Configuration

**Command Syntax**

`vtep mac-learning control-plane|data-plane`

**Related Commands**

- `service vxlan` places the switch in CVX-VXLAN configuration mode.

**Example**

- These commands configure CVX to use data-plane MAC address learning.

```bash
switch(config)#cvx
switch(config-cvx)#service vxlan
switch(config-cvx-vxlan)#vtep mac-learning data-plane
switch(config-cvx)#
```
Routing Protocols

The Routing Protocols chapter contains the following sections:

- Routing Information Protocol (RIP)
- Open Shortest Path First – Version 2
- Open Shortest Path First – Version 3
- IS-IS
- Border Gateway Protocol (BGP)
- Maintenance Mode
- Bidirectional Forwarding Detection
15.1 Routing Information Protocol (RIP)

This chapter contains the following sections.

- RIP Conceptual Overview
- Running RIP on the Switch
- Configuring RIP on Multiple VRFs
- RIP Commands

15.1.1 RIP Conceptual Overview

Routing Information Protocol (RIP) is a routing protocol typically used as an Interior Gateway Protocol (IGP). RIP uses hop counts only to determine the shortest path to a destination. To avoid loops, RIP limits its paths to a maximum of 15 hops, making it an ineffective protocol for large networks. RIP Version 2 supports Classless Inter-Domain Routing (CIDR) and uses IP multicast at address 224.0.0.9 to share the routing table with adjacent routers.

RIP sends updates whenever there is a change in the network topology and periodic updates when there are no changes. Receiving switches update their routing table whenever the update includes topology changes. Because RIP transmits the entire routing table every 30 seconds, RIP updates can generate heavy traffic loads in large or complicated networks.

Each switch also sends a list of distance-vectors to each of its neighbors periodically. The distance-vector is the metric RIP uses to express the cost of a route, and it describes the number of hops required to reach a destination. Each hop is typically assigned a hop count value of 1, and the router adds 1 to the metric when it receives a routing update and adds the network to its routing table.

To remove dead routes from its routing table, RIP marks a route for deletion if the router does not receive an advertisement for it within the expiration interval, then removes it from the routing table after the deletion interval.

15.1.2 Running RIP on the Switch

15.1.2.1 Accessing RIP Configuration Mode and Enabling RIP

15.1.2.1.1 RIP Configuration Mode

The `router rip` command places the switch in router-RIP configuration mode to configure Routing Information Protocol (RIP) routing.

**Example**

This command places the switch in router-RIP configuration mode.

```
switch(config)#router rip
switch(config-router-rip)#
```

Using the `router rip` command puts the switch in router-RIP configuration mode, but does not enable RIP on the switch.

15.1.2.1.2 Enabling RIP

Routing Information Protocol (RIP) is disabled on the switch by default. The `no shutdown (RIP)` command in router-RIP configuration mode will enable RIP.

**Example**
This command enables RIP on the switch.

```
switch(config-router-rip)#no shutdown
switch(config-router-rip)#
```

Issuing this command enables RIP, but to send and receive RIP route updates and to route packets via RIP you must also specify interfaces on which RIP will run by using the `network (RIP)` command.

### 15.1.2.1.3 Disabling RIP

You can disable RIP in two ways. The `shutdown (RIP)` command disables RIP on the switch but maintains all user-entered router-RIP configuration statements in the `running-config`. The `no router rip` command disables RIP and removes all user-entered router-RIP configuration statements from the `running-config`.

**Examples**

- This command disables RIP on the switch and removes all user-entered router-RIP configuration.

```
switch(config)#no router rip
switch(config)#
```

- This command disables RIP on the switch, but preserves all user-entered router-RIP configuration.

```
switch(config-router-rip)#shutdown
switch(config-router-rip)#
```

### 15.1.2.2 Configuring RIP

Issuing the `no shutdown (RIP)` command in router-RIP configuration mode enables RIP, but to run RIP on an interface you must specify a RIP network by using the `network (RIP)` command.

You can also configure the redistribution of routes learned from other protocols, set the default metric and administrative distance for redistributed routes, configure the timing of various RIP events, and configure specific interfaces to send RIP update packets by broadcast instead of multicast.

#### 15.1.2.2.1 Specifying RIP Networks

The `network (RIP)` command identifies networks on which RIP will run and also specifies which routes RIP will accept into its routing table. You can issue the `network (RIP)` command multiple times to build up a list of RIP networks. No RIP networks are configured by default, so in order to route packets and send and receive RIP updates you must specify one or more RIP networks.

To disable RIP on a specific network, use the `no network (RIP)` command.

**Examples**

- This command enables RIP on `10.168.1.1/24`.

```
switch(config-router-rip)network 10.168.1.1/24
switch(config-router-rip)#
```

- This command disables RIP on `10.168.1.1/24`.

```
switch(config-router-rip)#no network 10.168.1.1/24
switch(config-router-rip)#
```
15.1.2.2   Redistributing Routes Learned from Other Protocols into RIP

To enable route import from a specified protocol into RIP, use the `redistribute (RIP)` command. Additionally, you can apply a route map to the incoming routes to filter which routes are added to the RIP routing table. All connected routes are redistributed into RIP by default.

**Example**

This command redistributes all routes learned from OSPF into RIP.

```
switch(config-router-rip)#redistribute OSPF
switch(config-router-rip)#
```

15.1.2.3   Configuring RIP Timers

When RIP is running on the switch, it sends unsolicited route updates and deletes expired routes at regular intervals. To configure the timing of those events, use the `timers (RIP)` command. The command takes three parameters: the update interval, the route expiration time, and the route deletion time.

The update interval is the amount of time in seconds that the switch waits between sending unsolicited RIP route updates to its neighbors. The route expiration time is how long the switch waits before marking an unadvertised route for deletion (the counter resets whenever an advertisement for the route is received). And the route deletion time is how long the switch waits between marking a route for deletion and removing it from the routing table. During the deletion interval, the switch continues to forward packets on the route.

**Example**

This command sets the update interval to 60 seconds, expiration time to 90 seconds, and deletion time to 150 seconds.

```
switch(config-router-rip)#timers 60 90 150
switch(config-router-rip)#
```

15.1.2.4   Configuring an Interface to Transmit Broadcast RIP Updates

By default, the switch uses RIP version 2 and multicasts RIP update packets from all participating interfaces. To reconfigure a specific interface to send updates as broadcast packets, use the `rip v2 multicast disable` command in the configuration mode for the interface.

**Example**

The following commands configure RIP version 2 broadcasting on `interface ethernet 5`.

```
switch(config)#interface ethernet5
switch(config-if-Et5)#rip v2 multicast disable
switch(config-if-Et5)#exit
switch(config)#
```

15.1.3   Displaying RIP Information

15.1.3.1   Displaying RIP Routes

To see a listing of the RIP routes in the switch's routing table, use the `show ip rip database` command. (You can also display similar information using the RIP option in the `show ip route` command.)

**Examples**
Routing Protocols

• This command displays all active rip routes.

```
switch>show ip rip database
10.168.11.0/24 directly connected, Et4
10.168.13.0/24
[1] via 10.168.14.2, 00:00:25, Et4
[2] via 10.168.15.2, 00:00:20, Et1
10.168.13.0/24
[1] via 10.168.14.2, 00:00:25, Et3
```

• This command submits a query for RIP route information for a network.

```
switch>show ip rip database 10.168.13.0/16
10.168.13.0/24
[1] via 10.168.14.2, 00:00:25, Et4
[2] via 10.168.15.2, 00:00:20, Et1
```

15.1.2.3.2 Displaying RIP Route Gateways

To see information about the switch’s RIP route gateways, use the `show ip rip neighbors` command. The output displays the IPv4 address, the last heard time of the gateway, and characteristic flags applying to the gateway.

**Example**

This command displays information about all the gateways of RIP routes.

```
switch>show ip rip neighbors
Gateway     Last-Heard   Bad-Packets   Bad-Routes   Flags
10.2.12.33  00:00:15                                SRC, TRSTED, ACCPTED, RJCTED, Q_RJCTED, AUTHFAIL
```

15.1.3 Configuring RIP on Multiple VRFs

VRF support for Routing Information Protocol (RIP) allows instances of RIP on multiple non-default VRFs on the same router. By default, all interfaces belong to the default VRF until VRF forwarding is executed.

The `vrf instance` and `vrf (Interface mode)` commands configure a non-default VRF, enable routing in it, and configure the network command under the configuration router RIP for the prefix to which the interface belongs.

The `router rip vrf` command places the switch in router-RIP configuration mode to configure a RIP routing instance in a non-default VRF.

**Examples**

• These commands configure a non-default VRF and enable unicast routing in it.

```
switch(config)#vrf instance test
switch(config-vrf-test)#exit
switch(config)#ip routing vrf test
switch(config)#
```

• This command configures a RIP instance in a non-default VRF.

```
switch(config)#router rip vrf test
switch(config-router-rip-router-rip-vrf-test)#no shutdown
switch(config-router-rip)#exit
switch(config)#
```
• This command configures an interface as part of a non-default VRF by configuring the network command under the configuration router RIP for the prefix to which the interface belongs.

```bash
switch(config)#interface Ethernet 3 / 1
switch(config-if-Et3/1)#no switchport
switch(config-if-Et3/1)#ip address 1.0.0.1/24
switch(config-if-Et3/1)#vrf test
switch(config-if-Et3/1)#network 1.0.0.1
switch(config-if-Et3/1)#exit
switch(config)#
```
15.1.4 RIP Commands

Global Configuration Commands
• router rip
• router rip vrf

Interface Configuration Commands
• rip v2 multicast disable

Router-RIP Configuration Mode
• distance (RIP)
• distribute-list (RIP)
• metric default
• network (RIP)
• redistribute (RIP)
• shutdown (RIP)
• timers (RIP)

Display Commands – EXEC Mode
• show ip rip database
• show ip rip neighbors
15.1.4.1 distance (RIP)

The `distance` command assigns an administrative distance to routes that the switch learns through RIP. Routers use administrative distances to select a route when two protocols provide routing information to the same destination. Distance values range from 1 to 255; lower distance values correspond to higher reliability. The default RIP distance value is 120.

The `no distance` and `default distance` commands restore the administrative distance default value of 120 by removing the `distance` command from `running-config`.

**Command Mode**

Router-RIP Configuration

**Command Syntax**

```
distance distance_value
no distance
default distance
```

**Parameters**

- `distance_value` distance assigned to RIP routes. Values range from 1 to 255.

**Example**

These commands assign an administrative distance of 75 to RIP routes.

```
switch(config)#router rip
switch(config-router-rip)#distance 75
switch(config-router-rip)#
```
15.1.4.2 distribute-list (RIP)

The `distribute-list` command allows users to filter out routes that are received or sent out. The distribute-list command influences which routes the router installs into its routing table and advertises to its neighbors.

Configuration Notes:
- Only one inbound distribute-list is allowed per interface.
- Only one outbound distribute-list is allowed per interface.
- Only one globally-defined inbound distribute-list is allowed.
- Only one globally-defined outbound distribute-list is allowed.
- Not all match clauses in a route-map are supported using RIP routes filtering. These match clauses for distribute-lists are supported:
  - `match ip address access-list`
  - `match ip address prefix-list`
- The `distribute-list` command does not enforce the specified route-map to contain only supported match clauses.
- Permit or deny can be specified in both prefix/access list and route-map configurations. The following rules apply when filtering routes:
  - Routes permitted by the prefix/access lists are treated as matched.
  - Matched routes are filtered based on the permit or deny option configured for the route-map clause.
  - Unmatched routes are further evaluated by the next route-map clause.
  - If a route does not match any clause in a route-map, it is denied.
  - If the route-map given in the `distribute-list` command is not configured, then all routes are permitted.
  - When multiple inbound (or outbound) distribute-lists are configured, only the most specific one is applied.

The `no distribute-list` and `default distribute-list` commands remove the corresponding `distribute-list` command from `running-config`.

Command Mode
Router-RIP Configuration

Command Syntax
```
distribute-list DIRECTION MAP [INTF]
no distribute-list DIRECTION MAP [INTF]
default distribute-list DIRECTION MAP [INTF]
```

Parameters
- **DIRECTION** direction specifies if distribute-list is applied on inbound or outbound traffic. Valid options include:
  - `in`: specifies inbound as the direction the distribute-list is applied.
  - `out`: specifies outbound as the direction the distribute-list is applied.
- **MAP** specifies route map that assigns attribute values to the network. Options include:
  - `no parameter`: attributes are not assigned through a route map.
  - `route-map map_name`: attributes listed by specified route map are assigned to the network.
- **INTF** interface to be configured. Options include:
  - `ethernet e_num`: Ethernet interface.
  - `loopback l_num`: Loopback interface.
• **port-channel \textit{p\_num}** Port channel interface.
• **vlan \textit{v\_num}** VLAN interface.

**Examples**

• The following commands demonstrate that an \textit{access-list} or \textit{prefix-list} can be used within a \textit{route-map} for use in a \textit{distribute-list}.

```
switch(config)#ip prefix-list 8to24 seq 5 permit 0.0.0.0/0 ge 8 le 24
switch(config)#route-map myRouteMap permit 10
switch(config-route-map-myRouteMap)#match ip address prefix-list 8to24
switch(config-route-map-myRouteMap)#exit
switch(config)#router rip
switch(config-router-rip)#distribute-list in route-map myRouteMap
```

• These commands suppress routes advertised on a particular interface.

```
switch(config)#ip prefix-list 2 seq 10 deny 30.1.1.0/24
switch(config)#route-map myRmOut permit 10
switch(config-route-map-myRmOut)#match ip address prefix-list 2
switch(config-route-map-myRmOut)#exit
switch(config)#router rip
switch(config-router-rip)#distribute-list out route-map myRmOut
```
15.1.4.3 metric default

The `metric default` command specifies the metric value assigned to RIP routes learned from other protocols. All routes imported into RIP receive the default metric unless a matching route-map exists for the route. The route metric of 0 is assigned to redistributed connected and static routes. The default metric values range from 0 to 16 with a default value of 1.

The `no metric default` and `default metric default` commands remove the `metric default` command from `running-config` and returns the metric value to its default value of 1.

**Command Mode**

Router-RIP Configuration

**Command Syntax**

```
metric default metric_value
no metric default
default metric default
```

**Parameters**

- `metric_value` default metric value assigned. Values range from 0 to 16; default is 1.

**Example**

This command sets the default metric value to 5.

```
switch(config)#router rip
switch(config-router-rip)#metric default 5
switch(config-router-rip)#
```
The network command specifies which network the switch runs Routing Information Protocol (RIP), and also specifies which routes will be accepted into the RIP routing table. Multiple network commands can be issued to create a network list on which RIP runs.

The switch enables RIP on all interfaces in the specified network.

The no network and default network commands disable RIP on the specified network by removing the corresponding network command from running-config.

**Command Mode**

Router-RIP Configuration

**Command Syntax**

`network NETWORK_ADDRESS`

`no network NETWORK_ADDRESS`

`default network NETWORK_ADDRESS`

**Parameters**

`NETWORK_ADDRESS` network IP address. Entry formats include the following:

- `ipv4_subnet` IPv4 subnet (CIDR notation).
- `ipv4_addr mask` wildcard_mask IP address and wildcard-mask.

**Examples**

- This command enables RIP on `10.168.1.1/24`.

```
switch(config)#router rip
switch(config-router-rip)#network 10.168.1.1/24
switch(config-router-rip)#
```

- This command also enables RIP on `10.168.1.1/24`.

```
switch(config-router-rip)#network 10.168.1.1 mask 0.0.0.255
switch(config-router-rip)#
```
15.1.4.5 redistribute (RIP)

The redistribute command enables the importing of routes from a specified routing domain to RIP.

- **connected** by default, RIP redistributes all connected routes that are established when IP is enabled on an interface. The route-map parameter facilitates the exclusion of connected routes from redistribution by specifying a route map that denies the excluded routes.
- **BGP, OSPF, and IP static routes** by default, routes are not redistributed. The redistribute command without the route-map parameter facilitates the redistribution of all routes from the specified source.

The no redistribute and default redistribute commands reset the default route redistribution setting by removing the redistribute statement from running-config.

**Command Mode**

Router-RIP Configuration

**Command Syntax**

`redistribute connected ROUTE_MAP`

`redistribute ROUTE_TYPE [ROUTE_MAP]`

`no redistribute connected ROUTE_MAP`

`no redistribute ROUTE_TYPE`

`default redistribute connected ROUTE_MAP`

`default redistribute ROUTE_TYPE`

**Parameters**

- **ROUTE_TYPE** source from which routes are redistributed. Options include:
  - **BGP** routes from a BGP domain.
  - **OSPF** routes from an OSPF domain.
  - **OSPF match external** routes external to RIP, but imported from OSPF.
  - **OSPF match internal** OSPF routes that are internal to the AS.
  - **static** IP static routes.
- **ROUTE_MAP** route map that determines the routes that are redistributed. Options include:
  - **no parameter** all routes are redistributed.
  - **route-map map_name** only routes in the specified route map are redistributed.

**Example**

These commands redistribute OSPF routes into RIP.

```
switch(config)#router rip
switch(config-router-rip)#redistribute OSPF
switch(config-router-rip)#
```
15.1.4.6  rip v2 multicast disable

The `rip v2 multicast disable` command specifies the transmission of Routing Information Protocol (RIP) Version 2 update packets from the configuration mode interface as broadcast to `255.255.255.255`.

The `no rip v2 multicast disable` and `default rip v2 multicast disable` commands specify the transmission of update packets as multicast to `224.0.0.9` if the configuration mode interface is multicast capable. Updates are broadcast if the interface is not multicast capable.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

- `rip v2 multicast disable`
- `no rip v2 multicast disable`
- `default rip v2 multicast disable`

**Example**

The following example configures version 2 broadcasting on `interface Ethernet 5`.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#rip v2 multicast disable
switch(config-if-Et5)#exit
switch(config)#exit
```
15.1.4.7  router rip vrf

The `router rip` command places the switch in router-RIP configuration mode to configure an RIP routing instance in the non-default VRF.

The `no router rip vrf` and `default router rip vrf` commands disable an RIP routing instance in the non-default VRF, and remove all user-entered `router-rip` configuration statements from `running-config`. To disable RIP without removing configuration statements, use the `shutdown (RIP)` command.

The `exit` command returns the switch to global configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

`router rip vrf [RIP_INSTANCE]`

`no router rip vrf [RIP_INSTANCE]`

`default router rip vrf [RIP_INSTANCE]`

**Parameters**

RIP_INSTANCE configure a RIP VRF instance in the non-default VRF.

**Examples**

- This command configures a RIP instance in the non-default VRF.

```
switch(config)#router rip vrf test
switch(config-router-rip-router-rip-vrf-test)#no shutdown
switch(config-router-rip)#exit
switch(config)#
```

- This command disables a RIP instance in the non-default VRF.

```
switch(config)#no router rip vrf test
switch(config)#
```
15.1.4.8  router rip

The router rip command places the switch in router-rip configuration mode to configure the Routing Information Protocol (RIP) routing process. Router-rip configuration mode is not a group change mode; running-config is changed immediately upon command entry. The exit command does not affect running-config.

The no router rip and default router rip commands disable RIP and remove all user-entered router-rip configuration statements from running-config. To disable RIP without removing configuration statements, use the shutdown (RIP) command.

The exit command returns the switch to the global configuration mode.

Command Mode
Global Configuration

Command Syntax
router rip
no router rip
default router rip

Commands Available in router-rip Configuration Mode
- distance (RIP)
- network (RIP)
- redistribute (RIP)
- shutdown (RIP)
- timers (RIP)

Example
This command places the switch in the router-rip configuration mode.

```
switch(config)#router rip
switch(config-router-rip)#
```
The `show ip rip database` command displays information about routes in the Routing Information Base. The default command displays active routes and learned routes not used in deference to higher priority routes from other protocols.

This command has the following forms:

- **default (no arguments)**: information about all RIP routes.
- **IPv4 address and mask**: information about the referenced addresses.
- **active**: information about routes not superseded by routes from other protocols.

**Command Mode**

EXEC

**Command Syntax**

`show ip rip database [FILTER]`

**Parameters**

**FILTER**  routing table entries that the command displays. Values include :

- **no parameter**  displays all routing table entries.
- **active**  displays all active routing table entries.
- **net_addr**  subnet address (CIDR or address-mask). Command displays entries in this subnet.

**Examples**

- **This command displays all active rip routes.**
  
  ```
  switch> show ip rip database active
  10.168.11.0/24 directly connected, Et4
  10.168.13.0/24
  [1] via 10.168.14.2, 00:00:25, Et4
  [2] via 10.168.15.2, 00:00:20, Et1
  10.168.13.0/24
  [1] via 10.168.14.2, 00:00:25, Et3
  ```

- **This command submits a query for RIP route information for a network.**
  
  ```
  switch> show ip rip database 10.168.13.0/16
  10.168.13.0/24
  [1] via 10.168.14.2, 00:00:25, Et4
  [2] via 10.168.15.2, 00:00:20, Et1
  ```

- **This command returns information for all RIP routes.**
  
  ```
  switch> show ip rip database
  10.1.0.0/255.255.255.0
  [1] via 10.8.31.15, 00:00:21, Et2, holddown
  10.2.0.0/255.255.255.0
  [1] via 10.8.31.15, 00:00:21, Et2, holddown
  10.3.0.0/255.255.255.0
  [1] via 10.8.31.15, 00:00:21, Et2, inactive
  10.212.0.0/255.255.255.0
  [1] via 10.8.31.15, 00:00:21, Et2, active
  10.214.0.0/255.255.255.0
  [1] via 10.8.12.17, 00:00:30, Et4, active
  ```
15.1.4.10 show ip rip neighbors

The `show ip rip neighbors` command displays information about all RIP route gateways. The output displays the IPv4 address, the last heard time of the gateway, and characteristic flags applying to the gateway.

**Command Mode**

EXEC

**Command Syntax**

`show ip rip neighbors`

**Example**

The `show ip rip neighbors` command displays information about all gateways of RIP routes.

```
switch>show ip rip neighbors
Gateway    Last-Heard   Bad-Packets  Bad-Routes  Flags
10.2.12.33  00:00:15            SRC, TRSTED,
                                  ACCPTED, RJCTED,
                                  Q_RJCTED, AUTHFAIL
```

15.1.4.11  shutdown (RIP)

The **shutdown** command disables RIP on the switch without modifying the RIP configuration. RIP is disabled by default.

The **no shutdown** command enables RIP. The **default shutdown** command disables RIP.

**Command Mode**
Router-RIP Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Examples**

- This command disables RIP on the switch.

  switch(config)#router rip
  switch(config-router-rip)#shutdown
  switch(config-router-rip)#

- This command enables RIP on the switch.

  switch(config-router-rip)#no shutdown
  switch(config-router-rip)#
15.1.4.12 timers (RIP)

The `timers` command configures the update interval, the expiration time, and the deletion time for routes received and sent through RIP. The command requires value declaration of all values.

- The update time is the interval between unsolicited route responses.
- The expiration time is initialized when a route is established and any time an update is received for the route.
- The deletion time is initialized when the expiration time elapses and the route is invalid. It is retained in the routing table until deletion time expiry.

The `no timers` and `default timers` commands return the timer values to their default values by removing the `timers` command from `running-config`.

**Command Mode**
Router-RIP Configuration

**Command Syntax**
```
timers update_time expire_time deletion_time
```
```
o timers
```
```
default timers
```

**Parameters**
- `update_time`   Default is 30 seconds.
- `expire_time`   Default is 180 seconds.
- `deletion_time` Default is 120 seconds.

Parameter values are in seconds and range from 5 to 2147483647.

**Example**
This command sets the update (60 seconds), expiration (90 seconds), and deletion (150 seconds) times.

```
switch(config)#router rip
switch(config-router-rip)#timers 60 90 150
switch(config-router-rip)#
```
15.2 Open Shortest Path First – Version 2

Open Shortest Path First (OSPF) is a link-state routing protocol that operates within a single autonomous system. OSPF version 2 is defined by RFC 2328.

This section contains the following topics:

- OSPFv2 Introduction
- OSPFv2 Conceptual Overview
- Configuring OSPFv2
- OSPFv2 Configuration Examples
- OSPFv2 Commands

15.2.1 OSPFv2 Introduction

This section contains the following topics:

- Supported Features
- Features Not Supported

15.2.1.1 Features Not Supported

The following OSPFv2 functions are not supported in the current version:

- NBMA, demand circuit, and P2MP interfaces
- OSPFv2 MIB support

15.2.1.2 Supported Features

Arista switches support the following OSPFv2 functions:

- A single OSPFv2 instance.
- Intra- and inter-area routing.
- Type 1 and 2 external routing.
- Broadcast and P2P interfaces.
- Stub areas.
- Not so stubby areas (NSSA) (RFC 3101).
- MD5 Authentication.
- Redistribution of static, IP, and BGP routes into OSPFv2 with route map filtering.
- Opaque LSAs (RFC 2370).
- Graceful restart (RFC 3623).
- OSPF Routes over GRE Tunnels

15.2.2 OSPFv2 Conceptual Overview

This section contains the following topics:

- Storing Link States
- Topology
- Link Updates
- OSPFv2 Route Redistribution Instance
- OSPFv2 and BFD Sessions for Adjacencies in any State
- OSPFv2 Multiple Instances Support
- OSPF Routes over GRE Tunnels
15.2.2.1 Storing Link States

OSPFv2 is a dynamic, link-state routing protocol, where links represent interfaces or routable paths. Dynamic routing protocols calculate the most efficient path between locations based on bandwidth and device status.

A Link State Advertisement (LSA) is an OSPFv2 packet that communicates a router’s topology to other routers. The Link State Database (LSDB) stores an area's topology database and is composed of LSAs received from other routers. Routers update the LSDB by storing LSAs from other routers.

15.2.2.2 Topology

An Autonomous System (AS) is the IP domain within which a dynamic protocol controls the routing of traffic. In OSPFv2, an AS is composed of areas, which define the LSDB computation boundaries. All routers in an area store identical LSDBs. Routers in different areas exchange updates without storing the entire database, reducing information maintenance on large, dynamic networks.

An AS shares internal routing information from its areas and external routing information from other processes to inform routers outside the AS about routes the network can access. Routers that advertise routes on other ASs commit to carry data to the IP space on the route.

OSPFv2 defines these routers:

- Internal Router (IR) a router whose interfaces are contained in a single area. All IRs in an area maintain identical LSDBs.
- Area Border Router (ABR) a router that has interfaces in multiple areas. ABRs maintain one LSDB for each connected area.
- Autonomous System Boundary Router (ASBR) a gateway router connecting the OSPFv2 domain to external routes, including static routes and routes from other autonomous systems.
- OSPFv2 Router Types displays the OSPFv2 router types.

![OSPF Autonomous System](image)

Figure 44: OSPFv2 Router Types

OSPFv2 areas are assigned a number between 0 and 4,294,967,295 (2^{32} - 1). Area numbers are often expressed in dotted decimal notation, similar to IP addresses.

Each AS has a backbone area, designated as area 0, that connects to all other areas. The backbone receives routing information from all areas, then distributes it to the other areas as required.

OSPFv2 area types include:

- Normal area accepts intra-area, inter-area, and external routes. The backbone is a normal area.
- Stub area does not receive router advertisements external to the AS. Stub area routing is based on a default route.
• Not-So-Stubby-Area (NSSA) may import external routes from an ASBR, does not receive external routes from the backbone, and does not propagate external routes to other areas.

15.2.2.3 Link Updates

Routers periodically send hello packets to advertise status and establish neighbors. A router's hello packet includes IP addresses of other routers from which it received a hello packet within the time specified by the router dead interval. Routers become neighbors when they detect each other in their hello packets if they:

• share a common network segment.
• are in the same area.
• have the same hello interval, dead interval, and authentication parameters.

Neighbors form adjacencies to exchange LSDB information. A neighbor group uses hello packets to elect a Designated Router (DR) and Backup Designated Router (BDR). The DR and BDR become adjacent to all other neighbors, including each other. Only adjacent neighbors share database information.

OSPFv2 Neighbors illustrates OSPFv2 neighbors.

The DR is the central contact for database exchanges. Switches send database information to their DR, which relays the information to the other neighbors. All routers in an area maintain identical LSDBs. Switches also send database information to their BDR, which stores this data without distributing it. If the DR fails, the BDR distributes LSDB information to its neighbors.

OSPFv2 routers distribute LSAs by sending them on all of their active interfaces. The router generates an LSA for a network defined and active on a passive interface but will not transmit this LSA on the passive interface as no adjacencies are formed.

When a router's LSDB is changed by an LSA, it sends the changes to the DR and BDR for distribution to the other neighbors. Routing information is updated only when the topology changes.

Routers use Dijkstra's algorithm to calculate the shortest path to all known destinations, based on cumulative route cost. The cost of an interface indicates the transmission overhead and is usually inversely proportional to its bandwidth.
15.2.2.4 OSPFv2 Route Redistribution Instance

OSPFv2 Route Redistribution is used for redistributing OSPFv2 leaked and non-leaked routes from one instance to another when multiple OSPFv2 instances are configured. The OSPFv2 Route Redistribution is supported on all platforms in the multi-agent routing mode.

15.2.2.5 OSPFv2 and BFD Sessions for Adjacencies in any State

- BFD sessions are only established for OSPFv2 adjacencies that are in the FULL state. In a LAN environment this results in BFD sessions not being established for OSPFv2 adjacencies with DR Other neighbors.
- This feature provides configuration that enables the establishment of BFD sessions for OSPFv2 adjacencies that are in any state. This results in the BFD sessions being established for OSPFv2 adjacencies with DR Other neighbors.

15.2.2.6 OSPFv2 Multiple Instances Support

*EOS Release 4.22.1F* adds support for multiple OSPFv2 instances to be configured in the default VRF. OSPFv2 Multiple Instances Support provides isolation and allows segregating and dividing the link state database based on the interface.

Basic OSPFv2 functionality along with redistribution of OSPFv2 routes (all instances) into BGP and default information originate always is available forward from the *EOS Release 4.22.1F*. Support for graceful restart and BFD with multiple OSPFv2 instances was added in the *EOS Release 4.23.1*.

15.2.2.6.1 OSPFv2 Multiple Instances Support Platform Compatibility

OSPFv2 Multiple Instances Support is supported on all platforms.

15.2.2.7 OSPF Routes over GRE Tunnels

This feature introduces the support for OSPF routes over GRE tunnels under default as well as non-default VRFs. The feature is disabled by default.

15.2.2.7.1 Limitations

The platform does not support any arbitrarily created TCAM profile. When the TCAM profile cannot be programmed, the show command prints **ERROR** in the status column.

15.2.3 Configuring OSPFv2

These sections describe basic OSPFv2 configuration steps:

- Configuring the OSPFv2 Instance
- Configuring OSPFv2 Areas
- Support for OSPFv2 dn-bit-ignore
- OSPFv2 Area Filter by Prefix-List
- IPv4 Unnumbered Interfaces
- Configuring Interfaces for OSPFv2
- Enabling OSPFv2
- OSPFv2 Multiple Instances Support Configuration
- OSPF Routes over GRE Tunnels Configuration
- Displaying OSPFv2 Status
15.2.3.1 Configuring the OSPFv2 Instance

15.2.3.1.1 Entering OSPFv2 Configuration Mode

The `router ospf` command places the switch in router-ospf configuration mode and creates an OSPFv2 instance if one was not previously created. The switch only supports one OSPFv2 instance and all OSPFv2 configuration commands apply to this instance.

When an OSPFv2 instance is already configured, the command must specify its process ID. Any attempt to define additional instances will fail and generate errors.

The process ID is local to the router and is used to identify the running OSPFv2 process. Neighbor OSPFv2 routers can have different process ID’s.

**Example**

This command places the switch in `router-ospf` configuration mode and, if not previously created, creates an OSPFv2 instance with a process ID of **100**.

```
switch(config)#router ospf 100
switch(config-router-ospf)#
```

15.2.3.1.2 Defining the Router ID

The router ID is a 32-bit number assigned to a router running OSPFv2. This number uniquely labels the router within an Autonomous System. Status commands identify the switch through the router ID.

The switch sets the router ID to the first available alternative in the following list:

1. The `router-id` command.
2. The loopback IP address, if a loopback interface is active on the switch.
3. The highest IP address on the router.

**Note:** When configuring VXLAN on an MLAG, always manually configure the OSPFv2 router ID to prevent the switch from using the common VTEP IP address as the router ID.

The `router-id (OSPFv2)` command configures the router ID for an OSPFv2 instance.

**Example**

This command assigns **10.1.1.1** as the OSPFv2 router ID.

```
switch(config-router-ospf)#router-id 10.1.1.1
switch(config-router-ospf)#
```

15.2.3.1.3 Global OSPFv2 Parameters

These router-ospf configuration mode commands define OSPFv2 behavior.

**LSA Overload**

The `max-lsa (OSPFv2)` command specifies the maximum number of LSAs allowed in an LSDB database and configures the switch behavior when the limit is approached or exceeded. An LSA overload condition triggers these actions:

- **Warning:** the switch logs OSPF MAXLSAWARNING if the LSDB contains a specified percentage of the LSA maximum.
- **Temporary shutdown:** when the LSDB exceeds the LSA maximum, OSPFv2 is disabled and does not accept or acknowledge new LSAs. The switch re-starts OSPFv2 after a specified period (the default is **5** minutes).
**Permanent shutdown**: the switch permanently disables OSPFv2 after performing a specified number of temporary shutdowns (the default is 5). This state usually indicates the need to resolve a network condition that consistently generates excessive LSA packets.

OSPFv2 is re-enabled with a `router ospf` command.

The LSDB size restriction is removed by setting the LSA limit to zero.

**Note**: if OSPFv2 has entered permanent shutdown, it can also be restarted by increasing the LSA limit to a value larger than the number of LSAs in the database. Setting the max-LSA value to zero will also restart OSPFv2, and will disable overload protection.

**Example**

- This command configures the OSPFv2 maximum LSA count to 20000 and triggers these actions:
  - The switch logs an `OSPF MAXLSAWARNING` if the LSDB has 8000 LSAs (40% of 20000).
  - The switch temporarily disables OSPFv2 for 10 minutes if the LSDB contains 20000 LSAs.
  - The switch permanently disables OSPFv2 after four temporary OSPFv2 shutdowns.
  - The shutdown counter resets if the LSDB contains less than 20,000 LSAs for 20 minutes.

```
switch(config-router-ospf)#max-lsa 20000 40 ignore-time 10 ignore-count 4 reset-time 20
```

**Logging Adjacency Changes**

The `log-adjacency-changes` (OSPFv2) command configures the switch to log OSPFv2 link-state changes and transitions of OSPFv2 neighbors into the up or down state.

**Examples**

- This command configures the switch to log transitions of OSPFv2 neighbors into the up or down state.

```
switch(config-router-ospf)#log-adjacency-changes
```

- This command configures the switch to log all OSPFv2 link-state changes.

```
switch(config-router-ospf)#log-adjacency-changes detail
```

**OSPF RFC Compatibility**

*RFC 2328* and *RFC 1583* specify different methods for calculating summary route metrics. The `compatible` (OSPFv2) command allows the selective disabling of compatibility with *RFC 2328*.

**Example**

This command sets the OSPF compatibility list with *RFC 1583*.

```
switch(config)#router ospf 6
switch(config-router-ospf)#compatible rfc1583
```

**Administrative Distance**

The `distance ospf` (OSPFv2) command configures the administrative distance for intra-area, inter-area, or external OSPF routes. To configure the administrative distance for multiple route types,
the command must be entered multiple times. Administrative distances compare dynamic routes configured by different protocols. The default administrative distance for all routes is **110**.

**Note:** OSPF links will flap if the administrative distance value is adjusted while OSPF is running, whether it is adjusted by entering the `distance ospf` command directly through the CLI or by applying a configuration file that contains the command.

**Example**

This command configures an administrative distance of 95 for OSPFv2 intra-area routes, and will cause links to flap if issued while OSPF is running.

```
switch(config-router-ospf)#distance ospf intra-area 95
switch(config-router-ospf)#
```

**Passive Interfaces**

The `passive-interface <interface>` (OSPFv2) command prevents the transmission of hello packets on the specified interface. Passive interfaces drop all adjacencies and do not form new adjacencies. Passive interfaces send LSAs but do not receive them. The router does not send or process OSPFv2 packets received on passive interfaces. The router advertises the passive interface in the router LSA.

The `no passive-interface` command re-enables OSPFv2 processing on the specified interface.

**Examples**

- This command configures `vlan 2` as a passive interface.
  ```
  switch(config-router-ospf)#passive-interface vlan 2
  switch(config-router-ospf)#
  ```

- This command configures `vlan 2` as an active interface.
  ```
  switch(config-router-ospf)#no passive-interface vlan 2
  switch(config-router-ospf)#
  ```

**Redistributing Connected Routes**

Redistributing connected routes causes the OSPFv2 instance to advertise all connected routes on the switch as external OSPFv2 routes. Connected routes are routes that are established when IPv4 is enabled on an interface.

**Example**

The `redistribute (OSPFv2) connected` command converts connected routes to OSPFv2 external routes.

```
switch(config-router-ospf)#redistribute connected
switch(config-router-ospf)#
```

**Redistributing Static Routes**

Redistributing static routes causes the OSPFv2 instance to advertise all static routes on the switch as external OSPFv2 routes. The switch does not support redistributing individual static routes.

**Examples**

- The `redistribute (OSPFv2) static` command converts the static routes to OSPFv2 external routes.
  ```
  switch(config-router-ospf)#redistribute static
  ```
The `no redistribute (OSPFv2)` command stops the advertising of the static routes as OSPFv2 external routes.

Filtering Routes with Distribute Lists

An OSPF distribute list uses a route map or prefix list to filter specific routes from incoming OSPF LSAs; this filtering occurs after SPF calculation. The filtered routes are not installed on the switch, but are still included in LSAs sent by the switch. An OSPF router instance can have one distribute list configured.

If a prefix list is used, destination prefixes that do not match the prefix list will not be installed. If a route map is used, routes may be filtered based on address, next hop, or metric. OSPF external routes may also be filtered by metric type or tag.

The `distribute-list in` command specifies the filter to be used and applies it to the OSPF instance.

**Example**

These commands configure a prefix-list named `dist_list1` in OSPF instance `5` to filter certain routes from incoming OSPF LSAs.

```
switch(config)#router ospf 5
switch(config-router-ospf)#distribute-list prefix-list dist_list1 in

15.2.3.1.4 Configuring OSPFv2 Route Redistribution

Use the `redistribute ospf instance` command to redistribute either the non-leaked routes, or both leaked and non-leaked routes. This command is configured under the `router-ospf` mode.

**Examples**

- The `leaked` clause includes both internal and external routes.

```
switch(config-router-ospf)#redistribute ospf instance include leaked
Options:
    include Include leaked routes
    match Routes learned by the OSPF protocol
    route-map Specify which route map to use
```

- The `match` clause allows matching on the different OSPFv2 route types.

```
switch(config-router-ospf)#redistribute ospf instance match external
Options:
    external OSPF routes learned from external sources
    internal OSPF routes learned from internal sources
    nssa-external OSPF routes learned from external NSSA sources
```

- The following command redistributes the OSPFv2 external routes from all other OSPFv2 instances in the same VRF into the given instance.

```
switch(config-router-ospf)#redistribute ospf instance match external
```
• The following command redistributes the OSPFv2 internal leaked and non-leaked routes from all other instances in all VRFs into the given instance.

```bash
switch(config-router-ospf)#redistribute ospf instance include leaked match internal
```

• Matching based on the OSPFv2 instance ID is supported in the route-map.

```bash
switch(config)#route-map rm1 permit 10
switch(config-route-map-rm1)#match ospf instance 3
```

• The following command redistributes the OSPFv2 external routes from the OSPFv2 instance with ID 3 in the same VRF into the given instance.

```bash
switch(config-router-ospf)#redistribute ospf instance match external route-map rm1
```

**Show Commands**

• The `show ip ospf database external` command is used to verify if the AS-External LSAs are created in the instance for the redistributed route and advertised into the OSPFv2 domain.

• The `show route-map` command is used to display the details of a configured route-map.

### 15.2.3.2 Configuring OSPFv2 Areas

OSPFv2 areas are configured through area commands. The switch must be in `router-ospf` configuration mode, as described in [Entering OSPFv2 Configuration Mode](#), to run area commands.

Areas are assigned a 32-bit number that is expressed in decimal or dotted-decimal notation. When an OSPFv2 instance configuration contains multiple areas, the switch only configures areas associated with its interfaces.

#### 15.2.3.2.1 Configuring the Area Type

The `area` (OSPFv2) commands specifies the area type, refer OSPFv2 Commands section for the `area` commands. The switch supports three area types:

- **Normal area**: Area that accepts intra-area, inter-area, and external routes. The backbone area (area 0) is a normal area.
- **Stub area**: Area that does not advertise external routes. External routes are reached through a default summary route (0.0.0.0). Networks with no external routes do not require stub areas.
- **Not So Stubby Area (NSSA)**: ASBRs advertise external LSAs directly connected to the area. External routes from other areas are not advertised and are reached through a default summary route.

The default area type is normal.

**Examples**

• This command configures area **45** as a stub area.

```bash
switch(config-router-ospf)#area 45 stub
switch(config-router-ospf)#
```

• This command configures area **10.92.148.17** as an NSSA.

```bash
switch(config-router-ospf)#area 10.92.148.17 NSSA
switch(config-router-ospf)#
```
15.2.3.2.2 Blocking All Summary Routes from Flooding the NSSA

The *area nssa no-summary (OSPFv2)* command configures the router to not import type-3 summary LSAs into the Not-So-Stubby Area (NSSA) and injects a default summary route (*0.0.0.0/0*) into the NSSA to reach the inter-area prefixes.

**Example**

This command directs the device not to import type-3 summary LSAs into the NSSA area and injects a default summary route (*0.0.0.0/0*) into the NSSA area.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#area 1.1.1.1 nssa no-summary
switch(config-router-ospf)#
```

15.2.3.2.3 Assigning Network Segments to the Area

**Assigning Routes to an Area**

The *network area (OSPFv2)* command assigns the specified network segment to an OSPFv2 area. The network can be entered in CIDR notation or by an address and wildcard mask.

The switch zeroes the host portion of the specified network address e.g. *1.2.3.4/24* converts to *1.2.3.0/24* and *1.2.3.4/16* converts to *1.2.0.0/16*.

**Example**

Each of these equivalent commands assign the network segment *10.1.10.0/24* to area *0*.

```plaintext
switch(config-router-ospf)#network 10.1.10.0 0.0.0.255 area 0
switch(config-router-ospf)#network 10.1.10.0/24 area 0
```

In each case, *running-config* stores the command in CIDR (prefix) notation.

**Summarizing Routes**

By default, ABRs create a summary LSA for each route in an area and advertise them to adjacent routers. The *area range (OSPFv2)* command aggregates routing information, allowing the ABR to advertise multiple routes with one LSA. The *area range (OSPFv2)* command can be used to suppress route advertisements.

**Examples**

- Two *network area* command assigns subnets to an area. The *area range (OSPFv2)* command summarizes the addresses, which the ABR advertises in a single LSA.

```plaintext
switch(config-router-ospf)#network 10.1.25.80 0.0.0.240 area 5
switch(config-router-ospf)#network 10.1.25.112 0.0.0.240 area 5
switch(config-router-ospf)#area 5 range 10.1.25.64 0.0.0.192
switch(config-router-ospf)#
```

- The *network area* command assigns a subnet to an area, followed by an *area range (OSPFv2)* command that suppresses the advertisement of that subnet.

```plaintext
switch(config-router-ospf)#network 10.12.31.0 0.0.0.255 area 5
switch(config-router-ospf)#area 5 range 10.12.31.0 0.0.0.255 not-advertise
switch(config-router-ospf)#
```
15.2.3.2.4 Configuring Area Parameters

These router-ospf configuration mode commands define OSPFv2 behavior in a specified area.

Default Summary Route Cost

The `area default-cost` (OSPFv2) command specifies the cost of the default summary route that ABRs send into a stub area or NSSA. Summary routes, also called inter-area routes, originate in areas different than their destination.

**Example**

This command configures a cost of **15** for the default summary route in area **23**.

```
switch(config-router-ospf)#area 23 default-cost 15
```

Filtering Type 3 LSAs

The `area filter` (OSPFv2) command prevents an area from receiving Type 3 (Summary) LSAs from a specified subnet. Type 3 LSAs are sent by ABRs and contain information about one of its connected areas.

**Example**

This command prevents the switch from entering Type 3 LSAs originating from the **10.1.1.2/24** subnet into its **area 2** LSDB.

```
switch(config-router-ospf)#area 2 filter 10.1.1.2/24
```

15.2.3.3 Support for OSPFv2 dn-bit-ignore

The OSPFv2 `dn-bit-ignore` command allows enabling or disabling the inclusion of LSAs having “Down” (DN) bit set in SPF calculations. The DN Bit is a loop prevention mechanism that implements when using OSPF as a CE - PE IGP protocol.

OSPFv2 only honors the DN-bit in **type-3** LSAs in non-default VRFs. Starting with **Release EOS-4.25.0F**, OSPFv2 honors the DN-bit in **type-5** and **type-7** LSAs in non-default VRFs. This means that the type-3/5/7 LSAs with DN-bit set are not in SPF calculation, and any routes that carry LSAs are not installed in the routing table. This behavior changes when using the `dn-bit-ignore lsa type-5 type-7` command.

15.2.3.3.1 Configuration

**OSPFv2**

Use the command `dn-bit-ignore` to ignore the DN-bit in type-3/5/7 LSAs.

Use the command `dn-bit-ignore lsa type-5 type-7` to include only type-5, and type-7 LSAs having their DN-bit set in the SPF calculation. The commands `no dn-bit-ignore lsa type-5 type-7` or `default dn-bit-ignore lsa type-5 type-7` are configured to revert the behavior back to default. This command is available in `router ospf PROCESS_ID vrf VRF_NAME` configuration mode.

**Note:** This command is not available in the default VRF.
This command is for backwards compatibility to revert the behavior seen prior to Release EOS-4.25.0 where the type-5 and type-7 LSAs with DN-bit set would get included in the SPF calculations.

```
(config)#router ospf 1 vrf red
(config-router-ospf-vrf-red)#?
...
dn-bit-ignore Disable DN-bit check for Type-3, Type-5 and Type-7 LSAs in non-default VRFs
...
(config-router-ospf-vrf-red)#dn-bit-ignore ?
lsa Disable DN-bit check only for Type-5 and Type-7 LSAs in non-default VRFs
<cr>
(config-router-ospf-vrf-red)#dn-bit-ignore lsa type-5 type-7
```

**OSPFv3**

Use the command `dn-bit-ignore` to include type-3/5/7 LSAs having their DN-bit set in the SPF calculation.

Use the commands `dn-bit-ignore` or `default dn-bit-ignore` to revert the behavior back to default. This command is available in `ipv6 router ospf PROCESS_ID vrf VRF_NAME` configuration mode and `router ospfv3 vrf <VRF_NAME>` configuration mode. Note that this command is not available in the default VRF, and that both configuration styles are captured below.

**router ospfv3 Configuration Style**

The `dn-bit-ignore` command is available under the `router ospfv3 vrf VRF_NAME` configuration mode. This disables the dn-bit check for Type-3/5/7 LSAs in non-default VRFs.

```
(config)#router ospfv3 vrf red
(config-router-ospfv3-vrf-red)#dn-bit-ignore
```

**ipv6 router ospf Configuration Style**

The `dn-bit-ignore` command is also available under the `ipv6 router ospf PROCESS_ID vrf VRF_NAME` configuration mode. This disables the dn-bit check for Type-3/5/7 LSAs in non-default VRFs.

```
(config)#ipv6 router ospf 1 vrf red
(config-router-ospfv3-vrf-red)#dn-bit-ignore
```

15.2.3.3.2 Show Commands

Use the `show running-config` command to verify whether the `dn-bit-ignore` command is configured.

15.2.3.4 OSPFv2 Area Filter by Prefix-List

The `ospf area <area_id> filter` command configures the set of prefixes to be filtered for multi-agent routing and the ribd routing protocols. Area filters are used to prevent specific prefixes from being announced by an area as Type 3 summary LSAs in an OSPFv2 Area Border Router (ABR).

**Examples**

The following configures a prefix-list filter to permit two prefixes and deny all others.

```
switch(config)# ip prefix-list type3Permit
switch(config-ip-pfx)# ip seq 10 permit 10.0.1.0/24
```
**Routing Protocols**

```
switch(config-ip-pfx)# ip seq 20 permit 10.0.2.0/24
switch(config-ip-pfx)# ip seq 30 deny 10.0.0.0/0
switch(config-ip-pfx)# exit
```

The following applies the filter to the backbone area.

```
switch(config)# router ospf 1
switch(config-router-ospf)# area 0 filter prefix-list type3Permit
```

The following configures a prefix-list to deny a list of prefixes and permit all others.

```
switch(config)# ip prefix-list type3Deny
switch(config-ip-pfx)# ip seq 10 deny 10.0.1.0/24
switch(config-ip-pfx)# ip seq 20 deny 10.0.2.0/24
switch(config-ip-pfx)# exit
```

The following applies the filter.

```
switch(config)# router ospf 1
switch(config-router-ospf)# area 1.1.1.1 filter prefix-list type3Deny
```

**Show commands**

The following displays the output of `show ip ospf` with the area filter listed.

```
switch# show ip ospf
Area 3.3.3.3
  Number of interface in this area is 2
  It is a normal area
  Traffic engineering is disabled
  Area has None authentication
  SPF algorithm executed 1 times
  Number of LSA 1. Checksum Sum 53568
  Number of opaque link LSA 0. Checksum Sum 0
  Number of opaque area LSA 0. Checksum Sum 0
  Area ranges are
    3.3.0.0/16 Cost 0 Advertise
    3.30.0.0/16 Cost 0 Advertise
  Area filter prefix-list type3Permit
```

### 15.2.3.5 IPv4 Unnumbered Interfaces

The `ip address unnumbered` command specifies a lending interface from which many interfaces may borrow the same address, reducing the number of unique IPv4 addresses needed. A lending interface is a loopback interface. Only one borrowing interface is referenced to one lender at a time even though multiple loopbacks may be used as lending interfaces. Unnumbered interfaces may reference the same or different lending interfaces. Any IPv4 routed interface is configurable as unnumbered interface and is referenced to one lending interface.

The following configures an unnumbered borrowing interface.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#ip address unnumbered Loopback1
```
OSPF configuration

To enable OSPF on an unnumbered interface, configure the area and set the network type to point-to-point under the `interface` config mode.

```
switch(config-if-Et1)# ip ospf area 1
switch(config-if-Et1)# ip ospf network point-to-point
```

**Note:** The `network` command under `router ospf configuration mode` is not supported for the configuration of unnumbered interfaces. You must specify the area and `network point-to-point` command in the configuration context of the unnumbered interface.

Enabling OSPF on the lending interface in the same area as the borrowing interfaces is recommended. For different unnumbered interfaces in different areas, configure them to use different loopbacks.

```
switch(config)# interface loopback 1
switch(config-if-Lo1)# ip address 1.1.1.1/32
switch(config-if-Lo1)# ip ospf area 1
```

ISIS configuration

To enable ISIS on an unnumbered interface, configure the area and set the network type to point-to-point under the `interface` config mode.

```
switch(config-if-Et1)# isis enable inst1
switch(config-if-Et1)# isis network point-to-point
```

Enabling ISIS on the lending interface in the same area as the borrowing interfaces is recommended.

```
switch(config)# interface loopback 1
switch(config-if-Lo1)# ip address 1.1.1.1/32
switch(config-if-Et1)# isis enable inst1
switch(config-if-Et1)# isis network point-to-point
```

Show commands

The same IP address that may be in use on multiple interfaces at the same time, and is displayed as shown below.

The following displays the output of `show ip interface brief`. In this example, Ethernet 2-5 are all unnumbered and borrowing from `loopback1`.

```
switch(config-if-Et2)# show ip interface brief

Address   Interface   IP Address  Status  Protocol   MTU    Owner
----------- ----------- ------- --------- ------- -------
Ethernet1  1.1.2.1/24  up       up        1500
Ethernet2  1.1.1.1/32  up       up        1500    Lo1
Ethernet3  1.1.1.1/32  up       up        1500    Lo1
Ethernet4  1.1.1.1/32  up       up        1500    Lo1
Ethernet5  1.1.1.1/32  up       up        1500    Lo1
Loopback1  1.1.1.1/32  up       up        65535
```

The following displays OSPF with two adjacencies with the same peer via `Ethernet 2` and `Ethernet 3`. The same `Neighbor ID` is listed for both interfaces. IS-IS behaves similarly.

```
switch(config-if-Et2)# show ip ospf neighbor

Neighbor ID Instance VRF Pri State   Dead Time  Address  Interface
2.2.1.1 1 default 0 FULL 00:00:36 2.2.1.1 Ethernet3
```
Limitations

- Configuring the addresses on the lending loopbacks as /32 is recommended. In order to resolve routes via an unnumbered peer, the /32 address is required. Configuring a lending loopback as /32 and enabling OSPF/ISIS on it propagates that prefix.
- Use only loopback interfaces as a lending interface.
- Enable only one IGP on a lending loopback interface. For multiple IGPs enable each on a different loopback.
- Configure only one BFD multi-hop session per loopback.
- SSO is not supported for BFD multihop sessions over unnumbered interfaces.
- OSPFv3 does not support unnumbered interface addressing.

15.2.3.6 Configuring Interfaces for OSPFv2

OSPFv2 interface configuration commands specify transmission parameters for routed ports and SVIs that handle OSPFv2 packets.

15.2.3.6.1 Configuring Authentication

OSPFv2 authenticates packets through passwords configured on VLAN interfaces. Interfaces connecting to the same area can authenticate packets if they have the same key. By default, OSPFv2 does not authenticate packets.

OSPFv2 supports simple password and message digest authentication:

- Simple password authentication: A password is assigned to an area. Interfaces connected to the area can authenticate packets by enabling authentication and specifying the area password.
- Message digest authentication: Each interface is configured with a key (password) and key-id pair. When transmitting a packet, the interface generates a string, using the MD5 algorithm, based on the OSPFv2 packet, key, and key ID, then appends that string to the packet.

Message digest authentication supports uninterrupted transmissions during key changes by allowing each interface to have two keys with different key IDs. When a new key is configured on an interface, the router transmits OSPFv2 packets for both keys. Once the router detects that all neighbors are using the new key, it stops sending the old one.

Implementing authentication on an interface is a two step process:

1. Enabling authentication.
2. Configuring a key (password).

To configure simple authentication on a VLAN interface:

1. Enable simple authentication with the `ip ospf authentication` command.

```
switch(config-if-vl12)#ip ospf authentication
```

2. Configure the password with the `ip ospf authentication-key` command.

```
switch(config-if-vl12)#ip ospf authentication-key 0 code123
```

The `running-config` stores the password as an encrypted string, using a proprietary algorithm. To configure Message-Digest authentication on a VLAN interface:

1. Enable Message-Digest authentication with the `ip ospf authentication` command.

```
switch(config-if-vl12)#ip ospf authentication message-digest
```
2. Configure the key ID and password with the `ip ospf message-digest-key` command.

```
switch(config-if-vl12)#ip ospf message-digest-key 23 md5 0 code123
```

The running-config stores the password as an encrypted string, using a proprietary algorithm. The key ID (23) is between keywords `message-digest-key` and `md5`.

### 15.2.3.6.2 Configuring Intervals

Interval configuration commands determine OSPFv2 packet transmission characteristics for the specified VLAN interface and are entered in `interface-vlan` configuration mode.

#### Hello Interval

The hello interval specifies the period between consecutive hello packet transmissions from an interface. Each OSPFv2 neighbor should specify the same hello interval, which should not be longer than any neighbors dead interval. The `ip ospf hello-interval` command configures the hello interval for the configuration mode interface. The default is 10 seconds.

**Example**

This command configures a hello interval of 30 seconds for VLAN 2.

```
switch(config-if-Vl2)#ip ospf hello-interval 30
```

#### Dead Interval

The dead interval specifies the period that an interface waits for an OSPFv2 packet from a neighbor before it disables the adjacency under the assumption that the neighbor is down. The dead interval should be configured identically on all OSPFv2 neighbors and be longer than the hello interval of any neighbor. The `ip ospf dead-interval` command configures the dead interval for the configuration mode interface. The default is 40 seconds.

**Example**

This command configures a dead interval of 120 seconds for VLAN 4.

```
switch(config-if-Vl4)#ip ospf dead-interval 120
```

#### Retransmit Interval

Routers that send OSPFv2 advertisements to an adjacent router expect to receive an acknowledgment from that neighbor. Routers that do not receive an acknowledgment will retransmit the advertisement. The retransmit interval specifies the period between retransmissions. The `ip ospf retransmit-interval` command configures the LSA retransmission interval for the configuration mode interface. The default retransmit interval is 5 seconds.

**Example**

This command configures a retransmit interval of 15 seconds for VLAN 3.

```
switch(config-if-Vl3)#ip ospf retransmit-interval 15
```

Transmission Delay

The transmission delay is an estimate of the time that an interface requires to transmit a link-state update packet. OSPFv2 adds this delay to the age of outbound packets to more accurately reflect the age of the LSA when received by a neighbor. The default transmission delay is one second.

The `ip ospf transmit-delay` command configures the transmission delay for the configuration mode interface.

**Example**

This command configures a transmission delay of 5 seconds for `vlan 6`.

```bash
switch(config-if-Vl6)#ip ospf transmit-delay 5
switch(config-if-Vl6)#
```

15.2.3.6.3 Configuring Interface Parameters

Interface Cost

The OSPFv2 interface cost (or metric) reflects the overhead of sending packets across the interface. The cost is typically inversely proportional to the bandwidth of the interface. The default cost is 10.

The `ip ospf cost` command configures the OSPFv2 cost for the configuration mode interface.

**Example**

This command configures a cost of 15 for `vlan 2`.

```bash
switch(config-if-Vl2)#ip ospf cost 15
switch(config-if-Vl2)#
```

Router Priority

Router priority determines preference during Designated Router (DR) and Backup Designated Router (BDR) elections. Routers with higher priority numbers have preference over other routers. Routers with a priority of zero cannot be elected as a DR or BDR.

The `ip ospf priority` command configures router priority for the configuration mode interface. The default priority is 1.

**Examples**

- This command configures a router priority of 15 for `vlan 8`.
  ```bash
  switch(config-if-Vl8)#ip ospf priority 15
  switch(config-if-Vl8)#
  ```

- This command restores the router priority of 1 for `vlan 7`.
  ```bash
  switch(config-if-Vl7)#no ip ospf priority
  switch(config-if-Vl7)#
  ```

15.2.3.7 Enabling OSPFv2

15.2.3.7.1 Disabling OSPFv2

The switch can disable OSPFv2 operations without disrupting the OSPFv2 configuration.

- `shutdown (OSPFv2)` disables all OSPFv2 activity.
- `ip ospf disabled` disables OSPFv2 activity on a VLAN interface.
The no shutdown and no ip ospf disabled commands resume OSPFv2 activity.

Examples

- This command disables OSPFv2 activity on the switch.
  ```
  switch(config-router-ospf)#shutdown
  switch(config-router-ospf)#
  ```

- This command resumes OSPFv2 activity on the switch.
  ```
  switch(config-router-ospf)#no shutdown
  switch(config-router-ospf)#
  ```

- This command disables OSPFv2 activity on VLAN 5.
  ```
  switch(config-if-Vl5)#ip ospf disabled
  switch(config-if-Vl5)#
  ```

15.2.3.7.2 IPv4 Routing

OSPFv2 requires that IPv4 routing is enabled on the switch. When IP routing is not enabled, entering OSPFv2 configuration mode generates a message.

Examples

- This message is displayed if, when entering the router-ospf configuration mode, IP routing is not enabled.
  ```
  switch(config)#router ospf 100
  ! IP routing not enabled
  switch(config-router-ospf)#
  ```

- This command enables IP routing on the switch.
  ```
  switch(config)#ip routing
  switch(config)#
  ```

15.2.3.8 OSPFv2 Multiple Instances Support Configuration

The existing OSPFv2 configuration commands remain unchanged and are used for configuring multiple OSPFv2 instances. Each OSPFv2 instance in the default VRF is identified by a unique instance ID.

**router ospf id [vrf | general]**

15.2.3.8.1 Redistribute Configuration

Configuring the redistribute ospf command under the config-router-bgp mode with multiple OSPFv2 instances configured redistributes routes from all OSPFv2 instances into BGP.

These commands redistribute OSPFv2 routes into the BGP domain.

```
switch(config)#router bgp 1
switch(config-router-bgp)#redistribute OSPF
switch(config-router-bgp)#
```
Section 15.2.3.8.2 Special Cases

Route Selection in case of Ties between Instances

When the same prefix happens to be learned in multiple instances with the same metric, route-type are used as the first criteria to tie break:

O > O IA > N1 > N2 > E1 > E2

| Codes: O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1, E2 - OSPF external type 2, N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 |

When routes have identical route-type as well, the route with the lowest nexthop IP address is selected.

Note: An ECMP route is not created in this case.

Overlapping Network Statements Configured

The CLI does not guard against overlapping network statements configured in different instances. This state is a misconfiguration.

Section 15.2.3.8.3 OSPFv2 Multiple Instances Limitations

- OSPFv2 Multiple Instances is available only with the multi-agent routing protocol model.
- Only one interface can only have one instance of OSPFv2 running at any point in time.
- All the OSPFv2 instances must be in the default VRF.
- Multiple OSPFv2 instances can not be connected to the same network or configured with interfaces in the same area. In particular, multiple OSPFv2 instances may not be connected to the same instance on another router, in the same area.
- The following features are not supported with multiple OSPFv2 instances:
  - Redistributing routes from a specific OSPFv2 instance into BGP.
  - Redistribution of routes into an OSPFv2 instance.
  - Per interface area configuration.
  - Passive interface configuration.
  - SNMP.
  - Summary address.
  - Service ACL.
  - Max Metric with on-startup configuration.

Section 15.2.3.9 OSPF Routes over GRE Tunnels Configuration

The following commands may be employed in the router OSPF mode:

- tunnel routes
- no tunnel routes
- default tunnel routes

To enable OSPFv2 over GRE tunnels, use the following commands:

```
switch(config)#router ospf 6
switch(config-router-ospf)#tunnel routes
switch(config-router-ospf)#
```
To disable OSPFv2 routes over GRE tunnels, use the following commands:

switch(config)#router ospf 6
switch(config-router-ospf)#no tunnel routes
switch(config-router-ospf)#

To enable the default OSPFv2 routes over GRE tunnels, use the following commands:

switch(config)#router ospf 6
switch(config-router-ospf)#default tunnel routes
switch(config-router-ospf)#

15.2.3.9.1 TCAM Profile Configuration

On DCS-7020, DCS-7280R/R2, or DCS-7500R/R2 enabling OSPF routes over GRE tunnels requires the system TCAM profile to have “Tunnel IPv4” feature enabled so that control packets such as OSPF hellos received over GRE tunnel interfaces are appropriately classified. This can be achieved by creating a user defined TCAM profile as described below.

The user defined TCAM profile can be created either manually from scratch or by copying from an existing TCAM profile. The system TCAM profile must have the feature `tunnel ipv4` for the OSPFv2 over GRE tunnel interfaces to work. This is applicable regardless of whether the TCAM profile is copied from an existing profile or created from scratch.

15.2.3.9.2 User Defined PMF (or TCAM) Profiles

This section describes a set of CLI commands to create user defined PMF (or TCAM) profile. The profile is composed of a set of TCAM features, with each feature having customized lookup key, actions and packet types to hit.

All TCAM profile CLIs are under `hardware tcam` mode.

```
(config)#hardware tcam
(config-hw-tcam)#
```

There are two ways to create a TCAM profile. The recommended way is to create a profile based on an existing one. In this example, a copy of the profile `newprofile1` is created.

```
(config)#hardware tcam
(config-hw-tcam)#profile newprofile1 copy default
(config-hw-tcam-profile-newprofile1)#
```

The other way is to create one profile from scratch. In this example, the profile `newprofile2` is created.

```
(config)#hardware tcam
(config-hw-tcam)#profile newprofile2
(config-hw-tcam-profile-newprofile2)#
```

To remove a profile, use the `no profile` command similar to the following. In this example, the profile `newprofile2` is removed.

```
(config)#hardware tcam
(config-hw-tcam)#no profile newprofile2
```

Features can be turned on and off in the new profile. In this example, the feature `acl port ipv6` is turned on.

```
(config-hw-tcam-profile-<profile>)#feature acl port ipv6
```
Routing Protocols

Features can be turned on and off in the new profile. In this example, the feature `acl port ipv6` is turned off.

```
(config-hw-tcam-profile-<profile>)#no feature acl port ipv6
```

The features are described by hierarchical CLI tokens. For example, IPv4 port ACL is represented by `feature acl port ip` and IPv6 port ACL is represented by `feature acl port ipv6`. Under each feature mode, there are various fields that can be modified.

- **packet**
  This describes packet types that the feature will be applied on.

```
packet packet header tokens forwarding [bridged | routed | mpls][multicast][decap]
no packet packet header tokens forwarding [bridged | routed | mpls][multicast][decap]
```

The packet header is described a series of CLI packet header tokens after `packet` token. It starts from the outer most header after Ethernet. For example, a regular IPv4 packet is `packet ipv4` and a vxlan packet is `packet ipv4 vxlan eth ipv4`. The `forwarding` token indicates the forwarding type of the packet. `multicast` indicates if the packet is a multicast packet. Lastly, `decap` indicates if the packet is decapsulated after a tunnel.

- **key field**
  This describes the TCAM key format for the feature. The CLI can add or delete fields that are used to build the key.

```
(config-hw-tcam-profile-<profile>-feature-<feature>)
[#no]keyfield field
```

All supported key fields can be found with `key field ?`.

- **key size**
  This describes the TCAM key size limit. If too many key fields are added to the feature so that the key size goes beyond the limit, a Syslog will be issued. The default key size limit is `320`.

```
(config-hw-tcam-profile-<profile>-feature-<feature>)#[no]key size limit size
```

- **action**
  This describes the action to take if a TCAM entry is hit.

```
(config-hw-tcam-profile-<profile>-feature-<feature>)#[no]action action
```

The supported actions can be found through `action ?`.

- **sequence**
  This describes the programming order of each feature. Changing the order may affect the programming status of a profile. The default sequence is `0`.

```
(config-hw-tcam-profile-<profile>-feature-<feature>)
[#no]sequence sequence
```

The profile is saved after exiting the feature mode. To use the newly defined profile, a CLI is available to apply the profile to the system globally.

```
(config)#hardware tcam
(config-hw-tcam)#system profile newprofile1
```
15.2.3.10 Displaying OSPFv2 Status

This section describes OSPFv2 show commands that display OSPFv2 status. General switch methods that provide OSPFv2 information include pinging routes, viewing route status (show ip route command), and viewing the configuration (show running-config command).

15.2.3.10.1 OSPFv2 Summary

The show ip ospf command displays general OSPFv2 configuration information and operational statistics.

Example

This command displays general OSPFv2 information.

```
switch#show ip ospf
Routing Process "ospf 1" with ID 10.168.103.1
Supports opaque LSA
Maximum number of LSA allowed 12000
Threshold for warning message 75%
Ignore-time 5 minutes, reset-time 5 minutes
Ignore-count allowed 5, current 0
It is an area border router
Hold time between two consecutive SPF's 5000 msecs
SPF algorithm last executed 00:00:09 ago
Minimum LSA interval 5 secs
Minimum LSA arrival 1000 msecs
Number of external LSA 0. Checksum Sum 0x000000
Number of opaque AS LSA 0. Checksum Sum 0x000000
Number of LSA 27.
Number of areas in this router is 3. 3 normal 0 stub 0 nssa
Area BACKBONE(0.0.0.0)
Number of interfaces in this area is 2
It is a normal area
Area has no authentication
SPF algorithm executed 153 times
Number of LSA 8. Checksum Sum 0x03e13a
Number of opaque link LSA 0. Checksum Sum 0x000000
Area 0.0.0.2
Number of interfaces in this area is 1
It is a normal area
Area has no authentication
SPF algorithm executed 153 times
Number of LSA 11. Checksum Sum 0x054e57
Number of opaque link LSA 0. Checksum Sum 0x000000
Area 0.0.0.3
Number of interfaces in this area is 1
It is a normal area
Area has no authentication
SPF algorithm executed 5 times
Number of LSA 6. Checksum Sum 0x02a401
Number of opaque link LSA 0. Checksum Sum 0x000000
```

The output lists configuration parameters and operational statistics and status for the OSPFv2 instance, followed by a brief description of the areas located on the switch.

15.2.3.10.2 Viewing OSPFv2 on the Interfaces

The show ip ospf interface command displays OSPFv2 information for switch interfaces configured for OSPFv2. Different command options allow the display of either all interfaces or a specified interface. The command can also be configured to display complete information or a brief summary.
Examples

• This command displays complete OSPFv2 information for **vlan 1**.

```
switch#show ip ospf interface vlan 1
Vlan1 is up, line protocol is up (connected)
Internet Address 10.168.0.1/24, Area 0.0.0.0
Process ID 1, Router ID 10.168.103.1, Network Type BROADCAST, Cost: 10
Transmit Delay is 1 sec, State BDR, Priority 1
Designated Router is 10.168.104.2
Backup Designated router is 10.168.103.1
Timer intervals configured, Hello 10, Dead 40, Retransmit 5
Neighbor Count is 1
MTU is 1500
switch#
```

The display indicates the switch is an ABR by displaying a neighbor count, the Designated Router (DR), and Backup Designated Router (BDR).

• This command displays a summary of interface information for the switch.

```
switch#show ip ospf interface brief
InterfacePIDAreaIP AddressCostStateNbrs
Loopback010.0.0.010.168.103.1/2410DR0
Vlan110.0.0.010.168.0.1/2410BDR1
Vlan210.0.0.210.168.2.1/2410BDR1
Vlan310.0.0.310.168.3.1/2410DR0
switch#
```

Configuration information includes the Process ID (PID), area, IP address, and cost. OSPFv2 operational information includes the Designated Router status and number of neighbors.

15.2.3.10.3 Viewing the OSPFv2 Database

The **show ip ospf database <link state list>** command displays the LSAs in the LSDB for the specified area. If no area is listed, the command displays the contents of the database for each area on the switch. The database command provides options to display subsets of the LSDB database, a summary of database contents, and the link states that comprise the database.

Examples

• This command displays LSDB contents for **area 2**.

```
switch#show ip ospf 1 2 database
OSPF Router with ID(10.168.103.1)(Process ID 1)
Router Link States (Area 0.0.0.2)
Link IDADV RouterAgeSeq#Checksum Link count
10.168.103.110.168.103.100:29:080x80000031 0x001D5F 1
10.168.104.210.168.104.200:29:090x80000066 0x00A49B 1
Net Link States (Area 0.0.0.2)
Link IDADV RouterAgeSeq#Checksum
10.168.2.110.168.103.100:29:080x80000001 0x00B89D
Summary Net Link States (Area 0.0.0.2)
Link IDADV RouterAgeSeq#Checksum
10.168.0.010.168.103.100:13:200x80000028 0x0008C8
10.168.0.010.168.104.200:09:160x80000054 0x00A2FF
```
• This command displays an LSDB content summary for area 2.

switch#show ip ospf 1 2 database database-summary

OSPF Router with ID(10.168.103.1) (Process ID 1)

Area 0.0.0.2 database summary

switch#

• This command displays the router Link States contained in the area 2 LSDB.

switch#show ip ospf 1 2 database router

OSPF Router with ID(10.168.103.1) (Process ID 1)

Router Link States (Area 0.0.0.2)
LS age: 00:02:16
Options: (E DC)
LS Type: Router Links
Link State ID: 10.168.103.1
Advertising Router: 10.168.103.1
LS Seq Number: 80000032
Checksum: 0x1B60
Length: 36
Number of Links: 1

Link connected to: a Transit Network
(Link ID) Designated Router address: 10.168.2.1
(Link Data) Router Interface address: 10.168.2.1
Number of TOS metrics: 0
TOS 0 Metrics: 10

LS age: 00:02:12
15.2.3.10.4 Viewing OSPFv2 Neighbors

The `show ip ospf neighbor` command displays information about the routers that are neighbors to the switch. Command options allow the display of summary or detailed information about the neighbors for all areas and interfaces on the switch. The command also allows the display of neighbors for individual interfaces or areas. The `adjacency-changes` option displays the interfaces adjacency changes.

Examples

- This command displays the switch's neighbors.

  ```
  switch#show ip ospf neighbor
  Neighbor ID Pri State Dead Time Address Interface
  10.168.104.2 1 FULL/DR 00:00:35 10.168.0.2 Vlan1
  10.168.104.2 8 FULL/BDR 00:00:31 10.168.2.2 Vlan2
  ```

- This command displays details about the neighbors to `vlan 2`.

  ```
  switch#show ip ospf neighbor vlan 2 detail
  Neighbor 10.168.104.2, interface address 10.168.2.2
  In the area 0.0.0.2 via interface Vlan2
  Neighbor priority is 8, State is FULL, 13 state changes
  Adjacency was established 00:01:25:48 ago
  DR is 10.168.2.1 BDR is 10.168.2.2
  Options is E
  Dead timer due in 00:00:34
  ```

- This command displays the adjacency changes to `vlan 2`.

  ```
  switch#show ip ospf neighbor vlan 2 adjacency-changes
  [08-04 09:58:58] 10.168.104.2, interface Vlan2 adjacency established
  ```
The `show ip ospf neighbor state` command displays the state information for OSPF neighbors on a per-interface basis.

**Example**

This command displays OSPF information for neighboring routers that are fully adjacent.

```
switch#show ip ospf neighbor state full
Neighbor ID VRF Pri  State       Dead Time   Address          Interface
Test1    default 1 FULL/BDR 00:00:35 10.17.254.105 Vlan3912
Test2    default 1 FULL/BDR 00:00:36 10.17.254.29  Vlan3910
Test3    default 1 FULL/DR  00:00:35 10.25.0.1    Vlan101
Test4    default 1 FULL/DROTHER 00:00:34 10.17.254.64 Vlan3036
Test5    default 1 FULL/DROTHER 00:00:36 10.17.254.68 Vlan3908
Test6    default 1 FULL/BDR  00:00:36 10.17.254.67 Vlan3908
Test7    default 1 FULL/DROTHER 00:00:34 10.17.254.66 Vlan3908
Test8    default 1 FULL/BDR  00:00:35 10.17.254.63 Vlan3036
Test9    default 1 FULL/DROTHER 00:00:31 10.17.254.13 Vlan3902
Test10   default 1 FULL/DROTHER 00:00:37 10.17.254.11 Vlan3902
Test11   default 1 FULL/DROTHER 00:00:33 10.17.254.163 Vlan3925
Test12   default 1 FULL/DR   00:00:37 10.17.254.161 Vlan3925
Test13   default 1 FULL/DROTHER 00:00:31 10.17.254.154 Vlan3923
Test14   default 1 FULL/BDR  00:00:39 10.17.254.156 Vlan3923
Test15   default 1 FULL/DROTHER 00:00:33 10.17.254.35 Vlan3911
Test16   default 1 FULL/DR   00:00:34 10.17.254.33 Vlan3911
Test17   default 1 FULL/DR   00:00:36 10.17.254.138 Ethernet12
Test18   default 1 FULL/DR   00:00:37 10.17.254.2  Vlan3901
```

The `show ip ospf neighbor summary` command displays a single line of summary information for each OSPFv2 neighbor.

**Example**

This command displays the summary information for the OSPFv2 neighbors.

```
switch#show ip ospf neighbor summary
OSPF Router with (Process ID 1) (VRF default)
0 neighbors are in state DOWN
0 neighbors are in state GRACEFUL RESTART
2 neighbors are in state INIT
0 neighbors are in state LOADING
0 neighbors are in state ATTEMPT
18 neighbors are in state FULL
0 neighbors are in state EXCHANGE
0 neighbors are in state 2 WAYS
0 neighbors are in state EXCH START
switch>
```

15.2.3.10.5 Viewing OSPFv2 Routes

The `show ip routes` command provides an OSPFv2 option.

**Examples**

- This command displays all of a switchs routes.

```
switch#show ip route
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP
Gateway of last resort:
S0.0.0.0/0 [1/0] via 10.255.255.1
C10.255.255.0/24 is directly connected, Management1
C10.168.0.0/24 is directly connected, Vlan1
C10.168.2.0/24 is directly connected, Vlan2
O10.168.3.0/24 [110/20] via 10.168.0.1
O10.168.103.0/24 [110/20] via 10.168.0.1
```
C10.168.104.0/24 is directly connected, Loopback0

```
switch#
```

- This command displays the switch's OSPFv2 routes.

```
switch#show ip route ospf
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP

O10.168.3.0/24 [110/20] via 10.168.0.1
O10.168.103.0/24 [110/20] via 10.168.0.1

switch#
```

Use the ping command to determine the accessibility of a route.

**Example**

This command pings an OSPFv2 route.

```
switch#ping 10.168.0.1
PING 10.168.0.1 (10.168.0.1) 72(100) bytes of data.
80 bytes from 10.168.0.1: icmp_seq=1 ttl=64 time=0.148 ms
80 bytes from 10.168.0.1: icmp_seq=2 ttl=64 time=0.132 ms
80 bytes from 10.168.0.1: icmp_seq=3 ttl=64 time=0.136 ms
80 bytes from 10.168.0.1: icmp_seq=4 ttl=64 time=0.137 ms
80 bytes from 10.168.0.1: icmp_seq=5 ttl=64 time=0.136 ms

--- 10.168.0.1 ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 7999ms
rtt min/avg/max/mdev = 0.132/0.137/0.148/0.015 ms

switch#
```

15.2.3.10.6 Viewing OSPFv2 SPF Logs

The show ip ospf spf-log command displays when and how long the switch took to run a full SPF calculation for OSPF.

**Example**

This command displays the SPF information for OSPF.

```
switch#show ip ospf spf-log
OSPF Process 172.26.0.22
When   Duration(msec)
13:01:34  1.482
13:01:29  1.547
13:01:24  1.893
13:00:50  1.459
13:00:45  1.473
13:00:40  2.603
11:01:49  1.561
11:01:40  1.463
11:01:35  1.467
11:01:30  1.434
11:00:54  1.456
11:00:49  1.472
11:00:44  1.582
15:01:49  1.575
15:01:44  1.470
15:01:39  1.679
15:01:34  1.601
15:00:57  1.454
15:00:52  1.446
15:00:47  1.603
```

```
15.2.3.10.7 Viewing OSPFv2 multiple Instances Support

The `show ip ospf` commands will take an instance ID filter to get the information for a particular OSPFv2 instance. If no instance ID is specified in the show query, information for all the active OSPFv2 instances are shown.

The `show ip ospf` commands will also display instance ID along with router ID either in the output headers or as a separate column.

Sample output for the `show ip ospf` command with two OSPFv2 instances with ID 1 and ID 2.

```
switch#show ip ospf
OSPF instance 1 with ID 1.1.1.1 VRF default
  Supports opaque LSA
  Maximum number of LSA allowed 12000
  Threshold for warning message 75%
  Ignore-time 5 minutes, reset-time 5 minutes
  Ignore-count allowed 5, current 0
  It is not an autonomous system boundary router and is not an area border router
  ...
OSPF instance 2 with ID 2.2.2.2 VRF default
  Supports opaque LSA
  Maximum number of LSA allowed 12000
  Threshold for warning message 75%
  Ignore-time 5 minutes, reset-time 5 minutes
  Ignore-count allowed 5, current 0
  It is not an autonomous system boundary router and is not an area border router
  ...
```

Sample output for the `show ip ospf` command with Graceful Restart enabled for two OSPFv2 instances with ID 10 and 11.

```
switch#show ip ospf
OSPF instance 10 with ID 2.2.2.2 VRF default
  Supports opaque LSA
  Maximum number of LSA allowed 12000
  Threshold for warning message 75%
  Ignore-time 5 minutes, reset-time 5 minutes
  ...
  Graceful-restart is configured, grace-period 120 seconds
    State: In progress, expires in 113 seconds
    Graceful-restart-helper mode is enabled
  ...
OSPF instance 11 with ID 3.3.3.3 VRF default
  Supports opaque LSA
  Maximum number of LSA allowed 12000
  Threshold for warning message 75%
  Ignore-time 5 minutes, reset-time 5 minutes
  ...
  Graceful-restart is configured, grace-period 120 seconds
    State: In progress, expires in 113 seconds
    Graceful-restart-helper mode is enabled
```
Sample output for the `show ip ospf neighbor detail` command.

```bash
switch# show ip ospf neighbor
Neighbor ID  Instance  VRF      Pri  State      Dead Time   Address   Interface
2.2.2.2      1         default  1    FULL/DR    00:00:38    10.1.1.2   Ethernet1
4.4.4.4      2         default  1    FULL/DR    00:00:36    40.1.1.2   Ethernet4

switch# show ip ospf neighbor 2.2.2.2 detail
Neighbor 2.2.2.2, instance 1, VRF default, interface address 10.1.1.1
In area 0.0.0.0 interface Ethernet1
Neighbor priority is 1, State is FULL, 7 state changes
Adjacency was established 00:03:48 ago
Current state was established 00:03:48 ago
DR IP Address 10.1.1.2 BDR IP Address 10.1.1.1
Options is E
Dead timer is due in 00:00:35
Inactivity timer deferred 0 times
LSAs retransmitted 1 time to this neighbor
Graceful-restart-helper mode is Inactive
Graceful-restart attempts: 0

Sample output for `show ip ospf neighbor detail` with BFD enabled.

```bash
switch# show ip ospf neighbor 2.2.2.2 detail
Neighbor 3.3.3.3, instance 10, VRF default, interface address 1.0.0.1
In area 1.2.3.4 interface Ethernet1
Neighbor priority is 1, State is FULL, 7 state changes
Adjacency was established 22:03:05 ago
Current state was established 22:03:05 ago
DR IP Address 1.0.0.1 BDR IP Address 1.0.0.2
Options is E
Dead timer is due in 00:00:34
Inactivity timer deferred 0 times
LSAs retransmitted 1 time to this neighbor
Bfd request is sent and the state is Down
Graceful-restart-helper mode is Inactive
Graceful-restart attempts: 0
Neighbor 6.6.6.6, instance 10, VRF default, interface address 1.0.1.1
In area 1.2.3.4 interface Ethernet5
Neighbor priority is 1, State is FULL, 7 state changes
Adjacency was established 22:03:10 ago
Current state was established 22:03:10 ago
DR IP Address 1.0.1.1 BDR IP Address 1.0.1.2
Options is E
Dead timer is due in 00:00:30
Inactivity timer deferred 0 times
```
The CAPI outputs for OSPFv2 show commands are already indexed by instance ID and remains unchanged.

The `show ip route` and `show ip route ospf` commands show routes from all OSPFv2 instances with no mention of instance ID. For example,

- `11.1.1.0/24` is learned from instance `100` and `12.1.1.0/24` from instance `200`.

```
switch#show ip route
VRF: default
Codes: C - connected, S - static, K - kernel,
      O - OSPF, IA - OSPF inter area, E1 - OSPF external type 1,
      E2 - OSPF external type 2, N1 - OSPF NSSA external type 1,
      N2 - OSPF NSSA external type 2, B I - iBGP, B E - eBGP,
      R - RIP, I L1 - IS-IS level 1, I L2 - IS-IS level 2,
      O3 - OSPFv3, A B - BGP Aggregate, A O - OSPF Summary,
      NG - Nexthop Group Static Route, V - VXLAN Control
Service,
      DH - DHCP client installed default route, M - Martian,
      DP - Dynamic Policy Route, L - VRF Leaked
Gateway of last resort is not set

O E2 11.1.1.0/24 [110/1] via 20.1.1.2, Ethernet3
C 10.1.1.0/24 is directly connected, Ethernet1

```

### 15.2.3.10.8 Displaying OSPF Routes over GRE Tunnel Status

A show command is available to list the TCAM profile status on each linecard.

```
(config)#show hardware tcam profile
Configuration  Status FixedSystem  newprofile1  newprofile1
```

If the profile cannot be programmed, the Status column will print **ERROR**. See **Limitations** for additional information. The content of a PMF profile can be displayed with

```
(config)#show hardware tcam profile detail
```

**Example**

```
(config-hw-tcam)#show hardware tcam profile newprofile1 detail
Profile newprofile1 [ FixedSystem ]
Feature  mpls
----------------- --------------------------------------------------------
Key size     160
Actions      drop, redirect, set-ecn
```
Note that the profile contains all the features that are untouched after copying from the base profile.

**Example**

This example demonstrates how to create a new profile to match on `vlan` field in MAC ACL.

```
(config-hw-tcam)#profile macvlan copy default
(config-hw-tcam-profile-macvlan)#feature acl port mac
(config-hw-tcam-profile-macvlan-feature-acl-port-mac)#key field vlan
(config-hw-tcam-profile-macvlan-feature-acl-port-mac)#exit
Saving new profile 'macvlan'
(config-hw-tcam)#system profile macvlan
```

### 15.2.4 OSPFv2 Configuration Examples

This section describes the commands required to configure three OSPFv2 topologies.

- OSPFv2 Configuration Example 1
- OSPFv2 Configuration Example 2
- OSPFv2 Configuration Example 3

#### 15.2.4.1 OSPFv2 Configuration Example 1

The OSPF Autonomous System in Example 1 contains two areas that are connected through two routers. The backbone area also contains an internal router that connects two subnets.

#### 15.2.4.1.1 Example 1 Topology

**OSPFv2 Example 1** displays the Example 1 topology. Two ABRs connect area 0 and area 1. *Router A* and *Router B*. *Router C* is an internal router that connects two subnets in area 0.
Area 1 Configuration

Area 1 contains one subnet that is accessed by Router A and Router B.
- **Router A**: The subnet 10.10.1.0/24 is accessed through VLAN 1.
- **Router B**: The subnet 10.10.1.0/24 is accessed through VLAN 1.
- Each router uses simple authentication, with password `abcdefgh`.
- Designated Router (DR): **Router A**.
- Backup Designated Router (BDR): **Router B**.
- Each router defines an interface cost of 10.
- Router priority is not specified for either router on area 1.

Area 0 ABR Configuration

Area 0 contains one subnet that is accessed by ABRs Router A and Router B.
- **Router A**: The subnet 10.10.2.0/24 is accessed through VLAN 2.
- **Router B**: The subnet 10.10.2.0/24 is accessed through VLAN 2.
- Designated Router (DR): **Router B**.
- Backup Designated Router (BDR): **Router A**.
- Each router uses simple authentication, with password `ijklmnop`.
- Each router defines an interface cost of 20.
- Each router defines a retransmit-interval of 10.
- Each router defines a transmit-delay of 2.
- Router priority is specified such that **Router B** will be elected as the Designated Router.

Area 0 IR Configuration

Area 0 contains one internal router that connects two subnets.
- **Router C**: The subnet 10.10.2.0/24 is accessed through VLAN 2.
- **Router C**: The subnet 10.10.3.0/24 is accessed through VLAN 3.
- The subnet 10.10.2.0/24 link is configured as follows:
  - Interface cost of 20.
  - Retransmit-interval of 10.
  - Transmit-delay of 2.
The subnet 10.10.3.0/24 link is configured as follows:

- Interface cost of 20.
- Dead interval of 80 seconds.

15.2.4.1.2 Example 1 Code

This code configures the OSPFv2 instances on the three switches.

1. Configure the interface addresses.
   a. Router A interfaces:

```
switch-A(config)#interface vlan 1
switch-A(config-if-vl1)#ip address 10.10.1.1/24
switch-A(config-if-vl1)#interface vlan 2
switch-A(config-if-vl2)#ip address 10.10.2.1/24
```

b. Router B interfaces:

```
switch-B(config)#interface vlan 1
switch-B(config-if-vl1)#ip address 10.10.1.2/24
switch-B(config-if-vl1)#interface vlan 2
switch-B(config-if-vl2)#ip address 10.10.2.2/24
```

c. Router C interfaces:

```
switch-C(config)#interface vlan 2
switch-C(config-if-vl2)#ip address 10.10.2.3/24
switch-C(config-if-vl2)#interface vlan 3
switch-C(config-if-vl3)#ip address 10.10.3.3/24
```

2. Configure the interface OSPFv2 parameters.
   a. Router A interfaces:

```
switch-A(config-if-vl2)#interface vlan 1
switch-A(config-if-vl1)#ip ospf authentication-key abcdefgh
switch-A(config-if-vl1)#ip ospf cost 10
switch-A(config-if-vl1)#ip ospf priority 6
switch-A(config-if-vl1)#interface vlan 2
switch-A(config-if-vl2)#ip ospf authentication-key ijklnmop
switch-A(config-if-vl2)#ip ospf cost 20
switch-A(config-if-vl2)#ip ospf retransmit-interval 10
switch-A(config-if-vl2)#ip ospf transmit-delay 2
switch-A(config-if-vl2)#ip ospf priority 4
```

b. Router B interfaces:

```
switch-B(config-if-vl2)#interface vlan 1
switch-B(config-if-vl1)#ip ospf authentication-key abcdefgh
switch-B(config-if-vl1)#ip ospf cost 10
switch-B(config-if-vl1)#ip ospf priority 4
switch-B(config-if-vl1)#interface vlan 2
switch-B(config-if-vl2)#ip ospf authentication-key ijklnmop
switch-B(config-if-vl2)#ip ospf cost 20
switch-B(config-if-vl2)#ip ospf retransmit-interval 10
switch-B(config-if-vl2)#ip ospf transmit-delay 2
switch-B(config-if-vl2)#ip ospf priority 6
```

c. Router C interfaces:

```
switch-C(config-if-vl3)#interface vlan 2
```
3. Attach the network segments to the areas.

   a. Router A interfaces:

   switch-A(config-if-vl2)#router ospf 1
   switch-A(config-router-ospf)#router-id 169.10.0.1
   switch-A(config-router-ospf)#network 10.10.1.0/24 area 1
   switch-A(config-router-ospf)#network 10.10.2.0/24 area 0

   b. Router B interfaces:

   switch-B(config-if-vl2)#router ospf 1
   switch-B(config-router-ospf)#router-id 169.10.0.2
   switch-B(config-router-ospf)#network 10.10.1.0/24 area 1
   switch-B(config-router-ospf)#network 10.10.2.0/24 area 0

   c. Router C interfaces:

   switch-C(config-if-vl3)#router ospf 1
   switch-C(config-router-ospf)#router-id 169.10.0.3
   switch-C(config-router-ospf)#network 10.10.2.0/24 area 0
   switch-C(config-router-ospf)#network 10.10.3.0/24 area 0

15.2.4.2 OSPFv2 Configuration Example 2

The AS in Example 2 contains three areas. Area 0 connects to the other areas through different routers. The backbone area contains an internal router that connects two subnets. Area 0 is normal; the other areas are stub areas.

15.2.4.2.1 Example 2 Topology

OSPFv2 Example 2 displays the Example 2 topology. One ABR (Router B) connects area 0 and area 10.42.110.0; another ABR (Router C) connects area 0 and area 36.56.0.0. Router A is an internal router that connects two subnets in area 0.

Figure 47: OSPFv2 Example 2
Area 10.42.110.0 Configuration

Area 10.42.110.0 contains one subnet that is accessed by Router B.

- **Router B**: The subnet 10.42.110.0 is accessed through VLAN 15.
- **Router B** uses simple authentication, with password abcdefgh.
- Each router defines a interface cost of 10.

Area 10.56.0.0 Configuration

Area 10.56.0.0 contains one subnet that is accessed by Router C.

- **Router C**: The subnet 10.56.0.0 is accessed through VLAN 21.
- **Router C** uses simple authentication, with password ijklnnop.
- Each router defines a interface cost of 20.

Area 0 ABR Configuration

Area 0 contains two subnets. ABR Router B connects one subnet to area 10.42.110.0. ABR Router C connects the other subnet to area 10.56.0.0.

- **Router B**: The subnet 10.119.254.0/24 is accessed through VLAN 16.
- **Router C**: The subnet 10.119.251.0/24 is accessed through VLAN 20.
- Designated Router (DR): Router B.
- Backup Designated Router (BDR): Router C.
- Each ABR uses simple authentication, with password ijklnnop.
- Each router defines an interface cost of 20.
- Each router defines a retransmit-interval of 10.
- Each router defines a transmit-delay of 2.
Area 0 IR Configuration

Area 0 contains two subnets connected by an internal router.

- **Router A**: The subnet **10.119.254.0/24** is accessed through **VLAN 16**.
- **Router A**: The subnet **10.119.251.0/24** is accessed through **VLAN 20**.
- The subnet **10.42.110.0** is configured as follows:
  - Interface cost of **10**.
- The subnet **10.56.0.0/24** is configured as follows:
  - Interface cost of **20**.
  - Retransmit-interval of **10**.
  - Transmit-delay of **2**.

15.2.4.2.2 Example 2 Code

1. Configure the interface addresses.
   a. Router A interfaces:
      ```
      switch-A(config)#interface vlan 16
      switch-A(config-if-vl16)#ip address 10.119.254.2/24
      switch-A(config-if-vl16)#interface vlan 20
      switch-A(config-if-vl20)#ip address 10.119.251.1/24
      ```
   b. Router B interfaces:
      ```
      switch-B(config)#interface vlan 15
      switch-B(config-if-vl15)#ip address 10.42.110.1/24
      switch-B(config-if-vl15)#interface vlan 16
      switch-B(config-if-vl16)#ip address 10.119.254.1/24
      ```
   c. Router C interfaces:
      ```
      switch-C(config)#interface vlan 20
      switch-C(config-if-vl20)#ip address 10.119.251.2/24
      switch-C(config-if-vl20)#interface vlan 21
      switch-C(config-if-vl21)#ip address 10.56.0.1/24
      ```

2. Configure the interface OSPFv2 parameters.
   a. Router A interfaces:
      ```
      switch-A(config-if-vl20)#interface vlan 16
      switch-A(config-if-vl16)#ip ospf cost 10
      switch-A(config-if-vl16)#interface vlan 20
      switch-A(config-if-vl20)#ip ospf cost 20
      switch-A(config-if-vl20)#ip ospf retransmit-interval 10
      switch-A(config-if-vl20)#ip ospf transmit-delay 2
      ```
   b. Router B interfaces:
      ```
      switch-B(config-if-vl16)#interface vlan 15
      switch-B(config-if-vl15)#ip ospf authentication-key abcdefgh
      switch-B(config-if-vl15)#ip ospf cost 10
      switch-B(config-if-vl15)#interface vlan 16
      switch-B(config-if-vl16)#ip ospf authentication-key ijklnmop
      switch-B(config-if-vl16)#ip ospf cost 20
      switch-B(config-if-vl16)#ip ospf retransmit-interval 10
      switch-B(config-if-vl16)#ip ospf transmit-delay 2
      switch-B(config-if-vl16)#ip ospf priority 6
      ```
c. Router C interfaces:

```plaintext
switch-C(config-if-vl21)#interface vlan 20
switch-C(config-if-vl20)#ip ospf authentication-key ijklmnop
switch-C(config-if-vl20)#ip ospf cost 20
switch-C(config-if-vl20)#ip ospf retransmit-interval 10
switch-C(config-if-vl20)#ip ospf transmit-delay 2
switch-C(config-if-vl20)#ip ospf priority 4
switch-C(config-if-vl20)#interface vlan 21
switch-C(config-if-vl21)#ip ospf authentication-key ijklmnop
switch-C(config-if-vl21)#ip ospf cost 20
switch-C(config-if-vl21)#ip ospf dead-interval 80
```

3. Attach the network segments to the areas.

a. Router A interfaces:

```plaintext
switch-A(config-if-vl20)#router ospf 1
switch-A(config-router-ospf)#router-id 10.24.1.1
switch-A(config-router-ospf)#network 10.119.254.0/24 area 0
switch-A(config-router-ospf)#network 10.119.251.0/24 area 0
switch-A(config-router-ospf)#area 0 range 10.119.251.0 0.0.7.255
```

b. Router B interfaces:

```plaintext
switch-B(config-if-vl16)#router ospf 1
switch-B(config-router-ospf)#router-id 10.24.1.2
switch-B(config-router-ospf)#area 10.42.110.0 stub
switch-B(config-router-ospf)#network 10.42.110.0/24 area 10.42.110.0
switch-B(config-router-ospf)#network 10.119.254.0/24 area 0
```

c. Router C interfaces:

```plaintext
switch-C(config-if-vl21)#router ospf 1
switch-C(config-router-ospf)#router-id 10.24.1.3
switch-C(config-router-ospf)#area 10.56.0.0 stub 0
switch-C(config-router-ospf)#network 10.119.251.0/24 area 0
switch-C(config-router-ospf)#network 10.56.0.0/24 area 36.56.0.0
```

15.2.4.3 OSPFv2 Configuration Example 3

The AS in Example 3 contains two areas that connect through one ABR.

- **Area 0**: Backbone area contains two internal routers that connect three subnets, one ASBR, and one ABR that connects to **Area 1**.
- **Area 1**: NSSA contains one internal router, one ASBR, and one ABR that connects to the backbone.

15.2.4.3.1 Example 3 Topology

OSPFv2 Example 3 displays the Example 3 topology. One ABR connects area 0 and area 1. **Router C** is an ABR that connects the areas. **Router A** is an internal router that connects two subnets in area 1. **Router D** and **Router E** are internal routers that connect subnets in area 0. **Router B** and **Router F** are ASBRs that connect static routes outside the AS to area 1 and area 0, respectively.
Area 0 ABR Configuration

ABR **Router C** connects one area 0 subnet to an area 1 subnet.

- **Router C**: The subnet *10.10.0.0/24* is accessed through *VLAN 11*.
- Authentication is not configured on the interfaces.
- All interface OSPFv2 parameters are set to their default values.

Area 0 IR Configuration

Area 0 contains two internal routers, each of which connects two of the three subnets in the area.

- **Router D**: The subnet *10.10.2.0/24* is accessed through *VLAN 11*.
- **Router D**: The subnet *10.10.3.0/24* is accessed through *VLAN 12*.
- **Router E**: The subnet *10.10.3.0/24* is accessed through *VLAN 12*.
- **Router E**: The subnet *10.10.4.0/24* is accessed through *VLAN 13*.
- All interface OSPFv2 parameters are set to their default values.

Area 0 ASBR Configuration

ASBR **Router F** connects one area 0 subnet to an external subnet.

- **Router F**: The subnet *10.10.4.0/24* is accessed through **Router F**.
- **Router F**: The subnet *12.15.1.0/24* is accessed through *VLAN 14*.
- All interface OSPFv2 parameters are set to their default values.

Area 1 ABR Configuration

ABR **Router C** connects one area 0 subnet to area 1.

- **Router C**: The subnet *10.10.1.0/24* is accessed through *VLAN 10*.
- Authentication is not configured on the interface.
- All interface OSPFv2 parameters are set to their default values.
Area 1 IR Configuration

Area 1 contains one internal router that connects two subnets in the area.

- **Router A**: The subnet 10.10.1.0/24 is accessed through VLAN 10.
- **Router A**: The subnet 10.10.5.0/24 is accessed through **Router A**.
- All interface OSPFv2 parameters are set to their default values.

Area 1 ASBR Configuration

ASBR **Router B** connects one area 1 subnet to an external subnet.

- **Router B**: The subnet 10.10.1.0/24 is accessed through VLAN 10.
- **Router B**: The subnet 16.29.1.0/24 is accessed through VLAN 15.
- All interface OSPFv2 parameters are set to their default values.

15.2.4.3.2 Example 3 Code

1. Configure the interfaces.
   a. Router A interfaces:

   ```
   switch-A(config)#interface vlan 10
   switch-A(config-if-vl10)#ip address 10.10.1.1/24
   switch-A(config-if-vl10)#interface vlan 9
   switch-A(config-if-vl11)#ip address 10.10.5.1/24
   ```

   b. Router B interfaces:

   ```
   switch-B(config)#interface vlan 10
   switch-B(config-if-vl10)#ip address 10.10.1.2/24
   switch-B(config-if-vl10)#interface vlan 15
   switch-B(config-if-vl18)#ip address 16.29.1.1/24
   ```

   c. Router C interfaces:

   ```
   switch-C(config)#interface vlan 10
   switch-C(config-if-vl10)#ip address 10.10.1.3/24
   switch-C(config-if-vl10)#interface vlan 11
   switch-C(config-if-vl11)#ip address 10.10.2.2/24
   ```

   d. Router D interfaces:

   ```
   switch-D(config)#interface vlan 11
   switch-D(config-if-vl11)#ip address 10.10.2.1/24
   switch-D(config)#interface vlan 12
   switch-D(config-if-vl12)#ip address 10.10.3.1/24
   ```

   e. Router E interfaces:

   ```
   switch-E(config)#interface vlan 12
   switch-E(config-if-vl12)#ip address 10.10.3.2/24
   switch-E(config)#interface vlan 13
   switch-E(config-if-vl13)#ip address 10.10.4.1/24
   ```

   f. Router F interfaces:

   ```
   switch-F(config)#interface vlan 13
   switch-F(config-if-vl13)#ip address 10.10.4.2/24
   switch-F(config)#interface vlan 14
   switch-F(config-if-vl14)#ip address 12.15.1.1/24
   ```
2. Attach the network segments to the areas.

a. Router A interfaces:

```
switch-A(config-if-vl10)#router ospf 1
switch-A(config-router-ospf)#router-id 170.21.0.1
switch-A(config-router-ospf)#area 1 NSSA
switch-A(config-router-ospf)#network 10.10.1.0/24 area 1
```

b. Router B interfaces:

```
switch-B(config-if-vl10)#router ospf 1
switch-B(config-router-ospf)#router-id 170.21.0.2
switch-B(config-router-ospf)#area 1 NSSA
switch-B(config-router-ospf)#network 10.10.1.0/24 area 1
```

c. Router C interfaces:

```
switch-C(config-if-vl11)#router ospf 1
switch-C(config-router-ospf)#router-id 170.21.0.3
switch-C(config-router-ospf)#area 1 NSSA
switch-C(config-router-ospf)#network 10.10.1.0/24 area 1
switch-C(config-router-ospf)#network 10.10.2.0/24 area 0
```

d. Router D interfaces:

```
switch-D(config-if-vl12)#router ospf 1
switch-D(config-router-ospf)#router-id 170.21.0.4
switch-D(config-router-ospf)#network 10.10.2.0/24 area 0
switch-D(config-router-ospf)#network 10.10.3.0/24 area 0
```

e. Router E interfaces:

```
switch-E(config-if-vl13)#router ospf 1
switch-E(config-router-ospf)#router-id 170.21.0.5
switch-E(config-router-ospf)#network 10.10.3.0/24 area 0
switch-E(config-router-ospf)#network 10.10.4.0/24 area 0
```

f. Router F interfaces:

```
switch-F(config-if-vl14)#router ospf 1
switch-F(config-router-ospf)#router-id 170.21.0.6
switch-F(config-router-ospf)#network 10.10.4.0/24 area 0
switch-F(config-router-ospf)#redistribute static
```

15.2.5.1 auto-cost reference-bandwidth (OSPFv2)

The `auto-cost reference-bandwidth` command is a factor in the formula that calculates the default OSPFv2 cost for Ethernet interfaces.

\[ \text{OSPFv2-cost} = \frac{\text{auto-cost value} \times 1 \text{ Mbps}}{\text{interface bandwidth}}. \]

The switch uses a minimum OSPFv2-cost of 1. The switch rounds down all non-integer results.

On a 10G Ethernet interface:
- if auto-cost = 100, then \( \text{OSPFv2-cost} = \frac{100 \text{ Mbps}}{10 \text{ Gbps}} = 0.01 \), and the default cost is set to 1.
- if auto-cost = 59000, then \( \text{OSPFv2-cost} = \frac{59000 \text{ Mbps}}{10 \text{ Gbps}} = 5.9 \), and the default cost is set to 5.

The `no auto-cost reference-bandwidth` and `default auto-cost reference-bandwidth` command removes the `auto-cost reference-bandwidth` command from `running-config`. When this parameter is not set, the default cost for Ethernet interfaces is the default `ip ospf cost` value of 10.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
auto-cost reference-bandwidth rate
no auto-cost reference-bandwidth rate
default auto-cost reference-bandwidth rate
```

**Parameter**

`rate` Values range from 1 to 4294967. Default is 100.

**Example**

To configure a default cost of 20 on 10G Ethernet interfaces:

1. Calculate the required auto-cost value:
   \[ \text{auto-cost} = \frac{\text{OSPFv2-cost} \times \text{interface bandwidth}}{1 \text{ Mbps}} = \frac{20 \times 10000 \text{ Mbps}}{1 \text{ Mbps}} = 200000 \]
2. Configure this value as the auto-cost reference-bandwidth.

```
switch(config)#router ospf 6
switch(config-router-ospf)#auto-cost reference-bandwidth 200000
switch(config-router-ospf)#
```
15.2.5.2  adjacency exchange-start threshold (OSPFv2)

The **adjacency exchange-start threshold** command sets the exchange-start options for an OSPF instance.

The **no adjacency exchange-start threshold** and **default adjacency exchange-start threshold** command resets the default by removing the corresponding **adjacency exchange-start threshold** command from **running-config**.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

default adjacency exchange-start threshold
adjacency exchange-start threshold ***peers***
no adjacency exchange-start threshold

**Parameter**

*peers* Value ranges from 1- 4294967295. Default value is 10.

**Example**

This command sets the adjacency exchange start threshold to 20045623.

```
switch(config)#router ospf 6
switch(config-router-ospf)# adjacency exchange-start threshold 20045623
switch(config-router-ospf)#
```
15.2.5.3 area default-cost (OSPFv2)

The **area default-cost** command specifies the cost for the default summary routes sent into a specified area. The default-cost is set to **10**.

The no **area default-cost** and **default area default-cost** command resets the default-cost value of the specified area to **10** by removing the corresponding **area default-cost** command from **running-config**. The no area (OSPFv2) command removes all area commands for the specified area from **running-config**, including the **area default-cost** command.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
area area_id default-cost def_cost
no area area_id default-cost def_cost
default area area_id default-cost def_cost
```

**Parameters**

- **area_id** Area number: **0 to 4294967295** or **0.0.0.0 to 255.255.255.255** running-config stores value in dotted decimal notation.
- **def_cost** Value ranges from **1** to **65535**. Default value is **10**.

**Example**

This command configures a cost of **15** for default summary routes that an ABR sends into area **23**.

```
switch(config)#router ospf 6
switch(config-router-ospf)#area 23 default-cost 15
switch(config-router-ospf)#
```
15.2.5.4 area filter (OSPFv2)

The **area filter** command prevents an area from receiving Type 3 Summary LSAs from a specified subnet.

The **no area filter** and **default area filter** commands remove the specified **area filter** command from **running-config**. The **no area** command (see **no area** (OSPFv2)) removes all area commands for the specified area from **running-config**, including **area filter** commands.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```plaintext
area area_id filter net_addr
no area area_id filter net_addr
default area area_id filter net_addr
```

**Parameters**

- **area_id** Area number. 0 to 4294967295 or 0.0.0.0 to 255.255.255.255. **running-config** stores value in dotted decimal notation.
- **net_addr** Network IP address. Entry formats include address-prefix (CIDR) and address-mask. **running-config** stores value in CIDR notation.

**Example**

This command prevents the switch from entering Type 3 LSAs originating from the **10.1.1.0/24** subnet into its area **2** LSDB.

```
switch(config)#router ospf 6
switch(config-router-ospf)#area 2 filter 10.1.1.0/24
switch(config-router-ospf)#
```
15.2.5.5 area not-so-stubby lsa type-7 convert type-5 (OSPFv2)

The `area not-so-stubby lsa type-7 convert type-5` command configures the switch to always translate Type-7 Link-State Advertisement (LSAs) to Type-5 LSAs.

The no `area not-so-stubby lsa type-7 convert type-5` and no `area not-so-stubby lsa type-7 convert type-5` commands allow LSAs to be translated dynamically by removing the no `area not-so-stubby lsa type-7 convert type-5` command from `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
area area_id not-so-stubby lsa type-7 convert type-5
no area area_id not-so-stubby lsa type-7 convert type-5
default area area_id not-so-stubby lsa type-7 convert type-5
```

**Parameters**

`area_id` Area number.

- Valid formats: integer \(1\) to \(4294967295\) or dotted decimal \(0.0.0.1\) to \(255.255.255.255\).
- Area \(0\) (or \(0.0.0.0\)) is not configurable; it is always normal.
- `running-config` stores value in dotted decimal notation.

**Example**

This command configures the switch to always translate Type-7 Link-State Advertisement (LSAs) to Type-5 LSAs.

```
switch(config-router-ospf)#area 3 not-so-stubby lsa type-7 convert type-5
switch(config-router-ospf)#
```
15.2.5.6 area nssa (OSPFv2)

The `area nssa` command configures an OSPFv2 area as a Not-So-Stubby Area (NSSA). All routers in an AS must specify the same area type for identically numbered areas.

NSSA ASBRs advertise external LSAs that are part of the area, but do not advertise external LSAs from other areas.

Areas are *normal* by default; area type configuration is required only for stub NSSA areas. Area 0 is always a normal area and cannot be configured through this command.

The `no area nssa` command configures the specified area as a normal area by removing the specified `area nssa` command from *running-config*.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```
area area_id nssa [TYPE]
no area area_id nssa [TYPE]
default area area_id nssa [TYPE]
```

**Parameters**

- `area_id` All parameters except `area_id` can be placed in any order.
- Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
- Area 0 (or 0.0.0.0) is not configurable; it is always normal.
- *running-config* stores value in dotted decimal notation.
- `TYPE` Area type. Values include:
  - `no parameter`
  - `nssa-only`

**Example**

This command configures area 3 as a NSSA area.

```
switch(config-router-ospf)#area 3 nssa nssa-only
```

```
switch(config-router-ospf)#
```
15.2.5.7  area nssa default-information-originate (OSPFv2)

The `default area nssa default-information-originate` command sets default route origination for the Not-So-Stubby Area (NSSA), allowing the redistribute policy to advertise a default route if one is present. The resulting OSPF behavior depends on the presence of an installed static default route and on whether static routes are redistributed in OSPF (using the `redistribute (OSPFv2)` command). The `no area nssa default-information-originate` command disables advertisement of the default route for the NSSA regardless of the redistribute policy. See Advertisement of Default Route for details.

Areas are normal by default; area type configuration is required only for stub and NSSA areas. Area 0 is always a normal area and cannot be configured through this command.

Default route origination is configured differently for different area types and supports three area types:

- Normal areas: advertisement of the default route is configured for all normal areas using the `default-information originate (OSPFv2)` command.
- Stub areas: the default route is automatically advertised in stub areas and cannot be configured.
- Not So Stubby Areas (NSSAs): advertisement of the default route is configured per area using the `area nssa default-information-originate (OSPFv2)` or `area nssa no-summary (OSPFv2)` command.

Table 71: Advertisement of Default Route

Command Mode

Router-OSPF Configuration

Command Syntax

`area area_id nssa default-information-originate [VALUE][TYPE][EXCL]`

`no area area_id nssa default-information-originate`

`default area area_id nssa default-information-originate`
Parameters

- **area_id** All parameters except **area_id** can be placed in any order.
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - **running-config** stores value in dotted decimal notation.
- **VALUE** Values include:
  - **no parameter** Default value of 1.
  - **metric** 1-65535.
- **TYPE** Values include:
  - **no parameter**.
  - **metric-type** 1-2.
- **EXCL** Values include:
  - **no parameter**.
  - **nssa-only**.

Example

This command configures area 3 as an NSSA and generates a type 7 default LSA within the NSSA.

```
switch(config-router-ospf)#area 3 nssa default-information-originate
nssa-only
switch(config-router-ospf)#
```
The `area nssa no-summary` command configures the switch to stop importing type-3 summary LSAs into the Not-So-Stubby Area (NSSA) and sets the default summary route into the NSSA in order to reach the inter-area prefixes.

The `no area nssa no-summary` and `default area nssa no-summary` commands allow type-3 summary LSAs into the NSSA area.

The `no area nssa` and `default area nssa` commands configure the specified area as a normal area.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
area area_id nssa no-summary
no area area_id nssa no-summary
default area area_id nssa no-summary
```

**Parameters**

`area_id` Area number.

- Valid formats: integer `1` to `4294967295` or dotted decimal `0.0.0.1` to `255.255.255.255`.
- Area `0` (or `0.0.0.0`) is not configurable; it is always normal.
- `running-config` stores value in dotted decimal notation.

**Examples**

- This command directs the device not to import type-3 summary LSAs into the NSSA area.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#area 1.1.1.1 nssa no-summary
switch(config-router-ospf)#
```

- This command directs the device to import type-3 summary LSAs into the NSSA area.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#no area 1.1.1.1 nssa no-summary
switch(config-router-ospf)#
```
15.2.5.9  area range (OSPFv2)

The **area range** command configures OSPF Area Border Routers (ABRs) to consolidate or summarize routes, to set the cost setting routes, and to suppress summary route advertisements.

The **no area** (OSPFv2) command removes all area commands for the specified area from *running-config*.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
area area_id range net_addr [ADVERTISE_SETTING] [COST_SETTING]
no area area_id range net_addr [ADVERTISE_SETTING] [COST_SETTING]
default area area_id range net_addr [ADVERTISE_SETTING] [COST_SETTING]
```

**Parameters**

- **area_id** Area number. 0 to 4294967295 or 0.0.0.0 to 255.255.255.255 *running-config* stores value in dotted decimal notation.
- **net_addr**
- **ADVERTISE_SETTING** Values include:
  - no parameter
  - advertise
  - not-advertise
- **COST_SETTING** Values include:
  - no parameter
  - cost range_cost Value ranges from 1 to 65535.

**Examples**

- The **network area** command assigns two subnets to an area. The **area range** command summarizes the addresses, which the ABR advertises in a single LSA.

  ```
  switch(config)#router ospf 6
  switch(config-router-ospf)#network 10.1.25.80 0.0.0.240 area 5
  switch(config-router-ospf)#network 10.1.25.112 0.0.0.240 area 5
  switch(config-router-ospf)#area 5 range 10.1.25.64 0.0.0.192
  switch(config-router-ospf)#
  ```

- The **network area** command assigns a subnet to an area, followed by an **area range** command that suppresses the advertisement of that subnet.

  ```
  switch(config-router-ospf)#network 10.12.31.0/24 area 5
  switch(config-router-ospf)#area 5 range 10.12.31.0/24 not-advertise
  switch(config-router-ospf)#
  ```
15.2.5.10  area stub (OSPFv2)

The **area stub** command sets the area type of an OSPF area to **stub**. All devices in an Area Stub (AS) must specify the same area type for identically numbered areas.

The **no area stub** command remove the specified stub area from the OSPFv2 instance by deleting all **area stub** commands from **running-config** for the specified area.

The **no area stub** command configures the specified area as a normal area.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```plaintext
area area_id stub [summarize]

no area area_id stub [summarize]

default area area_id stub [summarize]
```

**Parameters**

- **area_id** Area number.
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - **running-config** stores value in dotted decimal notation.
  - **summarize** Area type. Values include:
    - **no parameter**
    - **no-summary**

**Examples**

- These commands configure area 45 as a stub area.

  ```plaintext
  switch(config)#router ospf 3
  switch(config-router-ospf)#area 45 stub
  switch(config-router-ospf)#
  ```

- This command configures area 10.92.148.17 as a stub area.

  ```plaintext
  switch(config-router-ospf)#area 10.92.148.17 stub
  switch(config-router-ospf)#
  ```
clear ip ospf neighbor

The `clear ip ospf` command clears the neighbors statistics per interface.

**Command Mode**
Privileged EXEC

**Command Syntax**
`clear ip ospf [PROCESS_ID] neighbor [LOCATION][VRF_INSTANCE]`

**Parameters**
- **PROCESS_ID** OSPFv2 process ID. Values include:
  - `no parameter`
  - `1 to 65535`.
- **LOCATION** Address or interface peer group name. Values include:
  - `*` clears all OSPF IPv4 neighbors.
  - `ipv4_addr`
  - `ethernet e_num`
  - `loopback l_num`
  - `port-channel p_num`
  - `vlan v_num`
- **VRF_INSTANCE** Specifies the VRF instance.
  - `vrf vrf_name` configures the `vrf_name` instance.

**Examples**
- This command resets all OSPF neighbor statistics.
  ```
  switch#clear ip ospf neighbor *
  switch#
  ```
- This command resets the OSPF neighbor statistics for the specified Ethernet 3 interface.
  ```
  switch#clear ip ospf neighbor ethernet 3
  switch#
  ```
15.2.5.12 compatible (OSPFv2)

The `compatible` command allows the selective disabling of compatibility with RFC 2328.

The `no compatible` and `default compatible` commands reverts OSPF to RFC 2328 compatible and removes the compatible statement from `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

`compatible rfc1583`

`no compatible rfc1583`

`default compatible rfc1583`

**Examples**

- This command sets the OSPF compatibility list with RFC 1583.

```
switch(config)#router ospf 6
switch(config-router-ospf)#compatible rfc1583
switch(config-router-ospf)#
```

- This command disables RFC 1583 compatibility.

```
switch(config)#router ospf 6
switch(config-router-ospf)# no compatible rfc1583
switch(config-router-ospf)#
```
15.2.5.13  default-information originate (OSPFv2)

The `default-information originate` command enables default route origination for normal areas. The user can configure the metric value and metric type used in LSAs. The `always` option will cause the ASBR to create and advertise a default route whether or not one is configured.

The `no default-information originate` command prevents the advertisement of the default route. The `default default-information originate` command enables default route origination with default values (metric type 2, metric=1).

Command Mode
Router-OSPF Configuration

Command Syntax
default-information originate [FORCE][VALUE][TYPE][MAP]

no default-information originate
default default-information originate

Parameters
All parameters can be placed in any order.

- **FORCE** Advertisement forcing option. Values include:
  - no parameter
  - always
- **VALUE** Values include:
  - no parameter
  - metric 1-65535
- **TYPE** Values include:
  - no parameter
  - metric-type 1-2
- **MAP** Sets attributes in the LSA based on a route map. Values include:
  - no parameter
  - route-map map_name.

Examples

- These commands always advertise the OSPFv2 default route regardless of whether the switch has a default route configured.

```
switch(config)#router ospf 1
switch((config-router-ospf)#default-information originate always
switch((config-router-ospf)#show active
router ospf 1
default-information originate always
```

- These commands advertise a default route with a metric of 100 and an external metric type of 1 if a default route is configured.

```
switch(config)#router ospf 1
switch((config-router-ospf)#default-information originate metric 100
metric-type 1
```
15.2.5.14  distance ospf (OSPFv2)

The `distance ospf` command specifies the administrative distance for intra-area, inter-area, or external OSPF routes. The command must be issued separately for each route type being configured. The default administrative distance for all routes is 110.

The `no distance ospf` and `default distance ospf` commands remove the corresponding `distance ospf` command from `running-config`, returning the OSPFv2 administrative distance setting for the specified route type to the default value of 110.

>Note: OSPF links will flap if the administrative distance value is adjusted while OSPF is running, whether it is adjusted by entering the `distance ospf` command directly through the CLI or by applying a configuration file that contains the command.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```markdown
distance ospf [external | inter-area | intra-area]
no distance ospf [external | inter-area | intra-area]
default distance ospf [external | inter-area | intra-area]
```

**Parameters**

- **external** Sets administrative distance for external routes.
- **inter-area** Sets administrative distance for inter-area routes.
- **intra-area** Sets administrative distance for intra-area routes.
- **distance** Values range from 1 to 255. Default value is 110 for all types.

**Example**

This command configures an administrative distance of 85 for all OSPFv2 intra-area routes on the switch. If issued while OSPF is running, this command will cause OSPF links to flap.

```
switch(config)#router ospf 6
switch(config-router-ospf)#distance ospf intra-area 85
switch(config-router-ospf)#
```
15.2.5.15  distribute-list in

A distribute list uses a route map or prefix list to filter specific routes from incoming OSPF LSAs. Filtering occurs after SPF calculation. The filtered routes are not installed on the switch, but are still included in LSAs sent by the switch. The `distribute-list in` command creates a distribute list in the configuration mode OSPF instance.

If a prefix list is used, destination prefixes that do not match the prefix list will not be installed. If a route map is used, routes may be filtered based on address, next hop, or metric. OSPF external routes may also be filtered by metric type or tag.

The `no distribute-list in` and `default distribute-list in` commands remove the `distribute-list in` command from `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
distribute-list (prefix-list | route-map) list_name in

no distribute-list (prefix-list | route-map)

default distribute-list (prefix-list | route-map)
```

**Parameters**

- `prefix-list` Specifies a prefix-list as the filter.
- `route-map` Specifies a route-map as the filter.
- `list_name` The name of the prefix-list or route-map used to filter routes from incoming LSAs.

**Related Commands**

`area filter (OSPFv2)`

`redistribute (OSPFv2)`

**Example**

These commands configure a prefix list named `dist_list1` in OSPF instance 5 to filter certain routes from incoming OSPF LSAs.

```
switch(config)#router ospf 5
switch(config-router-ospf)#distribute-list prefix-list dist_list1 in
switch(config-router-ospf)#
```
15.2.5.16  dn-bit-ignore (OSPFv2)

The `dn-bit-ignore` command results in the DN bit in Type 3 Summary LSAs to be ignored during the Shortest Path First (SPF) calculations.

The `no dn-bit-ignore` and `default dn-bit-ignore` commands result in the DN bit in Type 3 Summary LSAs to not be ignored during SPF calculations.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

dn-bit-ignore
no dn-bit-ignore
default dn-bit-ignore

**Examples**

- This command ignores the DN bit.

```bash
switch(config)#router ospf 6
switch(config-router-ospf)#dn-bit-ignore
switch(config-router-ospf)#
```

- This command causes the DN bit not to be ignored.

```bash
switch(config)#router ospf 6
switch(config-router-ospf)#no dn-bit-ignore
switch(config-router-ospf)#
```
15.2.5.17  interface Tunnel

OSPF packets by default are sent with Time to Live (TTL) value 1. This may not work in tunnel scenarios where the peer tunnel end point could be more than one hop away. It is recommended to explicitly configure TTL on the tunnel interface. TTL configuration is allowed only if `path-mtu-discovery` is configured.

**Command Mode**
Configuration mode

**Command Syntax**

```
interface Tunnel Tunnel No
```

**Parameters**

- **Tunnel No** Tunnel number.

**Example**

```
(config)#interface Tunnel 5
(config-if-Tu0)#tunnel path-mtu-discovery
(config-if-Tu0)#tunnel ttl 5
```
15.2.5.18  ip ospf area

The **ip ospf area** command enables OSPFv2 on an interface and associates the area to the interface.

The **no ip ospf area** and **default ip ospf area** commands disable OSPFv2 on the configuration mode interface and remove the configured area from the system.

**Note:** The per interface configuration has precedence over the OSPF Configuration mode. In other words, the area configured by the ip ospf area command has precedence over the area configured by the network area command.

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```
ip ospf area area_id
no ip ospf area area_id
default ip ospf area area_id
```

**Parameters**

*area_id* The area ID. The valid values are 0 to 4294967295 or a decimal range between 0.0.0.0 and 255.255.255.255.

**Example**

These commands enable OSPFv2 on the **et2** interface and associates area identifier **1.1.1.1** to the interface.

```
switch(config)#Interface ethernet 2
switch(config-if-Et2)# ip address 1.0.0.1/24
switch(config-if-Et2)# ip ospf area 1.1.1.1
router ospf 1
```
15.2.5.19  ip ospf authentication

The ip ospf authentication command enables OSPFv2 authentication for the configuration mode interface.

The no ip ospf authentication and default ip ospf authentication commands disable OSPFv2 authentication on the configuration mode interface by removing the corresponding ip ospf authentication command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax
ip ospf authentication [METHOD]
no ip ospf authentication
default ip ospf authentication

Parameters
METHOD OSPFv2 authentication method. Options include:
- no parameter
- message-digest

Examples
- This command enables simple authentication on vlan 12.
  
  switch(config)#interface vlan 12
  switch(config-if-vl12)#ip ospf authentication
  switch(config-if-vl12)#

- This command enables message-digest authentication on vlan 12.

  switch(config-if-vl12)#ip ospf authentication message-digest
  switch(config-if-vl12)#
15.2.5.20  ip ospf authentication-key

The **ip ospf authentication-key** command configures the OSPFv2 authentication password for the configuration mode interface.

The **no ip ospf authentication-key** and **default ip ospf authentication-key** commands removes the OSPFv2 authentication password from the configuration mode interface by removing the corresponding **ip ospf authentication-key** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```
ip ospf authentication-key [ENCRYPT_TYPE] key_text
no ip ospf authentication-key
default ip ospf authentication-key
```

**Parameters**

- **ENCRYPT_TYPE** Encryption level of the **key_text** parameter. Values include:
  - **no parameter** the **key_text** is in clear text.
  - **0** **key_text** is in clear text. Equivalent to **no parameter**.
  - **7** **key_text** is MD5 encrypted.
- **key_text** the authentication-key password.

**Example**

```
switch(config)#interface vlan 12
switch(config-if-Vl12)#ip ospf authentication-key 0 code123
switch(config-if-Vl12)#show active
interface Vlan12
   ip ospf authentication-key 7 baYllFzVbcx4yHql1hmMdw==
switch(config-if-Vl12)#
```

The **running-config** stores the password as an encrypted string.
15.2.5.21  ip ospf cost

The `ip ospf cost` command configures the OSPFv2 cost for the configuration mode interface. The default cost depends on the interface type:

- Ethernet: determined by the `auto-cost reference-bandwidth (OSPFv2)` command.
- Port channel: 10.
- VLAN: 10.

The `no ip ospf cost` and `default ip ospf cost` commands restore the default OSPFv2 cost for the configuration mode interface by removing the corresponding `ip ospf cost` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```plaintext
ip ospf cost interface_cost
no ip ospf cost
default ip ospf cost
```

**Parameters**

`interface_cost` Value ranges from 1 to 65535; default is 10.

**Example**

This command configures a cost of 15 for VLAN 2.

```
switch(config)#interface vlan 2
switch(config-if-Vl2)#ip ospf cost 15
switch(config-if-Vl2)#
```
15.2.5.22  ip ospf dead-interval

The ip ospf dead-interval command configures the dead interval for the configuration mode interface.

The no ip ospf dead-interval and default ip ospf dead-interval commands restore the default dead interval of 40 seconds on the configuration mode interface by removing the corresponding ip ospf dead-interval command from running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

ip ospf dead-interval time
no ip ospf dead-interval
default ip ospf dead-interval

Parameters

time Value ranges from 1 to 8192; default is 40.

Example

This command configures a dead interval of 120 seconds for vlan 4.

switch(config)#interface vlan 4
switch(config-if-Vl4)#ip ospf dead-interval 120
switch(config-if-Vl4)#
15.2.5.23  ip ospf disabled

The `ip ospf disabled` command disables OSPFv2 on the configuration mode interface without disrupting the OSPFv2 configuration. When OSPFv2 is enabled on the switch, the it is also enabled by default on all interfaces.

The OSPFv2 instance is disabled on the entire switch with the `shutdown (OSPFv2)` command.

The `no ip ospf disabled` and `default ip ospf disabled` commands enable OSPFv2 on the configuration mode interface by removing the corresponding `ip ospf disabled` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `ip ospf disabled`
- `no ip ospf disabled`
- `default ip ospf disabled`

**Examples**

- This command shuts down OSPFv2 activity on `vlan 5`.

```
switch(config)#interface vlan 5
switch(config-if-Vl5)#ip ospf disabled
switch(config-if-Vl5)#
```

- This command resumes OSPFv2 activity on `vlan 5`.

```
switch(config-if-Vl5)#no ip ospf disabled
switch(config-if-Vl5)#
```
15.2.5.24  ip ospf hello-interval

The *ip ospf hello-interval* command configures the OSPFv2 hello interval for the configuration mode interface.

The same hello interval should be specified for each OSPFv2 neighbor, and should not be longer than any neighbors dead interval.

The `no ip ospf hello-interval` and `default ip ospf hello-interval` commands restore the default hello interval of 10 seconds on the configuration mode interface by removing the `ip ospf hello-interval` command from *running-config*.

**Command Mode**

Interface-Ethernet Configuration  
Interface-Port-Channel Configuration  
Interface-VLAN Configuration

**Command Syntax**

```
ip ospf hello-interval time
no ip ospf hello-interval
default ip ospf hello-interval
```

**Parameter**

*time* Hello interval (seconds). Values range from 1 to 8192; default is 10.

**Example**

This command configures a hello interval of 30 seconds for *vlan 2*.

```
switch(config)#interface vlan 2
switch(config-if-Vl2)#ip ospf hello-interval 30
switch(config-if-Vl2)#
```
The `ip ospf message-digest-key` command configures a message digest authentication key for the configuration mode interface.

The `no ip ospf message-digest-key` and `default ip ospf message-digest-key` commands remove the message digest authentication key for the specified key ID on the configuration mode interface by deleting the corresponding `ip ospf message-digest-key` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

```
ip ospf message-digest-key key_id md5 ENCRYPT_TYPE key_text

no ip ospf message-digest-key key_id

default ip ospf message-digest-key key_id
```

**Parameters**

- `key_id` Key ID number. Value ranges from 1 to 255.
- `ENCRYPT_TYPE` Encryption level of the `key_text` parameters. Values include:
  - `no parameter`
  - `0 key_text`
  - `7 key_text`
- `key_text` message key (password).

**Example**

This command configures `code123` as the MD5 key with a corresponding key ID of 23.

```
switch(config)#interface vlan 12
switch(config-if-vl12)#ip ospf message-digest-key 23 md5 0 code123
switch(config-if-vl12)#
```

The `running-config` stores the password as an encrypted string.
15.2.5.26 ip ospf network point-to-point

The **ip ospf network point-to-point** command sets the configuration mode interface as a point-to-point link. By default, interfaces are configured as broadcast links.

The **no ip ospf network** and **default ip ospf network** commands set the configuration mode interface as a broadcast link by removing the corresponding **ip ospf network** command from **running-config**.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```
ip ospf network point-to-point
no ip ospf network
default ip ospf network
```

**Examples**

- These commands configure Ethernet interface 10 as a point-to-point link.

  ```
  switch(config)#interface ethernet 10
  switch(config-if-Etl0)#ip ospf network point-to-point
  switch(config-if-Etl0)#
  ```

- This command restores Ethernet interface 10 as a broadcast link.

  ```
  switch(config-if-Etl0)#no ip ospf network
  switch(config-if-Etl0)#
  ```
15.2.5.27  ip ospf retransmit-interval

The `ip ospf retransmit-interval` command configures the link state advertisement retransmission interval for the interface.

The `no ip ospf retransmit-interval` and `default ip ospf retransmit-interval` commands restore the default retransmission interval of 5 seconds on the configuration mode interface by removing the corresponding `ip ospf retransmit-interval` command from `running-config`.

Command Mode

- Interface-Ethernet Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

Command Syntax

- `ip ospf retransmit-interval period`
- `no ip ospf retransmit-interval`
- `default ip ospf retransmit-interval`

Parameters

- `period` Retransmission interval (seconds). Value ranges from 1 to 8192; default is 5.

Example

This command configures a retransmission interval of 15 seconds for `vlan 3`.

```
switch(config)#interface vlan 3
switch(config-if-Vl3)#ip ospf retransmit-interval 15
switch(config-if-Vl3)#
```
15.2.5.28 ip ospf router-id output-format hostnames

The `ip ospf router-id output-format hostnames` command causes the switch to display DNS names in place of numeric OSPFv2 router IDs in all OSPFv2 show commands, including:

- `show ip ospf`
- `show ip ospf border-routers`
- `show ip ospf database <link state list>`
- `show ip ospf database database-summary`
- `show ip ospf database <link-state details>`
- `show ip ospf interface`
- `show ip ospf neighbor`
- `show ip ospf request queue`
- `show ip ospf retransmission queue`

The `no ip ospf router-id output-format hostnames` and `default ip ospf router-id output-format hostnames` commands remove the `ip ospf router-id output-format hostnames` command from `running-config`, restoring the default behavior of displaying OSPFv2 router IDs by their numeric value.

**Command Mode**

Global Configuration

**Command Syntax**

- `ip ospf router-id output-format hostnames`
- `no ip ospf router-id output-format hostnames`
- `default ip ospf router-id output-format hostnames`

**Example**

This command programs the switch to display OSPFv2 router IDs by the corresponding DNS name in subsequent show commands.

```
switch(config)#ip ospf router-id output-format hostnames
switch(config)#
```
15.2.5.29  ip ospf transmit-delay

The `ip ospf transmit-delay` command configures the transmission delay for OSPFv2 packets over the configuration mode interface.

The `no ip ospf transmit-delay` and `default ip ospf transmit-delay` commands restore the default transmission delay (1 second) on the configuration mode interface by removing the corresponding `ip ospf transmit-delay` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

**Command Syntax**

`ip ospf transmit-delay trans`
`no ip ospf transmit-delay`
`default ip ospf transmit-delay`

**Parameters**

`trans` LSA transmission delay (seconds). Value ranges from 1 to 8192; default is 1.

**Example**

This command configures a transmission delay of 5 seconds for `vlan 6`.

```
switch(config)#interface vlan 6
switch(config-if-Vl6)#ip ospf transmit-delay 5
switch(config-if-Vl6)#
```
15.2.5.30  ip ospf priority

The `ip ospf priority` command configures OSPFv2 router priority for the configuration mode interface.

The `no ip ospf priority` and `default ip ospf priority` commands restore the default priority (1) on the configuration mode interface by removing the corresponding `ip ospf priority` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration  Interface-Port-Channel Configuration  Interface-VLAN Configuration

**Command Syntax**

- `ip ospf priority priority_level`
- `no ip ospf priority`
- `default ip ospf priority`

**Parameter**

`priority_level` priority level. Value ranges from 0 to 255. Default value is 1.

**Examples**

- This command configures a router priority of 15 for `vlan 8`.

  ```
  switch(config)#interface vlan 8
  switch(config-if-Vl8)#ip ospf priority 15
  switch(config-if-Vl8)#
  ```

- This command restores the router priority of 1 for `vlan 7`.

  ```
  switch(config)#interface vlan 7
  switch(config-if-Vl7)#no ip ospf priority
  switch(config-if-Vl7)#
  ```
15.2.5.31  line system

The **line system** command places the switch in the OSPF - Line System configuration mode. The **no line system** command removes the Line System configurations from the *running-config*.

**Command Mode**

Global Configuration Mode

**Command Syntax**

```
line system
no line system
```

**Parameters**

- The following parameters are allowed to be configured under LS mode.
  - **port number** Transceiver slot number. Value ranges from 1 - 66.
    - The following parameters are allowed under **LS port mode**:
      - booster Booster settings
      - pre-amp Pre-amp settings

**Example**

This command places the switch in the OSPF Line System configuration mode.

```
switch#config
switch(config)#line system
switch(config-ls)#
```
15.2.5.32 log-adjacency-changes (OSPFv2)

The **log-adjacency-changes** command enables syslog messages to be sent when it detects OSPFv2 link state changes or when it detects that a neighbor has gone up or down. Log message sending is enabled by default.

The **default log-adjacency-changes** command restores the default state by removing the **log-adjacency-changes** statement from **running-config**.

The default option (sending a message only when a neighbor goes up or down) is active when running-config does not contain any form of the command. Entering the command in any form replaces the previous command state in **running-config**.

The **no log-adjacency-changes** disables link state change syslog reporting.

The **default log-adjacency-changes** command restores the default state by removing the **log-adjacency-changes detail** or **no log-adjacency-changes** statement from **running-config**.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

- **log-adjacency-changes**
- **no log-adjacency-changes**
- **default log-adjacency-changes**

**Examples**
- This command configures the switch to send a syslog message when a neighbor goes up or down.

  ```
  switch(config)#router ospf 6
  switch(config-router-ospf)#log-adjacency-changes
  switch(config-router-ospf)#
  ```

- After entering the command, **show active** does not display a **log-adjacency-changes** statement.

  ```
  switch(config-router-ospf)#show active router ospf 1
  switch(config-router-ospf)#
  ```

- This command configures the switch to send a Syslog message when it detects any link state change.

  ```
  switch(config-router-ospf)#log-adjacency-changes detail
  switch(config-router-ospf)#
  ```

- After entering the command, **show active** displays a **log-adjacency-changes detail** command.

  ```
  switch(config-router-ospf)#show active router ospf 1
  switch(config-router-ospf)#log-adjacency-changes detail
  switch(config-router-ospf)#
  ```
15.2.5.33 maximum-paths (OSPFv2)

The **maximum-paths** command controls the number of parallel routes that OSPFv2 supports. The default maximum is **16** paths.

The **no maximum-paths** and **default maximum-paths** commands restore the maximum number of parallel routes that OSPFv2 supports on the switch to the default value of 16 by placing the **maximum-paths 16** statement in **running-config**.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
maximum-paths paths
no maximum-paths
default maximum-paths
```

**Parameters**

- **paths** Maximum number of parallel routes.

  Value ranges from **1** to the number of interfaces available per ECMP group, which is platform dependent.

- **Arad**: Value ranges from **1 to 128**. Default value is **128**.
  - **FM6000**: Value ranges from **1 to 32**. Default value is **32**.
  - **PetraA**: Value ranges from **1 to 16**. Default value is **16**.
  - **Trident**: Value ranges from **1 to 32**. Default value is **32**.
  - **Trident II**: Value ranges from **1 to 128**. Default value is **128**.

**Example**

This command configures the maximum number of OSPFv2 parallel paths to **12**.

```
switch(config)#router ospf 6
switch(config-router-ospf)#maximum-paths 12
switch(config-router-ospf)#
```
15.2.5.34  max-lsa (OSPFv2)

The **max-lsa** command specifies the maximum number of LSAs allowed in the LSDB. Setting the limit to zero removes the LSDB restriction and disables LSA overload actions. Actions triggered by LSDB overload conditions include:

- **Warning**: the switch logs OSPF MAXLSAWARNING if the LSDB contains a specified percentage of the LSA maximum.
- **Temporary shutdown**: when the LSDB exceeds the LSA maximum, OSPFv2 is disabled and does not accept or acknowledge new LSAs. The switch re-starts OSPFv2 after a specified period (the default is five minutes).
- **Permanent shutdown**: the switch permanently disables OSPFv2 after performing a specified number of temporary shutdowns (the default is 5). This state usually indicates the need to resolve a network condition that consistently generates excessive LSA packets.

The **no max-lsa** and **default max-lsa** commands restore all LSA overload parameters to their default settings.

**Note**: if OSPFv2 has entered permanent shutdown, it can also be restarted by increasing the LSA limit to a value larger than the number of LSAs in the database. Setting the max-LSA value to zero will also restart OSPFv2, and will disable overload protection.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
max-lsa  lsa_num [WARNING] [IGNORE_TIME] [IGNORE_COUNT] [RESET]
no max-lsa
default max-lsa
```

**Parameters**

- **lsa_num** Maximum number of LSAs. Value ranges from **0 to 100,000**.
  - 0 Disables overload protection.
  - 1 to 100000 Specifies maximum value; default value is 12,000.
- **WARNING** Warning threshold, as a percentage of the maximum number of LSAs (% of lsa_num).
  - no parameter Default of 75%.
  - percent Ranges from 25 to 99.
- **IGNORE_TIME** Temporary shutdown period (minutes). Options include:
  - no parameter Default value of 5 minutes.
  - ignore-time period Value ranges from 1 to 60.
- **IGNORE_COUNT** Number of temporary shutdowns required to trigger a permanent shutdown.
  - no parameter Default value of 5.
  - ignore-count episodes Ranges from 1 to 20.
- **RESET** Period of not exceeding LSA limit required to reset temporary shutdown counter to zero.
  - no parameter Default value of 5 minutes.
  - reset-time r_period Ranges from 1 to 60.

**Example**

This command defines an LSA limit of **8000** and other parameters.

```
switch(config-router-ospf)#max-lsa 8000 40 ignore-time 6 ignore-count 3 reset-time 20
switch(config-router-ospf)#
```
15.2.5.35 max-metric router-lsa (OSPFv2)

The max-metric router-lsa command configures OSPF to include the maximum value in LSA metric fields to keep other network devices from using the switch as a preferred intermediate SPF hop.

The no max-metric router-lsa and default max-metric router-lsa commands disable the advertisement of a maximum metric.

Command Mode
Router-OSPF Configuration

Command Syntax
max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]
no max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]
default max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]

Parameters
All parameters can be placed in any order.

- **EXTERNAL** Advertised metric value. Values include:
  - no parameter Default value of 1.
  - external-lsa Range: 1 to 16777215. Default value is 0xFF0000.
- **STUB** Advertised metric type. Values include:
  - no parameter Default value of 2.
  - include-stub
- **STARTUP** Limit scope of LSAs. Values include:
  - no parameter
  - on-startup
  - on-startup wait-for-bgp
  - on-startup Range: 5 to 86400.
  - wait-for-bgp or an on-start time value is not included in no and default commands.
- **SUMMARY** Advertised metric value. Values include:
  - no parameter
  - summary-lsa
  - summary-lsa Range: 1 to 16777215.

Example
This command configures OSPF to to include the maximum value in LSA metric fields until BGP has converged:

```
switch(config-router-ospf)#max-metric router-lsa on-startup wait-for-bgp
switch(config-router-ospf)#
```
15.2.5.36  network area (OSPFv2)

The network area command assigns the specified IPv4 subnet to an OSPFv2 area.

The no network area and default network area commands delete the specified network area assignment by removing the corresponding network area command from running-config.

Command Mode
Router-OSPF Configuration

Command Syntax

network ipv4_subnet area area_id
no network ipv4_subnet area area_id
default network ipv4_subnet area area_id

Parameters

• ipv4_subnet IPv4 subnet. Entry formats include address-prefix (CIDR) or address-wildcard mask. The running-config stores value in CIDR notation.
• area_id Area number. 0 to 4294967295 or 0.0.0.0 to 255.255.255.255. The running-config stores value in dotted decimal notation.

Example

These equivalent commands each assign the subnet 10.1.10.0/24 to area 0.

```
switch(config-router-ospf)#network 10.1.10.0 0.0.0.255 area 0
switch(config-router-ospf)#network 10.1.10.0/24 area 0
switch(config-router-ospf)#
```
15.2.5.37  no area (OSPFv2)

The `no area` command removes the corresponding `area` command from the `running-config`:

- `no/default area not-so-stubby lsa type-7 convert type-5` commands remove the translate type7 always parameter without changing the area type.
- `no/default area nssa, no/default area stub, and no/default area stub no-summary` commands restore the areas type to normal. OSPFv2 Commands.
- The `no/default area default-information-originate` command removes all area commands for the specified area from `running-config`.
- The `no/default area` command removes all area commands for the specified area from the `running-config`.
- The `no/default area` command removes all area commands for the specified area from the `running-config`.

Command Mode

Router-OSPF Configuration

Command Syntax

```
no area area_id [TYPE]
default area area_id [TYPE]
```

Parameters

- `area_id` area number.
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - The `running-config` stores value in dotted decimal notation.
- `TYPE` Area type. Values include:
  - nssa
  - nssa translate type7 always
  - stub
  - stub no-summary

Examples

- These commands remove area 1 from the running configuration.

```
switch(config)# router ospf 6
switch(config-router-ospf)# no area 1
switch(config-router-ospf)#
```

- These commands remove area 10.92.148.17 as an NSSA.

```
switch(config-router-ospf)# no area 10.92.148.17 nssa
switch(config-router-ospf)#
```
**15.2.5.38 packet**

This describes packet types that the feature is applied on.

**Command Mode**

`system-feature-source-profile (config-hw-tcam-profile-profile-feature-feature)`

**Command Syntax**

```
packet packet header tokens forwarding<[bridged | routed | mpls][multicast][decap]
```

**Parameters**

- **packet header tokens** The packet header is described as a series of CLI packet header tokens after the `packet` token. It starts from the outer most header after Ethernet. For example, a regular IPv4 packet is `packet ipv4` and a VXLAN packet is `packet ipv4 vxlan eth ipv4`.
- **forwarding** The `forwarding` token indicates the forwarding type of the packet.
  - bridged
  - routed
  - mpls
    - **multicast** Indicates if the packet is a multicast packet.
    - **decap** Indicates if the packet is decapsulated after a tunnel.

**Guidelines**

On DCS-7020, DCS-7280R/R2 or DCS-7500R/R2, enabling OSPF routes over GRE tunnels requires the system TCAM profile to have “Tunnel IPv4” feature enabled so that control packets such as OSPF hellos received over GRE tunnel interfaces are appropriately classified. This can be achieved by creating a user defined TCAM profile.

The user defined TCAM profile may be created either manually from scratch or by copying from an existing TCAM profile. The system TCAM profile must have the feature `tunnel ipv4` for OSPFv2 over GRE tunnel interfaces to work. This is applicable regardless of whether the TCAM profile is copied from an existing profile or created from scratch.

To create a user defined TCAM profile.

```
(config)#hardware tcam
(config-hw-tcam)#profile profilename copy default
(config-hw-tcam-profile-profile)#feature tunnel ipv4 copy system-feature-source-profile
```

The following steps are optional if the feature is added by copying from `system-feature-source-profile`.

- Set the packet types for the feature as follows to match GRE tunnelled ipv4 routed unicast and multicast packets.

```
(config-hw-tcam-profile-profile)#packet ipv4 non-vxlan forwarding routed decap
(config-hw-tcam-profile-profile)#packet ipv4 non-vxlan forwarding routed multicast decap
```

- Specify the qualifiers to match on.

```
(config-hw-tcam-profile-profile)#key field inner-dst-ip inner-ip-protocol inner-l4-dst-port inner-l4-src-port inner-ttl
```

- Set the key size limit to **160**.

```
(config-hw-tcam-profile-profile)#key size limit 160
(config-hw-tcam-profile-profile)#exit
```
It maybe necessary to disassociate some features which are not applicable to GRE encapsulated packets from the GRE TCAM program to make room for the `tunnel ipv4` feature.

**Related Commands**

- `system profile`
- `interface Tunnel`
- `show hardware tcam profile`
15.2.5.39  passive-interface default (OSPFv2)

The **passive-interface default** command configures all interfaces as OSPFv2 passive by default. The switch advertises the passive interface as part of the router LSA.

The **passive-interface <interface> (OSPFv2)** configures the OSPFv2 active-passive status for a specific interface:

- When **passive-interface default** is not set, all interfaces are OSPFv2 active by default and passive interfaces are denoted by **passive-interface** statements in **running-config**.
- When **passive-interface default** is set, all interfaces are OSPFv2 passive by default and active interfaces are denoted by **no passive-interface** statements in **running-config**.

The **no passive-interface** and **default passive-interface** commands configures all interfaces as OSPFv2 active by default by removing the **passive-interface default** statement from **running-config**.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

- passive-interface default
- no passive-interface default
- default passive-interface default

**Examples**

- This command configures the default interface setting as OSPFv2 passive. This command also removes all **passive-interface** statements from the **running-config**.

  ```
  switch(config)#router ospf 6
  switch(config-router-ospf)#passive-interface default
  switch(config-router-ospf)#
  ```

- This command configures the default interface setting as OSPFv2 active. This command also removes all **no passive-interface** statements from the **running-config**.

  ```
  switch(config-router-ospf)#no passive-interface default
  switch(config-router-ospf)#
  ```
15.2.5.40 passive-interface (OSPFv2)

The `passive-interface` command disables OSPFv2 on an interface range. The switch advertises the passive interface as part of the LSA.

The default OSPFv2 interface activity is configured by the `passive-interface default OSPFv2` command:

- When `passive-interface default` is not set, all interfaces are OSPFv2 active by default and passive interfaces are denoted by `passive-interface` statements in the `running-config`.
- When `passive-interface default` is set, all interfaces are OSPFv2 passive by default and active interfaces are denoted by `no passive-interface` statements in the `running-config`.

The `no passive-interface` command enables OSPFv2 on the specified interface range. The `default passive-interface` command sets the interface to the default interface activity setting by removing the corresponding `passive-interface` or `no passive-interface` statement from the `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

```
passive-interface INTERFACE_NAME
no passive-interface INTERFACE_NAME
default passive-interface INTERFACE_NAME
```

**Parameters**

- **INTERFACE_NAME** Interface to be configured. Options include:
  - `ethernet e_range`
  - `port-channel p_range`
  - `vlan v_range`
  - `vxlan vx_range`

**Examples**

- These commands configure Ethernet interfaces 2 through 5 as passive interfaces.

  ```
  switch(config)#router ospf 6
  switch(config-router-ospf)#passive-interface ethernet 2-5
  switch(config-router-ospf)#
  ```

- This command configures VLAN interfaces 50-54, 61, 68, and 102-120 as passive interfaces.

  ```
  switch(config-router-ospf)#passive-interface vlan 50-54,61,68,102-120
  switch(config-router-ospf)#
  ```

- This command configures `vlan 2` as an active interface.

  ```
  switch(config-router-ospf)#no passive-interface vlan 2
  switch(config-router-ospf)#
  ```
15.2.5.41 point-to-point routes (OSPFv2)

The **point-to-point routes** command enables the switch to maintain a local Routing Information Base (RIB) to store information it learns from its neighbors.

The **no point-to-point routes** and **default point-to-point routes** commands program the switch to include point-to-point links in its RIB by removing the **point-to-point routes** command from the `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

- `point-to-point routes`
- `no point-to-point routes`
- `default point-to-point routes`

**Examples**

• This command configures the switch to optimize the local RIB by not including point-to-point routes.

```
switch(config)#router ospf 6
switch(config-router-ospf)#no point-to-point routes
switch(config-router-ospf)#
```

• This command configures the switch to include point-to-point routes.

```
switch(config-router-ospf)#point-to-point routes
switch(config-router-ospf)#
```
15.2.5.42 redistribute (OSPFv2)

The `redistribute` command enables the advertising of all specified routes on the switch into the OSPFv2 domain as external routes.

The `no redistribute` and `default redistribute` commands remove the corresponding `redistribute` command from the `running-config`, disabling route redistribution for the specified route type.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```
redistribute ROUTE_TYPE [ROUTE_MAP]
no redistribute ROUTE_TYPE [ROUTE_MAP]
default redistribute ROUTE_TYPE [ROUTE_MAP]
```

**Parameters**
- `ROUTE_TYPE` Source from which routes are redistributed. Options include:
  - `connected` routes that are established when IPv4 is enabled on an interface.
  - `BGP` routes from a BGP domain.
  - `RIP` routes from a RIP domain.
  - `static` IP static routes.
- `ROUTE_MAP` Route map that determines the routes that are redistributed. Options include:
  - `no parameter`
  - `route-map map_name`

**Examples**
- The `redistribute static` command starts the advertising of static routes as OSPFv2 external routes.
  
  ```
  switch(config)#router ospf 6
  switch(config-router-ospf)#redistribute static
  switch(config-router-ospf)#
  ```

- The `no redistribute bgp` command stops the advertising of BGP routes as OSPFv2 external routes.
  
  ```
  switch(config-router-ospf)#no redistribute bgp
  switch(config-router-ospf)#
  ```
15.2.5.43 redistribute ospf

Redistributing connected routes causes the OSPFv2 instance to advertise all connected routes on the switch as external OSPFv2 routes. Connected routes are routes that are established when IPv4 is enabled on an interface.

**Command Mode**
config-router-bgp

**Command Syntax**
redistribute ospf [ include [ leaked ] | match [ external | internal ] | nssa-external ] | route-map word

no redistribute ospf [ match [ external | internal ] | nssa-external ]

default redistribute ospf [ match [ external | internal ] | nssa-external ]

**Parameters**
- include Include following routes while redistributing.
  - leaked Include leaked routes of this protocol while redistributing.
- match Routes learned by the OSPF protocol.
  - external OSPF routes learned from external sources.
  - internal OSPF routes learned from internal sources.
  - nssa-external OSPF routes learned from external NSSA sources.
- route-map Name a router map.
  - word Route map name.

**Example**
Use the following commands to redistribute OSPFv2 routes into the BGP domain.

```
switch(config)#router bgp 1
switch(config-router-bgp)#redistribute OSPF
switch(config-router-bgp)#
```
15.2.5.44  redistribute ospf instance

The `redistribute ospf instance` command redistributes either the non-leaked routes, or both leaked and non-leaked routes. The `exit` command returns the switch to the `global` configuration mode.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```
redistribute ospf instance [OPTIONS]
```

**Parameters**

- `include` Include leaked routes.
- `leaked` OSPF leaked routes.
- `match` Routes learned by the OSPF protocol.
  - `external` OSPF routes learned from external sources.
  - `internal` OSPF routes learned from internal sources.
  - `nssa-external` OSPF routes learned from external NSSA sources.

**Examples**

- This command redistributes the OSPFv2 external routes from all other OSPFv2 instances in the same VRF into the given instance.

  ```
  switch(config-router-ospf)#redistribute ospf instance match external
  ```

- This command redistributes the OSPFv2 internal leaked and non-leaked routes from all other instances in all VRFs into the given instance.

  ```
  switch(config-router-ospf)#redistribute ospf instance include leaked match internal
  ```
15.2.5.45  router ospf

The `router ospf` command places the switch in router-ospf configuration mode. The switch will create a process ID for the new instance if one does not already exist. The `exit` command returns the switch to the `global` configuration mode.

The `show ip ospf` command displays the process ID of the OSPFv2 instances configured on the switch.

The `no router ospf` and `default router ospf` commands delete the specified OSPFv2 instance.

The `router-ospf` configuration mode is not a group change mode; `running-config` is changed immediately upon entering commands. Exiting `router-ospf` configuration mode does not affect `running-config`. The `exit` command returns the switch to the `global` configuration mode.

Refer to the Router-OSPFv2 Configuration Mode for a list of commands available in `router-ospf` configuration mode.

**Command Mode**

Global Configuration

**Command Syntax**

```
router ospf process_id [VRF_INSTANCE]
no router ospf process_id [VRF_INSTANCE]
default router ospf process_id [VRF_INSTANCE]
```

**Parameters**

- `process_id` OSPFv2 process ID. Values range from 1 to 65535.
- `VRF_INSTANCE`
  - `no parameter` Configures the default VRF instance.
  - `vrf vrf_name` Configures the `vrf_name` instance.

**Examples**

- This command creates an OSPFv2 instance with process ID 145 in the main VRF.

```
switch(config)#router ospf 145
switch(config-router-ospf)#
```

- This command deletes the specified OSPFv2 instance.

```
switch(config)#no router ospf 145
switch(config)#
```
15.2.5.46  router-id (OSPFv2)

The `router-id` command assigns a router ID for an OSPFv2 instance. This number uniquely identifies the router within an Autonomous System. Status commands use the router ID to identify the switch.

The switch sets the router ID to the first available alternative in the following list:

1. The `router-id` command.
2. The loopback IP address, if a loopback interface is configured on the switch.
3. The highest IP address present on the router.

Note: When configuring VXLAN on an MLAG, always manually configure the OSPFv2 router ID to prevent the switch from using the common VTEP IP address as the router ID.

The `no router-id` and `default router-id` commands remove the router ID command from the `running-config`; the switch uses the loopback or highest address as the router ID.

Command Mode
Router-OSPF Configuration

Command Syntax

```
router-id [identifier]
no router-id [identifier]
default router-id [identifier]
```

Parameters

`identifier` Value ranges from `0.0.0.0` to `255.255.255.255`.

Example

This command assigns `10.5.4.2` as the router ID for the OSPFv2 instance.

```
switch(config)#router ospf 6
switch(config-router-ospf)#router-id 10.5.4.2
switch(config-router-ospf)#
```
15.2.5.47  **show hardware tcam profile**

Use the **show hardware tcam profile** command to verify that the user-defined-tcam profile is applied correctly without errors on the DCS-7020, DCS-7280R/R2, or DCS-7500R/R2 platforms.

This command is applicable the following platforms:

- DCS-7280E
- DCS-7280R
- DCS-7280R2
- DCS-7020R
- DCS-7500E
- DCS-7500R
- DCS-7500R2

**Command Mode**
- EXEC

**Command Syntax**

```
show hardware tcam profile [profile] detail
```

**Parameters**

- **tcam** Specifies the TCAM information.
- **profile** Specifies the TCAM profile information.
- **detail** Displays detailed tcam profile information.

**Example**

This example displays the detailed tcam profile information for profile named **newprofile1**.

```
(config-hw-tcam)#show hardware tcam profile newprofile1 detail
Profile newprofile1 [ FixedSystem ]
Feature         mpls
--------------- ----------------------------------------------------

```

...
15.2.5.48  show ip ospf border-routers

The `show ip ospf border-routers` command displays the internal OSPFv2 routing table entries to Area Border Routers (ABRs) and Autonomous System Boundary Routers (ASBRs) for each of the OSPFv2 areas.

Command Mode
EXEC

Command Syntax
`show ip ospf border-routers [VRF_INSTANCE]`

Parameters

VRF_INSTANCE  Specifies the VRF instance.

- no parameter  displays information from all VRFs, or from context-active VRF if set.
- vrf vrf_name  displays information from the specified VRF.

Example

This command displays the ABRs and ASBRs.

```
switch# show ip ospf border-routers
OSPF Process 10.17.0.42, VRF default

  Router ID  Area    Type
10.17.0.1   0.0.0.0  ASBR
switch>
```
15.2.5.49 show ip ospf database database-summary

The show ip ospf database database-summary command displays the number of link state advertisements in the OSPFv2 database.

Command Mode
EXEC

Command Syntax
show ip ospf [AREA] database database-summary [VRF_INSTANCE]

Parameters
- VRF_INSTANCE Specifies the VRF instance.
  - no parameter displays information from all VRFs, or from context-active VRF if set.
  - vrf vrf_name displays information from the specified VRF.
- AREA areas for which command displays data. Specifying an individual area requires entering the process ID where the area is located. Options include:
  - no parameter
  - process_id
  - process_id area_id
  - process_id input range: 1 to 65535.
  - area_id input range: 0 to 4294967295 or 0.0.0.0 to 255.255.255.255.

Example
This command displays the LSDB content summary for area 0.

```
switch#show ip ospf 1 0 database database-summary

LSA Type      Count
Router        18
Network       21
Summary Net   59
Summary ASBR  4
Type-7 Ext    0
Opaque Area   0
Type-5 Ext    4238
Opaque AS     0
Total         4340

switch>
```
15.2.5.50  show ip ospf database <link state list>

The `show ip ospf database <link state list>` command displays the OSPFv2 link state advertisements that originate on a specified switch.

**Command Mode**

EXEC

**Command Syntax**

`show ip ospf [AREA] database [ROUTER] [VRF_INSTANCE]`

**Parameters**

- **AREA** Areas for which command displays data. Specifying an individual area requires entering the process ID where the area is located. Options include:
  - `no parameter`
  - `process_id`
  - `process_id area_id`
  - `process_id` value ranges from 1 to 65535.
  - `area_id` is entered in decimal or dotted decimal notation.
- **ROUTER** Router or switch for which the command provides data. Options include:
  - `no parameter`
  - `adv-router [a.b.c.d]`
  - `self-originate`
- **VRF_INSTANCE** Specifies the VRF instance.
  - `no parameter` displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Example**

This command displays OSPFv2 LSAs that originate at the router with a router ID of 10.26.0.31.

```
switch#show ip ospf database adv-router 10.26.0.31
OSPF Router with ID(10.26.0.23) (Process ID 1) (VRF default)
10.26.0.31
Type-5 AS External Link States
  Link ID ADV Router Age Seq# Checksum
  10.24.238.238.10.26.0.316780x800003d20x8acf0
  10.24.238.24410.26.0.316780x800003d20x4e060
  10.24.238.22410.26.0.316780x800003d20x17510
  Type 11 Opaque LSDB

switch>
```
show ip ospf database <link-state details>

The `show ip ospf database` command displays details of the specified link state advertisements.

**Command Mode**
EXEC

**Command Syntax**
`show ip ospf [AREA] database LINKSTATE_TYPE linkstate_id [ROUTER] [VRF_INSTANCE]`

**Parameters**
- **AREA** Areas for which command displays data. Specifying an individual area requires entering the process ID where the area is located. Options include:
  - `no parameter`
  - `process_id`
  - `process_id area_id`
  - `process_id` input range: 1 to 65535.
  - `area_id` input range: 0 to 4294967295 or 0.0.0.0 to 255.255.255.255.
- **LINKSTATE_TYPE** Link state types. Parameter options include:
  - `detail` Displays all link states.
  - `router`
  - `network`
  - `summary`
  - `asbr-summary`
  - `external`
  - `nssa-external`
  - `opaque-link`
  - `opaque-area`
  - `opaque-as`
  - `linkstate_id` Network segment described by the LSA (dotted decimal notation).
    Value depends on the LSA type.
- **ROUTER** Router or switch for which the command provides data. Options include:
  - `no parameter`
  - `adv-router [a.b.c.d]`
  - `self-originate`
- **VRF_INSTANCE** Parameter has no effect; this command displays information about the specified process and area regardless of VRF.
  - `no parameter` displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Examples**
- This command displays the router link states contained in the area 2 LSDB.

```
switch#show ip ospf 1 2 database router

OSPF Router with ID(10.168.103.1) (Process ID 1) (VRF default)

switch>
```
15.2.5.52  show ip ospf interface brief

The `show ip ospf interface brief` command displays a summary of OSPFv2 information.

**Command Mode**

EXEC

**Command Syntax**

```
show ip ospf [PROCESS_ID] interface brief [VRF_INSTANCE]
```

**Parameters**

- **PROCESS_ID** OSPFv2 process ID. Values include:
  - `no parameter`
  - `1 to 65535`

- **VRF_INSTANCE** Specifies the VRF instance.
  - `no parameter` displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Related Command**

`show ip ospf interface`

**Example**

This command displays a summary of interface information for the switch.

```
switch#show ip ospf interface brief
InterfacePIDAreaIP AddressCostStateNbrs
Loopback010.0.0.0/2410.168.103.1/2410DR0

Vlan210.0.0.2/2410.168.2.1/2410BDR1
Vlan310.0.0.3/2410.168.3.1/2410DR0
switch>
```
15.2.5.53  show ip ospf interface

The show ip ospf interface command displays interface information that is related to OSPFv2.

Command Mode
EXEC

Command Syntax
show ip ospf [PROCESS_ID] interface [INTERFACE_NAME][VRF_INSTANCE]

Parameters
•  PROCESS_ID OSPFv2 process ID. Values include:
  •  no parameter
  •  1 to 65535
•  INTERFACE_NAME Interface type and number. Values include:
  •  no parameter
  •  ethernet e_num
  •  loopback l_num
  •  port-channel p_num
  •  vlan v_num
•  VRF_INSTANCE Specifies the VRF instance.
  •  no parameter displays information from all VRFs, or from context-active VRF if set.
  •  vrf vrf_name displays information from the specified VRF.

Related Command
show ip ospf interface brief

Example
This command displays complete OSPFv2 information for vlan 1.

```
switch#show ip ospf interface vlan 1
Vlan1 is up, line protocol is up (connected)
Internet Address 10.168.0.1/24, VRF default, Area 0.0.0.0
Process ID 1, Router ID 10.168.103.1, Network Type BROADCAST, Cost: 10
Transmit Delay is 1 sec, State BDR, Priority 1
Designated Router is 10.168.104.2
Backup Designated router is 10.168.103.1
Timer intervals configured, Hello 10, Dead 40, Retransmit 5
Neighbor Count is 1
MTU is 1500
switch>
```
show ip ospf lsa-log

The `show ip ospf lsa-log` command displays log entries when LSA update messages are sent or received for OSPF.

**Command Mode**
EXEC

**Command Syntax**
```
show ip ospf [PROCESS_ID] ospf-log
```

**Parameters**

- **PROCESS_ID** OSPFv2 process ID. Values include:
  - *no parameter*
  - *1 to 65535*

**Example**

This command displays log entries when LSA update messages are sent or received for OSPF.

```
switch# show ip ospf lsa-log
OSPF Process 3.3.3.3, LSA Throttling Log:
[04:21:09] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 2000 msecs
[04:21:08] type 1: 3.3.3.3/32 [3.3.3.3], event 2, backoff restarted, new hold value 900 msecs
[04:21:00] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 3000 msecs
[04:21:00] type 1: 3.3.3.3/32 [3.3.3.3], event 4, maxwait value changed, new hold value 3000 msecs
/* Here the maxwait value was changed to 3000 from earlier 32000, this is not part of the log */
[04:20:42] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 32000 msecs
[04:20:10] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 32000 msecs
[04:19:54] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 16000 msecs
[04:19:46] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 8000 msecs
[04:19:42] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 4000 msecs
[04:19:40] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold value 2000 msecs
[04:19:39] type 1: 3.3.3.3/32 [3.3.3.3], event 2, backoff restarted, new hold value 900 msecs
[04:19:22] type 1: 4.4.4.4/32 [4.4.4.4], event 3, discarded, was early by 995 msecs
[04:19:22] type 1: 3.3.3.3/32 [3.3.3.3], event 0, backoff started, new hold value 1000 msecs
switch#
```
15.2.5.55 show ip ospf neighbor adjacency-changes

The `show ip ospf neighbor adjacency-changes` command displays the OSPFv2 neighbor adjacency change log for specified interfaces.

**Command Mode**
EXEC

**Command Syntax**

```
show ip ospf neighbor [INTERFACE_NAME][NEIGHBOR] adjacency-changes [VRF_INSTANCE]
```

**Parameters**

- **INTERFACE_NAME** Interface type and number. Values include:
  - `no parameter`
  - `ethernet e_num`
  - `loopback l_num`
  - `port-channel p_num`
  - `vlan v_num`
- **NEIGHBOR** OSPFv2 neighbor. Options include:
  - `no parameter`
  - `ipv4_addr`
  - `host_name`
- **VRF_INSTANCE** Specifies the VRF instance.
  - `no parameter` displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Example**

This command displays the adjacency changes to **vlan 2**.

```
switch# show ip ospf neighbor vlan 2 adjacency-changes
[08-04 09:58:58] 10.168.104.2, interface Vlan2 adjacency established
[08-04 09:59:34] 10.168.104.2, interface Vlan2 adjacency dropped: interface went down
[08-04 09:59:42] 10.168.104.2, interface Vlan2 adjacency established
[08-04 10:01:40] 10.168.104.2, interface Vlan2 adjacency dropped: nbr did not list our router ID
[08-04 10:01:46] 10.168.104.2, interface Vlan2 adjacency established
switch>
```
The `show ip ospf neighbor state` command displays the state information on OSPF neighbors on a per-interface basis.

**Command Mode**

EXEC

**Command Syntax**

```
show ip ospf neighbor state STATE_NAME [VRF_INSTANCE]
```

**Parameters**

- **STATE_NAME** Output filtered by the device's OSPF state. Options include valid OSPF states:
  - 2-ways
  - attempt
  - down
  - exch-start
  - exchange
  - full
  - graceful-restart
  - init
  - loading
- **VRF_INSTANCE** Specifies the VRF instance.
  - no parameter displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Example**

This command displays OSPF information for neighboring routers that are fully adjacent.

```
switch# show ip ospf neighbor state full
Neighbor ID     VRF      Pri   State            Dead Time   Address        Interface
Test1           default    1   FULL/BDR         00:00:35    10.17.254.105  Vlan3912
Test2           default    1   FULL/BDR         00:00:36    10.17.254.29   Vlan3910
Test3           default    1   FULL/DR          00:00:35    10.25.0.1      Vlan101
Test4           default    1   FULL/DROTHER     00:00:36    10.17.254.67   Vlan3908
Test5           default    1   FULL/DROTHER     00:00:36    10.17.254.68   Vlan3908
Test6           default    1   FULL/BDR         00:00:32    10.17.254.66   Vlan3908

Test13          default    1   FULL/DROTHER     00:00:31    10.17.254.154  Vlan3923
Test14          default    1   FULL/BDR         00:00:39    10.17.254.156  Vlan3923
Test15          default    1   FULL/DROTHER     00:00:33    10.17.254.35   Vlan3911
Test16          default    1   FULL/DR          00:00:34    10.17.254.33   Vlan3911
Test17          default    1   FULL/DR          00:00:36    10.17.254.138  Ethernet12
Test18          default    1   FULL/DR          00:00:37    10.17.254.2     Vlan3901
switch>
```
15.2.5.57  show ip ospf neighbor summary

The `show ip ospf neighbor summary` command displays a single line of summary information for each OSPFv2 neighbor.

**Command Mode**

EXEC

**Command Syntax**

```
show ip ospf [PROCESS_ID] neighbor summary [VRF_INSTANCE]
```

**Parameters**

- **PROCESS_ID** OSPFv2 process ID. Values include:
  - `no parameter`
  - `1 to 65535`
- **VRF_INSTANCE** Specifies the VRF instance.
  - `no parameter` displays information from all VRFs, or from context-active VRF if set.
  - `vrf vrf_name` displays information from the specified VRF.

**Example**

This command displays the summary information for the OSPFv2 neighbors.

```
switch#show ip ospf neighbor summary
OSPF Router with (Process ID 1) (VRF default)
0 neighbors are in state DOWN
0 neighbors are in state GRACEFUL RESTART
2 neighbors are in state INIT
0 neighbors are in state LOADING
0 neighbors are in state ATTEMPT
18 neighbors are in state FULL
0 neighbors are in state EXCHANGE
0 neighbors are in state 2 WAYS
0 neighbors are in state EXCH START
switch>
```
15.2.5.58  show ip ospf neighbor

The `show ip ospf neighbor` command displays OSPFv2 neighbor information for specified interfaces.

Command Mode
EXEC

Command Syntax
`show ip ospf [PROCESS_ID] neighbor [INTERFACE_NAME] [NEIGHBOR] [DATA] [VRF_INSTANCE]`

Parameters
- **PROCESS_ID** OSPFv2 process ID. Values include:
  - *no parameter*
  - 1 to 65535
- **INTERFACE_NAME** Interface type and number. Values include:
  - *no parameter*
  - `ethernet e_num`
  - `loopback l_num`
  - `port-channel p_num`
  - `vlan v_num`
- **NEIGHBOR** OSPFv2 neighbor. Options include:
  - *no parameter*
  - `ipv4_addr`
- **DATA** Type of information the command displays. Values include:
  - *no parameter*
  - `detail`
- **VRF_INSTANCE** Specifies the VRF instance.
  - *no parameter*
  - `vrf vrf_name`

Examples
- This command displays the switch's neighbors.

```bash
switch#show ip ospf neighbor
Neighbor IDVRFPriStateDead TimeAddressInterface
10.168.104.2default1FULL/DR00:00:3510.168.0.2Vlan1
10.168.104.2default8FULL/BDR00:00:3110.168.2.2Vlan2
switch>
```

- This command displays details about the neighbors to `vlan 2`.

```bash
switch#show ip ospf neighbor vlan 2 detail
Neighbor 10.168.104.2, VRF default, interface address 10.168.2.2
In the area 0.0.0.2 via interface Vlan2
Neighbor priority is 8, State is FULL, 13 state changes
Adjacency was established 000:01:25:48 ago
DR is 10.168.2.1 BDR is 10.168.2.2
Options is E
Dead timer due in 00:00:34
switch>
```
### 15.2.5.59  show ip ospf request queue

The `show ip ospf request queue` command displays a list of all OSPFv2 Link State Advertisements (LSAs) requested by a router.

**Command Mode**

EXEC

**Command Syntax**

```
show ip ospf request queue [VRF_INSTANCE]
```

**Parameters**

**VRF_INSTANCE** Specifies the VRF instance.

- `no parameter` displays information from all VRFs, or from context-active VRF if set.
- `vrf vrf_name` displays information from the specified VRF.

**Example**

This command displays an LSA request list.

```
switch# show ip ospf request queue
Neighbor 10.168.104.2 vrf default interface: 10.168.0.2 address vlan1
Type LS ID ADV RTR Seq No Age Checksum
Neighbor 10.168.104.2 vrf default interface: 10.168.2.2 address vlan2
Type LS ID ADV RTR Seq No Age Checksum
switch>
```
15.2.5.60  show ip ospf retransmission queue

The show ip ospf retransmission queue command displays a list of all OSPFv2 Link State Advertisements (LSAs) waiting to be re-sent.

Command Mode
EXEC

Command Syntax
show ip ospf retransmission queue [VRF_INSTANCE]

Parameters
VRF_INSTANCE Specifies the VRF instance.

• no parameter displays information from all VRFs, or from context-active VRF if set.
• vrf vrf_name displays information from the specified VRF.

Example
This command displays an empty retransmission list.

```
switch# show ip ospf retransmission queue
Neighbor 10.168.104.2 vrf default interface vlan1 address 10.168.0.2
LSA retransmission not currently scheduled. Queue length is 0

Type Link ID Adv Router Age Seq# Checksum
Neighbor 10.168.104.2 vrf default interface vlan2 address 10.168.2.2
LSA retransmission not currently scheduled. Queue length is 0

Type Link ID Adv Router Age Seq# Checksum
switch>
```
The `show ip ospf spf-log` command displays when and how long the switch took to run a full SPF calculation for OSPF.

**Command Mode**
EXEC

**Command Syntax**
```
show ip ospf [PROCESS_ID] ospf-log
```

**Parameters**

**PROCESS_ID** OSPFv2 process ID. Values include:
- *no parameter*
- *1 to 65535*

**Example**
This command displays the SPF information for OSPF.

```plaintext
switch#show ip ospf spf-log
OSPF Process 172.26.0.22
When      Duration (msec)
13:01:34   1.482
13:01:29   1.547
13:01:24   1.893
13:00:50   1.459
13:00:45   1.473
13:00:40   2.603
11:00:49   1.561
11:00:40   1.463
11:00:35   1.467
11:00:30   1.434
11:00:25   1.456
11:00:49   1.472
11:00:44   1.582
15:01:49   1.575
15:01:44   1.470
15:01:39   1.679
15:01:34   1.601
15:00:57   1.454
15:00:52   1.446
15:00:47   1.603
switch>
```
The **show ip ospf** command displays OSPFv2 routing information.

**Command Mode**

EXEC

**Command Syntax**

`show ip ospf [PROCESS_ID][VRF_INSTANCE]`

**Parameters**

- **PROCESS_ID** OSPFv2 process ID. Values include:
  - `no parameter`
  - `1 to 65535`
- **VRF_INSTANCE** Specifies the VRF instance.
  - `no parameter` configures the default VRF instance.
  - `vrf vrf_name` configures the `vrf_name` instance.

**Example**

This command displays configuration parameters, operational statistics, status of the OSPFv2 instance, and a brief description of the areas on the switch.

```
switch# show ip ospf
Routing Process "ospf 1" with ID 10.168.103.1 VRF default
Supports opaque LSA
Maximum number of LSA allowed 12000
Threshold for warning message 75%
Ignore-time 5 minutes, reset-time 5 minutes
Ignore-count allowed 5, current 0
It is an area border router
Hold time between two consecutive SPFIs 5000 msecs
SPF algorithm last executed 00:00:09 ago
Minimum LSA interval 5 secs
Minimum LSA arrival 1000 msecs
Number of external LSA 0. Checksum Sum 0x000000
Number of opaque AS LSA 0. Checksum Sum 0x000000
Number of LSA 27.
Number of areas in this router is 3. 3 normal 0 stub 0 nssa
Area BACKBONE(0.0.0.0)
Number of interfaces in this area is 2
It is a normal area
Area has no authentication
SPF algorithm executed 153 times
Number of LSA 8. Checksum Sum 0x03e13a
Number of opaque link LSA 0. Checksum Sum 0x000000
Area 0.0.0.2
Number of interfaces in this area is 1
It is a normal area
Area has no authentication
SPF algorithm executed 153 times
Number of LSA 11. Checksum Sum 0x054e57
Number of opaque link LSA 0. Checksum Sum 0x000000
Area 0.0.0.3
Number of interfaces in this area is 1
It is a normal area
Area has no authentication
SPF algorithm executed 5 times
Number of LSA 6. Checksum Sum 0x02a401
Number of opaque link LSA 0. Checksum Sum 0x000000
```
show line system dom thresholds

The `show line system dom thresholds` command reports DOM information reported by the OSFP-LS module. This includes standard fields such as temperature and voltage. In addition to standard DOM fields, the OSFP-LS also monitors the laser temperature for each of its amplifiers. The reported RX power reflects the total RX power seen on that path. TX bias current monitoring is not supported on these modules and should be ignored.

**Command Mode**
EXEC

**Command Syntax**

```
show line system [[port RANGE] dom thresholds]
```

**Example**

This command displays the DOM information reported by the OSFP-LS module.

```
switch#show line system port 10 dom thresholds
Ch: Channel, mA: milliamperes, dBm: decibels (milliwatts),
C: Celsius, V: Volts, NA or N/A: not applicable.

Port 10

### 15.2.5.64 show line system status

The **show line system status** command displays module status. The OSFP-LS is compliant to the Common Management Interface Specification (CMIS), and implements various CMIS-defined status flags. Data path 1 reflects the outgoing booster path and data path 2 reflects the incoming pre-amp path.

**Command Mode**

EXEC

**Command Syntax**

```plaintext
show line system [port RANGE] status
```

**Example**

This command displays the displays module status.

```
switch(config-ls-port10,19)# show line system status
```

</table>

Some lines of output do not apply to the OSFP-LS modules (For example, **Operational speed**, **RX CDR LOL**). These lines of output should be ignored. The fields of interest are Module state, **Data**.
path 1 state, and Data path 2 state. Under normal operating conditions, Module state will read ready and the Data path state fields will read either initialized or activated. Initialized means that the module is ready to operate but is receiving no signal to amplify. Activated means that the amplifier is active.
15.2.5.65 shutdown (OSPFv2)

The `shutdown` command disables OSPFv2 on the switch. OSPFv2 is disabled on individual interfaces with the `shutdown (OSPFv2)` command.

The `no shutdown` and `default shutdown` commands enable the OSPFv2 instance by removing the `shutdown` statement from the OSPF block in `running-config`.

**Command Mode**

Router-OSPF Configuration

**Command Syntax**

- `shutdown`
- `no shutdown`
- `default shutdown`

**Examples**

- This command disables OSPFv2 activity on the switch.

```bash
switch(config)#router ospf 6
switch(config-router-ospf)#shutdown
switch(config-router-ospf)#
```

- This command resumes OSPFv2 activity on the switch.

```bash
switch(config-router-ospf)#no shutdown
switch(config-router-ospf)#
```
15.2.5.66 summary-address

The `summary-address` command allows aggregation of external routes advertised by an OSPF ASBR. It is used to aggregate AS External and NSSA External LSAs.

The `default summary-address` and `no summary-address` commands delete the current `summary-address` configurations.

Command Mode
Router Configuration Mode

Command Syntax

```
summary-address {ip_address subnet_mask | ip_prefix} [attribute_map WORD | not_advertise | tag]
default summary-address {ip_address summary_mask | ip_prefix}
no summary-address {ip_address summary_mask | ip_prefix}
```

Parameters

- `ip_address subnet_mask` IPv4 subnet in dotted decimal notation.
- `ip_prefix` IPv4 subnet in CIDR notation.
- `attribute_map WORD` allows using a route-map to set the attributes to be advertised in the LSA.
  
  Options include:
  - set metric
  - set metric-type
  - set tag
- `not_advertise` suppresses the advertisement of contributing external prefixes by the router.
- `tag` allows setting the tag in the advertised external LSA. The tag value ranges from 0 to 4294967295. The default value is 0.

Guidelines

This feature reduces the size of External LSDB in OSPF, does not impact inter area and intra area LSAs. This command installs a Null0 route in FIB when at least one contributor is present.

Restriction

Only OSPF redistributed routes are aggregated.

Example

This command advertises an external LSA for 50.0.0.0/16 prefix if at least one BGP contributing route is present which falls in the subnet 50.0.0.0/16.

```
switch(config)#router ospf 5
switch(config-router-ospf)#redistribute bgp
switch(config-router-ospf)#summary-address 50.0.0.0/16 attribute-map BGP_AGGR
switch(config-router-ospf)#exit
switch(config)#show ip route bgp
```

Note: The `show` commands display aggregation of BGP prefixes 50.0.0.0/24 and 50.0.1.0/24 into one OSPF AS External LSA for 50.0.0.0/16 prefix. A route-map is to set metric and tag for the advertised LSA.
switch(config)# show running-config
...$
route-map BGP_AGGR permit 10
  set metric 42
  set tag 19
...
router ospf 1
  router-id 1.0.0.10
  redistribute bgp
  max-lsa 12000
  summary-address 50.0.0.0/16 attribute-map BGP_AGGR
switch(config)# show ip ospf database external
    OSPF Router with ID(1.0.0.10) (Process ID 1) (VRF default)

    A O 50.0.0.0/16 is directly connected, Null0
15.2.5.67  system profile

Use the system profile command to apply the user defined TCAM profile to the system.

Command Mode

hardware tcam mode

Command Syntax

system profile profilename

Parameters

profilename Name of the selected system profile.

Example

(config-hw-tcam)#system profile profilename
15.2.5.68 timers lsa rx min interval (OSPFv2)

The `timers lsa rx min interval` command sets the minimum interval for acceptance of identical Link State Advertisements (LSAs) from OSPFv2 neighbors.

The `no timers lsa rx min interval` and `default timers lsa rx min interval` commands restore the minimum interval to the default of 1 second by removing the `timers lsa rx min interval` command from the `running-config`.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```
timers lsa rx min interval lsa_time
no timers lsa rx min interval
default timers lsa rx min interval
```

**Parameter**

`lsa_time` Minimum time (in milliseconds) after which the switch will accept an identical LSA from OSPFv2 neighbors. Default is 1000 (1 second).

**Example**

This command sets the minimum LSA arrival interval to 10 milliseconds.

```
switch(config)#router ospf 6
switch(config-router-ospf)#timers lsa rx min interval 10
switch(config-router-ospf)#
```
15.2.5.69  timers lsa tx delay initial (OSPFv2)

The `timers lsa tx delay initial` command sets the rate-limiting values for OSPF link-state advertisement generation.

The `no timers lsa tx delay initial` and `default timers throttle lsa all` commands restore the defaults by removing the `timers lsa tx delay initial` command from the `running-config`.

Command Mode
Router-OSPF Configuration

Command Syntax

```
timers lsa tx delay initial  initial_delay min_hold max_wait
no timers lsa tx delay initial
default timers lsa tx delay initial
```

Parameters

- `initial_delay` Value ranges from 0 to 600000 (ms). Default is 1000.
- `min_hold` Value ranges from 0 to 600000 (ms). Default is 5000.
- `max_wait` Value ranges from 0 to 600000 (ms). Default is 5000.

Example

This command sets the rate-limiting values for OSPF link-state advertisements to 10 milliseconds.

```
switch(config)#router ospf 6
switch(config-router-ospf)#timers lsa tx delay initial 10
switch(config-router-ospf)#
```
15.2.5.70  timers spf delay initial (OSPFv2)

The purpose of SPF throttling is to delay Shortest Path First (SPF) calculations when network topology is changing rapidly. The timers spf delay initial command controls the intervals at which the switch will perform SPF calculations. The command sets three values:

- **Initial delay**: how long the switch waits to perform an SPF calculation after a topology change in a network that has been stable throughout the hold interval. Because a topology change often causes several link state updates to be sent, the initial delay is configured to allow the network to settle before the switch performs an SPF calculation. If an additional topology change occurs during the initial interval, the SPF calculation still takes place after the expiration of the initial delay period and no other change is made to the throttle timers.

- **Hold interval**: this is an additional wait timer which scales to slow SPF calculations during periods of network instability. If a network change occurs during the hold period, an SPF calculation is scheduled to occur at the expiration of the hold interval. Subsequent hold intervals are doubled if further topology changes occur during a hold interval until either the hold interval reaches its configured maximum or no topology change occurs during the interval. If the next topology change occurs after the expiration of the hold interval, the hold interval is reset to its configured value and the SPF calculation is scheduled to take place after the initial delay.

- **Maximum interval**: the maximum time the switch will wait after a topology change before performing an SPF calculation.

The no timers spf delay initial and default timers spf delay initial commands restore the default OSPFv2 SPF calculation intervals by removing the timers spf delay initial command from the running-config.

**Command Mode**
Router-OSPF Configuration

**Command Syntax**

```plaintext
timers spf delay initial initial_delay hold_interval max_interval
no timers spf
default timers spf
```

**Parameters**

- **initial_delay**: Initial delay between a topology change and SPF calculation. Value ranges from 0 to 65535000 (ms). Default is 0 (ms).

- **hold_interval**: Additional wait time after SPF calculation to allow the network to settle. If a topology change occurs during the hold interval, another SPF calculation is scheduled to occur after the hold interval expires. The next hold interval is doubled if topology changes occur during the hold interval. If doubling exceeds the maximum value, the maximum value is used instead. Value ranges from 0 to 65535000 (ms). Default is 5000 (ms).

- **max_interval**: Maximum hold interval before the switch will perform an SPF calculation. Value ranges from 0 to 65535000 (ms). Default is 5000 (ms).

**Example**
These commands set the SPF timers on the switch.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#timers spf 5 100 20000
switch(config-router-ospf)#
```
15.2.5.71 tunnel routes

Use the tunnel routes command or the default form of the command to enable OSPFv2 routes over GRE tunnels. The tunnel routes are enabled, by default. Use the no form of the command to disable the tunnel routes.

Command Mode
Router OSPF configuration (config-router-ospf)

Command Syntax
tunnel routes
no tunnel routes
default tunnel routes

Examples
• To enable OSPFv2 routes over GRE Tunnels.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#tunnel routes
switch(config-router-ospf)#
```

• To disable OSPFv2 routes over GRE Tunnels.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#no tunnel routes
switch(config-router-ospf)#
```

• To enable the default OSPFv2 routes over GRE Tunnels.

```plaintext
switch(config)#router ospf 6
switch(config-router-ospf)#default tunnel routes
switch(config-router-ospf)#
```
15.3 Open Shortest Path First – Version 3

Open Shortest Path First (OSPF) is a link-state routing protocol that operates within a single autonomous system. OSPF version 3 is defined by RFC 5340.

This chapter contains the following sections.

- OSPFv3 Introduction
- OSPFv3 Conceptual Overview
- Configuring OSPFv3
- OSPFv3 Configuration Examples
- OSPFv3 Commands

15.3.1 OSPFv3 Introduction

OSPFv3 is based on OSPFv2 and includes enhancements that utilize IPv6 features. However, OSPFv3 is configured and operates independently of any implementation of OSPFv2 on the switch. OSPFv2 features that OSPFv3 implements include:

- Packet types
- Neighbor discovery and adjacency formation mechanisms
- LSA aging and flooding
- SPF calculations
- DR election procedure
- Multiple area support
- Router-ID (32 bits)

The following list describes the OSPFv3 differences and enhancements from OSPFv2:

- IPv6 128-bit addresses
- Use of link-local addresses
- OSPFv3 runs over links instead of subnets
- Support flood pacing

Arista switches support the following OSPFv3 functions:

- A single OSPFv3 instance for each VRF
- Intra- and inter-area routing
- Type 1 and 2 external routing
- Broadcast and P2P interfaces
- Stub areas
- Redistribution of static and connected routes into OSPFv3

15.3.2 OSPFv3 Conceptual Overview

This section contains the following topics:

- Storing Link States
- Topology
- Link Updates
- OSPFv3 Security
- Flood Pacing
- OSPFv3 BFD Sessions for Adjacencies in any State
- Support for OSPFv3 dn-bit-ignore
15.3.2.1 Storing Link States

OSPFv3 is a dynamic, link-state routing protocol, where links represent routable paths. Dynamic routing protocols calculate the most efficient path between locations based on bandwidth and device status.

A Link State Advertisement (LSA) is an OSPFv3 packet that communicates a router’s topology to other routers. The Link State Data Base (LSDB) stores an area’s topology database and is composed of LSAs received from other routers. Routers update the LSDB by storing LSAs from other routers.

15.3.2.2 Topology

An Autonomous System (AS) is the IP domain within which a dynamic protocol controls the routing of traffic. In OSPFv3, an AS is composed of areas, which define the LSDB computation boundaries. All routers in an area store identical LSDBs. Routers in different areas exchange updates without storing the entire database, reducing information maintenance on large, dynamic networks.

An AS shares internal routing information from its areas and external routing information from other processes to inform routers outside the AS about routes the network can access. Routers that advertise routes on other ASs commit to carry data to the IP space on the route.

OSPFv3 defines these routers:

- **Internal Router (IR):** a router whose interfaces are contained in a single area. All IRs in an area maintain identical LSDBs.
- **Area Border Router (ABR):** a router that has interfaces in multiple areas. ABRs maintain one LSDB for each connected area.
- **Autonomous System Boundary Router (ASBR):** a gateway router connecting the OSPFv3 domain to external routes, including static routes and routes from other autonomous systems.

**OSPFv3 Router Types** displays the OSPFv3 router types.

![OSPFv3 Router Types](image)

OSPFv3 areas are assigned a number between 0 and 4,294,967,295. Area numbers are often expressed in dotted decimal notation, similar to IP addresses.

Each AS has a backbone area, designated as area 0, that connects to all other areas. The backbone receives routing information from all areas, then distributes it to the other areas as required.

OSPFv3 area types include:

- Normal area accepts intra-area, inter-area, and external routes. The backbone is a normal area.
- Stub area does not receive router advertisements external to the AS. Stub area routing is based on a default route.
15.3.2.3  Link Updates

Routers periodically send hello packets to advertise status and establish neighbors. A router's hello packet includes IP addresses of other routers from which it received a hello packet within the time specified by the router dead interval. Routers become neighbors when they detect each other in their hello packets if they:

- share a common network segment.
- are in the same area.
- have the same hello interval, dead interval, and authentication parameters.

Neighbors form adjacencies to exchange LSDB information. A neighbor group uses hello packets to elect a Designated Router (DR) and Backup Designated Router (BDR). The DR and BDR become adjacent to all other neighbors, including each other. Only adjacent neighbors share database information.

**OSPFv3 Neighbors** illustrates OSPFv3 neighbors.

![OSPFv3 Neighbors Diagram](image)

The DR is the central contact for database exchanges. Switches send database information to their DR, which relays the information to the other neighbors. All routers in an area maintain identical LSDBs. Switches also send database information to their BDR, which stores this data without distributing it. If the DR fails, the BDR distributes LSDB information to its neighbors.

OSPFv3 routers distribute LSAs by sending them on all of their active interfaces. The router does not send hello packets from passive interfaces preventing adjacencies. The router does not process any OSPFv2 packets received on a passive interface.

When a router's LSDB is changed by an LSA, it sends the changes to the BDR and DR for distribution to the other neighbors. Routing information is updated only when the topology changes.

Routing devices use Dijkstra's algorithm to calculate the shortest path to all known destinations, based on cumulative route cost. The cost of an interface indicates the transmission overhead and is usually inversely proportional to its bandwidth.

15.3.2.4  OSPFv3 Security

The OSPFv3 protocol relies on the IPsec Authentication Header (AH) and Encapsulating Security Payload (ESP) header to provide data integrity, authentication and confidentiality. Transport mode provides IPsec to OSPFv3 packets.
The IPsec SA has Security Policy Index (SPI), HMAC algorithm, and a secret key as parameters. These parameters are used to compute Integrity Check Value (ICV), that is used to authenticate peers. When authentication is enabled, all corresponding peers must use same SA parameters to clear OSPFv3 ICV verification. SA can be configured at both area and interface levels.

Note: On the same area or interface, EOS allows security configuration with either AH or ESP but not both. We can have one area or interface configured with AH and another with ESP.

15.3.2.4.1 OSPFv3 Authentication

While sending OSPFv3 packets, the HMAC-MD5 or SHA algorithm hash is inserted in the IPsec header and the packet is sent over the wire for peer authentication.

While receiving OSPFv3 packets, the computed hash is verified with the one present in the IPsec header. If it fails, OSPFv3 packets are discarded.

15.3.2.4.2 OSPFv3 Encryption

ESP provides confidentiality to OSPFv3 packets. When confidentiality is enabled, ESP encrypts the sent data and decrypts the received data. OSPFv3 packets that are not encapsulated with security payload are discarded.

OSPFv3 encryption uses algorithms of Triple Data Encryption Standard (3DES) and Advanced Encryption Standard (AES). 3DES uses a 192 bit key, whereas the AES key length varies by 128, 192 and 256 bits.

15.3.2.5 Flood Pacing

OSPFv3 flood pacing allows configuring the minimum interval between the transmission of consecutive Link State (LS) update packets in a network. Flood pacing provides the following benefits:

- Prevents the rapid drain of flood queue by sending consecutive LSU packets with a delay.
- Helps mitigate high CPU or socket buffer utilization issues that occur when a switch instantly floods a large number of LSAs.
- When LSDB is updated frequently, an incremented flood pacing interval scales down LSA flooding.

Note: A high flood pacing interval may lead to convergence delays in large OSPF LSDBs.

15.3.2.6 OSPFv3 BFD Sessions for Adjacencies in any State

- BFD sessions are only established for OSPFv3 adjacencies that are in the FULL state. In a LAN environment this results in BFD sessions not being established for OSPFv3 adjacencies with DR Other neighbors.
- This feature provides configuration that enables the establishment of BFD sessions for OSPFv3 adjacencies that are in any state. This results in the BFD sessions being established for OSPFv3 adjacencies with DR Other neighbors.

15.3.2.7 Support for OSPFv3 dn-bit-ignore

The OSPFv3 dn-bit-ignore command allows enabling or disabling the inclusion of LSAs having “Down” (DN) bit set in SPF calculations. The DN Bit is a loop prevention mechanism that implements when using OSPF as a CE - PE IGP protocol.

The DN-bit usage in OSPFv3 is explained in RFC6565. With Release EOS-4.25.0F, OSPFv3 honors the DN-bit in type-3, type-5, or type-7 LSAs in non-default VRFs. LSAs are not used in SPF calculation, and are not installed in the routing table. Using the dn-bit-ignore command changes this behavior. It is recommended to understand the entire topology before configuring the dn-bit-ignore command as it may lead to forwarding loops.
15.3.3 Configuring OSPFv3

These sections describe basic OSPFv3 configuration steps:

- Configuring an OSPFv3 Instance
- Configuring OSPFv3 Areas
- Configuring Interfaces for OSPFv3
- Enabling OSPFv3
- Configuring OSPFv3 Security
- Configuring OSPFv3 Flood Pacing
- Configuring OSPFv3 dn-bit-ignore
- Displaying OSPFv3 Status

15.3.3.1 Configuring an OSPFv3 Instance

15.3.3.1.1 Entering OSPFv3 Configuration Mode

OSPFv3 configuration commands apply to the specified OSPFv3 instance. To perform OSPFv3 configuration commands, the switch must be in router-OSPFv3 configuration mode. The `ipv6 router ospf` command places the switch in router-OSPFv3 configuration mode, creating an OSPFv3 instance if OSPFv3 was not previously instantiated on the switch. If no VRF is specified, the OSPFv3 instance is in the default VRF. To instantiate or configure OSPFv3 on a non-default VRF, specify that VRF when using the `ipv6 router ospf` command.

The process ID identifies the OSPFv3 instance and is local to the router. Neighbor OSPFv3 routers can have different process IDs. OSPFv3 instances configured in different VRFs on the switch must have different process IDs.

The switch supports one OSPFv3 instance for each VRF. When an OSPFv3 instance already exists, the `ipv6 router ospf` command must specify its process ID (and VRF, if it is not configured in the default VRF). Attempts to define additional instances in the same VRF will generate errors. The `show ipv6 ospf` command displays information about OSPFv3 instances, including their process IDs.

Example

This command places the switch in router-OSPFv3 configuration mode for the default VRF. If OSPFv3 was not previously instantiated in the default VRF, the command creates an OSPFv3 instance in the default VRF with a process ID of 9.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#show active
ipv6 router ospf 9
switch(config-router-ospf3)#
```

15.3.3.1.2 Defining the Router ID

The router ID is a 32-bit number assigned to a router running OSPFv3. This number uniquely labels the router within an Autonomous System. Status commands identify the switch through the router ID. When configuring OSPFv3 instances in multiple VRFs, each should have a different router ID.

**Note:** A router ID is required to run OSPF, and Arista recommends setting the router ID manually for the following reasons:

1. If there are no IPv4 addresses configured on the switch, a manually configured router ID is required.
2. The router ID also does not change if the interface status or IP address changes, which can cause confusion if the ID has been selected automatically.

The switch sets the router ID to the first available alternative in the following list:
1. The router-id command.
2. The loopback IPv6 address, if a loopback interface is active on the switch.
3. The highest IPv6 address on the router.

Note: When configuring VXLAN on an MLAG, always manually configure the OSPFv3 router ID to prevent the switch from using the common VTEP IP address as the router ID.

The router-id (OSPFv3) command configures the router ID for an OSPFv3 instance.

Example
This command assigns 15.1.1.1 as the OSPFv3 router ID.

```
switch(config-router-ospf3)#router-id 15.21.4.9
switch(config-router-ospf3)#show active
ipv6 router ospf 9
   router-id 15.21.4.9
switch(config-router-ospf3)#
```

15.3.1.3 Global OSPFv3 Parameters
These router-OSPFv3 configuration mode commands define OSPFv3 behavior for the OSPFv3 instance under which they are used.

Logging Adjacency Changes
The log-adjacency-changes (OSPFv3) command configures the switch to log OSPFv3 link-state changes and transitions of OSPFv3 neighbors into the up or down state.

Examples
• This command configures the switch to log transitions of OSPFv3 neighbors into the up or down state.

```
switch(config-router-ospf3)#log-adjacency-changes
switch(config-router-ospf3)#
```

• This command configures the switch to log all OSPFv3 link-state changes.

```
switch(config-router-ospf3)#log-adjacency-changes detail
switch(config-router-ospf3)#
```

Intra-Area Distance
The distance ospf intra-area (OSPFv3) command configures the administrative distance for routes contained in a single OSPFv3 area. Administrative distances compare dynamic routes configured by different protocols. The default administrative distance for intra-area routes is 10.

Example
This command configures an administrative distance of 90 for OSPFv3 intra-area routes.

```
switch(config-router-ospf3)#distance ospf intra-area 90
switch(config-router-ospf3)#show active
ipv6 router ospf 9
   distance ospf intra-area 90
switch(config-router-ospf3)#
```
Passive Interfaces

The `passive-interface (OSPFv3)` command prevents the transmission of hello packets on the specified interface. Passive interfaces drop all adjacencies and do not form new adjacencies. Although passive interfaces do not send or receive LSAs, other interfaces may generate LSAs for the network segment. The router does not send OSPFv3 packets from a passive interface or process OSPFv3 packets received on a passive interface. The router advertises the passive interface in the router LSA.

The `no passive-interface` command re-enables OSPFv3 processing on the specified interface.

Examples

- This command configures `vlan 200` as a passive interface.

```
switch(config-router-ospf3)#passive-interface vlan 200
switch(config-router-ospf3)#show active
ipv6 router ospf 9
   passive-interface Vlan200
```

- This command configures `vlan 200` as an active interface.

```
switch(config-router-ospf3)#no passive-interface vlan 200
switch(config-router-ospf3)#show active
ipv6 router ospf 9
```

Redistributing Connected Routes

Redistributing connected routes causes the OSPFv3 instance to advertise all connected routes on the switch as external OSPFv3 routes. Connected routes are routes that are established when IPv6 is enabled on an interface.

Example

The `redistribute (OSPFv3) connected` command converts connected routes to OSPFv3 external routes.

```
switch(config-router-ospf3)#redistribute connected
switch(config-router-ospf3)#show active
ipv6 router ospf 9
   redistribute connected
```

Redistributing Static Routes

Redistributing static routes causes the OSPFv3 instance to advertise all static routes on the switch as external OSPFv3 routes. The switch does not support redistributing individual static routes.

Example

The `redistribute (OSPFv3) static` command converts static routes to OSPFv3 external routes.

```
switch(config-router-ospf3)#redistribute static
switch(config-router-ospf3)#show active
ipv6 router ospf 9
   redistribute static
```
15.3.3.2 Configuring OSPFv3 Areas

OSPFv3 areas are configured through area commands. The switch must be in router-OSPFv3 configuration mode, as described in Entering OSPFv3 Configuration Mode, to run area commands.

Areas are assigned a 32-bit number that is expressed in decimal or dotted-decimal notation. When an OSPFv3 instance configuration contains multiple areas, the switch only configures areas associated with its interfaces.

15.3.3.2.1 Configuring the Area Type

The \texttt{no area (OSPFv3)} command specifies the area type. The switch supports three area types:

- **Normal area**: Area that accepts intra-area, inter-area, and external routes. The backbone area (area 0) is a normal area.
- **Stub area**: Area where external routes are not advertised. External routes are reached through a default summary route (\texttt{0.0.0.0}) inserted into stub areas. Networks with no external routes do not require stub areas.

The default area type is normal.

**Example**

These commands configures area 200 as a NSSA area and 300 as a stub area.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 200 nssa
switch(config-router-ospf3)#area 300 stub
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  area 0.0.0.200
  area 0.0.1.44 stub
switch(config-router-ospf3)#
```

15.3.3.2.2 Configuring Area Parameters

These router-OSPFv3 configuration mode commands define OSPFv3 behavior in a specified area.

**Default Summary Route Cost**

The \texttt{area default-cost (OSPFv3)} command specifies the cost of the default summary route that ABRs send into a stub area or NSSA. Summary routes, also called inter-area routes, originate in areas different than their destination. When the \texttt{area default-cost} command is not configured for an area, the default-cost of that area is set to 10.

**Example**

This command configures a cost of 25 for the default summary route in area 0.0.1.194 (450).

```
switch(config-router-ospf3)#area 450 default-cost 25
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  area 0.0.1.194 default-cost 25
switch(config-router-ospf3)#
```

**Area Stub**

The \texttt{area stub (OSPFv3)} command configures the area type of an OSPFv3 area. All routers in an AS must specify the same area type for identically numbered areas.
Routing Protocols

Stub areas are areas in which external routes are not advertised. To reach these external routes, the stub area uses a default summary route (0.0.0.0). Networks without external routes do not require stub areas.

Areas are normal by default; area type configuration is required only for stub NSSA areas. Area 0 is always a normal area and cannot be configured through this command.

Examples

- This command configures area 45 as a stub area.

  switch(config)#ipv6 router ospf 3
  switch(config-router-ospf3)#area 45 stub
  switch(config-router-ospf3)#

- This command configures area 10.92.148.17 as a stub area.

  switch(config-router-ospf3)#area 10.92.148.17 stub
  switch(config-router-ospf3)#

Area Range

The area range (OSPFv3) command is used by OSPFv3 Area Border Routers (ABRs) to consolidate or summarize routes, to configure a cost setting for those routes, and to suppress summary route advertisements.

By default, an ABR creates a summary LSA for each route in an area and advertises that LSA to adjacent areas. The area range (OSPFv3) command aggregates routing information on area boundaries, allowing the ABR to use one summary LSA to advertise multiple routes.

Examples

- These commands consolidate and summarize routes at an area boundary 1.

  switch(config)#ipv6 router ospf 1
  switch(config-router-ospf3)#area 1 range 2001:0DB8:0:1::/64
  switch(config-router-ospf3)#

- These commands change the address range status to DoNotAdvertise. Neither one of the individual intra-area routes falling under range or the ranged prefix is advertised as summary LSA.

  switch(config)#ipv6 router ospf 1
  switch(config-router-ospf3)#area 1 range 2001:0DB8:0:1::/64 not-advertise
  switch(config-router-ospf3)#

15.3.3.3 Configuring Interfaces for OSPFv3

OSPFv3 interface configuration commands enable OSPFv3 on an interface, assign the interface to an area, and specify transmission parameters for routed ports and SVIs that handle OSPFv3 packets.

15.3.3.3.1 Assigning an Interface to an Area

The ipv6 ospf area command enables OSPFv3 on the configuration mode interface and associates the specified area to the interface. Each routed interface can be associated with one OSPFv3 area; subsequent ipv6 ospf area commands that designate a different area on an interface replace any existing command for the interface.

Example
These commands enable OSPFv3 instance 9 on interface vlan 200 and associate area 0 to the interface.

```bash
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 ospf 9 area 0
switch(config-if-Vl200)#show active
interface Vlan200
  ipv6 ospf 9 area 0.0.0.0
switch(config-if-Vl200)#
```

15.3.3.2 Configuring Intervals

Interval configuration commands determine OSPFv3 packet transmission characteristics for a specified VLAN interface. Interval configuration commands are entered in vlan-interface configuration mode.

**Hello Interval**

The hello interval specifies the period between consecutive hello packet transmissions from an interface. Each OSPFv3 neighbor should specify the same hello interval, which should not be longer than any neighbors dead interval.

The `ospfv3 hello-interval` command configures the hello interval for the configuration mode interface. The default is 10 seconds.

**Example**

These commands configure a hello interval of 45 seconds for VLAN 200.

```bash
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 hello-interval 45
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 hello-interval 45
switch(config-if-Vl200)#
```

**Dead Interval**

The dead interval specifies the period that an interface waits for an OSPFv3 packet from a neighbor before it disables the adjacency under the assumption that the neighbor is down. The dead interval should be configured identically on all OSPFv3 neighbors and be longer than the hello interval of any neighbor.

The `ospfv3 dead-interval` command configures the dead interval for the configuration mode interface. The default is 40 seconds.

**Example**

This command configures a dead interval of 75 seconds for VLAN 200.

```bash
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 dead-interval 75
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 dead-interval 75
switch(config-if-Vl200)#
```
Routing Protocols

Retransmission Interval
Routers that send OSPFv3 advertisements to an adjacent router expect to receive an acknowledgment from that neighbor. Routers that do not receive an acknowledgment will retransmit the advertisement. The retransmission interval specifies the period between retransmissions.

The `ospfv3 ipv6 retransmit-interval` command configures the LSA retransmission interval for the configuration mode interface. The default retransmission interval is 5 seconds.

Example
This command configures a retransmission interval of 25 seconds for `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 ipv6 retransmit-interval 25
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 ipv6 retransmit-interval 25
switch(config-if-Vl200)#
```

Transmission Delay
The transmission delay is an estimate of the time that an interface requires to transmit a link-state update packet. OSPFv3 adds this delay to the age of outbound packets to more accurately reflect the age of the LSA when received by a neighbor.

The `ospfv3 transmit-delay` command configures the transmission delay for the configuration mode interface. The default transmission delay is one second.

Example
This command configures a transmission delay of 10 seconds for `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 transmit-delay 10
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 transmit-delay 10
switch(config-if-Vl200)#
```

15.3.3.3 Configuring Interface Parameters

Interface Cost
The OSPFv3 interface cost reflects the overhead of sending packets across the interface. The cost is typically assigned to be inversely proportional to the bandwidth of the interface. The `ospfv3 cost` command configures the OSPFv3 cost for the configuration mode interface. The default cost is 10.

Example
This command configures a cost of 50 for `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 cost 50
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 cost 50
switch(config-if-Vl200)#
```
**Router Priority**

Router priority determines preference during Designated Router (DR) and Backup Designated Router (BDR) elections. Routers with higher priority numbers have preference over other routers. Routers with a priority of zero cannot be elected as a DR or BDR.

The `ospfv3 priority` command configures router priority for the configuration mode interface. The default priority is 1.

**Example**

This command configures a router priority of 128 for vlan 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 priority 128
switch(config-if-Vl200)#show active
```

---

**15.3.3.4 Enabling OSPFv3**

**15.3.3.4.1 IP Routing**

OSPFv3 requires that IPv6 unicast routing is enabled on the switch. When IP routing is not enabled, entering OSPFv3 configuration mode generates a message.

**Examples**

- This message is displayed if, when entering router-OSPFv3 configuration mode, IPv6 unicast routing is not enabled.

```
switch(config)#ipv6 router ospf 9
! IPv6 routing not enabled
switch(config-router-ospf3)#
```

- This command enables IP routing on the switch.

```
switch(config)#ipv6 unicast-routing
```

**15.3.3.4.2 Disabling OSPFv3**

The `shutdown` (OSPFv3) disables OSPFv3 operations on the switch without disrupting the OSPFv3 configuration. To disable OSPFv3 on an interface, remove the `ipv6 ospf area` statement for the corresponding interface.

The `no shutdown` command resumes OSPFv3 activity.

**Examples**

- This command disables OSPFv3 activity on the switch.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#shutdown
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  shutdown
switch(config-router-ospf3)#
```
• This command resumes OSPFv3 activity on the switch.

```plaintext
switch(config-router-ospf3)#no shutdown
switch(config-router-ospf3)#show active
ipv6 router ospf 9
switch(config-router-ospf3)#
```

15.3.3.5 Configuring OSPFv3 Security

You can configure OSPFv3 security for either an area or an interface, or both, using either an Authentication Header (AH) or an Encapsulating Security Payload (ESP).

When OSPFv3 security is configured on an area, the configured settings apply to all interfaces in that area. Interface-specific configuration overrides configuration on the area to which the interface belongs.

15.3.3.5.1 Configuring OSPFv3 Authentication

Configuring OSPFV3 Authentication for Areas

The `area authentication ipsec spi` command configures OSPFV3 authentication on an area.

**Example**

This command configures OSPFv3 authentication on an area with MD5 hash algorithm.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 0.0.0.0 authentication ipsec spi 34 md5 0 8FD6158BFE81ADD961241D8E4169D411
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    area 0.0.0.0 authentication ipsec spi 34 md5 7 $1$cNpcrQl1czqdvKgLtYvR6I7+R3niuWou0KKYCFNs4/XOWG/Iap5Q==
switch(config-router-ospf3)#
```

Configuring OSPFV3 Authentication for Interfaces

The `ospfv3 authentication ipsec spi` command configures OSPFV3 authentication on an interface.

**Example**

This command configures OSPFv3 authentication on an interface with MD5 hash algorithm.

```plaintext
switch(config-if-Et9)#ospfv3 authentication ipsec spi 3456 md5 0 8FD6158BFE81ADD961241D8E4169D411
switch(config-if-Et9)#show active
interface Ethernet9
    no switchport
    ospfv3 authentication ipsec spi 3456 md5 7 $1$xtmcMSPzEn+Njp8Lb4qryVVOjKcjsrYuv6dx10+nSwKQdaiRt2RPTQ==
switch(config-if-Et9)#
```

15.3.3.5.2 Configuring OSPFV3 Encryption

Configuring OSPFV3 Encryption for Areas

The `area encryption ipsec spi` command configures OSPFV3 security on an area.

**Example**

```plaintext
```
This command configures OSPFv3 security on an area with 3DES-CBC encryption and MD5 hash algorithm.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 0.0.0.0 encryption ipsec spi 5678 esp 3des-cbc md5 passphrase 0 8FD6158BFE81ADD961241D8E4169D411
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  area 0.0.0.0 encryption ipsec spi 5678 esp 3des-cbc md5 passphrase 7 $1$cNpcrQl1czqdvKAzKLtYr6I7+R3niuWouD0KCFNs4/X0WG/Iap5Q==
switch (config-router-ospf3)#
```

**Configuring OSPFv3 Encryption for Interfaces**

The `ospfv3 encryption ipsec spi` command configures OSPFv3 security on an interface.

**Example**

This command configures OSPFv3 security on an interface with 3DES-CBC encryption and SHA1 algorithm.

```
switch(config)#interface ethernet 9
switch(config-if-Et9)#ospfv3 encryption ipsec spi 345 esp 3des-cbc sha1 passphrase 0 2fd4e1c67a2d28fced849ee1bb76e7391b93eb12
switch(config-if-Et9)#show active
interface Ethernet9
  no switchport
  ospfv3 encryption ipsec spi 345 esp 3des-cbc sha1 passphrase 7 $1$VmUkWk6IL2S343bR3BbH0RhgyXHhwBpfvB4VXKNO0QF7HJBp5VtBaYbgCkWU
switch(config-if-Et9)#
```

### 15.3.3.6 Configuring OSPFv3 Flood Pacing

Flood pacing can be configured for global OSPFv3 instances and address families. The `timers pacing flood` command configures OSPFv3 flood pacing.

**Examples**

- This command configures OSPFv3 flood pacing timer to 50 ms in the global OSPFv3 instance.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#timers pacing flood 50
switch(config-router-ospf3)#show ipv6 ospf
Routing Process "ospfv3 9" with ID 13.13.13.13 and Instance 0 VRF default
  FIPS mode disabled
  It is not an autonomous system boundary router and is not an area
  border router
  Minimum LSA arrival interval 1000 msecs
  Initial LSA throttle delay 1000 msecs
  Minimum hold time for LSA throttle 5000 msecs
  Maximum wait time for LSA throttle 5000 msecs
  Interface flood pacing timer 50 msecs
  It has 0 fully adjacent neighbors
  Number of areas in this router is 1. 1 normal, 0 stub, 0 nssa
  Number of LSAs 1
  Initial SPF schedule delay 0 msecs
  Minimum hold time between two consecutive SPF 5000 msecs
  Current hold time between two consecutive SPF 5000 msecs
  Maximum wait time between two consecutive SPF 5000 msecs
  SPF algorithm last executed 21d19h ago
  No scheduled SPF
```
Routing Protocols

- Adjacency exchange-start threshold is 20
- Maximum number of next-hops supported in ECMP is 32
- Number of backbone neighbors is 0
- Graceful-restart is not configured
- Graceful-restart-helper mode is enabled
- Area 0.0.0.0
  - Number of interface in this area is 0
  - It is a normal area
  - SPF algorithm executed 2 times

- This command configures OSPFv3 flood pacing timer to 50 ms for ipv4 address family.

```bash
switch(config)#router ospfv3
switch(config-router-ospfv3)#address-family ipv4
switch(config-router-ospfv3-af)#timers pacing flood 50
switch(config-router-ospfv3-af)#show ospfv3
```

OSPFv3 address-family ipv4
Routing Process "ospfv3" with ID 11.1.11.1 and Instance 64 VRF default
FIPS mode disabled
- It is not an autonomous system boundary router and is not an area border router
  - Minimum LSA arrival interval 1000 msecs
  - Initial LSA throttle delay 1000 msecs
  - Minimum hold time for LSA throttle 5000 msecs
  - Maximum wait time for LSA throttle 5000 msecs
  - Interface flood pacing timer 50 msecs
  - It has 0 fully adjacent neighbors
  - Number of areas in this router is 1. 1 normal, 0 stub, 0 nssa
  - Number of LSAs 1
  - Initial SPF schedule delay 0 msecs
  - Minimum hold time between two consecutive SPFs 5000 msecs
  - Current hold time between two consecutive SPFs 5000 msecs
  - Maximum wait time between two consecutive SPFs 5000 msecs
  - SPF algorithm last executed 00:01:05 ago
  - No scheduled SPF
  - Adjacency exchange-start threshold is 20
  - Maximum number of next-hops supported in ECMP is 32
  - Number of backbone neighbors is 0
  - Graceful-restart is not configured
  - Graceful-restart-helper mode is enabled
  - Area 0.0.0.0
    - Number of interface in this area is 0
    - It is a normal area
    - SPF algorithm executed 2 times

15.3.3.7 Configurating OSPFv3 dn-bit-ignore

OSPFv3

Use the command **dn-bit-ignore** to include type-3/5/7 LSAs having their DN-bit set in the SPF calculation.

Use the commands **dn-bit-ignore** or default **dn-bit-ignore** to revert the behavior back to default. This command is available in ipv6 router ospf vrf configuration mode and the router ospfv3 vrf configuration mode. Note that this command is not available in the default VRF, and that both configuration styles are captured below.
router ospfv3 Configuration Style

The `dn-bit-ignore` command is available under the `router ospfv3 vrf` configuration mode. This disables the dn-bit check for Type-3/5/7 LSAs in non-default VRFs.

```
switch(config)#router ospfv3 vrf red
switch(config-router-ospfv3-vrf-red)#dn-bit-ignore
```

ipv6 router ospf Configuration Style

The `dn-bit-ignore` command is also available under the `ipv6 router ospf vrf` configuration mode. This disables the dn-bit check for Type-3/5/7 LSAs in non-default VRFs.

```
switch(config)#ipv6 router ospf 1 vrf red
switch(config-router-ospfv3-vrf-red)#dn-bit-ignore
```

15.3.3.8 Displaying OSPFv3 Status

This section describes OSPFv3 show commands that display OSPFv3 status. General switch methods that provide OSPFv3 information include pinging routes, viewing route status (`show ip route` command), and viewing the configuration (`show running-config` command).

15.3.3.8.1 OSPFv3 Summary

The `show ipv6 ospf` command displays general OSPFv3 configuration information, operational statistics and status for the OSPFv3 instance, followed by a brief description of the areas configured on the switch.

**Example**

This command displays OSPFv3 routing process information.

```
switch(config-router-ospfv3)#show ipv6 ospf
Routing Process "ospfv3 1" with ID 1.1.1.1 and Instance 0 VRF default
  It is not an autonomous system boundary router and is not an area
  border router
  Minimum LSA arrival interval 1000 msecs
  Initial LSA throttle delay 1000 msecs
  Minimum hold time for LSA throttle 5000 msecs
  Maximum wait time for LSA throttle 5000 msecs
  Interface flood pacing timer 50 msecs
  It has 0 fully adjacent neighbors
  ...
  Graceful-restart is not configured
  Graceful-restart-helper mode is enabled
```

15.3.3.8.2 Viewing OSPFv3 on the Interfaces

The `show ipv6 ospf interface` command displays OSPFv3 information for switch interfaces configured for OSPFv3. Different command options allow the display of either all interfaces or a specified interface. The command can also be configured to display complete information or a brief summary.

**Example**

This command displays OSPFv3 information for interfaces where OSPFv3 is enabled.

```
switch#show ipv6 ospf interface
Ethernet17 is up
```
15.3.8.3 Viewing the OSPFv3 Database

The `show ipv6 ospf database <link state list>` command displays the LSAs in the LSDB for the specified area. If no area is listed, the command displays the contents of the database for each area on the switch. The database command provides options to display subsets of the LSDB database, a summary of database contents, and the link states that comprise the database.

Example

This command displays the OSPFv3 database of Link State Advertisements (LSAs).

```
switch#show ipv6 ospf database
Routing Process "ospf 9":

    AS Scope LSDB
    Type     Link ID     ADV Router  Age     Seq#     Checksum
    AEX      0.0.0.5    10.37.0.37   15 0x80000005   0x00be82
    AEX      0.0.0.9    10.37.0.22 1747 0x8000002b   0x00df56
    AEX      0.0.0.3    10.37.0.46  599 0x8000002d   0x00651d

    Area 0.0.0.0 LSDB
    Type     Link ID     ADV Router  Age     Seq#     Checksum
    RTR      0.0.0.0    10.37.0.32  234 0x80000031   0x00585a
    NTW      0.0.0.26   10.37.0.32  271 0x80000005   0x005609
    NAP      0.0.0.26   10.37.0.32  274 0x80000005   0x00964c

    Interface vlan3911 LSDB
    Type     Link ID     ADV Router  Age     Seq#     Checksum
    LNK      0.0.0.38   10.37.0.22  267 0x80000005   0x00a45a
    LNK      0.0.0.23   10.37.0.23  270 0x8000002c   0x005b7e

    Interface vlan3902 LSDB
    Type     Link ID     ADV Router  Age     Seq#     Checksum
```
15.3.3.8.4 Viewing OSPFv3 Neighbors

The `show ipv6 ospf neighbor` command displays information about the routers that are neighbors to the switch. Command options allow the display of summary or detailed information about the neighbors to all areas and interfaces on the switch. The command also allows for the display of neighbors to individual interfaces or areas. The `adjacency-changes` option displays the interfaces adjacency changes.

**Example**

This command displays the switch's neighbors.

```
switch# show ipv6 ospf neighbor
Routing Process "ospf 9":
Neighbor 10.37.0.37 priority is 1, state is Full
   In area 0.0.0.0 interface et12
   DR is 10.37.0.37 BDR is 10.37.0.23
   Options is 0
   Dead timer is due in 37 seconds
Neighbor 10.37.0.22 priority is 1, state is Full
   In area 0.0.0.0 interface vlan3911
   DR is 10.37.0.22 BDR is 10.37.0.23
   Options is 0
   Dead timer is due in 31 seconds
Neighbor 10.37.0.22 priority is 1, state is Full
   In area 0.0.0.0 interface vlan3902
   DR is 10.37.0.11 BDR is 10.37.0.22
   Options is 0
   Dead timer is due in 31 seconds
Neighbor 10.37.0.22 priority is 1, state is Full
   In area 0.0.0.0 interface vlan3908
   DR is 10.37.0.22 BDR is 10.37.0.21
   Options is 0
   Dead timer is due in 39 seconds
```

15.3.3.8.5 Viewing OSPFv3 Routes

The `show ipv6 routes` command provides an OSPFv3 option.

**Example**

This command displays the switch's OSPFv3 routes.

```
switch# show ipv6 route ospf
IPv6 Routing Table - 43 entries
Codes: C - connected, S - static, K - kernel, O - OSPF, B - BGP, R - RIP, A - Aggregate
  O fd7a:3279:81a4:1112::/64 [150/11]
    via fe80::21c:41ff:fe00:d120, Ethernet12
  O fd7a:3279:81a4:1114::/64 [150/11]

15.3.3.8.6 Viewing OSPFv3 dn-bit-ignore

Use the `show running-config` command to verify whether the `dn-bit-ignore` command is configured.

15.3.4 OSPFv3 Configuration Examples

This section describes the commands required to configure three OSPFv3 topologies.

15.3.4.1 OSPFv3 Configuration Example 1

The AS in Example 1 contains two areas that are connected through two routers. The backbone area also contains an internal router that connects two links.

15.3.4.1.1 Example 1 Topology

**OSPFv3 Example 1** displays the Example 1 topology. Two ABRs connect area 0 and area 1: **Router A** and **Router B**. **Router C** is an internal router that connects two links in area 0. Area 0 is normal; area 1 is stub.

**Figure 51: OSPFv3 Example 1**

Area 1 Configuration

Area 1 contains links to ABRs **Router A** and **Router B**.

- **Router A** is accessed through **VLAN 301**.
- **Router B** is accessed through **VLAN 401**.
- Designated Router (DR): **Router A**.
- Backup Designated Router (BDR): **Router B**.
- Each router defines an interface cost of 10.
- Router priority is not specified for either router on area 1.
Area 0 ABR Configuration

Area 0 contains links to ABRs **Router A** and **Router B**.

- **Router A** is accessed through **VLAN 302**.
- **Router B** is accessed through **VLAN 402**.
- Designated Router (DR): **Router B**.
- Backup Designated Router (BDR): **Router A**.
- Each router defines an interface cost of **20**.
- Each router defines a retransmit-interval of **10**.
- Each router defines a transmit-delay of **2**.
- Router priority is specified such that **Router B** will be elected as the Designated Router.

Area 0 IR Configuration

Area 0 contains two links to an internal router.

- **Router C** is accessed through **VLAN 501** and **VLAN 502**.
- **VLAN 501** is configured as follows:
  - Interface cost of **20**.
  - Retransmit-interval of **10**.
  - Transmit-delay of **2**.
- **VLAN 502** is configured as follows:
  - Interface cost of **20**.
  - Dead interval of **80** seconds.

15.3.4.1.2 Example 1 Code

This code configures the OSPFv3 instances on the three switches.

1. Configure the areas and router IDs.
   a. **Router A** OSPFv3 instance configuration:

   ```
   switch-A(config)#ipv6 router ospf 100
   switch-A(config-router-ospfv3)#area 1 stub
   switch-A(config-router-ospfv3)#router-id 10.17.0.1
   ```

   b. **Router B** OSPFv3 instance configuration:

   ```
   switch-B(config)#ipv6 router ospf 100
   switch-B(config-router-ospfv3)#area 1 stub
   switch-B(config-router-ospfv3)#router-id 10.17.0.2
   ```

   c. **Router C** OSPFv3 instance configuration: interfaces:

   ```
   switch-C(config)#ipv6 router ospf 100
   switch-C(config-router-ospfv3)#router-id 10.17.0.3
   ```

2. Configure the interface OSPFv3 area and transmission parameters.
   a. **Router A** interfaces:

   ```
   switch-A(config)#interface vlan 301
   switch-A(config-if-Vl301)#ipv6 ospf 100 area 1
   switch-A(config-if-Vl301)#ospfv3 cost 10
   switch-A(config-if-Vl301)#ospfv3 priority 6
   switch-A(config-if-Vl301)#exit
   switch-A(config)#interface vlan 302
   ```
### 15.3.4.2 OSPFv3 Configuration Example 2

The AS in Example 2 contains three areas. Area 0 connects to the other areas through different routers and contains an internal router connecting two links. Area 0 is normal; the other areas are stub areas.

### 15.3.4.2.1 Example 2 Topology

**OSPFv3 Example 2** displays the Example 2 topology. One ABR (Router B) connects area 0 and area 1; another ABR (Router C) connects area 0 and area 2. **Router A** is an internal router that connects two links in area 0.

---

| switch-A(config-if-Vl302) | #ipv6 ospf 100 area 0  
|---------------------------|---------------------------|
| switch-A(config-if-Vl302) | #ospfv3 cost 20  
| switch-A(config-if-Vl302) | #ospfv3 ipv6 retransmit-interval 10  
| switch-A(config-if-Vl302) | #ospfv3 transmit-delay 2  
| switch-A(config-if-Vl302) | #ospfv3 priority 4  

b. **Router B** interfaces:

| switch-B(config) | #interface vlan 401  
|-------------------|-------------------|
| switch-B(config-if-Vl401) | #ipv6 ospf 100 area 1  
| switch-B(config-if-Vl401) | #ospfv3 cost 10  
| switch-B(config-if-Vl401) | #ospfv3 priority 4  
| switch-B(config-if-Vl401) | #exit  
| switch-B(config) | #interface vlan 402  
| switch-B(config-if-Vl402) | #ipv6 ospf 100 area 0  
| switch-B(config-if-Vl402) | #ospfv3 cost 20  
| switch-B(config-if-Vl402) | #ospfv3 ipv6 retransmit-interval 10  
| switch-B(config-if-Vl402) | #ospfv3 transmit-delay 2  
| switch-B(config-if-Vl402) | #ospfv3 priority 6  

c. **Router C** interfaces:

| switch-C(config) | #interface vlan 501  
|-------------------|-------------------|
| switch-C(config-if-Vl501) | #ipv6 ospf 100 area 0  
| switch-C(config-if-Vl501) | #ospfv3 cost 20  
| switch-C(config-if-Vl501) | #ospfv3 ipv6 retransmit-interval 10  
| switch-C(config-if-Vl501) | #ospfv3 transmit-delay 2  
| switch-C(config-if-Vl501) | #exit  
| switch-C(config) | #interface vlan 502  
| switch-C(config-if-Vl502) | #ipv6 ospf 100 area 0  
| switch-C(config-if-Vl502) | #ospfv3 cost 20  
| switch-C(config-if-Vl502) | #ospfv3 dead-interval 80  

---
Area 1 Configuration
Area 1 contains one link that is accessed by Router B.
- Router B is accessed through VLAN 601.
- The router defines a interface cost of 10.

Area 2 Configuration
Area 2 contains one link that is accessed by Router C.
- Router C is accessed through VLAN 802.
- The router defines a interface cost of 20.

Area 0 ABR Configuration
One ABR Router B link connects area 1 to area 0. One ABR Router C link connects area 0 to area 2.
- Router B is accessed through VLAN 602
- Router C is accessed through VLAN 801
- Designated Router (DR): Router B
- Backup Designated Router (BDR): Router C
- Each router defines an interface cost of 20.
- Each router defines a retransmit-interval of 10.
- Each router defines a transmit-delay of 2.

Area 0 IR Configuration
Area 0 contains links connected by an internal router.
• Router A is accessed through **VLAN 701** and **VLAN 702**.
• The **VLAN 701** link is configured as follows:
  • Interface cost of **10**.
• The **VLAN 702** link is configured as follows:
  • Interface cost of **20**.
  • Retransmit-interval of **10**.
  • Transmit-delay of **2**.

15.3.4.2.2 Example 2 Code

1. Configure the areas and router IDs.
   a. Router A OSPFv3 instance configuration:
      
      ```
      switch-A(config)#ipv6 router ospf 200
      switch-A(config-router-ospfv3)#router-id 10.24.1.10
      ```

   b. Router B OSPFv3 instance configuration:
      
      ```
      switch-B(config)#ipv6 router ospf 200
      switch-B(config-router-ospfv3)#area 1 stub
      switch-B(config-router-ospfv3)#router-id 10.24.2.10
      ```

   c. Router C OSPFv3 instance configuration:
      
      ```
      switch-C(config)#ipv6 router ospf 200
      switch-C(config-router-ospfv3)#area 1 stub
      switch-C(config-router-ospfv3)#router-id 10.25.2.12
      ```

2. Configure the interface OSPFv3 area and transmission parameters.
   a. **Router A** interfaces:
      
      ```
      switch-A(config)#interface vlan 701
      switch-A(config-if-Vl701)#ipv6 ospf 200 area 0
      switch-A(config-if-Vl701)#ospfv3 cost 10
      switch-A(config-if-Vl701)#exit
      switch-A(config)#interface vlan 702
      switch-A(config-if-Vl702)#ipv6 ospf 200 area 0
      switch-A(config-if-Vl702)#ospfv3 cost 20
      switch-A(config-if-Vl702)#ospfv3 ipv6 retransmit-interval 10
      switch-A(config-if-Vl702)#ospfv3 transmit-delay 2
      ```

   b. **Router B** interfaces:
      
      ```
      switch-B(config)#interface vlan 601
      switch-B(config-if-Vl601)#ospfv3 200 area 1
      switch-B(config-if-Vl601)#ospfv3 cost 10
      switch-B(config-if-Vl601)#exit
      switch-B(config)#interface vlan 602
      switch-B(config-if-Vl602)#ospfv3 200 area 0
      switch-B(config-if-Vl602)#ospfv3 cost 20
      switch-B(config-if-Vl602)#ospfv3 ipv6 retransmit-interval 10
      switch-B(config-if-Vl602)#ospfv3 transmit-delay 2
      switch-B(config-if-Vl602)#ospfv3 priority 6
      ```

   c. **Router C** interfaces:
      
      ```
      switch-C(config)#interface vlan 801
      switch-C(config-if-Vl801)#ospfv3 200 area 0
      ```
15.3.4.3  OSPFv3 Configuration Example 3

The AS in Example 3 contains two areas that connect through one ABR. Each area also contains an ASBR that connects static routes to the AS.

15.3.4.3.1  Example 3 Topology

**OSPFv3 Example 3** displays the Example 3 topology. One ABR connects area 0 and area 1. **Router C** is an ABR that connects the areas. **Router A** is an internal router that connects two links in area 1. **Router D** and **Router E** are internal routers that connect links in area 0. **Router B** and **Router F** are ASBRs that connect static routes outside the AS to area 1 and area 0, respectively.

![Figure 53: OSPFv3 Example 3](image_url)

**Area 0 ABR Configuration**

ABR **Router C** connects one area 0 link to an area 1 link.
- **Router C** is accessed through **VLAN 1302**.
- All interface OSPFv3 parameters are set to their default values.

**Area 0 IR Configuration**

Area 0 contains two internal routers, each of which connects two of the three links in the area.
- **Router D** is accessed through **VLAN 1401** and **VLAN 1402**.
- **Router E** is accessed through **VLAN 1501** and **VLAN 1502**.
• All interface OSPFv3 parameters are set to their default values.

**Area 0 ASBR Configuration**

ASBR *Router F* connects one area 0 link to an external link.
- *Router F* is accessed through *VLAN 1601*.
- *Router F* connects to the external AS through *VLAN 1602*.
- All interface OSPFv3 parameters are set to their default values.

**Area 1 ABR Configuration**

ABR *Router C* connects one area 0 link to an area 1 link.
- *Router C* is accessed by area 1 through *VLAN 1301*.
- *Router C* is accessed by area 0 through *VLAN 1302*.
- All interface OSPFv3 parameters are set to their default values.

**Area 1 IR Configuration**

Area 1 contains one internal router that connects two links in the area.
- *Router A* is accessed through *VLAN 1101* and *VLAN 1102*.
- All interface OSPFv3 parameters are set to their default values.

**Area 1 ASBR Configuration**

ASBR *Router B* connects one area 1 link to an external link.
- *Router B* is accessed through *VLAN 1201*.
- *Router B* connects to the external AS through *VLAN 1202*.
- All interface OSPFv3 parameters are set to their default values.

### 15.3.4.3.2 Example 3 Code

1. Configure the areas and router IDs.

   a. *Router A* OSPFv3 instance configuration:

   ```
   switch-A(config) #ipv6 router ospf 300
   switch-A(config-router-ospfv3)#router-id 10.12.15.10
   switch-A(config-router-ospfv3)#area 1 stub
   ```

   b. *Router B* OSPFv3 instance configuration:

   ```
   switch-B(config) #ipv6 router ospf 300
   switch-B(config-router-ospfv3)#router-id 10.12.15.12
   switch-B(config-router-ospfv3)#area 1 stub
   ```

   c. *Router C* OSPFv3 instance configuration:

   ```
   switch-C(config) #ipv6 router ospf 300
   switch-C(config-router-ospfv3)#router-id 10.12.15.13
   switch-C(config-router-ospfv3)#area 1 stub
   ```

   d. *Router D* OSPFv3 instance configuration:

   ```
   switch-D(config) #ipv6 router ospf 300
   switch-D(config-router-ospfv3)#router-id 10.12.15.14
   ```
e. Router E OSPFv3 instance configuration:

```bash
switch-E(config)#ipv6 router ospf 300
switch-E(config-router-ospfv3)#router-id 10.12.15.15
```

f. Router F OSPFv3 instance configuration:

```bash
switch-F(config)#ipv6 router ospf 300
switch-F(config-router-ospfv3)#router-id 10.12.15.31
```

2. Configure the interfaces.

a. Router A interfaces:

```bash
switch-A(config)#interface vlan 1101
switch-A(config-if-Vl1101)#ospfv3 300 area 1
switch-A(config-if-Vl1101)#exit
switch-A(config)#interface vlan 1102
switch-A(config-if-Vl1102)#ospfv3 300 area 1
```

b. Router B interfaces:

```bash
switch-B(config)#interface vlan 1201
switch-B(config-if-Vl1201)#ospfv3 300 area 1
switch-B(config-if-Vl1201)#exit
```

c. Router C interfaces:

```bash
switch-C(config)#interface vlan 1301
switch-C(config-if-Vl1301)#ospfv3 300 area 1
switch-C(config-if-Vl1301)#exit
switch-C(config)#interface vlan 1302
switch-C(config-if-Vl1302)#ospfv3 300 area 0
```

d. Router D interfaces:

```bash
switch-D(config)#interface vlan 1401
switch-D(config-if-Vl1401)#ospfv3 300 area 0
switch-D(config-if-Vl1401)#exit
switch-D(config)#interface vlan 1402
switch-D(config-if-Vl1402)#ospfv3 300 area 0
```

e. Router E interfaces:

```bash
switch-E(config)#interface vlan 1501
switch-E(config-if-Vl1501)#ospfv3 300 area 0
switch-E(config-if-Vl1501)#exit
switch-E(config)#interface vlan 1502
switch-E(config-if-Vl1502)#ospfv3 300 area 0
```

f. Router F interfaces:

```bash
switch-F(config)#interface vlan 1601
switch-F(config-if-Vl1601)#ospfv3 300 area 0
switch-F(config-if-Vl1601)#exit
```
15.3.5 OSPFv3 Commands

Global Configuration Mode
- clear ospfv3 ipv6 force-spf
- ipv6 router ospf

Interface Configuration Mode
- ipv6 ospf area
- ospfv3 authentication ipsec spi
- ospfv3 cost
- ospfv3 dead-interval
- ospfv3 encryption ipsec spi
- ospfv3 hello-interval
- ospfv3 ipv6 retransmit-interval
- ospfv3 network
- ospfv3 priority
- ospfv3 transmit-delay

Router-OSPFv3 Configuration Mode
- adjacency exchange-start threshold (OSPFv3)
- area authentication ipsec spi
- area default-cost (OSPFv3)
- area encryption ipsec spi
- area nssa (OSPFv3)
- area nssa default-information-originate (OSPFv3)
- area not-so-stubby lsa type-7 convert type-5 (OSPFv3)
- area range (OSPFv3)
- area stub (OSPFv3)
- default-information originate (OSPFv3)
- default-metric (OSPFv3)
- distance ospf intra-area (OSPFv3)
- log-adjacency-changes (OSPFv3)
- max-metric router-lsa (OSPFv3)
- maximum-paths (OSPFv3)
- no area (OSPFv3)
- passive-interface (OSPFv3)
- redistribute (OSPFv3)
- router-id (OSPFv3)
- shutdown (OSPFv3)
- timers
- timers lsa rx min interval (OSPFv3)
- timers lsa tx delay initial (OSPFv3)
- timers spf delay initial (OSPFv3)

Display Commands
- show ipv6 ospf
- show ipv6 ospf border-routers
- show ipv6 ospf database
• show ipv6 ospf database <link-state details>
• show ipv6 ospf database <link state list>
• show ipv6 ospf database link
• show ipv6 ospf database link if-name
• show ipv6 ospf database link if-type
• show ipv6 ospf interface
• show ipv6 ospf lsa-log
• show ipv6 ospf neighbor
• show ipv6 ospf neighbor state
• show ipv6 ospf neighbor summary
• show ipv6 ospf spf-log
• show ospfv3
15.3.5.1 adjacency exchange-start threshold (OSPFv3)

The adjacency exchange-start threshold command sets the exchange-start options for an OSPF instance.

The no adjacency exchange-start threshold and default adjacency exchange-start threshold command resets the default by removing the corresponding adjacency exchange-start threshold command from the running-config.

Command Mode
Router-OSPFv3 Configuration

Command Syntax
adjacency exchange-start threshold peers
no adjacency exchange-start threshold
default adjacency exchange-start threshold

Parameters
peers Value ranges from 1 - 4294967295. Default value is 10.

Example
This command sets the adjacency exchange start threshold to 156923.

```
switch(config)#ipv6 router ospf 3
switch(config-router-ospf3)#adjacency exchange-start threshold 156923
switch(config-router-ospf3)#
```
15.3.5.2 area authentication ipsec spi

The **area authentication ipsec spi** command configures OSPFv3 authentication on an area. The **default area authentication** and **no area authentication** commands delete the OSPFv3 authentication on an area.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```plaintext
area area_id authentication ipsec spi spi_value {md5|sha1} passphrase {0 unencrypted_key | 7 hidden_key | LINE}

no area area_id authentication ipsec spi spi_value {md5|sha1} passphrase {0 unencrypted_key | 7 hidden_key | LINE}

default area area_id authentication ipsec spi spi_value {md5|sha1} passphrase {0 unencrypted_key | 7 hidden_key | LINE}
```

**Parameters**
- **area area_id** configures OSPF area ID in either IP address or decimal formats. The value for decimal format ranges from 0 to 4294967295.
- **spi spi_value** configures the IPsec Security Parameter Index. The value ranges from 0 to 4294967295.
- **md5** configures HMAC-MD5 hash algorithm.
- **sha1** configures HMAC-SHA1 algorithm.
- **0 unencrypted_key** configures either a 192 bit 3DES key or 128/192/256 bit AES key in an unencrypted format.
- **7 encrypted_key** configures either a 192 bit 3DES key or 128/192/256 bit AES key in an encrypted format.
- **KEY** configures either a 128 bit MD5 key or a 140 bit SHA1 key.
- **passphrase** configures passphrase for authentication and encryption. Options include:
  - **0 unencrypted_passphrase** configures an unencrypted key.
  - **7 encrypted_passphrase** configures an encrypted key.
  - **LINE** uses passphrase string to derive keys for authentication and encryption.

**Related Commands**
- **ospfv3 authentication ipsec spi**
- **area encryption ipsec spi**

**Guidelines**
Passphrase and key value are exclusive. MD5 and SHA1 keys are derived from the configured passphrase.

**Restriction**
On the same area, EOS allows security configuration with either AH or ESP but not both. We can have one area configured with AH and another with ESP.

**Examples**
- This command configures OSPFv3 authentication on an area with MD5 hash algorithm.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 0.0.0.0 authentication ipsec spi 34 md5 0 8FD6158BFE81ADD961241D8E4169D411
switch(config-router-ospf3)#show active
ipv6 router ospf 9
```
area 0.0.0.0 authentication ipsec spi 34 md5 7 $1$cNpcrQ1lc
qdvKAzKltYVr6I7+R3niuWouDKKYCFNs4/XOWG/Iap5Q==
switch(config-router-ospf3)#

• This command configures OSPFv3 authentication on an area with SHA1 algorithm.

switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 0.0.0.0 authentication ipsec spi 5789
    sha1 passphrase 7 $1$Ab754G0OHbGllIKqlCl7lyUKscUlpFTpvcQxQIhzjMlOUzGJ
h4bLWxSDKkVWMo6
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    area 0.0.0.0 authentication ipsec spi 5789 sha1 passphrase 7
Ab754G0OHbGllIKqlCl7lyUKscUlpFTpvcQxQIhzjMlOUzGJd4bLWxSDKkVWMo6
switch(config-router-ospf3)#

• This command deletes the OSPFv3 authentication on an area.

switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    area 1.1.1.1 authentication ipsec spi 2437 md5 7 cNpcrQ1lcqdv
KAzKltYVr6I7+R3niuWouDKKYCFNs4/XOWG/Iap5Q==
    area 0.0.0.0 authentication ipsec spi 5789 sha1 passphrase 7
Ab754G0OHbGllIKqlCl7lyUKscUlpFTpvcQxQIhzjMlOUzGJd4bLWxSDKkVWMo6
switch(config-router-ospf3)#no area 0.0.0.0 authentication
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    area 1.1.1.1 authentication ipsec spi 2437 md5 7 cNpcrQ1lcqdv
KAzKltYVr6I7+R3niuWouDKKYCFNs4/XOWG/Iap5Q==
switch(config-router-ospf3)#
15.3.5.3  area default-cost (OSPFv3)

The **area default-cost** command sets the cost for the default summary routes sent into an area. When the **area default-cost** command is not configured for an area, the default-cost of that area is set to 10.

The **no area default-cost** and **default area default-cost** command resets the default-cost value of the specified area to 10 by removing the corresponding **area default-cost** command from **running-config**. The **no area (OSPFv3)** command removes all area commands for the specified area from **running-config**, including the **area default-cost** command.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```
area area_id default-cost def_cost
no area area_id default-cost
default area area_id default-cost
```

**Parameters**

- **area_id** area number. 0 to 4294967295 or 0.0.0.0 to 255.255.255.255. **Running-config** stores value in dotted decimal notation.
- **def_cost** Values range from 1 to 65535.

**Example**

These commands configure a cost of 15 for default summary routes that an ABR sends into area 100.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 100 default 15
switch(config-router-ospf3)#show active
ipv6 router ospf 9
area 0.0.0.100 default-cost 15
switch(config-router-ospf3)#
```
The `area encryption ipsec spi` command configures OSPFv3 security on an area. The `default area encryption` and `no area encryption` commands delete the OSPFv3 security on an area.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**
```
area area_id encryption ipsec spi spi_value esp{3des-cbc | aes-128-cbc | aes-192-cbc | aes-256-cbc}{ 0 unencrypted_key | 7 encrypted_key}{ md5 | sha1 }{ 0 unencrypted_key | 7 encrypted_key | KEY}
area area_id encryption ipsec spi spi_value esp null{ md5 | sha1 }{ 0 unencrypted_key | 7 encrypted_key | KEY}
area area_id encryption ipsec spi spi_value esp{3des-cbc | aes-128-cbc | aes-192-cbc | aes-256-cbc | null}{ md5 | sha1 }{ 0 unencrypted_key | 7 encrypted_key | LINE}
no area area_id encryption
default area area_id encryption
```

**Parameters**
- `area area_id` configures OSPF area ID in either IP address or decimal formats. The value for decimal format ranges from `0 to 4294967295`.
- `spi spi_value` configures the value for IPsec Security Parameter Index. The value ranges from `0 to 4294967295`.
- `3des-cbc` configures ESP with 3DES-CBC encryption.
- `aes-128-cbc` configures ESP with AES-128-CBC encryption.
- `aes-192-cbc` configures ESP with AES-192-CBC encryption.
- `aes-256-cbc` configures ESP with AES-256-CBC encryption.
- `null` configures ESP with null encryption.
- `0 unencrypted_key` configures either a 192 bit 3DES key or 128/192/256 bit AES key in an unencrypted format.
- `7 encrypted_key` configures either a 192 bit 3DES key or 128/192/256 bit AES key in an encrypted format.
- `KEY` configures either a 128 bit MD5 key or a 140 bit SHA1 key.
- `md5` configures HMAC-MD5 hash algorithm.
- `sha1` configures HMAC-SHA1 algorithm.
- `passphrase` configures passphrase for authentication and encryption. Options include:
  - `0 unencrypted_passphrase` configures an unencrypted key.
  - `7 encrypted_passphrase` configures an encrypted key.
  - `LINE` uses passphrase string to derive keys for authentication and encryption.

**Related Commands**
- `area authentication ipsec spi`
- `ospfv3 encryption ipsec spi`

**Guidelines**
Passphrase and `key` values are exclusive. MD5 and SHA1 keys are derived from the configured passphrase.

**Restriction**
On the same area, EOS allows security configuration with either AH or ESP but not both. We can have one area configured with AH and another with ESP.

**Examples**

- This command configures OSPFv3 security on an area with 3DES-CBC encryption and MD5 hash algorithm.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#area 0.0.0.0 encryption ipsec spi 5678 esp 3des-cbc md5 passphrase 0
8FD6158BBFE81ADD961241D8E4169D411
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  area 0.0.0.0 encryption ipsec spi 5678 esp 3des-cbc md5 passphrase
  7
$1$cnpcrQllczqdvKAzKLTyVr6I7+R3niuWouDkkyc6N0s4/XOWg/Iap5Q==
switch(config-router-ospf3)#
```

- This command deletes the OSPFv3 security on an area.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  area 0.0.0.0 encryption ipsec spi 5678 esp 3des-cbc md5 passphrase
  7
$1$cnpcrQllczqdvKAzKLTyVr6I7+R3niuWouDkkyc6N0s4/XOWg/Iap5Q==
switch(config-router-ospf3)#no area 0.0.0.0 encryption
switch(config-router-ospf3)#show active
ipv6 router ospf 9
switch(config-router-ospf3)#
```
The `area not-so-stubby lsa type-7 convert type-5` command configures the switch to always translate Type-7 Link-State Advertisement (LSAs) to Type-5 LSAs.

The `no area not-so-stubby lsa type-7 convert type-5` and `no area not-so-stubby lsa type-7 convert type-5` commands allow LSAs to be translated dynamically by removing the `no area not-so-stubby lsa type-7 convert type-5` command from the `running-config`.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

area `area_id` not-so-stubby lsa type-7 convert type-5
no area `area_id` not-so-stubby lsa type-7 convert type-5
default area `area_id` not-so-stubby lsa type-7 convert type-5

**Parameters**

`area_id`
- Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
- Area 0 (or 0.0.0.0) is not configurable; it is always normal.
- The `running-config` stores value in dotted decimal notation.

**Example**

These commands configure the switch to always translate Type-7 Link-State Advertisement (LSAs) to Type-5 LSAs.

```
switch(config)#ipv6 router ospf 3
switch(config-router-ospf3)#area 3 not-so-stubby lsa type-7 convert type-5
switch(config-router-ospf)#
```
15.3.5.6 area nssa (OSPFv3)

The `area nssa` command configures an OSPFv3 area as a Not-So-Stubby Area (NSSA). All routers in an AS must specify the same area type for identically numbered areas.

NSSA ASBRs advertise external LSAs that are part of the area, but do not advertise external LSAs from other areas.

Areas are normal by default; area type configuration is required only for stub NSSA areas. Area 0 is always a normal area and cannot be configured through this command.

The `no area nssa` command configures the specified area as a normal area by removing the specified `area nssa` command from `running-config`.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```plaintext
area area_id nssa [TYPE]
no area area_id nssa [TYPE]
default area area_id nssa [TYPE]
```

**Parameters**

- `area_id`
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - The `running-config` stores value in dotted decimal notation.

- `TYPE`
  - Values include:
    - `no parameter`
    - `nssa-only`

**Example**

This command configures area 3 as a NSSA area.

```
switch(config)#ipv6 router ospf 1
switch(config-router-ospf3)#area 3 nssa nssa-only
switch(config-router-ospf3)#
```
area nssa default-information-originate (OSPFv3)

The `area nssa default-information-originate` command sets an area as an NSSA and the generation of a type 7 default LSA is created if a default route exists in the routing table.

The switch supports three area types:

Areas are normal by default; area type configuration is required only for stub NSSA areas. Area 0 is always a normal area and cannot be configured through this command.

The `no area` and `default area` commands remove the specified area from the OSPFv3 instance by deleting all `area` commands from the `running-config` for the specified area, including the `area default-cost (OSPFv3)` command.

The `no area stub` and `default area stub` commands configure the specified area as a normal area.

Command Mode

Router-OSPFv3 Configuration

Command Syntax

```
area area_id nssa default-information-originate [VALUE][TYPE][EXCL]
no area area_id nssa default-information-originate [VALUE][TYPE][EXCL]
default area area_id nssa default-information-originate [VALUE][TYPE][EXCL]
```

Parameters

All parameters except `area_id` can be placed in any order.

- `area_id`.
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - `Running-config` stores value in dotted decimal notation.
- `VALUE` Values include:
  - `no parameter`.
  - metric 1-65535.
- `TYPE` Values include:
  - `no parameter`.
  - metric-type 1-2.
- `EXCL` Values include:
  - `no parameter`.
  - nssa-only.

Examples

- These commands sets area 1 as NSSA only and generates a type 7 default LSA if a default route exists in the routing table.

```
switch(config-router-ospf3)#area 3 nssa default-information-originate
nssa-only
switch(config-router-ospf3)#
```

- These commands generates a type 7 default route.

```
switch(config-router-ospf3)#area 3 nssa default-information-originate
switch(config-router-ospf3)#
```
15.3.5.8 area range (OSPFv3)

The **area range** command is used by OSPFv3 area border routers to summarize routes.

The **no area range** and **default area range** commands remove the area-range by deleting the corresponding **area range** command from the *running-config*.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```
area area_id range net_addr [ADVERTISE_SETTING][COST_SETTING]
no area area_id range net_addr [ADVERTISE_SETTING][COST_SETTING]
default area area_id range net_addr [ADVERTISE_SETTING][COST_SETTING]
```

**Parameters**

- **area_id**
  - 0 to 4294967295 or 0.0.0.0 to 255.255.255.255.
- **net_addr**
- **ADVERTISE_SETTING** specifies the LSA advertising activity. Values include:
  - no parameter
  - advertise
  - not-advertise
- **COST_SETTING** Values include:
  - no parameter
  - cost *range_cost* Value ranges from 1 to 65535.

**Examples**

- These commands summarize routes at an area boundary 1.

  ```
  switch(config)#ipv6 router ospf 1
  switch(config-router-ospf6-router)#area 1 range 2001:0DB8:0:1::/64
  switch(config-router-ospf3)#
  ```

- These commands modify the address range status to DoNotAdvertise.

  ```
  switch(config)#ipv6 router ospf 1
  switch(config-ospf6-router)#area 1 range 2001:0DB8:0:1::/64 not-advertise
  switch(config-ospf6-router)#
  ```
The `area stub` command configures the area type of an OSPFv3 area. Areas are normal by default. The `no area stub` command configures the specified area as a normal area.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```
area area_id stub
no area area_id stub
default area area_id stub
```

**Parameters**

*area_id*

- Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
- Area 0 (or 0.0.0.0) is not configurable; it is always normal.
- The `running-config` stores value in dotted decimal notation.

**Examples**

- This command configures area 45 as a stub area.

```
switch(config)#ipv6 router ospf 3
switch(config-router-ospf3)#area 45 stub
switch(config-router-ospf3)#
```

- This command configures area 10.92.148.17 as a stub area.

```
switch(config-router-ospf3)#area 10.92.148.17 stub
switch(config-router-ospf3)#
```
15.3.5.10 clear ospfv3 ipv6 force-spf

The clear ospfv3 ipv6 force-spf command starts the SPF algorithm without clearing the OSPF database.

Command Mode
Privileged EXEC

Command Syntax

```
clear ospfv3 ipv6 force-spf [VRF_INSTANCE]
```

Parameters

VRF_INSTANCE Values include:
- **no parameter** Action is performed in the default VRF.
- **vrf vrf_name** Action is performed in the specified VRF.

Example

This command restarts the SPF algorithm in the default VRF without first clearing the OSPFv3 database.

```
switch(config)# clear ospfv3 ipv6 force-spf
switch(config)#
```
15.3.5.11  default-information originate (OSPFv3)

The `default-information originate` command generates a default external route into an OSPF domain.

The `no default-information originate` and `default default-information originate` command removes the configuration from the `running-config`.

Command Mode

Router-OSPFv3 Configuration

Command Syntax

```
default-information originate [DURATION][VALUE][TYPE][MAP]
```

```
no default-information originate
```

```
default default-information originate
```

Parameters

All parameters can be placed in any order.

- **DURATION** Values include:
  - `no parameter`
  - `always`

- **VALUE** Values include:
  - `no parameter`
  - `metric 1-65535`

- **TYPE** Values include:
  - `no parameter`
  - `metric-type 1-2`

- **MAP** Values include:
  - `no parameter`
  - `route-map map_name`

Examples

- These commands will advertise the OSPFv3 default route regardless of whether the switch has a default route configured.

```
switch(config)#ipv6 router ospf 1
switch(config-router-ospf3)#default-information originate always
switch(config-router-ospf3)#show active
default-information originate always
```

- These commands configures OSPF area 1 as metric of 100 for the default route with an external metric type of *Type 1*.

```
switch(config)#ipv6 router ospf 1
switch(config-router-ospf3)#default-information originate metric 100
metric-type 1
switch(config-router-ospf3)#show active
ipv6 router ospf 1
default-information originate metric 100 metric-type 1
```

switch(config-router-ospf3)#
15.3.5.12  default-metric (OSPFv3)

The `default-metric` command sets default metric value for routes redistributed into the OSPFv3 domain.

The `no default-metric` and `default default-metric` commands restores the default metric to its default value of 10 by removing the `default-metric` command from the `running-config`.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**
```
default-metric def_metric
no default-metric
default default-metric
```

**Parameter**
`def_metric` Values range from 1 to 65535. Default value is 10.

**Example**
These commands configure a default metric of 30 for routes redistributed into OSPFv3.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#default-metric 30
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    default-metric 30
switch(config-router-ospf3)#
```
15.3.5.13 distance ospf intra-area (OSPFv3)

The `distance ospf intra-area` command sets the administrative distance for routes in a single OSPFv3 area. The default is 110.

The `no distance ospf intra-area` and `default distance ospf intra-area` commands remove the `distance ospf intra-area` command from the `running-config`, returning the OSPFv3 intra-area distance setting to the default value of 110.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

- `distance ospf intra-area distance`
- `no distance ospf intra-area`
- `default distance ospf intra-area`

**Parameter**

`distance` Values range from 1 to 255. Default is 110.

**Example**

This command configures a distance of 90 for all OSPFv3 intra-area routes on the switch.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#distance ospf intra-area 90
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  distance ospf intra-area 90
switch(config-router-ospf3)#
```
15.3.5.14  ipv6 ospf area

The `ipv6 ospf area` command enables OSPFv3 on the interface and associates the area to the interface.

OSPFv3 areas are configured in by `no area (OSPFv3)` commands in `router-OSPFv3` configuration mode.

The `no ipv6 ospf area` and `default ipv6 ospf area` commands disable OSPFv3 on the configuration mode interface by removing the corresponding `ipv6 ospf area` command from the `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ipv6 ospf process_id[area area_id]
no ipv6 ospf process_id[area area_id]
default ipv6 ospf process_id[area area_id]
```

**Parameters**

- `process_id` Values range from `1` to `65535`.
- `area_id`.
  - Valid formats: integer `0` to `4294967295`> or dotted decimal `0.0.0.0` to `255.255.255.255`.
  - *Running-config* stores value in dotted decimal notation.

**Example**

These commands enable OSPFv3 on VLAN interface `200` and associates area `0` to the interface.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ipv6 ospf 9 area 0
switch(config-if-Vl200)#show active
interface Vlan200
  ipv6 ospf 9 area 0.0.0.0
switch(config-if-Vl200)#
```
15.3.5.15 ipv6 router ospf

The `ipv6 router ospf` command places the switch in router-OSPFv3 configuration mode and creates and OSPFv3 instance if one does not already exist. Note that each OSPFv3 instance on the switch must have a unique process ID. A router ID for the new instance will be created if one does not already exist.

The `show ipv6 ospf` command displays the router ID of each OSPFv3 instance configured on the switch.

The `no ipv6 router ospf` and `default ipv6 router ospf` commands delete the OSPFv3 instance.

Refer to the **Router-OSPFv3 Configuration Mode** command for a list of commands available in router-OSPFv3 configuration mode.

**Command Mode**
Global Configuration

**Command Syntax**

`ipv6 router ospf process_id[ VRF_INSTANCE]`

`no ipv6 router ospf process_id[ VRF_INSTANCE]`

`default ipv6 router ospf process_id[ VRF_INSTANCE]`

**Parameters**

- `process_id` Values range from **1 to 65535**.
- `VRF_INSTANCE` Values include:
  - `no parameter` OSPF instance is in the default VRF.
  - `vrf vrf_name` OSPF instance is the specified VRF.

**Examples**

- This command creates an OSPFv3 instance in the default VRF with process ID **9**.

  ```
  switch(config)#ipv6 router ospf 9
  switch(config-router-ospf3)#show active
  ipv6 router ospf 9
  switch(config-router-ospf3)#
  ```

- This command deletes the OSPFv3 instance.

  ```
  switch(config)#no ipv6 router ospf 9
  switch(config)#
  ```
15.3.5.16 log-adjacency-changes (OSPFv3)

The log-adjacency-changes command enables syslog messages to be sent when it detects OSPFv3 link state changes or when it detects that a neighbor has gone up or down. Log message sending is enabled by default.

The default log-adjacency-changes command restores the default state by removing the log-adjacency-changes statement from the running-config.

The default option (sending a message only when a neighbor goes up or down) is active when the running-config does not contain any form of the command. Entering the command in any form replaces the previous command state in the running-config.

The no log-adjacency-changes disables link state change Syslog reporting.

The default log-adjacency-changes command restores the default state by removing the log-adjacency-changes detail or no log-adjacency-changes statement from the running-config.

Command Mode
Router-OSPFv3 Configuration

Command Syntax
log-adjacency-changes [INFO_LEVEL]
no log-adjacency-changes
default log-adjacency-changes

Parameters
INFO_LEVEL Options include:

- no parameter Sends messages when a neighbor goes up or down.
- detail Sends messages for all neighbor state changes.

Example
This command configures the switch to send a Syslog message when a neighbor state changes.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#log-adjacency-changes
switch(config-router-ospf3)#show active
ipv6 router ospf 9
    log-adjacency-changes
switch(config-router-ospf3)#
```
15.3.5.17 maximum-paths (OSPFv3)

The **maximum-paths** command sets the maximum number of parallel routes that OSPFv3 supports on the switch.

The **no maximum-paths** command restores the maximum number of parallel routes that OSPFv3 supports on the switch to the default value of 16 by removing the **maximum-paths** command from running-config.

Command Mode
Router-OSPFv3 Configuration

Command Syntax
```
maximum-paths paths
no maximum-paths
default maximum-paths
```

Parameters

**paths** Value range is platform dependent:

- **Arad**: Value ranges from 1 to 128. Default value is 128.
- **FM6000**: Value ranges from 1 to 32. Default value is 32.
- **PetraA**: Value ranges from 1 to 16. Default value is 16.
- **Trident**: Value ranges from 1 to 32. Default value is 32.
- **Trident II**: Value ranges from 1 to 128. Default value is 128.

Example

This command configures the maximum number of OSPFv3 parallel paths to 12.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#maximum-paths 12
switch(config-router-ospf3)#
```
15.3.5.18 max-metric router-lsa (OSPFv3)

The `max-metric router-lsa` command configures OSPF to include the maximum value in LSA metric fields to keep other network devices from using the switch as a preferred intermediate SPF hop.

The `no max-metric router-lsa` and `default max-metric router-lsa` commands disable the advertisement of a maximum metric.

Command Mode
Router-OSPFv3 Configuration

Command Syntax

```
max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]
no max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]
default max-metric router-lsa [EXTERNAL][STUB][STARTUP][SUMMARY]
```

Parameters

All parameters can be placed in any order.

- **EXTERNAL** Values include:
  - `no parameter` Default value of 1.
  - `external-lsa` Range: 1 to 16777215. The default value is 0xFF0000.

- **STUB** Values include:
  - `no parameter` Default value of 2.
  - `include-stub`.

- **STARTUP** Values include:
  - `no parameter`
  - `on-startup`
  - `on-startup wait-for-bgp`
  - `on-startup` Range: 5 to 86400.

  `wait-for-bgp` or an `on-start` time value is not included in `no` and `default` commands.

- **SUMMARY** Values include:
  - `no parameter` Metric is set to the default value of 1.
  - `summary-lsa`.
  - `summary-lsa` Range: 1 to 16777215.

Example

This command configures OSPFv3 to include the maximum value in LSA metric fields until BGP has converged:

```
switch(config-router-ospf3)#max-metric router-lsa on-startup wait-for-bgp
switch(config-router-ospf3)#
```
no area (OSPFv3)

The `no area` command removes all area configuration commands for the specified OSPFv3 area. Commands removed by the `no area` command include:

- area
- nssa
- range
- stub

Area settings can be removed individually; refer to the command description page of the desired command for details.

**Command Mode**

Router-OSPFv3 Configuration

**Command Syntax**

```
no area area_id [TYPE]
default area area_id [TYPE]
```

**Parameters**

- `area_id` area number.
  - Valid formats: integer 1 to 4294967295 or dotted decimal 0.0.0.1 to 255.255.255.255.
  - Area 0 (or 0.0.0.0) is not configurable; it is always normal.
  - The `running-config` stores value in dotted decimal notation.
- `TYPE` area type. Values include:
  - nssa.
  - nssa translate type7 always.
  - stub.
  - stub no-summary.

**Example**

This command remove the area 1 stub configuration.

```
switch(config)# ipv6 router ospf 9
switch(config-router-ospf3)# no area 1 stub
switch(config-router-ospf3)#
```
15.3.5.20 ospfv3 transmit-delay

The `ospfv3 transmit-delay` command configures the transmission delay for OSPFv3 packets.

The `no ospfv3 transmit-delay` and `default ospfv3 transmit-delay` commands restore the default transmission delay of 1 second on the configuration mode interface by removing the corresponding `ospfv3 transmit-delay` command from `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `ospfv3 transmit-delay trans`
- `no ospfv3 transmit-delay`
- `default ospfv3 transmit-delay`

**Parameter**

`trans` Value ranges from 1 to 65535; default is 1.

**Guideline**

Arista devices also support the legacy `ipv6 ospf transmit-delay` command in certain software releases of the EOS.

**Example**

This command configures a transmission delay of 10 seconds for VLAN 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 transmit-delay 10
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 transmit-delay 10
switch(config-if-Vl200)#
```
15.3.5.21 ospfv3 authentication ipsec spi

The ospfv3 authentication ipsec spi command configures OSPFv3 authentication on an interface.

The default ospfv3 authentication and no ospfv3 authentication commands delete the OSPFv3 authentication on an interface.

Command Mode
Interface-Ethernet Configuration

Command Syntax
ospfv3 authentication ipsec spi spi_value { md5 | sha1 } { 0 unencrypted_key | 7 hidden_key | KEY }

ospfv3 authentication ipsec spi spi_value { md5 | sha1 } passphrase { 0 unencrypted_passphrase | 7 hidden_passphrase | LINE }

no ospfv3 authentication
default ospfv3 authentication

Parameters
• spi spi_value configures IPsec Security Parameter Index. The value ranges from 0 to 4294967295.
• md5 configures HMAC-MD5 hash algorithm.
• sha1 configures HMAC-SHA1 algorithm.
• 0 unencrypted_key configures either a 192 bit 3DES key or 128/192/256 bit AES key in an unencrypted format.
• 7 encrypted_key configures either a 192 bit 3DES key or 128/192/256 bit AES key in an encrypted format.
• KEY configures either a 128 bit MD5 key or a 140 bit SHA1 key.
• passphrase configures passphrase for authentication and encryption. Options include:
  • 0 unencrypted_passphrase configures an unencrypted passphrase.
  • 7 encrypted_passphrase configures an encrypted passphrase.
  • LINE uses passphrase string to derive keys for authentication and encryption.

Related Commands
• area authentication ipsec spi
• ospfv3 encryption ipsec spi

Guidelines
Passphrase and key values are exclusive. MD5 and SHA1 keys are derived from the configured passphrase. Arista devices also support the legacy ipv6 ospf authentication ipsec spi command in certain software releases of the EOS.

Restriction
On the same interface, EOS allows security configuration with either AH or ESP but not both. We can have one interface configured with AH and another with ESP.

Examples
• This command configures OSPFV3 authentication on an interface with MD5 hash algorithm.

```sh
switch(config)#interface ethernet 9

switch(config-if-Et9)#
15.3.5.22 ospfv3 cost

The ospfv3 cost command sets the OSPFv3 cost for the interface. The default OSPFv3 cost is 10. The no ospfv3 cost and default ospfv3 cost commands restore the default cost of 10 for the configuration mode interface by removing the corresponding ospfv3 cost command from the running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax
 ospfv3 cost interface_cost
 no ospfv3 cost
 default ospfv3 cost

Parameters
interface_cost Value ranges from 1 to 65535; default is 10.

Guideline
Arista devices also support the legacy ipv6 ospf cost command in certain software releases of the EOS.

Example
This command configures a cost of 50 for vlan 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 cost 50
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 cost 50
switch(config-if-Vl200)#
```
15.3.5.23  ospfv3 dead-interval

The `ospfv3 dead-interval` command sets the OSPFv3 dead interval.

The `no ospfv3 dead-interval` and `default ospfv3 dead-interval` commands restore the default dead interval of 40 seconds on the configuration mode interface by removing the corresponding `ospfv3 dead-interval` command from the `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
ospfv3 dead-interval time
no ospfv3 dead-interval
default ospfv3 dead-interval
```

**Parameter**

`time` Value ranges from 1 to 65535; default is 40.

**Guideline**

Arista devices also support the legacy `ipv6 ospf dead-interval` command in certain software releases of the EOS.

**Example**

This command configures a dead interval of 75 seconds for `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 dead-interval 75
switch(config-if-Vl200)#show active
interface Vlan200
    ospfv3 dead-interval 75
switch(config-if-Vl200)#
```
The `ospfv3 encryption ipsec spi` command configures OSPFv3 security on an interface. The `default ospfv3 encryption` and `no ospfv3 encryption` commands delete the OSPFv3 security on an interface.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
ospfv3 encryption ipsec spi spi_value esp { 3des-cbc | aes-128-cbc | aes-128-cbc | aes-192-cbc}|\{ 0unencrypted_key | 7 encrypted_key}\{ md5 | sha1}\{ 0unencrypted_key | 7 encrypted_key | KEY\}
```

```
ospfv3 encryption ipsec spi spi_value esp { 3des-cbc | aes-128-cbc | aes-128-cbc | aes-192-cbc}|\{ 0unencrypted_key | 7 encrypted_key\}\{ md5 | sha1\} passphrase { 0unencrypted_passphrase | 7 encrypted_passphrase | LINE\}
```

```
ospfv3 encryption ipsec spi spi_value esp null { md5 | sha1}\{ 0unencrypted_key | 7 encrypted_key | KEY\}
```

```
ospfv3 encryption ipsec spi spi_value esp { md5 | sha1\} passphrase { 0unencrypted_passphrase | 7 encrypted_passphrase | LINE\}
```

```
default ospfv3 encryption
```

```
no ospfv3 encryption
```

**Parameters**

- `spi spi_value` configures the value for IPsec Security Parameter Index. The value ranges from 0 to 4294967295.
- `3des-cbc` configures ESP with 3DES-CBC encryption.
- `aes-128-cbc` configures ESP with AES-128-CBC encryption.
- `aes-192-cbc` configures ESP with AES-192-CBC encryption.
- `aes-256-cbc` configures ESP with AES-256-CBC encryption.
- `null` configures ESP with null encryption.
- `0 unencrypted_key` configures either a 192 bit 3DES key or 128/192/256 bit AES key in an unencrypted format.
- `7 encrypted_key` configures either a 192 bit 3DES key or 128/192/256 bit AES key in an encrypted format.
- `md5` configures HMAC-MD5 hash algorithm.
- `sha1` configures HMAC-SHA1 algorithm.
- `KEY` configures either a 128 bit MD5 key or a 140 bit SHA1 key.
- `passphrase` configures passphrase for authentication and encryption. Options include:
  - `0 unencrypted_passphrase` configures an unencrypted passphrase.
  - `7 encrypted_passphrase` configures an encrypted passphrase.
  - `LINE` uses passphrase string to derive keys for authentication and encryption.

**Related Commands**

- `area encryption ipsec spi`
- `ospfv3 authentication ipsec spi`

**Guidelines**

Passphrase and key value are exclusive. MD5 and SHA1 keys are derived from the configured passphrase. Arista devices also support the legacy `ipv6 ospf encryption ipsec spi` command in certain software releases of the EOS.
Restrictions
On the same interface, EOS allows security configuration with either AH or ESP but not both. We can have one interface configured with AH and another with ESP.

Examples
• This command configures OSPFv3 security on an interface with 3DES-CBC encryption and SHA1 algorithm.

```
switch(config)#interface ethernet 9
switch(config-if-Et9)#ospfv3 encryption ipsec spi 345 esp 3des-cbc sha1
    passphrase 0 2fd4e1c67a2d28fced849ee1bb76e7391b93eb12
switch(config-if-Et9)#show active
interface Ethernet9
    no switchport
ospfv3 encryption ipsec spi 345 esp 3des-cbc sha1 passphrase 7
    $1$VmUkWk61L2S343bR3BbH0RhgvxHhwBpfvB4VXKNOOQF7HJBp5VvXTfBaVYbgCkWU
switch(config-if-Et9)#
```

• This command configures OSPFv3 security on an interface with 3DES-CBC encryption and MD5 hash algorithm.

```
switch(config)#interface ethernet 9
switch(config-if-Et9)#ospfv3 encryption ipsec spi 345 esp 3des-cbc md5
    passphrase 7 $1$VmUkWk61L2S343bR3BbH0RhgvxHhwBpfvB4VXKNOOQF7HJBp5VvXTfBaVYbgCkWU
switch(config-if-Et9)#show active
interface Ethernet9
    no switchport
ospfv3 encryption ipsec spi 345 esp 3des-cbc md5 passphrase 7
    $1$VmUkWk61L2S343bR3BbH0RhgvxHhwBpfvB4VXKNOOQF7HJBp5VvXTfBaVYbgCkWU
switch(config-if-Et9)#
```

• This command deletes the OSPFv3 security on an interface.

```
switch(config)#interface ethernet 9
switch(config-if-Et9)#show active
interface Ethernet9
    no switchport
ospfv3 encryption ipsec spi 3456 md5 7 $1$xtmcMSPzEn+Njp8Lb4qryVV0jKcjarYuv6dx10+nSwKQda1RT2RPTQ==
switch(config-if-Et9)#no ospfv3 encryption
switch(config-if-Et9)#show active
interface Ethernet9
    no switchport
switch(config-if-Et9)#
```
15.3.5.25  ospfv3 hello-interval

The `ospfv3 hello-interval` command sets the OSPFv3 hello interval. The hello interval is the period between the transmission of consecutive hello packets.

Each OSPFv3 neighbor should be the same hello interval and should not be longer than any neighbors dead interval.

The `no ospfv3 hello-interval` and `default ospfv3 hello-interval` commands restore the default hello interval of 10 seconds on the configuration mode interface by removing the `ospfv3 hello-interval` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
- `ospfv3 hello-interval time`
- `no ospfv3 hello-interval`
- `default ospfv3 hello-interval`

**Parameter**
- `time`: Values range from 1 to 65535; default is 10.

**Guideline**
Arista devices also support the legacy `ipv6 ospf hello-interval` command in certain software releases of the EOS.

**Example**
This command configures a hello interval of 45 seconds for VLAN 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 hello-interval 45
switch(config-if-Vl200)#show active
interface Vlan200
    ospfv3 hello-interval 45
switch(config-if-Vl200)#
```
15.3.5.26  ospfv3 ipv6 retransmit-interval

The `ospfv3 ipv6 retransmit-interval` command configures the link state advertisement retransmission interval.

The `no ospfv3 ipv6 retransmit-interval` and `default ospfv3 ipv6 retransmit-interval` commands restore the default retransmission interval of 5 seconds on the configuration mode interface by removing the corresponding `ospfv3 ipv6 retransmit-interval` command from the `running-config`.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-Channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `ospfv3 ipv6 retransmit-interval period`
- `no ospfv3 ipv6 retransmit-interval`
- `default ospfv3 ipv6 retransmit-interval`

**Parameter**

`period` Value ranges from 1 to 65535; default is 5.

**Example**

This command configures a retransmission interval of 25 seconds for `vlan 200`.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 ipv6 retransmit-interval 25
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 ipv6 retransmit-interval 25
switch(config-if-Vl200)#
```
15.3.5.27  ospfv3 network

The `ospfv3 network` command sets the configuration mode interface as a point-to-point link. By default, interfaces are set as broadcast links.

The `no ospfv3 network` and `default ospfv3 network` commands set the configuration mode interface as a broadcast link by removing the corresponding `ospfv3 network` command from the `running-config`.

Command Mode

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

 ospfv3 network point-to-point
 no ospfv3 network
 default ospfv3 network

Guideline

Arista devices also support the legacy `ipv6 ospf network` command in certain software releases of the EOS.

Examples

- This command configures VLAN interface 200 as a point-to-point link.

  switch(config)#interface vlan 200
  switch(config-if-Vl200)#ospfv3 network point-to-point
  switch(config-if-Vl200)#show active
  interface Vlan200
  ospfv3 network point-to-point
  switch(config-if-Vl200)#

- This command restores Ethernet interface 10 as a broadcast link.

  switch(config)#interface vlan 200
  switch(config-if-Vl200)#no ospfv3 network
  switch(config-if-Vl200)#show active
  interface Vlan200
  switch(config-if-Vl200)#
15.3.5.28  ospfv3 priority

The ospfv3 priority command configures the OSPFv3 router priority.

The no ospfv3 priority and default ospfv3 priority commands restore the default priority (1) on the interface by removing the corresponding ospfv3 priority command from the running-config.

Command Mode

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax

ospfv3 priority priority_level
no ospfv3 priority
default ospfv3 priority

Parameter

priority_level Settings range from 0 to 255.

Guideline

Arista devices also support the legacy ipv6 ospf priority command in certain software releases of the EOS.

Example

This command configures a router priority of 128 for vlan 200.

```
switch(config)#interface vlan 200
switch(config-if-Vl200)#ospfv3 priority 128
switch(config-if-Vl200)#show active
interface Vlan200
  ospfv3 priority 128
switch(config-if-Vl200)#
```
passive-interface (OSPFv3)

The **passive-interface** command disables OSPF on an interface range. All interfaces are active by default.

The **no passive-interface** and **default passive-interface** commands enable OSPFv3 on the specified interface range by removing the corresponding **passive-interface** statements from the **running-config**.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```
passive-interface INTERFACE_NAME
no passive-interface INTERFACE_NAME
default passive-interface INTERFACE_NAME
```

**Parameters**

- **INTERFACE_NAME** Options include:
  - ethernet *e_range*
  - loopback *l_range*
  - management *m_range*
  - port-channel *p_range*
  - vlan *v_range*
  - vxlan *vx_range*
  - default

Valid **e_range**, **l_range**, **m_range**, **p_range**, **v_range**, and **vx_range** formats include number, range, or comma-delimited list of numbers and ranges.

**Example**

This command configures VLAN interfaces 101 through 103 as passive interfaces.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#passive-interface vlan 101-103
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  passive-interface Vlan101
  passive-interface Vlan102
  passive-interface Vlan103
switch(config-router-ospf3)#
```
15.3.5.30 redistribute (OSPFv3)

The `redistribute` command enables the advertising of all specified routes into the OSPFv3 domain as external routes.

The `no redistribute` and `default redistribute` commands remove the corresponding `redistribute` command from the `running-config`, disabling route redistribution for the specified route type.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

redistribute ROUTE_TYPE ROUTE_MAP
no redistribute ROUTE_TYPE
default redistribute ROUTE_TYPE

**Parameters**

- **ROUTE_TYPE** Options include:
  - BGP
  - connected
  - static

- **ROUTE_MAP** Options include:
  - route-map `map_name`

**Example**

The `redistribute static` command starts the advertising of static routes as OSPFv3 external routes.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#redistribute static
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  redistribute connected
  redistribute static
switch(config-router-ospf3)#
```
The `router-id` command assigns the router ID for an OSPFv3 instance. The switch sets the router ID to the first available alternative in the following list:

1. The `router-id` command.
2. The loopback IP address.
3. The highest IP address present on the device.

**Note:** When configuring VXLAN on an MLAG, always manually configure the OSPFv3 router ID to prevent the switch from using the common VTEP IP address as the router ID.

The `no router-id` and `default router-id` commands remove the router ID command from the `running-config`.

**Command Mode**
Router-OSPFv3 Configuration

**Command Syntax**

```
router-id identifier
no router-id
default router-id
```

**Parameters**

`identifier` Value ranges from **0.0.0.0 to 255.255.255.255** (dotted decimal notation).

**Example**

This command assigns **10.10.1.4** as the router ID for the OSPFv3 instance.

```bash
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#router-id 10.10.1.4
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  router-id 15.10.1.4
switch(config-router-ospf3)#
```
15.3.5.32  show ipv6 ospf border-routers

The `show ipv6 ospf border-routers` command displays the OSPF routing table entries.

**Command Mode**
EXEC

**Command Syntax**
`show ipv6 ospf border-routers [VRF_INSTANCE]`

**Parameters**
- **VRF_INSTANCE** Values include:
  - *no parameter* Displays information for all VRFs.
  - *vrf vrf_name* Displays information for the specified VRF.

**Example**
This command displays the ABRs and ASBRs configured in the switch in all VRFs.

```
switch#show ipv6 ospf border-routers
Routing Process "ospf 9", VRF default
 Router 10.37.0.32 area 0.0.0.0 ASBR
 Router 10.37.0.18 area 0.0.0.0 ASBR
 Router 10.37.0.22 area 0.0.0.0 ASBR ABR
 Router 10.37.0.31 area 0.0.0.0 ASBR ABR
 Router 10.37.0.58 area 0.0.0.0 ASBR
 Router 10.37.0.37 area 0.0.0.0 ASBR
 Router 10.37.0.22 area 0.0.0.2 ASBR ABR
 Router 10.37.0.31 area 0.0.0.2 ASBR ABR
switch>
```
15.3.5.33 show ipv6 ospf database link if-name

The `show ipv6 ospf database link` command displays link state advertisement details. The switch can return link state data about a single area or for all areas on the switch.

**Command Mode**
EXEC

**Command Syntax**
```
show ipv6 ospf database link if-name [INTF_ID][LS_ID][ROUTER][DATA_LEVEL]
```

**Parameters**
- **INTF_ID** Options include:
  - `ethernet` `e_range` Ethernet interface list.
  - `loopback` `l_range` Loopback interface list.
  - `management` `m_range` Management interface list.
  - `port-channel` `p_range` Channel group interface list.
  - `vlan` `v_range` VLAN interface list.
  - `vxlan` `vx_range` VXLAN interface list.
  Valid `range` formats include number, range, or comma-delimited list of numbers and ranges.
- **LS_ID** Options include:
  - `no parameter`
  - `A.B.C.D`
- **ROUTER** Options include:
  - `no parameter`
  - `adv-router a.b.c.d`
  - `self-originate`
- **DATA_LEVEL** Options include:
  - `no parameter`
  - `detail`

**Example**
This command displays information for *Ethernet 4/1* link state advertisements.

```
switch#show ipv6 ospf database link if-name ethernet 4/1
Codes: AEX - AS External, GRC - Grace,
      IAP - Inter Area Prefix, IAR - Inter Area Router,
      LNK - Link, NAP - Intra Area Prefix,
      NSA - Not So Stubby Area, NTW - Network,
      RTR - Router
Routing Process "ospf 1":
switch>
```

2374
15.3.5.34  show ipv6 ospf database link if-type

The `show ipv6 ospf database link` command displays information of the link state advertisements. The switch can return link state data about a single area or for all areas on the switch.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 ospf database link if-type [INTF_TYPE][LS_ID][ROUTER][DATA_LEVEL]
```

**Parameters**

- **INTF_TYPE**
  - broadcast
  - nbma
  - p2mp
  - p2p
- **LS_ID** Options include:
  - no parameter
  - A.B.C.D
- **ROUTER** Options include:
  - no parameter
  - adv-router a.b.c.d
  - self-originate
- **DATA_LEVEL** Options include:
  - no parameter
  - detail

**Example**

This command displays LSA information for the interfaces configured for broadcast transmissions.

```
switch#show ipv6 ospf database link if-type broadcast
Codes: AEX - AS External, GRC - Grace,
       IAP - Inter Area Prefix, IAR - Inter Area Router,
       LNK - Link, NAP - Intra Area Prefix,
       NSA - Not So Stubby Area, NTW - Network,
       RTR - Router

15.3.5.35  show ipv6 ospf database <link state list>

The show ipv6 ospf database command displays the OSPF link state advertisements that originate on a switch.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 ospf database [FILTER][LINKSTATE_ID][ROUTER][DATA_LEVEL]`

**Parameters**

- **FILTER** Filters the output of the command by specifying areas. Options include:
  - no parameter
  - area A.B.C.D
  - area backbone
  - as
  - as external
- **LINKSTATE_ID** Options include:
  - no parameter
  - A.B.C.D
- **ROUTER** Options include:
  - no parameter
  - adv-router a.b.c.d
  - self originate
- **DATA_LEVEL** Options include:
  - no parameter
  - detail

**Example**

This command displays the OSPFv3 database of link state advertisements.

```
switch#show ipv6 ospf database 10.26.0.23
Codes: AEX - AS External, GRC - Grace,
IAP - Inter Area Prefix, IAR - Inter Area Router,
LNK - Link, NAP - Intra Area Prefix,

15.3.5.36  **show ipv6 ospf database link**

The **show ipv6 ospf database link** command displays details of the specified link state advertisements. The switch can return link state data about a single area or for all areas on the switch.

**Command Mode**
EXEC

**Command Syntax**

```
show ipv6 ospf database link [LINKSTATE_ID][ROUTER][DATA_LEVEL]
```

**Parameters**

- **LINKSTATE_ID** Options include:
  - `no parameter`
  - `A.B.C.D`
- **ROUTER** Options include:
  - `no parameter`
  - `adv-router a.b.c.d`
  - `self-originate`
- **DATA_LEVEL** Options include:
  - `no parameter`
  - `detail`

**Example**

This command displays information about the Open Shortest Path First (OSPF).

```
switch#show ipv6 ospf database link
Codes: AEX - AS External, GRC - Grace,
IAP - Inter Area Prefix, IAR - Inter Area Router,
LNK - Link, NAP - Intra Area Prefix,
NSA - Not So Stubby Area, NTW - Network,
RTR - Router

Routing Process "ospf 9":

switch>
```
show ipv6 ospf database

The `show ipv6 ospf database` command displays data from the OSPF database. The switch can return link state data for a single VRF or for all VRFs on the switch.

Command Mode
EXEC  

Command Syntax
`show ipv6 ospf database [VRF_INSTANCE]`

Parameters
- **VRF_INSTANCE** Values include:
  - *no parameter* Displays information for all VRFs.
  - *vrf vrf_name* Displays information for the specified VRF.

Example
This command displays OSPF database information for VRF blue.

```bash
switch# show ipv6 ospf database vrf blue
Codes: AEX - AS External, GRC - Grace,
  IAP - Inter Area Prefix, IAR - Inter Area Router,
  LNK - Link, NAP - Intra Area Prefix,
  NSA - Not So Stubby Area, NTW - Network,
  RTR - Router
Routing Process "ospf 9", VRF blue
AS Scope LSDB
switch>
```
show ipv6 ospf database <link-state details>

The `show ipv6 ospf database <link-state details>` command displays detailed information about the specified link state advertisements. The switch can return link state data about a single area or for all areas on the switch.

**Command Mode**
EXEC

**Command Syntax**
```
show ipv6 ospf database [FILTER][LINK_TYPE][LINKSTATE_ID][ROUTER][DATA_LEVEL]
```

**Parameters**
- **FILTER** Filters the output of the command by specifying areas. Options include:
  - `area A.B.C.D`
  - `area backbone`
- **LINK_TYPE** Parameter options include:
  - `router`
  - `network`
  - `inter-area-prefix`
  - `inter-area-router`
  - `intra-area-prefix`
  - `nssa`
- **LINKSTATE_ID** Options include:
  - `no parameter`
  - `A.B.C.D`
- **ROUTER** Options include:
  - `no parameter`
  - `adv-router a.b.c.d`
  - `self-originate`
- **DATA_LEVEL** Options include:
  - `no parameter`
  - `detail`

**Example**

This command displays the OSPF database summary.

```
switch# show ipv6 ospf database detail
Codes: AEX - AS External, GRC - Grace,
      IAP - Inter Area Prefix, IAR - Inter Area Router,
      LNK - Link, NAP - Intra Area Prefix,
      NSA - Not So Stubby Area, NTW - Network,
      RTR - Router

switch>
show ipv6 ospf interface

The `show ipv6 ospf interface` command displays OSPFv3 information on interfaces where OSPFv3 is enabled.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 ospf interface [VRF_INSTANCE]`

**Parameters**

- **VRF_INSTANCE** Values include:
  - *no parameter* Displays information for all VRFs.
  - `vrf vrf_name` Displays information for the specified VRF.

**Example**

This command displays OSPFv3 information for interfaces where OSPFv3 is enabled.

```
switch#show ipv6 ospf interface
Ethernet17 is up
  Interface Address fe80::48c:73ff:fe00:1319, VRF default, Area 0.0.0.0
  Network Type Broadcast, Cost 10
  Transmit Delay is 1 sec, State Backup DR, Priority 1
  Designated Router is 10.37.0.37
  Backup Designated Router is 10.37.0.23
  Timer intervals configured, Hello 10, Dead 40, Retransmit 5
  Neighbor Count is 1
  Options are R E V6

Vlan31 is up

  Neighbor Count is 2
  Options are R E V6
switch>
```
15.3.5.40  show ipv6 ospf lsa-log

The `show ipv6 ospf lsa-log` command displays log entries when LSA update messages are sent or received for OSPFv3.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 ospf [PROCESS_ID] lsa-log [VRF_INSTANCE]`

**Parameters**

- **PROCESS_ID** OSPFv3 process ID. Values include:
  - no parameter Displays information for all process IDs.
  - 1 to 65535 Displays information for the specified process ID.
- **VRF_INSTANCE** Values include:
  - no parameter Displays information for all VRFs.
  - vrf `vrf_name` Displays information for the specified VRF.

**Example**

This command displays log entries when LSA update messages are sent or received for OSPFv3.

```
switch# show ipv6 ospf lsa-log
OSPF3 Process 3.3.3.3, VRF default, LSA Throttling Log:
[04:21:09] type 1: 3.3.3.3/32 [3.3.3.3], event 1, backed off, new hold 
  value 2000 msecs
[04:21:08] type 1: 3.3.3.3/32 [3.3.3.3], event 2, backoff restarted, new 
  hold value 900 msecs

  hold value 1000 msecs
switch>
```
show ipv6 ospf neighbor state

The show ipv6 ospf neighbor state command displays the state information on OSPF neighbors on a per-interface basis.

Command Mode
EXEC

Command Syntax
show ipv6 ospf neighbor state STATE_NAME [VRF_INSTANCE]

Parameters
- **STATE_NAME** Values include:
  - 2-ways
  - attempt
  - down
  - exch-start
  - exchange
  - full
  - restart
  - init
  - loading
- **VRF_INSTANCE** Values include:
  - no parameter Displays information for all VRFs.
  - vrf vrf_name Displays information for the specified VRF.

Example
This command displays OSPF information for neighboring devices that are adjacent.

```
switch# show ipv6 ospf neighbor state full
Routing Process "ospf 3":
switch>
```
15.3.5.42  show ipv6 ospf neighbor summary

The `show ipv6 ospf neighbor summary` command displays a single line of state information for each OSPFv3 neighbor.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 ospf neighbor summary [VRF_INSTANCE]`

**Parameters**

`VRF_INSTANCE` Values include:

- `no parameter` Displays information for all VRFs.
- `vrf vrf_name` Displays information for the specified VRF.

**Example**

This command shows the summary information for the OSPFv3 neighbors.

```
switch#show ipv6 ospf neighbor summary
Routing Process "ospf 1":
  3 neighbors are in state Down
  3 neighbors are in state Full
  5 neighbors are in state Init
  0 neighbors are in state Loading
  0 neighbors are in state Attempt
  3 neighbors are in state Restarting
  0 neighbors are in state Exchange
  3 neighbors are in state 2 Ways
  0 neighbors are in state Exch Start
switch>
```
15.3.5.43  show ipv6 ospf neighbor

The `show ipv6 ospf neighbor` command displays OSPFv3 neighbor information.

**Command Mode**

EXEC

**Command Syntax**

`show ipv6 ospf neighbor [VRF_INSTANCE]`

**Parameters**

**VRF_INSTANCE** Values include:

- `no parameter` Displays information for all VRFs.
- `vrf vrf_name` Displays information for the specified VRF.

**Example**

This command displays the switch's neighbors.

```
switch#show ipv6 ospf neighbor
Routing Process "ospf 9":

switch>
```
15.3.5.44  **show ipv6 ospf spf-log**

The `show ipv6 ospf spf-log` command displays when and how long the switch took to run a full SPF calculation for OSPFv3.

**Command Mode**

EXEC

**Command Syntax**

```
show ipv6 ospf [PROCESS_ID] spf-log [VRF_INSTANCE]
```

**Parameters**

- **PROCESS_ID** OSPFv3 process ID. Values include:
  - *no parameter* Displays information for all process IDs.
  - *1 to 65535* Displays information for the specified process ID.
- **VRF_INSTANCE** Values include:
  - *no parameter* Displays information for all VRFs.
  - *vrf vrf_name* Displays information for the specified VRF.

**Example**

This command displays the SPF information for OSPFv3 in all VRFs.

```
switch#show ipv6 ospf spf-log
OSPF3 Process 172.26.0.22, VRF default
TIME          EVENT                     REASON

04:53:33.081  Scheduled after 0 ms     ECMP max nexthop cfg change
switch>
```
The `show ipv6 ospf` command displays information about OSPFv3 routing.

**Command Mode**
EXEC

**Command Syntax**
```
show ipv6 ospf [access-list | border-routers | database | interface | lsa-log | neighbor | request-list | retransmission-list | spf-log | vrf ] Process ID
```

**Parameters**
- **no parameters** displays the complete configuration of OSPFv3 address family and routing process.
- **access-list** displays the information of configured OSPFv3 access-list. Options include:
  - **no parameters** displays the information of all configured OSPFv3 access lists.
  - **WORD** displays the information of the specified access list.
  - **summary** displays the summary of all configured access lists.
- **border-routers** displays the information of configured OSPFv3 border and boundary routers. Options include:
  - **no parameters** displays the information of all configured OSPFv3 borders and boundary routers.
  - **vrf** displays the OSPFv3 borders and boundary routers information of the specified Virtual Routing and Forwarding (VRF).
- **database** displays the summary of database. Options include:
  - **no parameters** displays the complete summary of database.
  - **ipv4** displays the database information of link state ID.
  - **adv-router** displays the database information of advertising router link states.
  - **area** displays the database information filtered by area scope LSAs.
  - **as** displays the database information filtered by AS scope LSAs.
  - **database-summary** displays the count of LSAs in OSPFv3 database.
  - **detail** displays the detailed information of LSA.
  - **link** displays the database information filtered by link scoped LSAs.
  - **self-originate** displays the database information of self-originated link states.
  - **vrf** displays the VRF information in OSPFv3 database.
- **interface** displays the information of OSPFv3 interfaces. Options include:
  - **no parameters** displays the information of all OSPFv3 interfaces.
  - **Ethernet eth_num** displays the information of the specified Ethernet interface. The value ranges from 1 to 24.
  - **Loopback lb_num** displays the information of the specified loop back interface. The value ranges from 0 to 1000.
  - **Port-Channel pc_num** displays the interface or sub-interface information of the specified port channel. The interface and sub-interface values of port channel ranges from 1-1000 and 1-2000, 1-4094 respectively.
  - **Tunnel t_num** displays the information of the specified tunnel. The value ranges from 0 to 255.
  - **Vlan vlan_num** displays the information of the specified VLAN interface. The value ranges from 1 to 4094.
  - **vrf vrf_name** displays the information of the specified VRF.
- **lsa-log** displays the log entries of OSPFv3 LSA updates.
- **neighbor** displays the list of OSPFv3 neighbors.
- **request-list** displays the list of all OSPFv3 LSAs requested by a router.
- **retransmission-list** displays the list of all OSPFv3 LSAs waiting to be re-sent.
- **spf-log** displays the start-time, duration of completion, and reason of delay to calculate the OSPFv3 Sender Policy Framework (SPF).
- **vrf vrf_name** displays the information of specified VRF.
- **Process ID** displays the OSPFv3 configuration of the specified process ID. The value ranges from **1 to 65535**.

**Examples**

- This command displays OSPFv3 routing information for all VRFs.

```
switch#show ipv6 ospf
Routing Process "ospfv3 0" with ID 11.1.11.1 and Instance 0 VRF default
FIPS mode disabled
It is not an autonomous system boundary router and is not an area border router
Minimum LSA arrival interval 1000 msecs
Initial LSA throttle delay 1000 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
It has 0 fully adjacent neighbors
Number of areas in this router is 0. 0 normal, 0 stub, 0 nssa
Number of LSAs 0
Initial SPF schedule delay 0 msecs
Minimum hold time between two consecutive SPFs 5000 msecs
Current hold time between two consecutive SPFs 5000 msecs
Maximum wait time between two consecutive SPFs 5000 msecs
SPF algorithm last executed 00:07:13 ago
No scheduled SPF
Adjacency exchange-start threshold is 20
Maximum number of next-hops supported in ECMP is 32
Number of backbone neighbors is 0
Graceful-restart is not configured
Graceful-restart-helper mode is enabled
```

- This command displays the log entries of OSPFv3 LSA updates.

```
switch#show ipv6 ospf lsa-log

2391
The `show ospfv3` command displays the OSPFv3 configuration of OSPFv3 address family and routing process.

**Command Mode**

**EXEC Command Syntax**

```bash
show ospfv3 [access-list | border-routers | database | interface | ipv4 | ipv6 | lsa-log | neighbor | request-list | retransmission-list | spf-log | vrf]
```

**Parameters**

- **no parameters** displays the complete configuration of OSPFv3 address family and routing process.
- **access-list** displays the information of configured OSPFv3 access-list. Options include:
  - **no parameters** displays the information of all configured OSPFv3 access lists.
  - **WORD** displays the information of the specified access list.
  - **summary** displays the summary of all configured access lists.
- **border-routers** displays the information of configured OSPFv3 border and boundary routers. Options include:
  - **no parameters** displays the information of all configured OSPFv3 borders and boundary routers.
  - **vrf** displays the OSPFv3 borders and boundary routers information of the specified Virtual Routing and Forwarding (VRF).
- **database** displays the summary of database. Options include:
  - **no parameters** displays the complete summary of database.
  - **ipv4** displays the database information of link state ID.
  - **adv-router** displays the database information of advertising router link states.
  - **area** displays the database information filtered by area scope LSAs.
  - **as** displays the database information filtered by AS scope LSAs.
  - **database-summary** displays the count of LSAs in OSPFv3 database.
  - **detail** displays the detailed information of LSA.
  - **link** displays the database information filtered by link scoped LSAs.
  - **self-originate** displays the database information of self-originated link states.
  - **vrf** displays the VRF information in OSPFV3 database.
- **interface** displays the information of OSPFv3 interfaces. Options include:
  - **no parameters** displays the information of all OSPFv3 interfaces.
  - **Ethernet eth_num** displays the information of the specified Ethernet interface. The value ranges from 1 to 24.
  - **Loopback lb_num** displays the information of the specified loop back interface. The value ranges from 0 to 1000.
  - **Port-Channel pc_num** displays the interface or sub-interface information of the specified port channel. The interface and sub-interface values of port channel ranges from 1-1000 and 1-2000, 1-4094 respectively.
  - **Tunnel t_num** displays the information of the specified tunnel. The value ranges from 0 to 255.
  - **Vlan vlan_num** displays the information of the specified VLAN interface. The value ranges from 1 to 4094.
  - **vrf vrf_name** displays the information of the specified VRF.
- **ipv4** displays the IPv4 address family information.
- **ipv6** displays the IPv6 address family information.
- **lsa-log** displays the log entries of OSPFv3 LSA updates.
- **neighbor** displays the list of OSPFv3 neighbors.
Routing Protocols

- **request-list** displays the list of all OSPFv3 LSAs requested by a router.
- **retransmission-list** displays the list of all OSPFv3 LSAs waiting to be re-sent.
- **spf-log** displays the start-time, duration of completion, and reason of delay to calculate the OSPFv3 Sender Policy Framework (SPF).
- **vrf vrf_name** displays the information of specified VRF.

**Examples**

- This command displays the complete configuration of OSPFv3 address family and routing process.

```plaintext
switch#show ospfv3
OSPFv3 address-family ipv6
Routing Process "ospfv3" with ID 13.13.13.13 and Instance 0 VRF default
  FIPS mode disabled
  It is not an autonomous system boundary router and is not an area border router
  Minimum LSA arrival interval 1000 msecs
  Initial LSA throttle delay 1000 msecs
  Minimum hold time for LSA throttle 5000 msecs
  Maximum wait time for LSA throttle 5000 msecs
  Interface flood pacing timer 50 msecs
  It has 0 fully adjacent neighbors
  Number of areas in this router is 1. 1 normal, 0 stub, 0 nssa
  Number of LSAs 1
  Initial SPF schedule delay 0 msecs
  Minimum hold time between two consecutive SPFs 5000 msecs
  Maximum wait time between two consecutive SPFs 5000 msecs
  SPF algorithm last executed 3d23h ago
  No scheduled SPF
  Adjacency exchange-start threshold is 20
  Maximum number of next-hops supported in ECMP is 32
  Number of backbone neighbors is 0
  Graceful-restart is not configured
  Graceful-restart-helper mode is enabled
  Area 0.0.0.0
    Number of interface in this area is 0
    It is a normal area
    SPF algorithm executed 2 times
```

- This command displays the count of LSAs in OSPFv3 database.

```
15.3.5.47 shutdown (OSPFv3)

The `shutdown` command disables OSPFv3 on the switch. OSPFv3 is disabled by default on individual interfaces and enabled through `ipv6 ospf area` commands.

The `no shutdown` and `default shutdown` commands enable the OSPFv3 instance by removing the `shutdown` statement from the OSPFv3 block in `running-config`.

**Command Mode**

Router-OSPFv3 Configuration

**Command Syntax**

```
shutdown
no shutdown
default shutdown
```

**Example**

This command disables OSPFv3 activity on the switch.

```
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#shutdown
switch(config-router-ospf3)#show active
ipv6 router ospf 9
  shutdown
switch(config-router-ospf3)#
```
15.3.5.48 timers lsa rx min interval (OSPFv3)

The `timers lsa rx min interval` command sets the minimum interval for accepting identical Link-State Advertisements (LSAs) from OSPFv3 neighbors.

The `no timers lsa rx min interval` and `default timers lsa rx min interval` commands restore the minimum interval to the default value of one second by removing the `timers lsa rx min interval` command from the `running-config`.

**Command Mode**
- Router-OSPFv3 Configuration
- Router-OSPFv3 Address-Family
- IPv4/IPv6 Configuration

**Command Syntax**

```
timers lsa rx min interval lsa_time
no timers lsa rx min interval
default timers lsa rx min interval
```

**Parameter**

`lsa_time` Minimum time (in milliseconds) after which the switch accepts an identical LSA from OSPFv3 neighbors. Value ranges from 0 to 600000 (ms). Default value is 1000 milliseconds (1 second).

**Example**

This command sets the minimum LSA arrival interval to 10 milliseconds.

```
switch(config)#router ospfv3
switch(config-router-ospfv3)#timers lsa rx min interval 10
switch(config-router-ospfv3)#
```
15.3.5.49  timers lsa tx delay initial (OSPFv3)

The **timers lsa tx delay initial** command sets the rate-limiting values for OSPFv3 Link-State Advertisement (LSA) generation.

The **no timers lsa tx delay initial** and **default timers lsa tx delay initial** commands restore the default LSA rate-limiting values by removing the **timers lsa tx delay initial** command from the **running-config**.

**Command Mode**
- Router-OSPFv3 Configuration
- Router-OSPFv3 Address-Family
- IPv4/IPv6 Configuration

**Command Syntax**

```
timers lsa tx delay initial initial_delay min_hold max_wait
no timers lsa tx delay initial
default timers lsa tx delay initial
```

**Parameters**

- **initial_delay** Initial delay in milliseconds to generate the first instance of LSAs. Value ranges from **0** to **600000** (ms). The default value is **1000** ms.
- **min_hold** Minimum hold interval availed in milliseconds between the generation of same LSA. Value ranges from **1** to **600000** (ms). The default interval is **5000** ms.
- **max_wait** Maximum hold interval availed in milliseconds between the generation of same LSA. Value ranges from **1** to **600000** (ms). The default interval is **5000** ms.

**Example**

These commands set the LSA transmission timers on the switch.

```
switch(config)#router ospfv3
switch(config-router-ospfv3)#
switch(config-router-ospfv3)#timers lsa tx delay initial 5 100 20000
switch(config-router-ospfv3)#
```

15.3.5.50  timers spf delay initial (OSPFv3)

The purpose of SPF throttling is to delay Shortest Path First (SPF) calculations when network topology is changing rapidly. The `timers spf delay initial` command controls the intervals of SPF calculations in a switch. The command sets three values:

- **Initial delay**: Initial wait by a switch to calculate SPF after a topology change in a network that has been stable throughout the hold interval. Because a topology change often requires several link state updates to be sent, the initial delay is configured to allow the network to settle before the switch calculates SPF. If an additional topology change occurs during the initial interval, the SPF calculation still takes place after the initial delay period has expired and no other change is made to the throttle timers.

- **Hold interval**: This is an additional wait timer that reduces the frequency of SPF calculations during periods of network instability. If a network change occurs during the hold period, an SPF calculation is scheduled to occur when the hold interval expires. Subsequent hold intervals are doubled if further topology changes occur during a hold interval until either the hold interval reaches its configured maximum or no topology change occurs during the interval. If the next topology change occurs after the hold interval expires, the hold interval is reset to its configured value and the SPF calculation is scheduled to take place after the initial delay.

- **Maximum interval**: The maximum wait time of a switch after a topology change before performing an SPF calculation.

The `no timers spf delay initial` and `default timers spf delay initial` commands restore the default OSPFv3 SPF calculation intervals by removing the `timers spf delay initial` command from `running-config`.

**Command Mode**

Router-OSPFv3 Configuration

Router-OSPFv3 Address-Family

IPv4/IPv6 Configuration

**Command Syntax**

`timers spf delay initial initial_delay hold_interval max_interval`

`no timers spf`

`default timers spf`

**Parameters**

- **initial_delay** Initial delay between a topology change and SPF calculation. Value ranges from 0 to 65535000 (ms). The default value is 0 ms.

- **hold_interval** Additional wait time after SPF calculation to allow the network to settle. If a topology change occurs during the hold interval, another SPF calculation is scheduled to occur after the hold interval expires. The next hold interval is doubled if topology changes occur during the hold interval. If doubling exceeds the maximum value, the maximum value is used instead. Value ranges from 0 to 65535000 (ms). The default value is 5000 ms.

- **max_interval** The maximum hold interval before a switch calculates SPF. Value ranges from 0 to 65535000 (ms). The default value is 5000 ms.

**Example**

These commands set the SPF timers on the switch.

```
switch(config)#router ospfv3
switch(config-router-ospfv3)#
switch(config-router-ospfv3)#timers spf delay initial 5 100 20000
switch(config-router-ospfv3)#
```
15.3.5.51 timers

The **timers** command configures the minimum interval between the transmission of consecutive LS update packets in a network.

The **no timers** and **default timers** commands set the configured timer value to its default.

**Command Mode**

Router-OSPFv3 Configuration

**Command Syntax**

```plaintext
timers { lsa  | out-delay | pacing  | throttle }
no timers { lsa  | out-delay | pacing  | throttle }
default timers { lsa  | out-delay | pacing  | throttle }
```

**Parameters**

- **lsa** configures threshold for the retransmission of LSA. Option includes:
  - **arrival** configures the OSPF LSA arrival timer.
- **out-delay** configures the delay to flood router LSA in milliseconds. Option includes:
  - **out-delay_time** minimum interval in milliseconds between accepting the same LSAs. The value ranges from 0 to 65000 milliseconds. The default value is 0.
- **pacing** configures the OSPF packet pacing. Option includes:
  - **flood** configures the OSPF flood pacing.
- **throttle** configures OSPF throttle timers. Options include:
  - **lsa** configures threshold for the retransmission of LSA.
  - **spf** configures the time between SPF calculations.

**Examples**

- This command configures OSPFv3 flood pacing timer to 50 ms in the global OSPFv3 instance.

```plaintext
switch(config)#ipv6 router ospf 9
switch(config-router-ospf3)#timers pacing flood 50
switch(config-router-ospf3)#show ospfv3
Routing Process "ospfv3 9" with ID 13.13.13.13 and Instance 0 VRF
default
FIPS mode disabled
It is not an autonomous system boundary router and is not an area border router
Minimum LSA arrival interval 1000 msecs
Initial LSA throttle delay 1000 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Interface flood pacing timer 50 msecs
It has 0 fully adjacent neighbors
Number of areas in this router is 1. 1 normal, 0 stub, 0 nssa
Number of LSAs 1
Initial SPF schedule delay 0 msecs

15.4 IS-IS

Intermediate System-to-Intermediate System (IS-IS) intra-domain routing information exchange protocol is designed by the International Organization for Standardization to support connectionless networking. This protocol is a dynamic routing protocol.

This chapter contains the following sections.

- IS-IS Introduction
- IS-IS Segment Routing
- IS-IS Graceful Restart
- IS-IS Dynamic Flooding
- IS-IS Configuration
- IS-IS Commands

15.4.1 IS-IS Introduction

IS-IS is a link-state protocol, which uses the Shortest Path First (SPF) algorithm. IS-IS and the OSPF protocol are similar in many aspects. As an Interior Gateway Protocol (IGP), IS-IS runs inside an Autonomous System (AS).

To enable IS-IS, you must instantiate an IS-IS routing instance and assign it to an interface. Arista IS-IS support includes IS-IS segment routing and IS-IS graceful restart.

15.4.2 IS-IS Segment Routing

Segment Routing (SR) provides a mechanism to simplify the definition of end-to-end paths within IGP topologies by encoding paths as sequences of topological sub-paths, called segments. The IS-IS protocol advertises these segments in four different ways: node segments, prefix segments, proxy-node segments, and adjacency segments.

Node segments represent a node in an IGP topology. A proxy segment are generally associated with an IPv6 address received from a router that does not support IS-IS SR. Prefix segments represent an ECMP-aware shortest path to a prefix (or a node), as per the state of the IGP topology. Adjacency segments represent a hop over a specific adjacency between two nodes in IGP.

15.4.2.1 TI-LFA FRR using IS-IS Segment-Routing

Topology Independent Fast Reroute, or TI-LFA, uses IS-IS SR to build loop-free alternate paths along the post-convergence path. These loop-free alternates provide fast convergence in the range of sub-50 ms.

This section describes TI-LFA FRR using IS-IS SR, including configuration instructions and command descriptions. Topics covered by this chapter include:

- TI-LFA FRR using IS-IS Segment-Routing Configuration
- TI-LFA FRR using IS-IS SR Commands
- Limitations

The (Point of Local Repair (PLR)- the router where TI-LFA is configured) PLR switches to these loop-free alternate backup paths in the event of a link down (link-protection) or BFD neighbor down (node-protection) event, protecting traffic destined to IS-IS SR node segments, adjacency segments, and anycast segments while the IGP converges and the post-convergence paths are computed. Anycast segment protection is restricted to those segments which are attached to prefixes with host mask (/32 for V4 address and /128 for v6 address).

Note: Unlike node segments, anycast segments do not have the ‘N’ flag set described in section 2.1.1.2 of RFC8667.
The following enhancements are available by release:

- **EOS Release 4.22.1F** adds support for TI-LFA backup paths that protect IS-IS SR labeled traffic corresponding to a node segment or adjacency segment on a transit router.
- **EOS Release 4.23.1F** adds support for TI-LFA backup paths that protect IS-IS SR tunnels.
- **EOS Release 4.24.1** adds support for protecting IS-IS SR labeled traffic corresponding to anycast segments.
- **EOS Release 4.24.2F** adds support for calculating TI-LFA backup paths that exclude the SRLG configured on the failing link.

Backup paths are only installed for IS-IS SR labeled routes and tunnels corresponding to node segments, adjacency segments, and anycast segments. When requesting node-protection, and no node-protecting LFAs are available, a link-protecting LFA is computed instead. TI-LFA FRR using IS-IS Segment-Routing is available with the multi-agent routing protocol model and the ribd routing protocol model.

Other traffic that resolves over IS-IS SR tunnels, such as LDP pseudowires, BGP LU tunnels, BGP IP routes, L2 EVPN, MPLS L3 VPN, and so on, are also protected by the TI-LFA tunnel that protects the resolving IS-IS SR tunnel.

### 15.4.2.1.1 TI-LFA FRR using IS-IS Segment-Routing Configuration

The following configuration tasks can be performed by Topology Independent Fast Reroute (TI-LFA FRR) using IS-IS Segment-Routing.

- Configuring Link or Node Protection on a Specific Interface
- Configuring a Local LFIB Convergence Delay for Protected Node or Adjacency Segments
- Making Locally-originated Adjacency Segments Backup Eligible
- Enabling SRLG Protection
- show ip route

### 15.4.2.1.2 TI-LFA FRR using IS-IS SR Commands

**TI-LFA FRR using IS-IS SR Show Commands**

- show ip route
- show isis interface
- show isis local-convergence-delay
- show isis segment-routing prefix-segments
- show isis segment-routing adjacency-segments
- show isis segment-routing tunnel
- show isis ti-lfa path
- show isis ti-lfa tunnel
- show mpls lfib route
- show tunnel fib

### 15.4.2.1.3 Limitations

- Backup paths are not computed for prefix segments that do not have a host mask (/32 for v4 and /128 for v6).
- When TI-LFA is configured, the number of anycast segments generated by a node cannot exceed 10.
- Computing TI-LFA backup paths for proxy node segments is not supported.
- Backup paths are not computed for node segments corresponding to multi-homed prefixes. The multi-homing could be the result of them being anycast node segments, loopback interfaces on
different routers advertising SIDs for the same prefix, node segments leaked between levels, and thus being seen as originated from multiple L1-L2 routers.

- Backup paths are only computed for segments that are non-ECMP.
- Only IS-IS interfaces that are using the point-to-point network type are eligible for protection.
- Link/node protection is only supported in the default VRF owing to the lack of non-default VRF support for IS-IS segment-routing.
- Backup paths are computed in the same IS-IS level topology as the primary path.
- Even with IS-IS GR configured, ASU2, SSO, agent restart are not hitless events for IS-IS SR LFIB routes or tunnels being protected by backup paths.

### 15.4.3 IS-IS Graceful Restart

IS-IS Graceful Restart (GR) is a mechanism to prevent routing protocol re-convergence during a processor switchover or device downtime. Normally, when a router restarts, all the neighboring routers associated with that router detect that the device has gone down and remove routes from that neighbor. When the router restarts, the session is re-established and data transfer continues. During the restart, the removal and re-insertion of routes will result in data loss. This can be prevented by configuring graceful restart on the device.

When IS-IS is used as the interior gateway protocol (IGP), the following EOS features require nonstop forwarding (NSF) and support for the graceful restart from IS-IS:

- Accelerated Software Upgrade phase 2 (ASU2).
- planned Stateful SwitchOver (SSO) initiated by an operator for maintenance, or unplanned SSO due to failures on the active supervisor.
- RIB agent restart due to software failures.

With IS-IS Graceful Restart (GR) configured, a redundancy switchover from active to standby supervisor, or ASU2, or restart of the IS-IS software (the RIB agent) should be a hitless event if the GR completes successfully. Neighboring routers will continue to forward traffic to the restarting router and traffic forwarding through the restarting router continues without loss. If GR is successful, the failure of a router should be completely transparent to network applications.

ISIS Graceful Restart (GR) is compatible with the following platforms:

- IS-IS GR with unplanned software restart is supported on all platforms.
- IS-IS GR with SSO is supported on modular dual-supervisor platforms.
- IS-IS GR with ASU2 is supported on platforms that support ASU2.

### 15.4.4 IS-IS Dynamic Flooding

Dynamic Flooding allows IS-IS to scale to large, dense topologies such as Leaf-Spine topologies. In such topologies, legacy IS-IS can exhibit a congestive collapse due to the control plane load created by excessively redundant flooding.

The concept in Dynamic Flooding is to dynamically compute a restricted topology for flooding (the **flooding topology**). Since this can be much smaller than the full physical topology, this can reduce the redundancy seen by each node, thereby reducing the control plane load and avoiding a congestive collapse.

To do this, first select one node within the IS-IS area as the **area leader**. Leverage the Designated Intermediate System (DIS) election algorithm for this, except instead of applying it to the neighbors on an interface, compute it across all of the nodes within the area.

The area leader is responsible for computing the flooding topology. This is distributed to the other nodes in the area through the Area System IDs TLV and the Flooding Path TLV.

All nodes within the area then flood only on the flooding topology.
Figure 54: Flooding Topology

A flooding topology on a dense graph. The flooding topology is shown by the solid lines. Dotted lines indicate non-flooding links.

In a dense topology, this can reduce the amount of flooding by an order of magnitude or more, with a resulting increase in scalability.

15.4.5 IS-IS Configuration

These sections describe IS-IS configuration tasks:

- Enabling IS-IS
- Configuring IS-IS Optional Global Parameters
- Configuring Optional IS-IS Interface Parameters
- Configuring IS-IS Segment Routing
- Configuring Redistribution of DHCP for IS-IS Agent (IPv6)
- Disabling IS-IS
- Configuring IS-IS Graceful Restart (GR)
- TI-LFA FRR using IS-IS Segment-Routing Configuration
- IS-IS Dynamic Flooding Configuration
- Relax Address-Family Check for IS-IS Adjacency
- Displaying IS-IS Information
15.4.5.1 Enabling IS-IS

To enable IS-IS, each of the following tasks must be performed.

- **Enabling IS-IS Globally and Specifying an IS-IS Instance**
- **Configuring the Network Entity Title (NET)**
- **Setting the Address Family Configuration**
- **Enabling IS-IS on a Specified Interface**

15.4.5.1.1 Enabling IS-IS Globally and Specifying an IS-IS Instance

The switch supports only one IS-IS routing instance per VRF. The routing instance uniquely identifies the switch to other devices. IS-IS configuration commands apply globally to the IS-IS instance.

The switch must be in router IS-IS configuration mode to run IS-IS configuration commands. The `router isis` command places the switch in router IS-IS configuration mode.

Example

These commands create an IS-IS routing instance named Osiris in the default VRF and place the switch in IS-IS configuration mode for that instance.

```
switch(config)#router isis Osiris
switch(config-router-isis)#
```

15.4.5.1.2 Configuring the Network Entity Title (NET)

After creating an IS-IS routing instance, configure the Network Entity Title (NET) with the `net` command. The NET defines the IS-IS area address and the system ID of the device.

Example

These commands configure the NET by specifying the IS-IS area address and the system ID of the device.

```
switch(config)#router isis Osiris
switch(config-router-isis)#net 49.0001.1010.1040.1030.00
```

15.4.5.1.3 Setting the Address Family Configuration

The `address-family` command enables the address families that IS-IS will route and places the switch in the configuration mode for that address family. The address families supported are IPv4 unicast and IPv6 unicast.

Example

These commands enable and enter the address family mode for IPv4 unicast.

```
switch(config)#router isis Osiris
switch(config-router-isis)#address-family ipv4 unicast
switch(config-router-isis-af)#
```

15.4.5.1.4 Enabling IS-IS on a Specified Interface

After enabling IS-IS globally, enable it on an interface with the `isis enable` command.

Example
These commands enable IS-IS on *interface ethernet 4*.

```bash
switch(config-router-isis)#interface ethernet 4
switch(config-if-Eth4)#isis enable Osiris
```

### 15.4.5.2 Configuring IS-IS Optional Global Parameters

After globally enabling IS-IS, the following global parameters may be configured.

- Setting the Router Type
- Configuring Redistribution of Connected or Static Non-IS-IS Routes
- Configuring Redistribution of Connected or Static non-IS-IS Routes into Level-1 or Level-2
- Configuring Redistribution of BGP Routes into IS-IS
- Setting the Overload Bit
- Configuring IS-IS MD5 Authentication
- Setting the SPF Interval
- Configuring IS-IS Segment Routing Global Adjacency-SID
- Enabling Logging for Peer Changes
- Setting the IS-IS hostname
- Configuring IS-IS Multi-Topology

#### 15.4.5.2.1 Setting the Router Type

The *is-type* command sets the routing level for an IS-IS instance.

**Example**

These commands specify level-2 for the IS-IS instance.

```bash
switch(config)#router isis Osiris
switch(config-router-isis)#is-type level-2
switch(config-router-isis)#
```

#### 15.4.5.2.2 Configuring Redistribution of Connected or Static Non-IS-IS Routes

The *redistribute (IS-IS)* command configures redistribution of connected or static non-IS-IS routes.

**Example**

These commands redistribute connected routes into the IS-IS domain.

```bash
switch(config)#router isis Osiris
switch(config-router-isis)#redistribute connected
switch(config-router-isis)#
```

#### 15.4.5.2.3 Configuring Redistribution of Connected or Static non-IS-IS Routes into Level-1 or Level-2

Non-IS-IS routes can be exported into Level-1, Level-2, or both using a route map. By default, the routes are exported only to Level-2; to export to Level-1 or to both levels, configure the route map using the *set isis level* command. The Level-1 or Level-2 routes can also be filtered using the route maps match statement. The route map is then used when redistributing routes in ISIS with the *redistribute (IS-IS)* command.

Use the *show isis database detail* command to make sure that the route shows up in the exported level.

**Examples**
The following commands configure a route map called **rm** to set the IS-IS level to Level-1, then use it to redistribute connected routes.

```plaintext
switch(config)#route-map rm
switch(config-route-map-rm)#set isis level level-1
switch(config-route-map-rm)#router isis osiris
switch(config-router-isis)#redistribute connected route-map rm
```

The following command displays IS-IS database information and confirms that the level has been set to Level-1.

```plaintext
switch#show isis database detail
ISIS Instance: inst1 VRF: default
ISIS Level 1 Link State Database
LSPID Seq Num Cksum Life IS Flags
1111.1111.1001.00-00 10 63306 751 L2 <>
NLPID: 0xCC(IPv4) 0x8E(IPv6)
Area address: 49.0001
<--------OUTPUT OMITTED FROM EXAMPLE-------->
```

### 15.4.5.2.4 Configuring Redistribution of BGP Routes into ISIS

The **redistribute bgp route-map** command redistributes the BGP routes from the specified route map into IS-IS. Only one route map can be specified; reissuing the command overrides any previous configuration.

The **no redistribute bgp** and **default redistribute bgp** commands disable BGP route redistribution from the specified domain by removing the **redistribute bgp** statement from **running-config**.

The command is available in both **router IS-IS** configuration mode and the **address-family** submode. The command is rejected if configured in both modes at the same time. Issuing the **no** or **default** command in **router IS-IS** configuration mode has no effect on redistribution configured in the **address-family** submode.

**Note:** If the command is configured in an **address-family** submode, it only redistributes routes from that address family. If it is configured in router-ISIS mode, it applies to all enabled address families.

**Examples**

- These commands redistribute IPv4 BGP routes from the route map called **bgp-to-isis-v4** into the IS-IS domain.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv4
switch(config-router-isis-af)#redistribute bgp route-map bgp-to-isis-v4
```

- These commands redistribute all BGP routes from the route map **bgp-to-isis** into IS-IS.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#redistribute bgp route-map bgp-to-isis
```

### 15.4.5.2.5 Setting the Overload Bit

The **set-overload-bit** command used without the on-startup option, informs other devices not to use the local router to forward transit traffic. When used with the on-startup option, the overload bit is set for the interval specified after startup.
In scenarios when Border Gateway Protocol (BGP) routes are resolved using an Interior Gateway Protocol (IGP), if the transit router reboots and becomes available again, the IGP will consider the transit router as an optimal path again. After rebooting, the transit router will blackhole traffic until the transit router learns the external destination reachability information via BGP.

Examples
- These commands configure the switch and sets the overload bit to 120 seconds after startup.

```
switch(config)#router isis Osiris
switch(config-router-isis)#set-overload-bit on-startup 120
```

- These commands configure the overload bit until BGP converges. If BGP fails to converge within the set timeout default period, then the overload bit gets cleared.

```
switch(config)#router isis Osiris
switch(config-router-isis)#set-overload-bit on-startup wait-for-bgp
switch(config-router-isis)#set-overload-bit on-startup wait-for-bgp
timeout 750
```

15.4.5.2.6 Configuring IS-IS MD5 Authentication

To configure authentication for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated, use the `authentication mode` and `authentication key` commands. To configure authentication on the interface, causing IS-IS Hellos to be authenticated, use the `isis authentication mode` and `isis authentication key` commands on the interface.

Two forms of authentication are supported by the IS-IS routing protocol: Clear-text authentication and MD5 authentication. The difference between the two forms of authentication is in the level of security provided. In the case of clear-text authentication, the password is specified as text in the authentication TLV, making it possible for an attacker to break authentication by sniffing and capturing IS-IS PDUs on the network. Arista recommends using the MD5 authentication.

HMAC MD5 authentication provides much stronger authentication by computing the message digest (on the IS-IS PDU contents) using the secret key to produce a hashed message authentication code (HMAC). Different modes of authentication can be specified on the interface, which authenticates IIH PDUs (IS-IS hello PDUs), and globally in the router IS-IS mode, in which the LSPs, CSNPs and PSNPs are authenticated. Area-wide and domain-wide authentication can be specified for L1 and L2 routers respectively.

Example
- These commands configure authentication for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated.

```
switch(config)#router isis 1
switch(config-router-isis)#authentication mode md5
switch(config-router-isis)#authentication key secret
```

- These commands configure authentication on the interface causing IS-IS Hellos to be authenticated.

```
switch(config)#interface Ethernet 3/6
switch(config-if-Et3/6)#isis authentication mode text
switch(config-if-Et3/6)#isis authentication key 7 cAm28+9a/xPi04o7hjd8Jw==
```

2408
Routing Protocols

To maximize interoperability, Arista recommends using the same key in both interface mode and in the `router isis` mode.

### 15.4.5.2.7 Setting the SPF Interval

The SPF timer interval defines the maximum interval between two successive SPF calculations. IS-IS runs SPF calculations following a change in the network topology or the link-state database. The `spf-interval` command defines the following intervals:

- **Maximum wait interval**: The maximum time a switch will wait before running an SPF after a topology change.
- **Initial wait interval**: In a network that has been stable throughout the hold interval, this interval defines the initial wait time of a switch for performing an SPF calculation after a topology change. As several link-state updates must be sent after a topology change, the initial wait interval allows the network to settle before a switch computes an SPF. If the topology changes during an initial wait interval, an SPF is calculated after the initial wait interval expires and no further changes are made to throttle timers.
- **Hold time**: This interval delays SPF calculations during network instability. If the topology changes during a hold time, an SPF is computed when the hold time expires. Subsequent hold intervals are doubled up to the configured maximum wait interval for continuous topology changes. If the next topology change occurs after the hold interval expires, the hold interval is reset to its configured value and the SPF is computed after the initial wait interval.

Note: EOS does not support configuring topology-specific SPF timers in multi-topology deployments and IS-IS level-specific SPF timers.

**Example**

This command configures maximum wait interval, initial wait interval, and hold time to 10 seconds, 2000 ms, and 1000 ms respectively.

```
switch(config)#router isis inst1
switch(config-router-isis)#spf-interval 10 2000 1000
```

### 15.4.5.2.8 Configuring IS-IS Segment Routing Global Adjacency-SID

IS-IS Segment Routing (SR) supports global adjacency SIDs for point-to-point interfaces. The adjacency SID is configured as an index using the adjacency-segment command. Global adjacency segments are represented using an index instead of actual MPLS labels. The index is an offset into the Segment Routing Global Block (SRGB) advertised by a router, resulting in an MPLS label. The default value of SRGB in EOS is Base: `900000` and Size: `65536`.

The same index may be used to configure multiple interfaces so that MPLS forms an ECMP group, and the same index may be applied to IPv4 and IPv6 adjacencies.

**Example**

- In this example, the global adjacency is configured on a point-to-point interface Ethernet `Et1`, with an index value 10.

```
switch(config-if-Et1)#adjacency-segment ipv4 p2p index 10 global
```

**Displaying Adjacency SID Information**

The command `show isis segment-routing adjacency-segments` displays the global adjacency SID value and other related information.

**Examples**
In this example an interface is configured as follows:

```
interface Ethernet1
  ip address 1.1.1.1/24
  ipv6 address 1000::1/64
  isis enable isis1
  isis network point-to-point
  adjacency-segment ipv4 p2p index 1 global
  adjacency-segment ipv6 p2p index 2 global
```

The show output for the above interface configuration:

```
Switch# show isis segment-routing adjacency-segments
System ID: 1000.0000.0002                       Instance: isis1
SR supported Data-plane: MPLS                   SR Router ID: 1.1.1.4
Adj-SID allocation mode: SR-adjacencies
Adj-SID allocation pool: Base: 1000000     Size: 16384
Adjacency Segment Count: 2
Flag Descriptions: F:Ipv6 address family, B:Backup, V:Value
                  L:Local, S:Set
Segment Status codes: L1 - Level-1 adjacency, L2 - Level-2 adjacency, P2P - Point-to-Point adjacency, LAN - Broadcast adjacency

Locally Originated Adjacency Segments
 Adj IP Address  Local Intf  SID     SID Source   Flags                 Type
-----------------  ----------  ------  -----------  ---------------       -------
 1.1.1.2            Et1         1       Configured    F:0 B:0 V:0 L:0 S:0  P2P L1
fe80::1:ff:fe65:0  Et1         2       Configured    F:1 B:0 V:0 L:0 S:0  P2P L1

Received Global Adjacency Segments
 SID              Originator             Neighbor          Flags
---------        --------------------   ----------------  ---------
 0                 rtrmpls1          1000.0000.0002     F:0 B:0 V:0 L:0 S:0
```

15.4.5.2.9 Enabling Logging for Peer Changes

The `log-adjacency-changes (IS-IS)` command configures the switch to send syslog messages when it detects IS-IS neighbor adjacency state changes.

**Example**

These commands configure the switch to send a Syslog message when a neighbor goes up or down.

```
switch(config)#router isis Osiris
switch(config-router-isis)#log-adjacency-changes
switch(config-router-isis)#
```

15.4.5.2.10 Setting the IS-IS hostname

The `is-hostname` command configures the use of a human-readable string to represent the symbolic name of an IS-IS router. It also changes the output of IS-IS show commands, to show the IS-IS hostname in place of system IDs if the corresponding IS-IS hostname is known. However, syslogs still use IS-IS system IDs and not the IS-IS hostname.

By default if there's a hostname configured on the switch, it is used as the IS-IS hostname. It is also possible to deconfigure an assigned hostname for IS-IS using the `no is-hostname` command. When the IS-IS hostname is removed, the switch goes back to using the switch's hostname as the IS-IS hostname.

**Examples**
• These commands configure the IS-IS hostname to the symbolic name `ishost1` for the IS-IS router.

```console
switch(config)#router isis inst1
switch(config-router-isis)#is-hostname ishost1
switch(config-router-isis)#
```

• These commands unconfigure the IS-IS hostname of the symbolic name `ishost1` for the IS-IS router.

```console
switch(config)#router isis inst1
switch(config-router-isis)#no is-hostname ishost1
switch(config-router-isis)#
```

15.4.5.2.11 Configuring IS-IS Multi-Topology

The `multi-topology` command configures IS-IS Multi-Topology (MT) support (disabled by default), enabling an IS-IS router to compute a separate topology for IPv4 and IPv6 links in the network. With MT configured, not all the links in a network need to support both IPv4 and IPv6. Some can support IPv4 or IPv6 individually. The IPv4 SPF will install IPv4 routes using the IPv4 topology, and similarly, the IPv6 SPF will install IPv6 routes using the IPv6 topology. Without MT support, all links in an IS-IS network need to support the same set of address families.

When MT is enabled, and each link has a separate IPv4 metric and IPv6 metric.

The `isis ipv6 metric` command configures the IPv6 metric.

The `isis multi-topology` command configures the IPv4 or IPv6 address family individually on an interface with both IPv4 and IPv6 addresses.

The address families that are enabled on an interface are based on the global address families enabled in router IS-IS configuration mode, and the addresses configured on the interface. To enable a particular address family on an interface, it needs to have an address configured in that address family. In the case where both IPv4 and IPv6 address families are enabled in router IS-IS configuration mode, then if an interface has IPv4 and IPv6 addresses, both IPv4 and IPv6 address families are enabled on that interface. In the case of an interface with only an IPv4 address family, the IPv4 address family is enabled on that interface. Where an interface only has an IPv6 address family, the IPv6 address family is enabled on that interface. Finally, where only the IPv6 address family is enabled in router IS-IS config mode and MT is enabled, then the IPv6 address family is enabled on all interfaces which have an IPv6 address configured.

**Examples**

• These commands configure MT for the IS-IS router.

```console
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv6 unicast
switch(config-router-isis-af)#multi-topology
switch(config-router-isis-af)#
```

• These commands unconfigure MT for the IS-IS router.

```console
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv6 unicast
switch(config-router-isis-af)#no multi-topology
switch(config-router-isis-af)#
```

• These commands configure the IPv6 metric.

```console
switch(config)#interface Ethernet 5/6
switch(config-if-Et5/6)#isis ipv6 metric 30
switch(config-if-Et5/6)#
```
• These commands configure the IPv4 address family on an interface with both IPv4 and IPv6 addresses.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#isis multi-topology address-family ipv4 unicast
```

• These commands configure the IPv6 address family on an interface with both IPv4 and IPv6 addresses.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#isis multi-topology address-family ipv6 unicast
```

• These commands configure both the IPv4 and IPv6 address families on an interface.

```
switch(config)#interface Ethernet1
switch(config-if-Et1)#no isis multi-topology address-family unicast
```

15.4.5.3 Configuring Optional IS-IS Interface Parameters

After globally enabling IS-IS, the following parameters may be configured on individual interfaces.

- Setting the Hello Packet Interval
- Configuring the Hello Multiplier for the Interface
- Configuring the IS-IS Metric
- Setting the LSP Transmission Interval
- Setting the IS-IS Priority
- Configuring an Interface as Passive
- Configuring BFD support for IS-IS for IPv4

15.4.5.3.1 Setting the Hello Packet Interval

The `isis hello-interval` command sets the time interval between the hello packets that maintain an IS-IS adjacency.

**Example**

These commands configure a hello interval of **60** seconds for `interface ethernet 4`.

```
switch(config)#interface ethernet 4
switch(config-if-Et4)#isis hello-interval 60
switch(config-if-Et4)#
```

15.4.5.3.2 Configuring the Hello Multiplier for the Interface

The switch maintains the adjacency by sending/receiving hello packets. When receiving no hello packets from the peer within a time interval, the local switch considers the neighbors invalid.

The `isis hello-multiplier` command calculates the hold time announced in hello packets by multiplying this number with the configured `isis hello-interval`.

**Example**

These commands configure a hello multiplier of **5** for `interface ethernet 4`.

```
switch(config)#interface ethernet 4
switch(config-if-Et4)#isis hello-interval 60
```
### Configuring the IS-IS Metric

The `isis metric` command sets the cost for sending information over a specific interface. At present only wide metrics are supported.

**Example**

These commands configure a metric cost of 30 for sending information over `interface ethernet 5`.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#isis metric 30
switch(config-if-Et5)#
```

### Setting the LSP Transmission Interval

The `isis lsp tx interval` command configures the minimum interval between successive LSP transmissions on an interface.

**Example**

This command sets the LSP transmission interval on interface `interface ethernet 5` to 50 milliseconds.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#isis lsp tx interval 50
switch(config-if-Et5)#
```

### Setting the IS-IS Priority

The `isis priority` command determines which device will be the Designated Intermediate System (DIS). The device with the highest priority on the LAN will become the DIS.

**Example**

These commands configure a device priority of 60 on interface `interface ethernet 5`.

```bash
switch(config)#interface ethernet 5
switch(config-if-Et5)#isis priority 60
switch(config-if-Et5)#
```

### Configuring an Interface as Passive

A passive IS-IS interface does not send or receive IS-IS packets and will not form adjacencies, but is still included in LSP advertisements, making its IP address visible to the IS-IS domain. To configure an IS-IS interface as passive, use the `isis passive` command in interface configuration mode or the `passive (IS-IS)` command in router IS-IS configuration mode.

**Examples**

- These commands configure Ethernet interface 10 as a passive interface.

  ```bash
  switch(config)#interface ethernet 10
  switch(config-if-Et10)#isis passive
  switch(config-if-Et10)#
  ```

- These commands also configure Ethernet interface 10 as a passive interface.

  ```bash
  switch(config)#router isis Osiris
  ```
15.4.5.3 Configuring BFD support for IS-IS for IPv4

The `isis bfd` and `bfd all-interfaces` commands configure Bidirectional Forwarding Detection (BFD). BFD is supported for both IS-IS IPv4 and IPv6 routes.

**Examples**

- These commands enable BFD (for the IPv4 address family) for all the interfaces on which IS-IS is enabled. By default, BFD is disabled on all interfaces.

  ```
  switch(config)#router isis 1
  switch(config-router-isis)#address-family ipv4
  switch(config-router-af)#bfd all-interfaces
  switch(config-router-af)#
  ```

- These commands enable BFD on an IS-IS interface.

  ```
  switch(config)#interface Ethernet 5/6
  switch(config-if-Et5/6)#isis bfd
  switch(config-if-Et5/6)#
  ```

15.4.5.4 Configuring IS-IS Segment Routing

Global IS-IS Segment Routing (IS-IS SR) commands are accessed in Segment-Routing MPLS mode, under the router IS-IS configuration mode. Interface-specific IS-IS SR commands are accessed in interface configuration mode.

15.4.5.4.1 Starting the MPLS Agent

The Routing Information Base (RIB) or IS-IS agent provides IS-IS segment routing, but the actual installation of LFIB entries pertaining to SR information provided by IS-IS is handled by the MPLS agent in EOS, which is disabled by default. To enable the MPLS agent, use the following commands.

⚠ Note: IP(v6) routing must be enabled as a prerequisite.

**Example**

The following commands enable IP routing and the MPLS agent on the switch.

```
switch(config)#ip routing
switch(config)#mpls ip
switch(config)#
```

15.4.5.4.2 Enabling IS-IS SR

By default, IS-IS SR is disabled. You must enable it explicitly by issuing the `no shutdown (IS-IS SR)` command in `segment-routing mpls` configuration mode.

**Example**

The following commands enable IS-IS SR.

```
switch(config)#router isis instance1
switch(config-router-isis)#segment-routing mpls
switch(config-router-isis-sr-mpls)#no shutdown
switch(config-router-isis-sr-mpls)#
```
### 15.4.5.3 Disabling IS-IS Segment Routing

To administratively disable IS-IS SR, issue the `shutdown (IS-IS SR)` command in Segment-Routing MPLS configuration mode. To disable `isis sr` and delete all `isis sr` configuration, issue the `no segment-routing mpls` command in `router isis` configuration mode.

**Example**

- The following commands administratively disable `router isis`.

  ```
  switch(config)#router isis instancel
  switch(config-router-isis)#segment-routing mpls
  switch(config-router-isis-sr-mpls)#shutdown
  ```

- The following commands disable `router isis` and delete all `router isis` configuration.

  ```
  switch(config)#router isis instancel
  switch(config-router-isis)#no segment-routing mpls
  ```

### 15.4.5.4 SRGB (Segment Routing Global Range)

The global segments such as Prefix-SID, Node-SID, Proxy-node-SID are represented using indices of actual MPLS labels. These indices are offset on the SRGB advertised by a router to derive the respective MPLS label. The default value of SRGB in EOS is Base: \(900000\), Size: \(65536\). In other words, the labels that any global segment could represent is between \(900000 - 965535\). The MPLS label range is categorized and reserved into pools based on the applications using these labels. The default values of label ranges in these pools are:

- **Dynamic Global Range**--\((100000,262144)\)
- **IS-IS SR Global Range** -- \(900000-65536\)
- **Static Global Range** -- \(16-99984\)

**Note:** SRGB can be configured to fit in different MPLS ranges as long as it does not fall under an MPLS range already assigned for usage by other applications.

**Example**

```
switch(config)#mpls label range isis-sr 900000 65536
```

### 15.4.5.5 IS-IS Maximum LSP Size

The IS-IS maximum LSP size provides the ability to configure the maximum LSP size that the IS-IS protocol accepts and sends. The default value of LSP size is \(9000\). The `lsp size maximum` command configures maximum size of an LSP that is sent or received. The default LSP maximum size is \(9000\). The minimum value is \(512\).

**Example**

```
switch(config)#lsp size maximum 400
```

The `no lsp size maximum` and `default lsp size maximum` commands remove the specified `lsp size maximum` command from `running-config`.

```
switch(config)#no lsp size maximum

switch(config)#default lsp size maximum
```
15.4.5.4.6 Configuring Node-SID

Node segments are indices associated with routers within an IS-IS SR domain. This is done by associating node-segments with prefix mask length /32 (IPV4) or /128 (IPV6) addresses. Node segments are carried as sub-TLVs (type-length-value) in IP reachability TLVs for the prefixes with which these segments are associated. Node segments are configured on IS-IS enabled Loop-back interface(s) as shown in the example below.

Examples

- The following commands are used to associate a node-segment with an IPv4 address.

```
switch(config)#int loopback 1
switch(config-if-Lo1)#ip address 21.1.1.1/32
switch(config-if-Lo1)#node-segment ipv4 index 5
```

- The following commands are used to associate a node-segment with an IPv6 address.

```
switch(config)#int loopback 1
switch(config-if-Lo1)#ipv6 add 2000::24/128
switch(config-if-Lo1)#node-segment ipv6 index 5
```

- The following example shows a warning thrown at the CLI when a /32 or /128 address is not configured on the interface.

```
switch(config)#int loopback 1
switch(config-if-Lo1)#ip address 21.1.1.1/24
switch(config-if-Lo1)#node-segment ipv4 index 1
! /32 IPv4 address is not configured on the interface
```

- The following command removes the node-segment from IS-IS SR from an interface.

```
switch(config-if-Lo1)#no node-segment ipv4 index 1
```

15.4.5.4.7 Configuring Prefix-SIDs

Prefix segments are associated with any IS-IS prefix a router is originating an IP Reachability TLV for. These segments are carried as sub-TLVs in IP Reachability TLVs of the prefixes with which these segments are associated. Prefix segments are configured under segment-routing MPLS configuration mode in IS-IS.

Note: The configured prefix segment is effective, only if, the prefix for which a prefix-SID configured becomes a part of IS-IS by enabling IS-IS on interfaces, or by redistribution from other protocols etc.

Example

The following commands are used to associate a prefix segment with an IPv4 address with index value of 50.

```
switch(config)#router isis instance1
switch(config-router-isis)#segment-routing mpls
switch(config-router-isis-sr-mpls)#prefix-segment 1.1.1.0/24 index 50
```

15.4.5.4.8 Configuring Proxy-Node SIDs

Node segments represent a device (node) by attaching a segment (index) with a /32, /128 prefix which generally is configured on a loopback interface. There are routers which do not support segment routing, and there might be a situation where it is required to assign node identifiers on such routers.
To overcome this shortfall, a router that supports IS-IS SR is made to proxy by configuring a proxy-node-SID for a IS-IS prefix originating from the router that does not support IS-IS SR.

**Example**

A proxy-node SID associates a /32 or a /128 route with an SID as shown below.

```
switch(config)# router isis instance1
switch(config-router-isis)# segment-routing mpls
switch(config-router-isis-sr-mpls)# proxy-node-segment 1.1.1.0/32 index 50
```

Although the general use case is to configure a proxy node segment on a router that is not originating the prefix with which we want to associate the proxy-node SID, it is not prohibited to configure one for self-originated prefixes.

Configuring proxy-node-SIDs enables a router to send out a Binding-SID TLV with details pertaining to the prefix and SID.

**Note:** A Binding-SID can carry a range of prefixes and an associated range of SIDs, but at present the EOS does not support to configure such ranges with one binding segment TLV in IS-IS SR. However, we do process ranges of prefixes and SIDs if received from devices that support such configurations.

### 15.4.5.4.9 Configuring Anycast-SID

An Anycast-SID is a prefix segment that identifies a set of routers and not a specific router. It enforces the ECMP-aware shortest-path forwarding towards the closest node of the anycast set.

An example of such an anycast group could be a set of routers A1, A2, A3, and A4 where at least one router of A1, A2, A3, and A4 advertises the prefix SID corresponding to the anycast address (which can be a prefix originating on all of A1, A2, A3 and A4 a loop-back address, maybe).

In general use case, all the routers of the anycast group would have the same prefix-SID configured for the anycast IP address present on them.

**Note:** That for Anycast-SID to work as expected, the SRGB on the members of the anycast group should be same.

### 15.4.5.4.10 Configuring router-ID

A router that support IS-IS SR need to advertise its SR data-plane capability and the range of MPLS label values it uses for segment routing, this is advertised by inserting SR-Capability sub-TLV in the Router Capabilities TLV.

A Router Capability TLV is now sent in IS-IS LSPs when Segment routing is enabled and it is necessary for a Router Capability TLV to carry a router-ID. This router-ID could be configured in EOS under the segment routing MPLS configuration mode. If no router-ID is configured, the router automatically picks up the highest IPv4 address configured on the router for a router-ID.

### 15.4.5.4.11 Configuring IS-IS Static Adjacency SID

Adjacency segments for IS-IS adjacencies are statically configured on the switch, so that these values are preserved even when the switch restarts. Static adjacency segments are configured per address family on any interface (including Port-Channel, VLANs and SVIs). They are configured and advertised as labels.

These are the few points to be considered while configuring the static adjacency SIDs:

- The same label can be configured on multiple interfaces so that MPLS can form ECMP, the same value can be applied to IPv4 and IPv6 adjacency.
• Static adjacency SID is applied only to p2p interface, and has local scope. When interface type changes to LAN, then dynamic adjacency SID is assigned.
• When Static adjacency SIDs are configured, then simply replace dynamic adjacency SIDs which are advertised to other routers and installed in the local LFIB.
• Static adjacency SID is applied regardless of Adjacency Segment Allocation Mode.
• When Static adjacency SID is disabled, then normal rules for dynamic adjacency SID is applied (it automatically applies a value based on Adjacency Segment Allocation Mode as described in IS-IS Segment Routing TOI document).

Example

```
switch(config-if-Et1)#adjacency-segment ipv4 p2p index 50 global
```

They can be a label (local) or index (global) and we can assign multiple adjacency segments per link. Where label-value must be within the SR Local Block (SRLB) that can be found in the output of show mpls label range command as shown.

15.4.5.4.12 Configuring Adjacency Segment Label Range

Adjacency Segments are MPLS labels assigned to IS-IS adjacencies. These labels are shared with other routers in the domain by adding them in adjacency-SID sub-TLVs which are inserted in neighbor Reachability TLVs in IS-IS.

The MPLS labels (adjacency segments) are incrementally allocated to adjacencies, as the transition to Up state, from a adjacent set of MPLS labels pre-allocated by MPLS agent. This label range extends from 100000 to 116383 (base: 100000, size: 16384) by default. This could be changed by the following configuration:

Example

```
switch(config)#mpls label range dynamic 200000 131072
```

The dynamic label pool is shared between LDP and IS-IS SR Adjacency Segments.

15.4.5.4.13 Configuring Adjacency Segment Allocation Mode

Adjacency Segments are allocated to all IS-IS adjacencies based on the IS-IS routers that have advertised IS-IS SR capability or to none of the adjacencies. The command adjacency-segment allocation is used to configure this under the segment-routing mpls configuration mode.

The default behavior is to allocate adjacency segments to adjacencies of SR supporting devices.

Example

```
switch(config-router-isis-sr-mpls)#adjacency-segment allocation sr-peer
```
15.4.5.4.14 Adjacency Segment Persistence across Link Flaps

Adjacency segments are allocated to IS-IS adjacencies based on configured adjacency segment allocation mode mentioned above.

If an adjacency that has been allocated label L goes down, L is reserved for this adjacency for a duration of \(3600\) seconds from the time of the adjacency down event. Only the adjacency that owned this label before going down could reclaim label L in this duration.

15.4.5.4.15 Troubleshooting IS-IS Segment Routing

- The `show tech-support ribd` command has a section starting with the string SR Book Keeper which has extensive information on state of IS-IS SR on the router.
- In-case, if IS-IS SR is configured but SR related TLVs/sub, but, TLVs are not being sent in IS-IS LSPs.
  - Ensure that MPLS has been enabled (MPLD IP) enabled.
  - Check if segment routing is administratively shut down.
  - A segment might have been configured for a prefix not yet being advertised in IS-IS.
- In case, if Adjacency Segments are not being advertised.
  - Check if the adjacency segment mode is correctly set.
  - Adjacency Mode is set to all SR supported interfaces (default setting) and the peer does not support SR.

Generally, it is good to not have same prefix with different indices or same index with different prefixes. There are CLI prohibitions that ensure that a router is not sending out conflicting sets of prefixes and associated SIDs. As there is possibility of receiving conflicting prefix-segments from other devices, there are ways to resolve the following three types of conflicts: prefix+SID conflict, SID conflict and prefix conflict.

- Prefix+SID Conflict: When there are two prefix segments which have both the prefix and SID have same values, the one from the higher system ID is chosen for LFIB processing.
- Prefix Conflict: If the two prefix segments which have same Prefix are from two different system than the one from higher system ID is chosen. If they are originated from same system ID than we choose the prefix segment of smaller SID.
- SID Conflict: If the two prefix segments which have same SID are from two different system than the one from higher system ID is chosen. If they are originated from same system than the one which is of smaller prefix length is chosen. If prefix length is also same than the one with smaller address is chosen.

For a given prefix, if both a proxy-node segment and prefix-SID are received, the prefix-SID advertised is preferred while the proxy-node segment is ignored.

The `show tech-support ribd` displays detail information about IS-IS SRs internal state, and more information on conflicts and chosen active segments could be found under the SR Book Keeper section of `show tech-support ribd` command as shown.

```
Received Prefix Segments:
-----------------------------------------------

```

10 Index Proxy 1111.1111.1003 39
15.4.5.5 Configuring Redistribution of DHCP for IS-IS Agent (IPv6)

The `redistribute dhcp` command redistributes DHCPv6 routes in IS-IS when using multi-agent routing protocol mode.

The `redistribute dhcp` command enables DHCP route redistribution in IS-IS when using the multi-agent routing protocol mode.

- These commands redistribute IPv6 DHCP routes into the ISIS domain.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv6
switch(config-router-isis-af)#redistribute dhcp

switch(config-router-isis-af)#
```

- The following command shows the DHCPv6 routes distributed into IS-IS.

```plaintext
switch(config)#show isis database detail
IS-IS Instance: inst1 VRF: default
IS-IS Level 1 Link State Database
LSPID               Seq Num  Cksum  Life  IS Flags
1111.1111.1001.00-00  10        19778  1101  L1 <>
... 
Reachability (MT-IPv6): 3ffe:701:ffff:101::10/128 Metric: 0 Type: 1 Up
...
```

15.4.5.6 Disabling IS-IS

An IS-IS instance can be shut down globally or can be disabled on individual interfaces.

The `shutdown (IS-IS)` command shuts down an IS-IS instance globally.

Example

These commands disable IS-IS globally without modifying the IS-IS configuration.

```plaintext
switch(config)#router isis Osiris
switch(config-router-isis)#shutdown

switch(config-router-isis)#
```

The `no isis enable` command disables IS-IS on an interface.

Example

These commands disable IS-IS on interface `interface ethernet 4`.

```plaintext
switch(config-router-isis)#interface ethernet 4
switch(config-if-Eth4)#no isis enable
```

15.4.5.7 Configuring IS-IS Graceful Restart (GR)

By default, IS-IS graceful restart is disabled. Use the `graceful-restart` command to configure graceful restart on an IS-IS router. By default IS-IS graceful-restart-helper functionality is enabled, and to disable it use `no graceful-restart-helper` command.

Examples

In this example IS-IS graceful restart is configured with t2 wait time of 30 seconds for level-1 routes.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#graceful-restart t2 level-1 30
```
t2 is the maximum wait time for the LSP database to synchronize (SPF computation is not done while t2 is running). t2 can be configured for either Level-1 or Level-2 through the CLI. The default value is 30 seconds, and the allowed configuration range is 5 to 300 seconds.

**Example**

In this example an ISIS graceful restart is configured with restart-hold-time of 50 seconds.

```
switch(config)#router isis 1
switch(config-router-isis)#graceful-restart restart-hold-time 50
```

In case of a planned restart, the hold time advertised by the IS-IS router prior to restart should be greater than the time for which the router is expected to be offline. Otherwise, neighboring routers will bring down the adjacency before the restarting router has a chance to send a restart request in its hello packet, which may result in traffic loss.

In case of ASU2, the IS-IS router instance will advertise a hello hold time of `restart-hold-time` on those interfaces for which the configured hold time is less than `restart-hold-time`. This is done just before the router restarts.

**Note:** Once the router has restarted, the routers advertised hello hold time will depend on the hello-interval and hello-multiplier configuration on each interface as before. By default, the `restart-hold-time` is disabled.

For Graceful Restart to be successful, the hold time advertised by the router should be greater than the time it takes for Graceful Restart to complete. If the restarting router is DIS, hold time advertised is 1/3rd of the configured value (default is 9s). We recommend increasing the hold time for the DIS to a higher value before a planned restart; otherwise, it may result in traffic loss.

### 15.4.5.8 TI-LFA FRR using IS-IS Segment-Routing Configuration

The following configuration tasks can be performed by Topology Independent Fast Reroute (TI-LFA FRR) using IS-IS Segment-Routing.

- Configuring Link or Node Protection on a Specific Interface
- Configuring a Local LFIB Convergence Delay for Protected Node or Adjacency Segments
- Making Locally-originated Adjacency Segments Backup Eligible
- Enabling SRLG Protection
- `show ip route`

#### 15.4.5.8.1 Configuring Link or Node Protection on a Specific Interface

To enable link or node protection for node segments and Adjacency segments learned on a specific IS-IS interface, use the following command in the interface configuration mode.

```
switch(config-if-Et1)#[no|default] isis fast-reroute ti-lfa mode [link-protection|node-protection|disabled] [level-1|level-2]
```

The interface TI-LFA configuration inherits the address-family sub-mode configuration by default.

On an L1-L2 router, the `[level-1|level2]` optional keyword in both the router IS-IS address-family sub-mode and interface configuration mode CLIs is used to restrict protection to node segments and Adjacency segments learned through either Level-1 or Level-2 topologies only.
15.4.5.8.2 Configuring a Local LFIB Convergence Delay for Protected Node or Adjacency Segments

The Point of Local Repair (PLR) switches to the TI-LFA backup path on link failure or BFD neighbor failure but switches back to the post-convergence path once the PLR computes SPF and updates its LFIB. This sequence of events can lead to micro-loops in the topology if the PLR converges faster than other routers along the post-convergence path. So a configuration option is provided to apply a delay, after which the LFIB route being protected by the TI-LFA loop-free repair path will be replaced by the post-convergence LFIB route.

To configure a convergence delay only to LFIB routes that are being protected, the following command is used either in the router IS-IS mode or the `router isis address-family` sub-mode. A default of 10 seconds is used when using the command without an explicitly specified delay.

```
switch (config-router-isis-af)#timers local-convergence-delay
[ delay_in_milliseconds ] protected-prefixes
```

15.4.5.8.3 Making Locally-originated Adjacency Segments Backup Eligible

The PLR computes backup paths for an adjacency segment only if the Adjacency SID sub-TLV has the B-flag (backup flag) set.

To set the B-flag in originated Adjacency SID sub-TLVs corresponding to adjacency segments dynamically allocated on the router, the following command is used in the `segment-routing mpls` sub-mode in the `router isis` mode.

```
switch(config-router-isis-sr-mpls)#adjacency-segment allocation [ all-interfaces | sr-peers ]
```

To set the B-flag in originated Adjacency SID sub-TLVs corresponding to adjacency segments statically configured on the router, the following command is used in the interface configuration mode.

```
switch(config-if-Et1)#adjacency-segment [ ipv4 | ipv6 ] p2p [ multiple ] [ label label ]
index index | backup-eligible
```

`backup-eligible` is the newly introduced optional keyword in both the CLIs mentioned above that controls the setting of the B-flag in the Adjacency SID sub-TLV.

15.4.5.8.4 Enabling SRLG Protection

To enable SRLG protection on all interfaces, use the `fast-reroute ti-lfa srlg` command. This command is used in addition to configuring link-protection or node-protection. If SRLG protection is enabled, the backup paths are computed after excluding all the links that share the same SRLG with the active link that is being used by all prefix segments and adjacency segments.

```
switch(config-router-isis-af)#fast-reroute ti-lfa srlg [ strict ]
```

If the optional argument `strict` is configured, the backup path is only programmed if a backup path that excludes all the SRLGs configured on the primary interface. If the keyword is not provided and an SRLG excluding path is not available, TI-LFA programs the backup path that excluded the maximum number of SRLGs possible.
To selectively disable SRLG protection on an interface, use the `isis [ipv4|ipv6] fast-reroute ti-lfa srlg disabled` command. This is useful if SRLG protection is enabled globally for all interfaces but needs to be selectively disabled for a specific interface.

```
switch(config-intf-et1)#isis [ipv4 | ipv6] fast-reroute ti-lfa srlg disabled
```

**Sample Configuration**

![Sample Configuration Diagram](image)

The above topology will be used to demonstrate the configuration and show command output. You will see the backup paths that the PLR computes to protect the node segments of R1 and R2, the global adjacency segment on R2, and the local adjacency segment on the `vlan 2387` on the PLR.

Here is a snippet of the configuration on the PLR.

```
switch(config)#interface vlan 2138
switch(config-if-Vl2138)#ip address 10.1.1.1/24
switch(config-if-Vl2138)#isis enable inst1
switch(config-if-Vl2138)#isis metric 11
switch(config-if-Vl2138)#isis network point-to-point

switch(config)#interface vlan2387
switch(config-if-Vl2387)#ip address 10.1.2.1/24
switch(config-if-Vl2387)#isis enable inst1
switch(config-if-Vl2387)#isis network point-to-point
switch(config-if-Vl2387)#adjacency-segment ipv4 p2p label 965537 backup-eligible

switch(config)#interface vlan2968
switch(config-if-Vl2968)#ip address 10.1.3.1/24
switch(config-if-Vl2968)#isis enable inst1
switch(config-if-Vl2968)#isis network point-to-point
switch(config-if-Vl2968)#isis fast-reroute ti-lfa mode disabled
...
switch(config)#router isis inst1
```
The protection of anycast segments does not need any new configuration. The above configuration enables protection of anycast segments.

To demonstrate the protection of anycast segments consider the following topology.

![Topology Number 2](image)

**R1 and R4 are originators of the host prefix 10.10.10.1/32 and advertise prefix segment 900010. Note that this should be configured as a prefix segment and not a node segment.**

**Figure 56: Topology Number 2**

R1 and R4 are originators of the host prefix **10.10.10.1/32** and advertise prefix segment **900010**. This must be configured as a prefix segment and not a node segment.

R1 and R4’s configuration should look similar to the following:

```
switch(config)#router isis inst1
switch(config-router-isis)#interface Loopback0
switch(config-if-Lo0)#ip address 10.10.10.1/32
switch(config-if-Lo0)#isis enable inst1
!
...
switch(config)#router isis inst1
switch(config-router-isis)#segment-routing mpls
switch(config-router-isis-sr-mpls)#prefix-segment 10.10.10.1/32 index 10
```
The prefix in the prefix-segment command must belong to an interface enabled with IS-IS or must be an active route in the RIB of another protocol redistributed into IS-IS.

When the link or node protection is configured on the PLR, then the primary path to the segment **900010** is PLR - R1 and the backup path is PLR - R2 - R3 - R4. In other words, the destination in the backup path is the segment originated by R4 as the segment originated by R1 and is not reachable when link PLR-R1 or the node R1 goes down.

### 15.4.5.8.5 show ip route

When services like LDP pseudowires, BGP LU, L2 EVPN, or L3 MPLS VPN use IS-IS SR tunnels as an underlay, these services are automatically protected by TI-LFA tunnels that protect the IS-IS SR tunnels. The `show ip route` command displays the hierarchy of the overlay-underlay-TI-LFA tunnels.

<table>
<thead>
<tr>
<th>B</th>
<th>2001:db8:3::/48 [200/0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>via 2002::b00:301:128, IS-IS SR tunnel index 3, label 122697</td>
</tr>
<tr>
<td></td>
<td>via TI-LFA tunnel index 5, label imp-null(3)</td>
</tr>
<tr>
<td></td>
<td>via fe80::200:76ff:fe03:0, Ethernet26/1, label imp-null(3)</td>

<td>backup via fe80::200:76ff:fe01:0, Ethernet30/1, label 900002 900003</td>
</tr>
</tbody>
</table>

### 15.4.5.9 IS-IS Dynamic Flooding Configuration

Configure Dynamic flooding using the `lsp flooding dynamic` command under the `router config` mode. For example:

```
switch(config)#router isis Amun
switch(config-router-isis)#net 49.0000.0000.3333.00
switch(config-router-isis)#is-hostname ip3
switch(config-router-isis)#lsp flooding dynamic
```

Dynamic flooding should be enabled on all routers in the area. To enable Dynamic Flooding on all routers, use the following command:

```
lsp flooding dynamic [level-1 | level-2]
nolsp flooding dynamic [level-1 | level-2]
default lsp flooding dynamic [level-1 | level-2]
```

If necessary, the area leader election process can be tuned or disabled with the commands:

```
area leader [level-1 | level-2] priority 0-255 area leader [level-1 | level-2] disabled
no area leader [level-1 | level-2] priority 0-255 area leader [level-1 | level-2] disabled
default area leader [level-1 | level-2] priority 0-255 area leader [level-1 | level-2] disabled
```
15.4.5.9.1 Limitations

On a sparse topology, Dynamic Flooding is not effective and only adds overhead. Leaf-spine and Clos networks are appropriate dense topologies.

15.4.5.10 Relax Address-Family Check for IS-IS Adjacency

Address-Family Check for IS-IS creates the adjacency between devices with different address families. For example, a router supporting IPv4 and IPv6 is connected to a IPv4 only router, Address-Family Check is verified by comparing the NLPID TLV (Type #129) advertised in IIH hellos exchanged between peers. It is useful in following scenarios.

Incrementally enable IPv6 in an existing IPv4 network

Relaxing the Address-Family Check is useful to gradually add IPv6 support in an IPv4 network, without disturbing the IPv4 connectivity.

IPV4 Controller Peering IPv4/v6 Dual Stack Router

A controller forms an IS-IS adjacency with a router and uses the IS-IS database for topology discovery. If the controller only supports IPv4 IS-IS or only IPv4 tunnels, to relax the Address-Family Check on the dual stack IPv4/v6 router for adjacency is useful in establishment.

Disabling the Address-family check

Under IS-IS instance, configure the following to disable the Address-Family Check during IIH processing.

```
switch(config-router-isis)## adjacency
  adjacency Configure parameters for adjacency formation
switch(config-router-isis)## adjacency?
  address-family Configure address-family related parameters for adjacency formation
switch(config-router-isis)## adjacency address-family?
  match Configure address-family match check related parameters for adjacency formation
switch(config-router-isis)## adjacency address-family match?
  disabled Relax address-family match check for bringing up adjacency
switch(config-router-isis)## adjacency address-family match disabled?
```

Show command

The show isis neighbor detail command displays address family details at each end of the adjacency.

        Link-ID: 23
        Authentication mode: None
        TI-LFA link protection is enabled for the following IPv4 segments:
            node segments, adjacency segments
    TI-LFA protection is disabled for IPv6
    Adjacency 1111.1111.1002:
        State: UP, Level: 2 Type: Level 2 IS
        Advertised Hold Time: 30
        **Neighbor Supported Address Families: IPv4**
        **Address Family Match: Disabled**
        IPv4 Interface Address: 1.0.0.2
        Areas:
            49.0001
```

**Usage Guidelines**

For IPv6 network upgrade, ensure the knob is incrementally configured on a contiguous section of the network, at any point the choice of routers for upgrade should not bisect the upgraded (supporting IPv4/v6) part of the network. All the routers bordering the upgraded network should always have the knob enabled.

When a proper set of router is established, the following steps are carried on each router.

1. Enable the CLI knob.
2. Enable IPv6 address family in the IS-IS instance.
3. Configure IPv6 on all the IS-IS interfaces.
15.4.5.11 Displaying IS-IS Information

The following sections describe display and verification of IS-IS settings and of peer and connection configuration:

- Displaying the Link State Database
- Displaying the Interface Information for the IS-IS Instance
- Displaying IS-IS Neighbor Information
- Displaying IS-IS Instance Information
- Displaying IS-IS Segment Routing Information
- Displaying show isis local-convergence-delay
- timers local-convergence-delay
- Verifying IS-IS Graceful Restart (GR) Information
- IS-IS Dynamic Flooding Show Commands

15.4.5.11.1 Displaying the Link State Database

To display the link state database of IS-IS, use the `show isis database` command.

Example

This command displays the IS-IS link state database.

```
switch#show isis database
ISIS Instance: Osiris
ISIS Level 2 Link State Database
LSRID      Seq Num  Cksum  Life  IS Flags
1212.1212.1212.00-00  4         714    1064  L2 <>
1212.1212.1212.0a-00 1         57417  1064  L2 <>
2222.2222.2222.00-00 6         15323  1116  L2 <>
2727.2727.2727.00-00 10        15596  1050  L2 <>
3030.3030.3030.00-00 12        62023  1104  L2 <>
3030.3030.3030.c7-00 4         53510  1104  L2 <>
switch>
```

15.4.5.11.2 Displaying the Interface Information for the IS-IS Instance

To display interface information related to the IS-IS instance, use the `show isis interface` command.

Example

This command displays IS-IS interface information.

```
switch#show isis interface
ISIS Instance: Osiris
Interface Vlan20:
    Index: 59 SNPA: 0:1c:73:c:5:7f
    MTU: 1497 Type: broadcast
    Level 2:
        Metric: 10, Number of adjacencies: 2
    LAN-ID: 1212.1212.1212, Priority: 64
    DIS: 1212.1212.1212, DIS Priority: 64
Interface Ethernet30:
    Index: 36 SNPA: 0:1c:73:c:5:7f
    MTU: 1497 Type: broadcast
    Level 2:
        Metric: 10, Number of adjacencies: 1
```
15.4.5.11.3 Displaying IS-IS Neighbor Information

To display general information for IS-IS neighbors that the device sees, use `show isis neighbors`.

Example

This command displays information for IS-IS neighbors that the device sees.

```
switch# show isis neighbor
Inst Id  System Id       Type  Interface   SNPA          State  Hold
time
10        2222.2222.2222  L2    Vlan20       2:1:0:c:0:0   UP    30
10        1212.1212.1212  L2    Vlan20       2:1:0:d:0:0   UP     9
10        3030.3030.3030  L2    Ethernet30   2:1:0:b:0:0   UP     9
```

15.4.5.11.4 Displaying IS-IS Instance Information

To display the system ID, Type, Interface, IP address, State and Hold information for IS-IS instances, use the `show isis summary` command. The command is also used to verify the configured maximum wait interval, initial wait interval, and hold time of SPF timers in IS-IS instances. This command also displays values of the current SPF interval, last Level-1 SPF run, and last Level-2 SPF run.

Example

- This command displays general information about IS-IS instances.

```
switch# show isis summary
ISIS Instance: Osiris
  System ID: 1010.1040.1030, administratively enabled, attached
  Internal Preference: Level 1: 115, Level 2: 115
  External Preference: Level 1: 115, Level 2: 115
  IS-Type: Level 2, Number active interfaces: 1
  Routes IPv4 only
  Last Level 2 SPF run 2:32 minutes ago
  Area Addresses: 12.0001
  level 2: number dis interfaces: 1, LSDB size: 1
```

- This command displays the SPF interval information about IS-IS instances.

```
switch(config-router-isis-af)# show isis summary
IS-IS Instance: 1 VRF: default
  System ID: 0000.0000.0001, administratively enabled
  Multi Topology disabled, not attached
  IPv4 Preference: Level 1: 115, Level 2: 115
  IPv6 Preference: Level 1: 115, Level 2: 115
  IS-Type: Level 1 and 2, Number active interfaces: 0
  Routes both IPv4 and IPv6
  Max wait(s) Initial wait(ms) Hold interval(ms)
  LSP Generation Interval: 5 50 50
  SPF Interval: 2 1000 1000
  Current SPF hold interval(ms): Level 1: 1000, Level 2: 1000
  Last Level 1 SPF run 1 seconds ago
```
15.4.5.11.5 Displaying IS-IS Segment Routing Information

IS-IS Segment Routing information is displayed using the following commands:

- `show isis database detail`
- `show isis segment-routing`
- `show isis segment-routing global-blocks`
- `show isis segment-routing prefix-segments`
- `show isis segment-routing prefix-segments self-originated`
- `show isis segment-routing adjacency-segments`
- `show mpls label ranges`
- `show mpls segment-routing bindings`
- `show mpls lfib route`
- `show mpls lfib route <label value>`

show isis database detail

The `show isis database detail` command provides a view of LSPDB of different devices in the IS-IS domain. The output displays the TLVs and sub-TLVs that are being self-originated or the ones that have been received from other routers.

Example

```
switch#show isis database detail
ISIS Instance: inst1 VRF: default
ISIS Level 2 Link State Database
LSPID Seq Num Cksum Life IS Flags
1111.1111.1001.00-00 10 63306 751 L2 <>
NLPID: 0xCC(IPv4) 0x8E(IPv6)
Area address: 49.0001
Interface address: 1.0.7.1
Interface address: 1.0.0.1
Interface address: 2000:0:0:47::1
Interface address: 2000:0:0:40::1
IS Neighbor : lf319.53 Metric: 10
LAN-Adj-sid: 10000 flags: [ L V ] weight: 0 system ID: 1111.1111.1002
IS Neighbor (MT-IPv6): 1f319.53 Metric: 10
LAN-Adj-sid: 100001 flags: [ L V F ] weight: 0 system ID: 1111.1111.1002
Reachability : 1.0.11.0/24 Metric: 1 Type: 1 Up
SR Prefix-SID: 10 Flags: [ R ] Algorithm: 0
Reachability : 1.0.3.0/24 Metric: 1 Type: 1 Up
Reachability : 1.0.7.1/32 Metric: 10 Type: 1 Up
SR Prefix-SID: 2 Flags: [ N ] Algorithm: 0
Reachability : 1.0.0.0/24 Metric: 10 Type: 1 Up
SR Prefix-SID: 11 Flags: [ R ] Algorithm: 0
Reachability (MT-IPv6): 2000:0:0:4b::/64 Metric: 1 Type: 1 Up
SR Prefix-SID: 11 Flags: [ R ] Algorithm: 0
Reachability (MT-IPv6): 2000:0:0:43::/64 Metric: 1 Type: 1 Up
Reachability (MT-IPv6): 2000:0:0:47::1/128 Metric: 10 Type: 1 Up
SR Prefix-SID: 3 Flags: [ N ] Algorithm: 0
Reachability (MT-IPv6): 2000:0:0:40::/64 Metric: 10 Type: 1 Up
```
show isis segment-routing

The **show isis segment-routing** command displays the summary information on IS-IS SR status.

**Example**

```bash
switch(config)#show isis segment-routing
System ID: 1111.1111.1002 Instance: inst1
SR supported Data-plane: MPLS SR Router ID: 252.252.2.252
SR Global Block( SRGB ): Base: 900000 Size: 65536
Adj-SID allocation mode: SR-adjacencies
Adj-SID allocation pool: Base: 100000 Size: 16384
All Prefix Segments have : P:0 E:0 V:0 L:0
All Adjacency Segments have : F:0 B:0 V:1 L:1 S:0
ISIS Reachability Algorithm : SPF (0)
Number of ISIS segment routing capable peers: 3
Self-Originated Segment Statistics:
  Node-Segments : 2
  Prefix-Segments : 2
  Proxy-Node-Segments : 0
  Adjacency Segments :
```

**About the Output**

The first line of the output shows the IS-IS system ID of this device and the name of the instance with which IS-IS is configured.

The supported data plane is shown against the SR supported Data-plane field whereas the Router ID being advertised in the Router Capability is mentioned in the SR Router ID Field.

The SRGB in use and the MPLS label pool being used for adjacency segment allocation are mentioned in this output. The current adjacency allocation mode which refers to whether we are allocating adjacency segments to all IS-IS adjacencies or only those adjacencies which support SR or None of the adjacencies is shown in the Adj-SID allocation mode field.

Flag contents of All Prefix Segments originated on this router, Flag contents of All Adjacency Segments originated on this router and supported IS-IS Reachability Algorithm have been provided through this command output and they carry the meaning as per the IS-IS SR IETF draft.

This show command provides a statistics related to IS-IS SR in terms of various counters ranging from number of IS-IS SR enabled peers, number of Node-SIDs, prefix-SIDs, proxy-node-segments and adjacency segments being originated on this router in IS-IS.

The **show isis segment-routing** command also provides information if segment routing has been administratively disabled as shown.

```bash
switch(config-router-isis-sr-mpls)#show isis segment-routing
! IS-IS (Instance: inst1) Segment Routing has been administratively shutdown
```
**show isis segment-routing global-blocks**

The **show isis segment-routing global-blocks** command lists the SRGBs in use by all SR supporting devices in IS-IS domain including the SRGB in use by IS-IS SR on this device.

**Example**

```
switch#show isis segment-routing global-blocks
System ID: 1111.1111.1002              Instance: inst1
SR supported Data-plane: MPLS          SR Router ID: 252.252.2.252
SR Global Block( SRGB ): Base: 900000  Size: 65536
Number of ISIS segment routing capable peers: 3
SystemId             Base         Size
-------------------- ------------ ----- 
1111.1111.1002        900000      65536
1111.1111.1001        900000      65536
```

**show isis segment-routing prefix-segments**

The **show isis segment-routing prefix-segments** command provides the details of all prefix segments being originated as well as the segments received from IS-IS SR speakers in the domain.

**Example**

```
switch#show isis segment-routing prefix-segments
System ID: 1111.1111.1002         Instance: inst1
SR supported Data-plane: MPLS     SR Router ID: 252.252.2.252
Node: 2 Proxy-Node: 2 Prefix: 2 Total Segments: 6
Flag Descriptions: R: Re-advertised, N: Node Segment, P: no-PHP
E: Explicit-NULL, V: Value, L: Local
Segment status codes: * - Self originated Prefix, L1 - level 1, L2 - level 2
Prefix        SID     Type        Flags                    SystemID        Type
--------------------- ---------   ----------------         ---------------------
1.0.7.1/32    2      Node        R:0 N:1 P:0 E:0 V:0 L:0   1111.1111.1001  L1
* 1.0.8.1/32   4      Node        R:0 N:1 P:0 E:0 V:0 L:0   1111.1111.1002  L2
1.0.10.11/24  10     Prefix      R:1 N:0 P:0 E:0 V:0 L:0   1111.1111.1002  L2
* 1.0.12.0/24  12     Prefix      R:1 N:0 P:0 E:0 V:0 L:0   1111.1111.1002  L2
1.0.15.1/32   18     Proxy-Node  R:0 N:0 P:0 E:0 V:0 L:0   1111.1111.1001  L2
1.0.16.1/32   20     Proxy-Node  R:0 N:0 P:0 E:0 V:0 L:0   1111.1111.1003  L2
```

**About the Output**

After the usual output header that represents the system ID, instance name, etc and parameters of a router, there is a line depicting prefix segment counters. Each field in this line relates to the number of segments that are present in this routers IS-IS instance. For example, the above example shows that this device has 2 Node Segments (Self originated as well as the ones received from other IS-IS SR devices).

The main section of this show commands output is the section that lists all the prefix segments and related information like prefix, SID, type of segment (Prefix, Node, Proxy-Node), the flag values being carried in the sub-TLVs of these prefix segments and the system ID of the originating router. The Type field will be useful on a IS type level-1-2 router. It shows whether the installed prefix segment is from a level-1 prefix or a level-2 prefix.

**show isis segment-routing prefix-segments self-originated**

The **show isis segment-routing prefix-segments self-originated** command output is identical to show isis segment-routing prefix-segments except, the fact that the former lists only self-originated prefix segments.

**show isis segment-routing adjacency-segments**

The **show isis segment-routing adjacency-segments** displays list of all the adjacency segments that are being originated by IS-IS SR on a router.
**Example**

```bash
switch#show isis segment-routing adjacency-segments
System ID: 1111.1111.1002             Instance: inst1
SR supported Data-plane: MPLS       SR Router ID: 252.252.2.252
Adj-SID allocation mode: SR-adjacencies
Adj-SID allocation pool: Base: 100000     Size: 16384
Adjacency Segment Count: 4

<table>

<td>100003</td>
<td>Dynamic F:0 B:0 V:1</td>
<td>L:1 S:0</td>
<td>P2P L2</td>
<td></td>
</tr>
</tbody>
</table>
```

**About the Output**

It consists allocation mode, MPLS label pool from which labels would be allocated to adjacencies, total count of adjacency segments allocated so far and the default flag values carried in all adj-SID sub-TLVs originating from this device.

The main section of the output lists all the adjacency segments allocated so far in six columns each pertaining to Adjacency IP address, local interface name, MPLS label value, SID source, flags in the sub-TLV and the type of adj-SID respectively. The type of the adjacency segments depends on the IS-IS type of adjacency and the IS level.

**show mpls label ranges**

The `show mpls label ranges` command displays the MPLS label range available on a router is categorized into different pools which cater to different applications running on the router.

The isis-sr refers to the SRGB use-case in IS-IS, and isis (dynamic) refers to the label pool that is used for dynamic allocation of adjacency segments in IS-IS.

**Example**

```bash
switch#show mpls label ranges
Start    End      Size     Usage
--------- ------- ------- -------------
0        15       16       reserved
16       99999    99984    static mpls
100000   116383   16384    isis (dynamic)
116384   362143   245760   free (dynamic)
362144   899999   537856   unassigned
900000   965535   65536    isis-sr
```

**show mpls segment-routing bindings**

The `show mpls segment-routing bindings` command displays the local label bindings and label bindings on the peer routers for each prefix that has a segment advertised. Peer ID here represents the IS-IS system ID of the peer.

**Example**

```bash
switch#show mpls segment-routing bindings
1.0.7.1/32
Local binding: Label: 900002
Remote binding: Peer ID: 1111.1111.1001, Label: imp-null
Remote binding: Peer ID: 1111.1111.1003, Label: 900002
1.0.8.1/32
Local binding: Label: imp-null
Remote binding: Peer ID: 1111.1111.1001, Label: 900004
Remote binding: Peer ID: 1111.1111.1003, Label: 900004
1.0.9.1/32
```
Local binding: Label: 900006
Remote binding: Peer ID: 1111.1111.1001, Label: 900006
Remote binding: Peer ID: 1111.1111.1003, Label: imp-null

**show mpls lfib route**

The `show mpls lfib route` command displays the LFIB. Each LFIB entry has In-Label, Out-Label, metric, payload type, nexthop information, etc. fields. The source column depicts the MPLS control plane protocol that is responsible for the label binding that resulted in this LFIB route.

**Example**

```
switch#show mpls lfib route
MPLS forwarding table (Label [metric] Vias) - 7 routes
MPLS next-hop resolution allow default route: False
Via Type Codes:
  M - Mpls Via, P - Pseudowire Via,
  I - IP Lookup Via, V - Vlan Via,
  VA - EVPN Vlan Aware Via, ES - EVPN Ethernet Segment Via,
  VF - EVPN Vlan Flood Via, AF - EVPN Vlan Aware Flood Via,
  NG - Nexthop Group Via
Source Codes:
  S - Static MPLS Route, B2 - BGP L2 EVPN,
  B3 - BGP L3 VPN, R - RSVP,
  P - Pseudowire, L - LDP,
  IP - IS-IS SR Prefix Segment, IA - IS-IS SR Adjacency Segment,
  IL - IS-IS SR Segment to LDP, LI - LDP to IS-IS SR Segment,
  BL - BGP LU, ST - SR TE Policy,
  DE - Debug LFIB
IA 100000 [1]
  via M, 1.0.1.2, pop
  payload autoDecide, ttlMode uniform, apply egress-acl
  interface Vlan2930
IA 100001 [1]
  via M, fe80::200:eff:fe02:0, pop
  payload autoDecide, ttlMode uniform, apply egress-acl
  interface Vlan2930
IP 900008 [1]
  via M, 1.0.1.2, swap 900008
  payload autoDecide, ttlMode uniform, apply egress-acl
  interface Vlan2930
IP 900009 [1]
  via M, fe80::200:eff:fe02:0, swap 900009
  payload autoDecide, ttlMode uniform, apply egress-acl
  interface Vlan2930
```

**show mpls lfib route <label value>**

The `show mpls lfib route <label value>` command provides information relevant to just the label value passed as an extension to the show command.

**Example**

```
switch#show mpls lfib route 900008
MPLS forwarding table (Label [metric] Vias) - 7 routes
MPLS next-hop resolution allow default route: False
Via Type Codes:
  M - Mpls Via, P - Pseudowire Via,
  I - IP Lookup Via, V - Vlan Via,
  VA - EVPN Vlan Aware Via, ES - EVPN Ethernet Segment Via,
  VF - EVPN Vlan Flood Via, AF - EVPN Vlan Aware Flood Via,
```
NG - Nexthop Group Via
Source Codes:
S - Static MPLS Route, B2 - BGP L2 EVVPN,
B3 - BGP L3 VPN, R - RSVP,
P - Pseudowire, L - LDP,
IP - IS-IS SR Prefix Segment, IA - IS-IS SR Adjacency Segment,
IL - IS-IS SR Segment to LDP, LI - LDP to IS-IS SR Segment,
BL - BGP LU, ST - SR TE Policy,
DE - Debug LFIB
IP 900008 [1]
via M, 1.0.1.2, swap 900008
payload autoDecide, ttlMode uniform, apply egress-acl
interface Vlan2930

15.4.5.11.6 Displaying show isis local-convergence-delay

The **show isis local-convergence-delay** command shows the current or last attempt at delaying the convergence of protected routes on a link down/BFD neighbor down event. If the timer aborts for some reason (such as a topology change causing a new SPF), the attempt fails.

```
switch#show isis local-convergence-delay
IS-IS Instance: inst1 VRF: default
  System ID: 1111.1111.1001
  IPv4 local convergence delay configured, 5000 msecs
  IPv6 local convergence delay configured, 5000 msecs
  Level 1 attempts 0, failures 0
  Level 2 attempts 3, failures 1

  Level 2 in progress due to LINK DOWN on Vlan2138
    TI-LFA node protection is enabled for IPv4
    IPv4 Routes delayed: 0
      Delay timer expires in 2 secs
    TI-LFA protection is disabled for IPv6

  Level 2 last attempt due to LINK DOWN on Vlan2138, Succeeded
    TI-LFA node protection is enabled for IPv4
    IPv4 Routes delayed: 3
      Delay timer started at: 2019-07-25 23:14:51
      Delay timer stopped at: 2019-07-25 23:14:56
    TI-LFA protection is disabled for IPv6
```

The **detail** keyword also lists all the routes that have been delayed.

```
switch#show isis local-convergence-delay detail
...
  Level 2 last attempt due to LINK DOWN on Vlan2138, Succeeded
    TI-LFA node protection is enabled for IPv4
    IPv4 Routes delayed: 3
      Delay timer started at: 2019-07-25 23:14:51
      Delay timer stopped at: 2019-07-25 23:14:56
    Delayed routes:
      10.0.7.1/32
      10.0.9.1/32
      10.0.10.1/32
```
TI-LFA protection is disabled for IPv6
15.4.5.11.7 timers local-convergence-delay

The point of local repair (PLR) switches to the TI-LFA backup path on link failure or BFD neighbor failure but switches back to the post-convergence path once the PLR computes SPF and updates its LFIB. This sequence of events can lead to micro-loops in the topology if the PLR converges faster than other routers along the post-convergence path. So a configuration option is provided to apply a delay, after which the LFIB route being protected by the TI-LFA loop-free repair path will be replaced by the post-convergence LFIB route.

Command Mode
IS-IS address-family sub-mode

Command Syntax

timers local-convergence-delay [delay_in_seconds] protected-prefixes

Parameters
- **delay_in_seconds** The convergence delay, in seconds. A default of 10 seconds is used when the command is used without an explicitly specified delay.
- **protected-prefixes** The prefix which the LFIB route being protected by the TI-LFA loop-free repair path will be replaced by the post-convergence LFIB route.

15.4.5.11.8 Verifying IS-IS Graceful Restart (GR) Information

GR State can be one of the following:
- Last Start/Restart was completed successfully.
- Last Start/Restart exited after t2 (level-1/level-2) expiry.
- Last Restart exited after t3 expiry.
- Start/Restart in progress.
- Graceful Restart was disabled during startup.

The following show commands are used to display the IS-IS graceful restart information.

- The **show isis graceful-restart vrf [vrf-name]** command displays the GR configuration and graceful-restart related state of the IS-IS instance as well as its neighbors.

  **Example**

  switch#show isis graceful-restart vrf default
  IS-IS Instance: 1 VRF: default
  System ID: 0000.0000.0001
  Graceful Restart: Enabled, Graceful Restart Helper: Enabled
  State: Last Start exited after T2 (level-1) expiry
  T1 : 3s
  T2 (level-1) : 30s/20s remaining
  T2 (level-2) : 30s/not running
  T3 : not running

  System ID       Type   Interface     Restart Capable  Status
  is-hostname-1   L1L2   Ethernet1     Yes              Running
  is-hostname-2   L1     Ethernet2     Yes              Restarting

- The **show isis summary vrf [vrf-name]** command displays the graceful restart state and helper configuration.

  **Example**

  switch#show isis summary vrf default
  IS-IS Instance: 1 VRF: default
  System ID: 0000.0000.0001, administratively enabled
  ....
Graceful Restart: Enabled, Graceful Restart Helper: Enabled

- The `show isis neighbors detail vrf [vrf-name]` command displays the helpers view of a restarting router.

**Example**

```
switch# show isis neighbors detail vrf default
Instance  VRF      System Id  Type Interface  SNPA     State  Hold time   Circuit Id
1         default  OT1        L1   Ethernet1  2:1:0:b  4:0:0  UP          29839   OT3.05
Area Address(es): 49.0001
SNPA: 2:1:0:b4:0:0
...
Graceful Restart: Supported, Status: Restarting (RR rcvd, RA sent, CSNP sent)
```

- The `show isis interface detail vrf [vrf-name]` command displays the graceful restart related stats for that interface.

**Example**

```
switch# show isis interface detail vrf default
ISIS Instance: ISISQ VRF: default
Interface Ethernet1:
    Index: 2 SNPA: P2P
    ...
    Level 1:
    Graceful Restart Status: RR sent, SA sent, RA rcvd, CSNP rcvd
```

**15.4.5.11.9 IS-IS Dynamic Flooding Show Commands**

Several show commands are available to monitor Dynamic Flooding. To see the flooding topology, use the `show isis dynamic flooding topology` command:

```
switch# show isis dynamic flooding topology
IS-IS Instance: Amun VRF: default
    Level 1:
    Path: ip6.00 ip4.00 ip2.00 ip1.00 ip3.00 ip5.00 ip6.00
```

This command displays a list of paths that describe the flooding topology. Each path is a list of nodes in the network.

To see which interfaces dynamic flooding will use, use the `show isis dynamic flooding interfaces` command:

```
switch# show isis dynamic flooding interfaces
IS-IS Instance: Amun VRF: default
    Level 1:
    Ethernet5
    Ethernet4
```

This shows that the system is currently flooding only on **Ethernet4** and **Ethernet5**. Normally at least two interfaces are selected.
15.4.6 IS-IS Commands

Global Configuration Commands
- clear isis neighbor
- router isis

Interface Configuration Commands
- area leader
- adjacency-segment
- adjacency-segment (allocation)
- authentication key
- authentication mode
- bfd all-interfaces
- isis [ipv4|ipv6] fast-reroute ti-lfa srlg
- isis fast-reroute ti-lfa mode
- isis authentication key
- isis authentication mode
- isis bfd
- isis enable
- isis hello-interval
- isis hello-multiplier
- isis ipv6 metric
- isis lsp tx interval
- isis metric
- isis multi-topology
- isis network
- isis passive
- isis priority

Router IS-IS Configuration Mode (Includes Address-Family Mode)
- address-family
- fast-reroute ti-lfa mode
- fast-reroute ti-lfa srlg
- graceful-restart (IS-IS)
- is-hostname
- is-type
- log-adjacency-changes (IS-IS)
- lsp dynamic flooding
- match isis level
- multi-topology
- net
- passive (IS-IS)
- redistribute (IS-IS)
- set isis level
- set-overload-bit
- shutdown (IS-IS)
- spf-interval
IS-IS Segment Routing Commands

- segment-routing mpls
- mpls label range
- node-segment
- prefix-segment
- proxy-node-segment
- adjacency-segment (static)

Display Commands EXEC Mode

- show ip route
- show isis database
- show isis database detail
- show isis dynamic flooding
- show isis graceful-restart vrf
- show isis hostname
- show isis interface
- show isis local-convergence-delay
- show isis neighbors
- show isis network topology
- show isis segment-routing
- show isis segment-routing prefix-segments
- show isis segment-routing adjacency-segments
- show isis segment-routing global-blocks
- show isis segment-routing tunnel
- show isis ti-lfa path
- show isis ti-lfa tunnel
- show mpls label ranges
- show mpls flib route
- show mpls segment-routing bindings
- show tunnel fib
- show mpls flib route
- show mpls flib route <label value>
- show isis summary
The \texttt{address-family} command places the switch in address-family configuration mode. Address-family configuration mode is not a group change mode; \textit{running-config} is changed immediately after commands are executed. The \texttt{exit} command does not affect the configuration.

The switch supports these address families:

- ipv4-unicast
- ipv6-unicast

The \texttt{no address-family} and \texttt{default address-family} commands delete the specified address-family from \textit{running-config} by removing all commands previously configured in the corresponding address-family mode.

The \texttt{exit} command returns the switch to the \textit{isis} configuration mode.

**Command Mode**

Router-IS-IS Configuration

**Command Syntax**

\begin{verbatim}
address-family [ipv4 | ipv6][MODE]
no address-family [ipv4 | ipv6][MODE]
default address-family [ipv4 | ipv6][MODE]
\end{verbatim}

**Parameters**

- \texttt{address_family} Options include:
  - \texttt{ipv4} IPv4 unicast
  - \texttt{ipv6} IPv6 unicast
- \texttt{MODE} Options include:
  - \texttt{no parameter} Defaults to unicast.
  - \texttt{unicast} All IPv4 or IPv6 addresses are active.

**Example**

- These commands enter the \textit{address family} mode for IPv4 unicast.

\begin{verbatim}
switch(config)#router isis Osiris
switch(config-router-isis)#address-family ipv4 unicast
switch(config-router-isis-af)#
\end{verbatim}

- To exit from the IPv4 IS-IS unicast \textit{address family} configuration mode, enter the following command.

\begin{verbatim}
switch(config)#router isis Osiris
switch(config-router-isis)#address-family ipv4 unicast
switch(config-router-isis-af)#exit
switch(config-router-isis)#
\end{verbatim}
15.4.6.2 adjacency-segment

Use the `adjacency-segment` command in the interface configuration mode to have the PLR computes backup paths for an adjacency segment only if the Adjacency SID sub-TLV has the B-flag (backup flag) set.

**Command Mode**

Interface configuration mode

**Command Syntax**

```
adjacency-segment [ipv4|ipv6] p2p [multiple][label label | index index] backup-eligible
no adjacency-segment [ipv4 | ipv6]p2p [multiple][label label | index index] backup-eligible
default adjacency-segment [ipv4 | ipv6]p2p multiple][label label | index index] backup-eligible
```

**Parameters**

- `ipv4` IPv4 related.
- `ipv6` IPv6 related.
- `p2p` P2P interface type.
- `multiple` Configure multiple Adj-SIDs.
- `label label` Label value to be assigned as Adj-SID for adjacency on this interface. `label` range **16 -1048575**.
- `index index` Prefix segment identifier. `index` range **0-65535**.
- `backup-eligible` Eligible for protection.
15.4.6.3 adjacency-segment (static)

The adjacency-segment command configures IS-IS adjacencies statically on the switch, so that these values are preserved even when the switch restarts. The no and the default form of the command places the switch back to the global configuration mode.

Command Mode
Interface Ethernet Configuration

Command Syntax
adjacency-segment ipv4 | ipv6 p2p [[label label-value][[index index-value global]]]

Parameters
• ipv4 IS-IS SR adjacency segment IPv4 interface configuration.
• ipv6 IS-IS SR adjacency segment IPv6 interface configuration.
• label Label value to be assigned as Adj-SID for adjacency on this interface. Value ranges from 16 to 1048575.
• index Index to be assigned as Adj-SID for adjacency on this interface. Value ranges from 0 to 65535.
• global global adjacency SID.

Example
• This command allocates the adjacency segment to an IPv4 p2p interface with a index value 50.

```bash
switch(config-if-Et1)#adjacency-segment ipv4 p2p index 50 global
```
15.4.6.4 adjacency-segment (allocation)

The **adjacency-segment** command allocates adjacency segments to all IS-IS adjacencies, or only those adjacencies which are to IS-IS routers that have advertised IS-IS SR capability, or to none of the adjacencies.

**Command Mode**
Segment-Routing MPLS Configuration

**Command Syntax**

```
adjacency-segment allocation [all-interface | none | sr-peers]
```

**Parameters**
- **allocation** Allocation of Adjacency Segments.
- **all-interface** Allocates adjacency segments to all IS-IS adjacencies.
- **none** Disable automatic adjacency segment allocation.
- **sr-peers** Allocate adjacency segments to IS-IS adjacencies with SR peers.

**Example**

This command allocates the adjacency segment to an sr-peer.

```
switch(config-router-isis-sr-mpls)# adjacency-segment allocation sr-peer
```
15.4.6.5  area leader

Use the area leader command to tune or disable the area leader election process.

Command Mode
Router configuration mode

Command Syntax
area leader [disabled | level-1 [disabled] | level-2 [disabled] | priority [num [level-1 | level-2]]]
no area leader
default area leader

Parameters
• disabled Disables becoming the area leader.
• level-1 Configure at Level 1.
  • disabled Disables becoming the area leader.
  • level-2 Configure at Level 2.
  • disabled Disables becoming the area leader.
• priority Sets the area leader priority.
  • level-1 Configure at Level 1.
  • level-2 Configure at Level 2.
15.4.6.6  authentication key

The `authentication key` command configures the authentication key for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated.

The `no authentication key` and `default authentication key` commands disables the authentication key for the IS-IS instance.

**Command Mode**

ISIS-Router Configuration

**Command Syntax**

`authentication key [0 | 7] [LAYER_VALUE]`

`no authentication key [0 | 7] [LAYER_VALUE]`

`default authentication key [0 | 7] [LAYER_VALUE]`

**Parameters**

`LAYER_VALUE` layer value. Options include:

- level-1
- level-2

**Example**

These commands configure authentication for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated.

```
switch(config)# router isis 1
switch(config-router-isis)# authentication key secret
switch(config-router-isis)#
```
15.4.6.7  **authentication mode**

The **authentication mode** command configures authentication for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated.

The **no authentication mode** and **default authentication mode** commands disables authentication for the IS-IS instance.

**Command Mode**

ISIS-Router Configuration

**Command Syntax**

- **authentication mode [md5 | text] [LAYER_VALUE]**
- **no authentication mode [md5 | text] [LAYER_VALUE]**
- **default authentication mode [md5 | text] [LAYER_VALUE]**

**Parameters**

- **LAYER_VALUE** Layer value. Options include:
  - level-1
  - level-2

**Example**

These commands configure authentication for the IS-IS instance causing LSPs, CSNPs and PSNPs to be authenticated.

```
switch(config)#router isis 1
switch(config-router-isis)#authentication mode md5
switch(config-router-isis)#
```
15.4.6.8 bfd all-interfaces

The bfd all-interfaces command enables Bidirectional Forwarding Detection (BFD) for all IS-IS-enabled interfaces in the IPv4 or IPv6 address family.

Use the isis bfd command to configure BFD on a specific interface.

Command Mode
Router-IS-IS Address-Family Configuration

Command Syntax
bfd all-interfaces

Example
These commands enable BFD for all the interfaces on which IS-IS is enabled. By default, BFD is disabled on all the interfaces.

```
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv4
switch(config-router-af)#bfd all-interfaces
switch(config-router-af)#
```
15.4.6.9  clear isis neighbor

The **clear isis neighbor** command clears IS-IS adjacencies that exist on an interface, or at a specific level, or the adjacencies formed with a given neighbor (either with a system ID or a hostname).

**Command Mode**
Privileged EXEC

**Command Syntax**
```
clear isis neighbor {Neighbor-ID | all | interface} [level-1 | level-2 | level-1-2]
```

**Parameters**
- **Neighbor-ID** Clears adjacencies based on the system ID or the hostname of a neighbor.
- **all** Clears all adjacencies.
- **interface** Clears adjacencies for a specific interface.
- **level-1** level 1 only.
- **level-1-2** level 1-2 point-to-point only.
- **level-2** level 2 only.

**Examples**
- This command clears IS-IS adjacencies with a neighbor **af86.3032.1a0f**.
  ```
switch#clear isis neighbor af86.3032.1a0f
2 neighbors cleared on instance 1
switch#
  ```
- This command clears all IS-IS adjacencies on an interface **et1**.
  ```
switch#clear isis neighbor interface et1
4 neighbors cleared on instance 1
switch#
  ```
- This command clears IS-IS adjacencies with a neighbor **af86.3032.1a0f** and on interface **et1**.
  ```
switch#clear isis neighbor af86.3032.1a0f interface et1
2 neighbors cleared on instance 1
switch#
  ```
- This command clears all IS-IS adjacencies at Level 1 and on interface **et1**.
  ```
switch#clear isis neighbor interface et1 level-1
2 neighbors cleared on instance 1
switch#
  ```
- This command clears Level 1-2 point-to-point adjacencies only.
  ```
switch#clear isis neighbor all level-1-2
0 neighbors cleared on instance 1
switch#
  ```
15.4.6.10 fast-reroute ti-lfa mode

Use the **fast-reroute ti-lfa mode** to enable link or node protection for node segments and adjacency segments of a specific address-family learned on all IS-IS interfaces.

**Command Mode**

address-family sub-mode of the router isis mode (config-router-isis-af)

**Command Syntax**

```
fast-reroute ti-lfa mode [[[ link-protection | node-protection][level-1 | level-2]] | disabled]
```

**Parameters**

- **link-protection** Protects against the failure of the link.
- **node-protection** Protects against the failure of the neighbor mode.
- **level-1** Protects prefixes only in level-1.
- **level-2** Protects prefixes on in level-2. Disables the fast-reroute TI-LFA mode.

**Guidelines**

FRR using TI-LFA is disabled globally by default in the router IS-IS address-family sub-modes. The interface TI-LFA configuration inherits the address-family sub-mode configuration by default.
15.4.6.11 fast-reroute ti-lfa srlg

Use the `fast-reroute ti-lfa srlg` command to enable SRLG protection on all interfaces. This command is used in addition to configuring link-protection or node-protection. When SRLG protection is enabled, the backup paths are computed after excluding all the links that share the same SRLG with the active link that is being used by all prefix segments and adjacency segments.

**Command Mode**

IS-IS router address-family configuration mode

**Command Syntax**

`fast-reroute ti-lfa srlg [strict]`

**Parameters**

`strict` The backup path is only programmed if a backup path that excludes all the SRLGs configured on the primary interface.
15.4.6.12  graceful-restart (IS-IS)

The **graceful-restart** command configures IS-IS graceful-restart. The command provides options to configure the t2 time or the restart-hold-time.

- **t2** is the maximum wait time for the LSP database to synchronize (SPF computation is not done while t2 is running). t2 can be configured for either Level-1 or Level-2 routes.
- **restart-hold-time** is the hold time advertised by the router to its neighbors before undergoing ASU2 fast reboot.

The **no graceful-restart** and **default graceful-restart** commands disables the IS-IS graceful-restart configuration from *running-config*.

**Command Mode**
Router-IS-IS Configuration

**Command Syntax**

```plaintext
graceful-restart t2 | restart-hold-time value
no graceful-restart t2 | restart-hold-time value
default graceful-restart t2 | restart-hold-time value
```

**Parameters**

- **value** The time in seconds. Value ranges from 5 to 300 seconds.
- **restart-hold-time** Sets the hold time when restarting.
- **t2** Sets the LSP database sync wait time.

**Examples**

- In this example an ISIS graceful restart is configured with t2 wait time of 30 seconds for Level-1 routes.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#graceful-restart t2 level-1 30
```

- In this example an ISIS graceful restart is configured with restart-hold-time of 50 seconds.

```plaintext
switch(config)#router isis 1
switch(config-router-isis)#graceful-restart restart-hold-time 50
```
15.4.6.13  is-hostname

The `is-hostname` command configures the use of a human-readable string to represent the symbolic name of an IS-IS router. It also changes the output of IS-IS show commands, to show the IS-IS hostname in place of system IDs if the corresponding IS-IS hostname is known. However, syslogs still use IS-IS system IDs and not the IS-IS hostname.

By default, if a hostname is configured on the switch, it is used as the IS-IS hostname. It is also possible to unconfigure an assigned hostname for IS-IS using the `no is-hostname` command. When the IS-IS hostname is removed, the switch goes back to using the switch’s hostname as the IS-IS hostname.

**Command Mode**
Router-IS-IS Configuration

**Command Syntax**

```plaintext
is-hostname string
no is-hostname
```

**Examples**

- These commands configure the IS-IS hostname to the symbolic name `ishost1` for the IS-IS router.

```plaintext
switch(config)#router isis inst1
switch(config-router-isis)#is-hostname ishost1
switch(config-router-isis)#
```

- These commands unconfigure the IS-IS hostname of the symbolic name `ishost1` for the IS-IS router.

```plaintext
switch(config)#router isis inst1
switch(config-router-isis)#no is-hostname ishost1
switch(config-router-isis)#
```
15.4.6.14  isis authentication key

The `isis authentication key` command configures the authentication key on the interface causing IS-IS Hellos to be authenticated.

The `no isis authentication mode` and `default isis authentication mode` commands disables the authentication key for the IS-IS instance.

**Command Mode**
Interface-Ethernet Configuration

**Command Syntax**

```
isis authentication key [0 | 7] [LAYER_VALUE]
no isis authentication key [0 | 7] [LAYER_VALUE]
default isis authentication key [0 | 7] [LAYER_VALUE]
```

**Parameters**

`LAYER_VALUE` Layer value. Options include:

- level-1
- level-2

**Example**

These commands configure authentication on the interface causing IS-IS Hellos to be authenticated.

```
switch(config)#interface Ethernet 3/6
switch(config-if-Et3/6)#isis authentication mode text
switch(config-if-Et3/6)#isis authentication key 7 cAm28+9a/xPi0
4o7hjd8Jw==
switch(config-if-Et3/6)#
```

2454
15.4.6.15  isis authentication mode

The isis authentication mode command configures authentication on the interface causing IS-IS Hellos to be authenticated.

The no isis authentication mode and default isis authentication mode commands disables authentication for the IS-IS instance.

Command Mode
Interface-Ethernet Configuration

Command Syntax

isis authentication mode [md5 | text][LAYER_VALUE]
no isis authentication mode [md5 | text][ -LAYER_VALUE]-
default isis authentication mode [md5 | text][LAYER_VALUE]

Parameters

LAYER_VALUE Layer value. Options include:
  • level-1
  • level-2

Example

These commands configure authentication on the interface causing IS-IS Hellos to be authenticated.

switch(config)#interface Ethernet 3/6
switch(config-if-Et3/6)#isis authentication mode text
switch(config-if-Et3/6)#isis authentication key 7 cAm28+9a/xPi0
4o7hjd8Jw==
switch(config-if-Et3/6)#
15.4.6.16  isis bfd

The `isis bfd` command activates the corresponding IS-IS routing instance on the configuration mode interface. By default, the IS-IS routing instance is not enabled on an interface.

The `no isis enable` and `default isis enable` commands disable IS-IS on the configuration mode interface by removing the corresponding `isis enable` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

- `isis bfd`
- `no isis bfd`
- `default isis bfd`

**Example**

These commands enable BFD on IS-IS interfaces.

```
switch(config)#interface Ethernet 5/6
switch(config-if-Et5/6)#isis bfd
switch(config-if-Et5/6)#
```
15.4.6.17  isis enable

The `isis enable` command activates the corresponding IS-IS routing instance on the configuration mode interface. By default, the IS-IS routing instance is not enabled on an interface.

The `no isis enable` and `default isis enable` commands disable IS-IS on the configuration mode interface by removing the corresponding `isis enable` command from `running-config`.

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

**Command Syntax**

`isis enable instance_id`
`no isis enable`
`default isis enable`

**Parameters**

`instance_id` IS-IS instance name.

**Examples**

- These commands enable the IS-IS protocol on the `interface ethernet 4`.

  ```
  switch(config)#router isis Osiris
  switch(config-router-isis)#net 49.0001.1010.1040.1030.00
  switch(config-router-isis)#interface ethernet 4
  switch(config-if-Eth4)#isis enable Osiris
  ```

- These commands disable the IS-IS protocol on the `interface ethernet 4`.

  ```
  switch(config)#interface ethernet 4
  switch(config-if-Eth4)#no isis enable
  ```
15.4.6.18  isis fast-reroute ti-lfa mode

Use the **isis fast-reroute ti-lfa mode** command to enable link or node protection for node segments and adjacency segments learned on a specific IS-IS interface. By default, the interface TI-LFA configuration inherits the address-family sub-mode configuration.

The **no isis fast-reroute ti-lfa mode** and **default isis fast-reroute ti-lfa mode** commands disable link or node protection for node segments and adjacency segments learned on a specific IS-IS interface.

**Command Mode**

Interface configuration mode.

**Command Syntax**

```
isis fast-reroute ti-lfa mode [ link-protection | node-protection | disabled ][ level-1 | level-2]
no isis fast-reroute ti-lfa mode [ link-protection | node-protection | disabled ][ level-1 | level-2 ]
default isis fast-reroute ti-lfa mode [ link-protection | node-protection | disabled ][ level-1 | level-2 ]
```

**Parameters**

- **link-protection** Configures link-protection.
- **node-protection** Configures node-protection.
- **disabled** Disables protection over the link.
- **level-1** Optional keyword in both the `router isis address-family` sub-mode and interface configuration mode CLIs is used to restrict protection to node segments and adjacency segments learned through either Level-1 topologies only.
- **level-2** Optional keyword in both the `router isis address-family` sub-mode and interface configuration mode CLIs is used to restrict protection to node segments and adjacency segments learned through Level-2 topologies only.
15.4.6.19  isis hello-interval

The **isis hello-interval** command sends Hello packets from applicable interfaces to maintain the adjacency through the transmitting and receiving of Hello packets. The Hello packet interval can be modified.

The `no isis hello-interval` and `default isis hello-interval` commands restore the default hello interval of 10 seconds on the configuration mode interface by removing the **isis hello-interval** command from **running-config**.

**Command Mode**

- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

- `isis hello-interval time`
- `no isis hello-interval`
- `default isis hello-interval`

**Parameters**

- `time` Values range from 1 to 300; default is 10.

**Examples**

- These commands configure a hello interval of **45** seconds for **vlan 200**.

  ```
  switch(config)#interface vlan 200
  switch(config-if-Vl200)#isis hello-interval 45
  switch(config-if-Vl200)#
  ```

- These commands remove the configured hello interval of **45** seconds from **vlan 200**.

  ```
  switch(config)#interface vlan 200
  switch(config-if-Vl200)#no isis hello-interval
  switch(config-if-Vl200)#
  ```

- These commands configure a hello interval of **60** seconds for **interface ethernet 5**.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#isis hello-interval 60
  switch(config-if-Et5)#
  ```

- These commands remove the configured hello interval of **60** seconds from **interface ethernet 5**.

  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no isis hello-interval
  switch(config-if-Et5)#
  ```
isis hello-multiplier

The `isis hello-multiplier` command specifies the number of IS-IS hello packets missed by a neighbor before the adjacency is considered down.

The `no isis hello-multiplier` and `default isis hello-multiplier` commands restore the default hello interval of 3 on the configuration mode interface by removing the `isis hello-multiplier` command from `running-config`.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**
- `isis hello-multiplier factor`
- `no isis hello-multiplier`
- `default isis hello-multiplier`

**Parameters**
- `factor` Values range from 3 to 100; default is 3.

**Examples**
- These commands configure a hello multiplier of 4 for `vlan 200`.
  ```
  switch(config)#interface vlan 200
  switch(config-if-Vl200)#isis hello-multiplier 4
  switch(config-if-Vl200)#
  ```
- These commands remove the configured hello multiplier of 4 from `vlan 200`.
  ```
  switch(config)#interface vlan 200
  switch(config-if-Vl200)#no isis hello-multiplier
  switch(config-if-Vl200)#
  ```
- These commands configure a hello multiplier of 45 for `interface ethernet 5`.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#isis hello-multiplier 45
  switch(config-if-Et5)#
  ```
- These commands remove the configured hello multiplier of 45 from `interface ethernet 5`.
  ```
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no isis hello-multiplier
  switch(config-if-Et5)#
  ```
15.4.6.21  isis [ipv4|ipv6] fast-reroute ti-lfa srlg

Use the `isis [ipv4|ipv6] fast-reroute ti-lfa srlg` command to enable protection selectively on a specific interface. This command only enables SRLG protection for prefix segments and adjacency segments enabled on the interface.

**Command Mode**

Interface configuration mode

**Command Syntax**

```
isis [ipv4 | ipv6][fast-reroute ti-lfa srlg][strict | disabled]
no isis [ipv4 | ipv6][fast-reroute ti-lfa srlg][strict | disabled]
default isis [ipv4 | ipv6][fast-reroute ti-lfa srlg][strict | disabled]
```

**Parameters**

- `ipv4`: IS-IS IPv4 interface configuration.
- `ipv6`: IS-IS IPv6 interface configuration.
- `fast-reroute`: Configures fast reroute.
- `ti-lfa`: Configures TI-LFA FRR.
- `srlg`: Excludes same SRLG links from backup path.
- `strict`: The backup path is only programmed only if a backup path that excludes all the SRLGs configured on the primary interface. If `strict` is not provided and an SRLG excluding path is not available, TI-LFA programs the backup path that excluded the maximum number of SRLGs possible.
- `disabled`: Use to selectively disable SRLG protection on an interface. This is useful when SRLG protection is enabled globally for all interfaces but needs to be selectively disabled for a specific interface.

---

15.4.6.22  isis ipv6 metric

The `isis ipv6 metric` command configures the IPv6 metric.

The `no isis ipv6 metric` and `default isis ipv6 metric` commands restore the default metric of 10 on the configuration mode interface.

**Command Mode**

Interface-Ethernet Configuration

**Command Syntax**

```
isis ipv6 metric  metric_value
no isis ipv6 metric
default isis ipv6 metric
```

**Parameters**

- `metric_value`: Values range from 1 to 16777214; default is 10.

**Example**

These commands configure the IPv6 metric.

```
switch(config)#interface Ethernet 5/6
switch(config-if-Et5/6)#isis ipv6 metric 30
switch(config-if-Et5/6)#
```

---
15.4.6.23  **isis lsp tx interval**

The **isis lsp tx interval** command sets the interval at which IS-IS sends link-state information on the interface.

The **no isis lsp tx interval** and **default isis lsp tx interval** commands restores the default setting of **33 ms.** by removing the **isis lsp tx interval** command from **running-config.**

**Command Mode**

Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

**Command Syntax**

```plaintext
isis lsp tx interval period
no isis lsp tx interval
default isis lsp tx interval
```

**Parameters**

`period` Value ranges from **1** through **3000.** Default interval is **33 ms.**

**Examples**

- This command sets the LSP interval on interface **interface ethernet 5** to **600** milliseconds.

  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#isis lsp tx interval 600
  switch(config-if-Et5)#
  ```

- This command removes the LSP interval on **interface ethernet 5.**

  ```plaintext
  switch(config)#interface ethernet 5
  switch(config-if-Et5)#no isis lsp tx interval
  switch(config-if-Et5)#
  ```
15.4.6.24  isis metric

The isis metric command sets cost for sending information over an interface.
The no isis metric and default isis metric commands restore the metric to its default value of 10 by removing the isis metric command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-channel Configuration
Interface-VLAN Configuration

Command Syntax
isis metric metric_cost
no isis metric
default isis metric

Parameters
metric_cost Values range from 1 to 16777214. Default value is 10.

Examples
• These commands configure a metric cost of 30 for sending information over interface ethernet 5.

```
switch(config)#router isis Osiris
switch(config-router-isis)#interface ethernet 5
switch(config-if-Et5)#isis metric 30
switch(config-if-Et5)#
```

• These commands remove the configured metric cost of 30 from interface ethernet 5.

```
switch(config)#router isis Osiris
switch(config-router-isis)#interface ethernet 5
switch(config-if-Et5)#no isis metric
switch(config-if-Et5)#
```
15.4.6.25  isis multi-topology

The isis multi-topology command configures the IPv4 or IPv6 address family individually on an interface with both IPv4 and IPv6 addresses.

The no isis multi-topology and default isis multi-topology commands restores the default interface to both IPv4 and IPv6 address families.

Command Mode
Interface-Ethernet Configuration

Command Syntax
isis multi-topology address-family ipv4 unicast
no isis multi-topology address-family ipv4 unicast
default isis multi-topology address-family ipv4 unicast

Examples
• These commands configure the IPv4 address family on an interface with both IPv4 and IPv6 addresses.

  switch(config)#interface Ethernet 5/6
  switch(config-if-Et5/6)#isis multi-topology address-family ipv4 unicast
  switch(config-if-Et5/6)#

• These commands configure the IPv6 address family on an interface with both IPv4 and IPv6 addresses.

  switch(config)#interface Ethernet 5/6
  switch(config-if-Et5/6)#isis multi-topology address-family ipv6 unicast
  switch(config-if-Et5/6)#

• These commands configure both the IPv4 and IPv6 address families on an interface.

  switch(config)#interface Ethernet 5/6
  switch(config-if-Et5/6)#no isis multi-topology address-family unicast
  switch(config-if-Et5/6)#
15.4.6.26  isis network

The isis network command sets the configuration mode interface as a point-to-point link. By default, interfaces are configured as broadcast links.

The no isis network and default isis network commands set the configuration mode interface as a broadcast link by removing the corresponding isis network command from running-config.

Command Mode
Interface-Ethernet Configuration
Interface-Loopback Configuration
Interface-Port-Channel Configuration
Interface-VLAN Configuration

Command Syntax
isis network point-to-point
no isis network
default isis network

Examples
• These commands configure interface ethernet 10 as a point-to-point link.
  
  switch(config)#interface ethernet 10
  switch(config-if-Etl0)#isis network point-to-point
  switch(config-if-Etl0)#

• This command restores interface ethernet 10 as a broadcast link.
  
  switch(config-if-Etl0)#no isis network
  switch(config-if-Etl0)#
15.4.6.27  isis passive

The **isis passive** command configures the configuration-mode interface as passive. The switch will continue to advertise the IP address in the LSP, but the interface will not send or receive IS-IS control packets.

The **no isis passive** command removes the passive configuration, allowing the interface to send and receive IS-IS control packets. The **default isis passive** command sets the interface to the default interface activity setting by removing the corresponding **isis passive** or **no isis passive** statement from **running-config**.

**Command Mode**

Interface-Ethernet Configuration

Interface-Loopback Configuration

Interface-Port-Channel Configuration

Interface-VLAN Configuration

**Command Syntax**

isis passive

no isis passive

default isis passive

**Examples**

- These commands configure Ethernet interface 10 as a passive interface.

  switch(config)#interface ethernet 10
  switch(config-if-Etl0)#isis passive
  switch(config-if-Etl0)#

- These commands restore Ethernet interface 10 as an active interface.

  switch(config)#interface ethernet 10
  switch(config-if-Etl0)#no isis passive
  switch(config-if-Etl0)#
**15.4.6.28 isis priority**

The **isis priority** command sets the IS-IS priority for the interface.

The default priority is **64**. The network device with the highest priority will be elected as the designated intermediate router to send link-state advertisements for that network.

The **no isis priority** and **default isis priority** commands restore the default priority (64) on the configuration mode interface.

**Command Mode**
- Interface-Ethernet Configuration
- Interface-Loopback Configuration
- Interface-Port-channel Configuration
- Interface-VLAN Configuration

**Command Syntax**

```
isis priority priority_level
no isis priority
default isis priority
```

**Parameters**

*priority_level* Value ranges from 0 to 127. Default value is 64.

**Examples**

- These commands configure a IS-IS priority of **60** on **interface ethernet 5**.

  ```
  switch(config)#router isis Osiris
  switch(config-router-isis)#interface ethernet 5
  switch(config-if-Et5)#isis priority 60
  switch(config-if-Et5)#
  ```

- These commands restores the default IS-IS priority of **64** from **interface ethernet 5**.

  ```
  switch(config)#router isis Osiris
  switch(config-router-isis)#interface ethernet 5
  switch(config-if-Et5)#no isis priority
  switch(config-if-Et5)#
  ```

- These commands configure the switch with a priority of **64** for **interface vlan 7**.

  ```
  switch(config)#interface vlan 7
  switch(config-if-Vl7)#isis priority 64
  switch(config-if-Vl7)#
  ```

- These command restores the default IS-IS priority of **64** for **64**.

  ```
  switch(config)#interface vlan 7
  switch(config-if-Vl7)#no isis priority
  switch(config-if-Vl7)#
  ```
15.4.6.29  is-type

The `is-type` command configures the routing level for an IS-IS instance.

An IS-IS router can be configured as Level-1-2 which can form adjacencies and exchange routing information with both Level-1 and Level-2 routers. A Level-1-2 router can be configured to transfer routing information from Level-1 to Level-2 areas and vice versa (via route leaking). By default, all routes from Level-1 area are always leaked into Level-2 network.

**Command Mode**
Router-IS-IS Configuration

**Command Syntax**

`is-type LAYER_VALUE`

**Parameters**

- `LAYER_VALUE` Layer value options include:
  - `level-1`
  - `level-1-2`
  - `level-2`

**Examples**

- These commands configure Level 1-2 routing.
  ```
  switch(config)#router isis Osiris
  switch(config-router-isis)#is-type level-1-2
  switch(config-router-isis)#
  ```

- These commands configure Level 2 routing.
  ```
  switch(config)#router isis Osiris
  switch(config-router-isis)#is-type level-2
  switch(config-router-isis)#
  ```
15.4.6.30  log-adjacency-changes (IS-IS)

The log-adjacency-changes command sets the switch to send Syslog messages when it detects link state changes or when it detects that a neighbor state has changed.

The default option is active when running-config does not contain any form of the command. Entering the command in any form replaces the previous command state in running-config.

Command Mode
Router-IS-IS Configuration

Command Syntax
log-adjacency-changes
no log-adjacency-changes
default log-adjacency-changes

Examples
• These commands configure the switch to send a Syslog message when a neighbor state changes.

```
switch(config)#router isis Osiris
switch(config-router-isis)#log-adjacency-changes
switch(config-router-isis)#
```

• These commands configure not to log the peer changes.

```
switch(config)#router isis Osiris
switch(config-router-isis)#no log-adjacency-changes
switch(config-router-isis)#
```
15.4.6.31 lsp dynamic flooding

Use the `lsp flooding dynamic` command to configure dynamic flooding. Dynamic flooding must be enabled on all routers in the area. The `no` form of the command removes LSP dynamic flooding. LSP flooding dynamic is disabled by default.

**Command Mode**
Router configuration mode

**Command Syntax**

```
lsp flood dynamic [level-1 | level-2]
no lsp flood dynamic [level-1 | level-2]
default lsp flood dynamic [level-1 | level-2]
```

**Parameters**

- `level-1` Level 1 adjacencies.
- `level-2` Level 2 adjacencies.

**Example**

```
switch(config)#router isis Amun
switch(config-router-isis)#net 49.0000.0000.3333.00
switch(config-router-isis)#is-hostname ip3
switch(config-router-isis)#lsp flooding dynamic
```

```
15.4.6.32  match isis level

The `match isis level` command configures a route map to match on ISIS level. It filters the Level-1 or Level-2 routes by using route maps match statement.

The `no match isis level` and `default match isis level` commands disables the match ISIS level configuration from `running-config`.

Command Mode
Route-map Configuration

Command Syntax

```
match isis level [level-1 | level-2]
no match isis level [level-1 | level-2]
default match isis level [level-1 | level-2]
```

Parameters

- `level-1` IS-IS level 1.
- `level-2` IS-IS level 2.

Example

These commands place the switch in `route-map` mode, and configures a route map to match isis level to Level-1.

```
switch(config)#route-map Test
switch(config-route-map-test)#match isis level level-1
```
15.4.6.33  mpls label range

The mpls label range command derives the indices of the actual MPLS label on the SRGB advertised by the router. The default value of SRGB in EOS is Base: 900000, Size: 65536. In other words, the labels that any global segment could represent is between 900000-965535.

Command Mode
Global Configuration

Command Syntax
mpls label range value

Parameters

value Specifies the Segment Routing global range.

• dynamic Specifies labels reserved for dynamic assignment. Default value is (100000) (262144).
  • IS-IS-sr Specifies labels reserved for IS-IS SR global segment identifiers (SIDs). Default value is (900000) (65536).
  • static Specifies labels reserved for static MPLS routes. Default value is (16) (99984).

Example
The following command configures an IS-IS SR global range with a value of (900000) -- starting label range, (65536) -- Numbers of labels to reserve.

switch(config)#mpls label range isis-sr 900000 65536
multi-topology

The `multi-topology` command configures IS-IS Multi-Topology (MT) support (disabled by default), enabling an IS-IS router to compute a separate topology for IPv4 and IPv6 links in the network. With MT configured, not all the links in a network need to support both IPv4 and IPv6. Some can support IPv4 or IPv6 individually. The IPv4 SPF will install IPv4 routes using the IPv4 topology, and similarly the IPv6 SPF will install IPv6 routes using the IPv6 topology. Without MT support, all links in an IS-IS network need to support the same set of address families. When MT is enabled, and each link has a separate IPv4 metric and IPv6 metric.

The `no multi-topology` and `default multi-topology` commands restores the default interface to both IPv4 and IPv6 address families.

**Command Mode**
Router IS-IS Address-Family Configuration

**Command Syntax**

`multi-topology`
`no multi-topology`
`default multi-topology`

**Examples**

- These commands configure MT for the IS-IS router.

```
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv6 unicast
switch(config-router-isis-af)#multi-topology
switch(config-router-isis-af)#
```

- These commands unconfigure MT for the IS-IS router.

```
switch(config)#router isis 1
switch(config-router-isis)#address-family ipv6 unicast
switch(config-router-isis-af)#no multi-topology
switch(config-router-isis-af)#
```
The `net` command configures the Network Entity Title of the IS-IS instance. By default, no NET is defined.
